A conference managed by ACPI, UK

The Proceedings of the

13th European Conference on Innovation and Entrepreneurship
ECIE 2018

Hosted By
University of Aveiro
Portugal

20-21 September 2018

Edited by

Carlos Costa
Manuel Au-Yong-Oliveira
Marlene Paula Castro Amorim

Review Process
Papers submitted to this conference have been double-blind peer reviewed before final acceptance to the conference. Initially, abstracts were reviewed for relevance and accessibility and successful authors were invited to submit full papers. Many thanks to the reviewers who helped ensure the quality of all the submissions.

Ethics and Publication Malpractice Policy
ACPIL adheres to a strict ethics and publication malpractice policy for all publications – details of which can be found here:
http://www.academic-conferences.org/policies/ethics-policy-for-publishing-in-the-conference-proceedings-of-academic-conferences-and-publishing-international-limited/

Conference Proceedings
The Conference Proceedings is a book published with an ISBN and ISSN. The proceedings have been submitted to a number of accreditation, citation and indexing bodies including Thomson ISI Web of Science and Elsevier Scopus.

Author affiliation details in these proceedings have been reproduced as supplied by the authors themselves.

The Electronic version of the Conference Proceedings is available to download from DROPBOX https://tinyurl.com/ECIE18 Select Download and then Direct Download to access the Pdf file. Free download is available for conference participants for a period of 2 weeks after the conference.
The Conference Proceedings for this year and previous years can be purchased from http://academic-bookshop.com

E-Book ISBN: 978-1-911218-98-2
E-Book ISSN: 2049-1069
Print version ISBN: 978-1-911218-97-5
Print Version ISSN: 2049-1050

Preface

These proceedings represent the work of contributors to the 13th European Conference on Innovation and Entrepreneurship (ECIE 2018), hosted this year by the University of Aveiro, Portugal on 20-21 September 2018. The Conference Chair is Professor Carlos Costa and the Programme Co-Chairs are Dr. Manuel Au-Yong-Oliveira and Dr. Marlene Paula Castro Amorim.

ECIE is now a well-established event on the academic research calendar and now in its 13th year the key aim remains the opportunity for participants to share ideas and meet the people who hold them. The scope of papers will ensure an interesting two days. The subjects covered illustrate the wide range of topics that fall into this important and ever-growing area of research.

The opening keynote presentation is given by Professor Marina van Geenhuizen on the topic of "*University Spin-Off Firms' Internationalization: The influence of Founding Teams and Networks in Early Years*". The second keynote will be given by Prof João José Pinto Ferreira, who will be discussing *Entrepreneurship Learning Outcomes*.

In addition to the main themes of the conference there are a number of specialist mini tracks on topics including Entrepreneurial Education and Learning and Micro-Entrepreneurship.

With an initial submission of 250 abstracts, after the double blind, peer review process there are 103 Academic research papers, 11 PhD research papers, 6 Masters Research papers and 4 work-in-progress papers published in these Conference Proceedings. These papers represent research from Austria, Belgium, Brazil, Canada, China, Colombia, Czech Republic, Denmark, Egypt, Finland, France, Germany, Ghana, Greece, India, Indonesia, Iran, Ireland, Israel, Italy, Japan, Kazakhstan, Kenya, Lebanon, Lithuania, the Netherlands, New Zealand, Nigeria, Norway, Oman, Peru, Poland, Portugal, Russia, Slovakia, Slovenia, South Africa, Spain, Sri Lanka, Turkey, UK, UAE, and USA.

We hope you enjoy the conference.

Carlos Costa,
Manuel Au-Yong-Oliveira
and
Marlene Paula Castro Amorim

Biographies

Conference and Programme Chairs

Professor Carlos Costa is a full professor and entrepreneur based at the University of Aveiro, Portugal. Carlos started out doing an undergraduate degree in regional and urban planning (University of Aveiro). This was followed by a specialization in tourism, at the master's and doctoral level, at the University of Surrey, in the UK. Carlos is now Head of Department, at DEGEIT – the largest department of the University of Aveiro. With publications at the highest level, Carlos also enjoys writing down-to-earth articles for the media and for the general public. As the Director of the PhD in Marketing and Strategy, as well as of the PhD in Tourism, both at the University of Aveiro, Carlos is an inspiration to colleagues and students alike – to perform beyond their dreams and achieve new entrepreneurial heights, whatever the domain may be.

Dr. Marlene Paula Castro Amorim was born in Oporto, in 1974, and received her PhD in Management from IESE Business School (Barcelona, Spain). Marlene holds a first degree in Economics, by the University of Porto, and a Master's degree in Management of Science Technology and Innovation, by the University of Aveiro (Portugal). She initiated her career in industry, holding managerial positions in marketing and internationalization in food manufacturing companies, in Portugal, The Netherlands and Belgium. She then moved to the academic landscape, firstly as a manager, for the internationalization of the University of Aveiro in the year 2000. Currently Marlene serves as Pro-rector for the Internationalization of the University of Aveiro. She is also an Assistant Professor at this University for the Department of Economics Management Industrial Engineering and Tourism. She has been Director of the Master's in Industrial Engineering and Management and is a member of the Scientific Commission of the Doctoral Program in Industrial Engineering. Marlene is also a researcher integrated at the Research Unit GOVCOPP.

Dr. Manuel Au-Yong Oliveira was born in London, England, in 1969. After a brief period working in the textile industry, Manuel did an MBA at Cardiff Business School, in Wales (1992-1993). Under the supervision of the Director of the Cardiff Business School, Professor Roger Mansfield, Manuel wrote a dissertation on human motivation, which was awarded a distinction. Manuel has ten years of work experience with multinational corporations – including for Accenture (1998-1999), Worthington Cylinders (2000-2004) and Waterco (2005-2009). Manuel has also worked for smaller more entrepreneurial enterprises. Manuel has a Ph.D in Industrial Engineering and

Management (FEUP), and was awarded a distinction for his thesis on innovation. Manuel is currently an Assistant Professor at the University of Aveiro, in Portugal, where he is a member of the Executive Committee for his department (Department of Economics, Management, Industrial Engineering and Tourism) and the Director of the Master's in Management degree. Manuel as a researcher is affiliated to GOVCOPP.

Keynote Speakers

Professor Marina van Geenhuizen has been a Full Professor at Faculty of Technology, Policy and Management at TU Delft in the Netherlands since 2007. She was awarded her PhD from Erasmus University Rotterdam in applied economics. Professor van Geenhuizen's research focus is on responsible/sustainable innovation and transition in energy, transport and medical/healthcare systems. Her focus is also on effectiveness in knowledge commercialization, including growth of university spin-off firms, living labs, networks, incubators and science parks, and contribution to the regional/urban knowledge economy. Theoretical perspectives include resource-based view, capabilities and social capital, and urban innovation theory. The approach is often quantitative modelling, eventually illustrated with qualitative case studies.

Professor João José Pinto Ferreira is an Associate Professor with Habilitation at the Faculty of Engineering at the University of Porto. He founded (a number of years ago, in 2004) one of the most successful and innovative Master's degrees in Northern Portugal called MIETE - The Master's in Innovation and Technological Entrepreneurship. Professor João José is an expert on entrepreneurship and has been to Babson College in the USA to further his knowledge and training in the area.

Mini Track Chairs

Alexandros Kakouris, PhD, is an adjunct lecturer in entrepreneurship and innovation at the University of Peloponnese, at the Hellenic Open University and he is also innovation consultant at the National Observatory of Athens. He holds PhD in Physics, PhD in Entrepreneurship and a MSc in Adult Education. He has been involved in entrepreneurship since 2006 researching educational and learning issues. His special interest concerns fostering entrepreneurship and innovation to science graduates and the support of youth entrepreneurship through teaching and counselling. He also specialises in nascent entrepreneurship, creativity, transformative and experiential learning.

Professor Matti Muhos is the research director of Micro-entrepreneurship at University of Oulu, the research professor of Industrial engineering and management, renewing business and digitalization and he has the title of docent in technology business at the University of Jyväskylä. Muhos received his D.Sc. (Tech.) in industrial engineering and management from the University of Oulu. He is an associate editor, guest editor and advisory board member for several international journals. He is also a popular keynote speaker and invited co-chair of academic conferences in his research field. His primary research interests are growth management in new technology and service-based firms, the development of SMEs (with a particular focus on micro-sized enterprises), technology business, technology management, agility, and internationalization processes. The micro-entrepreneurship research team, MicroENTRE, is an internationally well-known and valued expert and partner specialising in micro-entrepreneurship in northern areas. Its results are published in valued scientific forums. Activities of the team promote the operating area as a growth platform for micro-enterprises. The research team focuses on micro-enterprises and research, development and training which is important to micro-enterprises.

Biographies of Contributing Authors

Katariina Ala-Rämi is a postdoctoral researcher at MicroENTRE, University of Oulu. In the project Energy-mine she is responsible for activities related to micro-enterprises in business potential using geothermal energy. She is holding PhD in Applied Geography and Regional Planning, the doctoral theses was about Networking, collaboration and communication in SMEs' product innovation in Northern Finland.

Thamer Alkhaldi is a Doctoral student doing PhD in the area of entrepreneurship at Manchester Metropolitan University Business School, Manchester, UK. Thamer's research aim is to explore the role of government and private institutions in supporting early stage entrepreneurs in Saudi Arabia. In his data analysis stage of the research project, looking forward to benefit from the ECIE.

Marlene Amorim is Assistant professor at the Department of Economics, Management, Industrial Engineering and Tourism, University of Aveiro, Portugal and a member of the Research Unit in Governance Competitiveness and Public Policies. She serves as Pro-rector for Internationalization and currently integrates the editorial team of the International Journal of Supply Chain and Operations Resilience.

Emre Arslan holds an MA in International Business Administration from Bournemouth University. He currently works in completing his PhD thesis that deals with Strategic Entrepreneurship within Voluntary Organisations in England. He has also worked as a Lecturer in Research Methods in Bournemouth Business School.

Dr Ramika Bansi recipient of the 2014 Howard Bremer Scholarship awarded to professionals bringing creativity and innovation to the technology transfer profession. Masters topic: Management of Intellectual Property at Universities. Doctoral study focused on Technology Transfer & Commercialization of University Innovation. Dr Bansi serves as MANAGER: Intellectual Property Rights & Innovation Specialists at Durban University of Technology - South Africa.

Raphael Bar-El is Professor Emeritus at Ben Gurion University and the Chair of the Applied Economics Department at the Sapir Academic College, where he established the specialization of entrepreneurship and innovation. He led projects of regional economic development and of innovation promotion in Brazil and in Latin America.

José Jacinto Bilau: Coordinator Professor at Polytechnic Institute of Beja (Portugal) with a PhD. In Management (Technical University of Lisbon-ISEG), MBA (Technical University of Lisbon-ISEG) and Bachelor in Management (Technical University of Lisbon-ISEG). His research Interests are Entrepreneurship /Entrepreneurial Finance

Sarah Louisa Birchley Professor Birchley works in the Graduate School of Business Administration and Faculty of Business Administration, Toyo Gakuen University. She is currently on sabbatical researching expatriate entrepreneurship as a Visiting Scholar at the University of Cardiff, Wales and the University of Texas at Austin.

Thomas Bjerre Bojsen has a bachelor's degree from Department of Business Development and Technology at Aarhus University in business development engineering and is currently pursuing a master of science in technology-based business development. Thomas's main interests are within management of innovation and engineering processes in complex product development processes with emphasis on digital technologies. Thomas is working as junior compliance officer in the Dovista company.

Nancy Bouchra Hanna is an assistant lecturer at the German University in Cairo. She received her master degree from the German University in Cairo in the field of strategic management. She also worked as a part time consultant for Nestle Egypt, CSR division. She is currently pursuing her PhD in the field of strategic management and more specifically in capability development. Research interest includes: CSR, competitiveness and developing capabilities and competences, Entrepreneurship, Cognitive Psychology.

Dr. Tiina Brandt works as Research and Development specialist at Tampere University of Applied Sciences. Her research interests concerns about entrepreneurship, organizational behaviour, personality related topics

Natalia Bukhshtaber is an Associate Professor at Lomonosov Moscow State University Business School in Moscow, Russia. She has been involved in the field of entrepreneurship since 2008. Her main research interests relate to national innovation systems and entrepreneurial behaviour in the context of transitional economies, including the role of networking and social capital in innovation.

Sofia Cardim is a Professor at the Polytechnic Institute of Bragança, Portugal, where she teaches diverse courses in the field of Economics and Management. With a PhD in Applied Economics her actual research

concerns labour market, gender and development policies and entrepreneurship. She also works as a business and management consultant since 2003.

Angelo Cavallo, Ph.D., is Postdoctoral Researcher at Politecnico di Milano, Italy. The main research areas in which he operates are: Strategic Management, Entrepreneurial Strategy and Entrepreneurial Dynamics. Since 2013, he has been coordinating startup scouting projects at PoliHub - the startup incubator of Politecnico di Milano.

Jesper Lindgaard Christensen is an associate professor at Department of Business and Management, Aalborg University, Denmark. JLC is the research group manager of a reserach group with 27 scholars specialised on innovation and entrepreneurship. JLC has researched SME development and entrepreneurial finance, economic geography, innovation systems, entrepreneurship, and innovation policy.

Jeppe Christensen holds a bachelors degree in global business engineering from VIA University College. He is currently pursuing a master of science in technology-based business development from Department of Business Development and Technology at Aarhus University. Jeppe's main interests include technological development, project management and sustainable development.

Atanásio Cossa holds a master in Management, specialization in Finance, at University of Aveiro, where is currently attending Doctoral Program in Economic and Business Sciences. He has been working as teacher of corporate finance, international finance and financial analyses at Eudardo Mondlane University – Mozambique. He is a researcher in behavioral finance, financial literacy, entrepreneurship.

Diana Dias is associate professor with habilitation at Universidade Europeia Laureate International Universities and, vice-rector for research and academic development. She is also senior research fellow at Centre for Research in Higher Education Policies (CIPES) and holds a PhD in Educational Sciences and the Habilitation in Educational Psychology. Her research interests focus on the higher education topics, namely: learning outcomes and competencies; academic success; access and equity; and curriculum development (hybrid and face to face). She is also author of several publications in the national and international scope, indexed in Web of Science and/or SCOPUS.

Dr Gareth Davies is an Associate Professor in Swansea University's School of Management. His work involves research and teaching in the fields of Innovation Management and Regional Economic Development, with practitioner roles in a range of major initiatives including the Swansea Bay City Region Internet Coast City Deal.

M.Sc. Marvin Drewel studied industrial engineering at the University of Paderborn, specialising in innovation management. Since March 2016 he has been a research assistant at the Heinz Nixdorf Institute of Prof. Gausemeier in the department of Strategic Product Planning and Systems Engineering. His research focuses on industry 4.0 and strategic planning of digital platforms.

Ingunn Elvekrok is an associate professor at University College of Southeast-Norway, School of Business. Her research interests include innovation, networks and regional innovation politics, as well as change management and tourism studies. She has published in journals such as Regional Studies and Journal of Travel research.

Maria de Fátima Ferreiro: Assistant Professor at ISCTE-IUL and researcher at Dinâmia'CET-IUL. Teaching and research areas in innovation and territory, social innovation and sustainality, and food security. Currently head of the Departament of Political Economy and deputy director of the School of Social and Human Sciences at ISCTE-IUL.

Dr. Paul Flynn is a Fellow of the International Society of Design & Development in Education. Co-PI STARTED Project (Erasmus+), Co-Director of Breaking the SEAL Programme. Graduate of Entrepreneurship Development Programme at MIT (Sloan) and Director of Innovate21 - a newly formed innovation based outreach programme at NUI Galway. Co- Founder of LaunchPad Education.

M.Sc. (Econ.) Riitta Forsten-Astikainen works as project researcher at the Microentrepreneurship group MicroENTRE at the University of Oulu in Finland. Her current research focuses on entrepreneurship as practice,

microenterprises and growth management, entrepreneurs' work values and resilience and discourses on entrepreneurship.

Michael Fowle won DTI Startup of the Year 2004 and the MIT International Business Plan Competition 2010, with two of his own companies. He taught at Edinburgh and Strathclyde Universities, directed the applied entrepreneurship programmes at Northumbria and is now developing BA and MSc programmes at Heriot-Watt. His research focus is the promotion of entrepreneurship.

Anderson Galvão, researcher at Centre for Transdisciplinary Development Studies (CETRAD), is a PhD student in Management at University of Beira Interior, has a Masters in Management from the University of Trás-os-Montes and Alto Douro, where he developed a master's thesis with the following themes: Training of entrepreneurship in Vocational Schools. Currently, are main areas of interest including entrepreneurship, innovation, education or training for entrepreneurship and regional development.

Oleg Golichenko has a degree of Doctor of Economic Sciences. He is a chief research associate at the Central Economics and Mathematics Institute of the RAS. He is also a professor at the Moscow Physics and Technique Institute. His research interests are related to investigation of innovation development processes and design of public policy.

Theresia Gunawan is a lecturer and researcher in Business Administration Department- Parahyangan Catholic University Bandung. She got her Ph.D from Eindhoven University of Technology in Department of Industrial Engineering & Innovation Sciences. Theresia is also involved in Ministry of Human Development and Culture's research as well as in International NGO's.

Angela Hamouda (School of Business and Humanities, Dundalk Institute of Technology, Ireland) Angela is a lecturer of Entrepreneurship, Creativity and Innovation and has extensive experience of working with students across multiple disciplines at both graduate and post graduate level. Her areas of research interest include; entrepreneurship education, female entrepreneurship, social innovation, engineering entrepreneurship, entrepreneurial networks and enterprise support mechanisms.

Ahmad Hijazi is passionate about the dynamics of Innovation and Culture. Somehow a professional and intellectual flâneur, he currently works on designing and developing systems, consulting on brands, localization, innovation strategy, and creating innovative educational tools. He's also a Lecturer and Corporate Trainer. Interests range from markets, algorithms, and gamification, to literature, philosophy, and spirituality.

Thomas Howson, PhD Scholar Medicine and Healthcare Studies, Swansea University Medical School and The Life Sciences Hub Wales. Howson is currently a third year PhD scholar and early career researcher at Swansea University Medical School. Mr. Howson completed his Batchelor of Science (BSc) degree in Biological and Medical Sciences at The University of Liverpool, UK and also has a background in Intellectual Property. Thomas has recently undertaken a review for the Welsh Government on behalf of Swansea University, as well as working alongside other major organisations including PriceWaterhouse Cooper (PwC) and the Welsh Blood Service. Thomas has a passion for Health Technology, Health System Improvement and models of Integrated Healthcare.

Yuko Inada is currently a PhD student of advanced management at Kwansei Gakuin University in Japan. She received international MBA in IE Business School in Spain. Her research interests include entrepreneurship education, collaborating learning, cross-cultural management, and EMI (English as a Medium of Instruction) in higher education.

Alexis Jacoby is a professor at the Master's programme in Product Development of the University of Antwerp. He holds a PhD in Product Development and teaches innovation, strategic design and product development methodology. He worked as a design consultant in industry. His research focuses on methods and tools in the Front-end of Innovation.

Lukas Keicher M.Sc. After his Master degree in Technology Management at the University of Stuttgart, he started his career at the Institute of Human Factors and Technology Management IAT at the University of Stuttgart, where he is currently employed as research fellow in the department for Technology Management.

Alena Klapalová is the senior lecturer at Masaryk University, Faculty of Economics and Administration, Department of Corporate Economics and at College of Polytechnics Jihlava, Department of Economics Studies Czech Republic. Her teaching focuses on Quality management, Logistics and Supply Chain Management, Marketing, Management, International, Global and Cross-cultural Marketing. Her research interests are primary in Innovation and Knowledge Management and Reverse Logistics and Reverse Supply Chain Management, general Management, Social media and Customer/consumer behaviour.

Monika Klimontowicz, Ph.D, is an Assistant Professor at University of Economics in Katowice, Department of Banking and Financial Markets. Her scientific interests focus on business strategy, banking innovations, creating value for customers, knowledge and intellectual capital, and competition on banking market. She has been working as a bank's marketing manager and business consultant for over 15 years.

Ilker Kose is currently working as a faculty member of MIS and the director of TTO in Istanbul Medipol University, Turkey. Aside from his main study area, data mining, he is also working on innovation management, technology transfer and university-industry relationships. He has more than 15 years of experience in healthcare and health insurance domains.

Tatiana Jurievna Kudryavtseva – associate professor at Graduate School of Industrial economics of Peter the Great St. Petersburg Polytechnic University. I conduct the following courses: financial management, economic analysis, financial analysis.

Inês Costa Lima holds an undergraduate degree in Design from the University of Aveiro and integrates the top management team in human resources, quality, commercial and design communication departments as the Operations Coordinator at RealBase, an organization that acts in the graphic arts sector.

Ekaterina Litau is ITMO University Assistant Professor (Department of Financial Management and Audit). She has 8 years of experience in teaching and research and 15 years in business. Her research deals with entrepreneurship, cognitive economics, enterprise development, and financial management. She has authored 2 textbooks, more than 20 papers and developed master and bachelor courses.

Diana Loio obtained a degree in Business Management (2013) and a degree in Tourism (2008) by the Polytechnic Institute of Viseu. She is currently attending the Master's degree course in Management at the University of Aveiro. She collaborates in the organization and management of international sports events and has collaborated with Enotourism projects.

Luciano Barcellos de Paula holds a Doctor in Business (cum laude) and a Master's Degree in Business, Finance and Insurance from Universidad de Barcelona, Spain, a MBA from Universitat Politècnica de Catalunya, a MBA and Leisure Management from the EAE Business School, Spain, and a Bachelor's degree in Economic Sciences from Universidad Federal Fluminense, Brazil.

Kamila Malewska is an assistant professor in the Theory of Organization and Management Department at the Poznan University of Economics and Business (Poland). She defended her PhD dissertation in 2008 (her thesis was related to the resource-based view of strategic management). Currently the subject of her research is the role of intuition in the management, especially in decision-making process.

Carla S. E. Marques is Assistant Professor (w/Aggregation) at the University of Trás-os-Montes e Alto Douro (UTAD), Portugal. Currently, she coordinates the 'Innovation, Markets and Organization' research group at UTAD's Centre for Transdisciplinary Development Studies (CETRAD). Her research on innovation and entrepreneurship has been presented at numerous international conferences and journals. Her research interests include innovation, management of change and entrepreneurship.

Lurdes Martins is an Adjunct Professor at the Polytechnic Institute of Viseu, Portugal, where she teaches Business English and English for Tourism to undergraduate students. She holds a PhD in Linguistics (2012). Her research interests include Web 2.0 enhanced foreign language learning, social networked language learning, collaborative language learning, digital literacy, and English as a Lingua Franca.

Dr Ana Martins is Associate Professor in Leadership at the Graduate School of Business & Leadership (GSB&L), University of KwaZulu-Natal, Durban, South Africa. She holds a PhD in Leadership, Information Systems and Organisational Behaviour with over 25 years of experience in scholarship and teaching experience. Her research interests are on emerging concerns for humanising organisations and Leadership; developing human capital, nurturing spiritual and emotional capitals, trust and tacit knowledge; harnessing communities of practice, social capital, innovation and creativity in teams. She is an associate reviewer for various international peer-reviewed academic journals.

Carla Mascarenhas, researcher at the Center for Transdisciplinary Development Studies (CETRAD) is a PhD student in Management at University of Beira Interior, has a Master in Science. She developed at the beginning of her carrier research in Chemistry. Currently, she is the IP Managerat University of Trás-os-Montes e Alto Douro. Her main areas of interest include innovation, university-industry cooperation, technology/ knowledge transfer, entrepreneurship and regional development.

Adam Mazurkiewicz, Prof., CEO at the Institute for Sustainable Technologies - National Research Institute, Radom, Poland. Manager and expert in research projects in the areas of systems engineering, machine construction and maintenance, materials engineering, technology transfer, foresight. Mazurkiewicz is an expert in FP6, COST, Polish interdisciplinary research groups. He is also Head of strategic national and international programmes and author of 300 publications including 22 monographs.

Daniel Michelis has a professorship with a focus on Online-Communication at Anhalt University of Applied Sciences. His research focuses on how the Internet has changed marketing and communication. He is the founder of the master's program in online communication at Anhalt University.

Alejandra Molina Osorio, Professor in the Business and Economics department, Universidad Autónoma de Manizales – Colombia. Ph.D. student in economics from Universidad EAFIT. She holds an MBA and undergraduate degree in Economics from Universidad Autónoma de Manizales. Her research interest revolves around industrial organization, microeconomics and development microeconomics

Viviana Molina Osorio, Professor in the Business and Economics department, Universidad Autónoma de Manizales – Colombia. Ph.D. candidate in design from Universidad de Caldas. She holds an MBA in Finance from Universidad EAFIT, and undergraduate degree in Economics from Universidad Autónoma de Manizales. Her research interest revolves around design, entrepreneurship and complex artifacts. Part of *"Manizales-Más"* since 2013.

Chris Moon is a multiple award winning eco and social entrepreneur and the founder of several eco businesses. Moon was also formerly Head of Sustainability for two companies and Divisional Director, Energy and Sustainability for the UKs largest private firm of consulting engineers and is founder of CSR Global, Certified and accredited CSR consultant and Social Auditor.

Reseach Professor Matti Muhos is the Research Director of Micro-Entrepreneurship at the University of Oulu. He is the Research Professor of Industrial Engineering and Management, Renewing Business and Digitalisation at the University of Jyväskylä. He has a title of docent in technology business at University of Jyväskylä. D.Sc. (Tech.) Muhos has received his doctorate in industrial engineering and management from Universtity of Oulu.

Marina Novikova Bachelor in Sociology and Master in Studies in European Societies at Saint Petersburg State University (SPBU), Russia. Currently an Early Stage Researcher in RurAction Project "Social Entrepreneurship in Structurally Weak Rural Regions: Analysing Innovative Troubleshooters in Action" (Marie Sklodowska-Curie Action) and a PhD student at Instituto Universitario de Lisboa (ISCTE-IUL), Portugal.

Prof. Celina M. Olszak, Ph.D. is a dean of Faculty of Economics, a chair of the Department of Business Informatics as well as Deutsche Akademische Austausch Dienst and Swiss Government scholarship holder. Her research focuses on decision support systems, organizational creativity, business intelligence and big data.

Michael O'Sullivan Michael studied Product Design at the University of Limerick and is currently a researcher for the Horizon 2020 project 'IBUS', which aims to develop an integrated business model for customer-driven

custom product supply chain. Through this research he is pursuing a PhD in New Product Development, with a particular focus on mass customization and co-design.

Bakhtnur Otarbayeva Otarbayeva B, Ph.D. in political science is an associate professor in the School of Public Policy, director of NGO Expert Center of ALMA U., Fulbright scholar. She had 10 years of work experience in non-profit sector. In 2014, she worked out a curriculum of the MBA program "Management in Non-profit Sector".

Luciano Barcellos de Paula holds a Doctor in Business (cum laude) and a Master's Degree in Business, Finance and Insurance from Universidad de Barcelona, Spain, a MBA from Universitat Politècnica de Catalunya, a MBA and Leisure Management from the EAE Business School, Spain, and a Bachelor's degree in Economic Sciences from Universidad Federal Fluminense, Brazil.

Ruslan Pavlov is a senior researcher at the Central Economics and Mathematics Institute, and post graduated from the same institution. His research interests include the diversification of business within a context of the long waves theory; institutions of social entrepreneurship as factors of social innovations.

João Pereira holds a Bachelor degree in Renewable Energy Systems Engineering (Polytechnic Institute of Viana do Castelo) and a Master Degree in Industrial Engineering in the field of Project and Innovation Evaluation and Management (University of Minho). Today he is responsible for the department of innovation in the company Gelado Colorido.

Adriana Perez Encinas, Ph.D., consecutively completed her MBA and a doctorate on business Economics, with a special focus on strategies for welcoming international students and support services provided. She is lecturer and researcher on business organisations and internationalisation of higher education at Universidad Autónoma de Madrid, Spain. Her research focus on internationalization of Higher Education, strategy, entrepreneurship and university services for students.

Noemí Pérez-Macías, PhD student at Universidad Pontificia Comillas, Madrid, focusing her lines of investigation on entrepreneurship form different perspectives. Professional experience on external (Deloitte, Madrid) and internal auditing (House of Fraser, Londres) as well as finance and commercial experience in other enterprises. Currently associate professor at Universidad International Isabel I de Castilla.

Edita Petrylaite is Lecturer in Strategy and Leadership at Northumbria University, UK. She is a Fellow of the Higher Education Academy (HEA) and member of Charted Management Institute (CMI). She holds a PhD degree in Business Management studies. Her research interests include masculinity, consumer behaviour, leadership, entrepreneurship and entrepreneurial marketing.

Jorge Hermínio Pires: is Adjunct Professor at Polytechnic Institute of Beja (Portugal). Pires has a PhD. In Management (Universidad de Extremadura-UNEX, Spain), an MBA (European University - EU, Spain and Portugal) and a Bachelor in Management (ISCTE-IUL, Portugal). Hi research interests are Entrepreneurship, Innovation.

Dr. Sergei N. Polbitsyn is Professor of Innovation Management and Entrepreneurship at Ural Federal University. He is also a senior researcher at the Institute of Economy of the Ural Chapter of Russian Academy of Sciences. His research interests include rural entrepreneurship, innovation policies and systems, food supply systems, social and economic development of rural communities.

David Postolski, a partner at Gearhart Law, is a registered patent attorney and Intellectual Property attorney. David specializes in assisting inventors, creators, artists, start-ups, entrepreneurs, early stage companies and emerging companies with their U.S and International intellectual property strategy, protection, enforcement and monetization. David is a frequent speaker and author on intellectual property issues surrounding emerging technologies (cannabis, crypto currency, 3d printing, gig economy), raising capital, business formation, licensing, and reward and equity based crowd funding. David is also a Professor at Parsons School of Design and is founder of the International Action Group and editor of their monthly newsletter.

Beata Poteralska, senior researcher, PhD in economics, head of the Innovation Strategies Centre in the Institute for Sustainable Technologies-National Research Institute in Radom, Poland. She has been involved in execution of 18 international projects (Horizon 2020, FP7, FP5, COST, ERASMUS+) and 36 national projects. She is author and co-author of over 90 publications.

Hossein Rahimi Jafari holds an MA in business management from Azad university (Semnan Branch). Hossein has participated in two national and one international conferences and has a published article in international journals. Hossein has been conducting international business for 12 years (in the area of cooling and heating systems for residential purpose) and has a factory for manufacturing heating system (for residential purpose), Hossein is the General manager in this company . In 2014 Hossein`s company was selected as a top entrepreneural company by the government .

Assunção Mariana Ramos graduated in Agronomic Engineering from the University of Trás-os-Montes and Alto Douro. In the same year she attended the Intensive Quality Management Program for the Horticulture Supply Chain (IP-QMHortChains) at the University of Hannover, coordinated by the University of Wageningen. Assunção Ramos did a curricular internship in a Farmers' Organization in sustainable production and she was a consultant in computer science in agrarian management. Assunção returned to CAP - Farmers of Portugal and currently works in the central region for the districts of Aveiro, Coimbra and Viseu. Ramos is finishing her Master's degree at the University of Aveiro.

Mario Raposo, phd in Mangement, full professor of Marketing and Strategy and vice-rector at the University of Beira Interior, is researcher at NECE – Research Center in Business Science in the area of entrepreneurship, competitiveness and innovation, coordinator of several European projects and author or co-author of more than seventy papers published in international journals.

Diego Araujo Reis - PhD student in the Post-Graduate Program in Intellectual Property Science of the Federal University of Sergipe (UFS). He holds a degree in Economics and a Master in Regional Development from UFS. Has experience in the area of economy, entrepreneurship and innovation.

Maria Ribeiro obtained a bachelors degree in Public Administration and a Master's degree in Management, both from the University of Aveiro, Portugal. Maria has been participating in various activities throughout her academic career. You're looking for your first job

Dr. Pete Rive is the former Chairman of Film Auckland, a New Zealand producer with over thirty years experience in the screen industry. Pete has a PhD in digital design specializing in innovation and commercialization in virtual worlds. His current research is in speculative design, the Anthropocene and the weaponization of education.

Andreia Rodrigues is a student at the University of Aveiro (Portugal), where she took the undergraduate degree in Languages and Business Relations. Currently, she studies on the Master's Degree in Management. Andreia has several interests in the Management area, such as Human Resources and Marketing.

Henk Roelofs (drs. econometrics) is senior lecturer at NHL-Stenden University in Emmen and co-owner of LE-Network, a company, founded in 2002, specialized in role game simulations using LEGO. He has lead several EU co-financed projects for start-ups in his university and partner organizations and has published several articles using the experimental method with his simulations

Irene Rothe received the Diploma in mathematics from the University of Jena, Germany, and her PhD in 1995. After working in a team as a software developer and as a team leader as a software designer she joined Bonn-Rhein-Sieg University in Sankt Augustin, Germany, in 2003 as a professor for computer science and mathematics.

Frank Rouault, DBA: Since 1999, Frank has created and manages Practical Learning France, a boutique consulting that helps management teams render explicit and execute their strategies in domestic / international contexts. As a French Foreign Trade Advisor, Frank sensitizes young generations to international

business and intercultural awareness. Frank has published + 20 books. www.frankrouault.com www.practicalearning.com

Dr Michele Rusk is an experienced senior academic, public sector adviser and management consultant. Her PhD addresses Entrepreneurial Leadership by Design - The Role of Design in Socio-Economic Innovation. A Fellow of the Chartered Institute of Marketing, and Fellow of the Higher Education Academy she holds a primary degree in Design and an MBA. Her expertise is in entrepreneurial leadership, strategic design, development and innovation management and marketing communications. Her experience spans new product and international market development; government strategy and policy development; and international development work in Poland, Russia, Armenia and the Ukraine.

Dr Krzysztof Sala A graduate of International Economic Relations (specialization European Studies) at the Cracow University of Economics (master's degree) completed diploma, post-graduate studies in the field of quality management and environmental protection School of Management and Banking in Krakow and the College of Management and Finance School of Economics in Warsaw, leading to a doctoral degree in economic sciences. Many years of experience in business practice in various positions unions. The main areas of interest include economic policy and tourism Polish and European Union, entrepreneurship in small and medium-sized businesses, and strategic management.

Isabel Salavisa, PhD, is Associate Professor of Economics at ISCTE- IUL, and researcher at DINAMIA'CET-IUL, Lisbon. Her main research areas are economics of innovation and sustainability. Recently, she has published in Technovation, IJIRD, EJIM and SER. Currently, she conducts research at SPLACH Project - Spatial Planning for Change.

Svetlana Samovoleva, PhD, specialist in the field of innovation, is a lead research associate of the Central Economics and Mathematics Institute of RAS. Her main research interests are the innovation policy, knowledge diffusion, technology transfer.

Ana Maria Serrano Bedia is Associate Professor of Operations Management in the Department of Business Administration at the University of Cantabria. Her primary research interests are in the fields of innovation management, manufacturing flexibility, entrepreneurship and family firms.

Lukasz Serwanski holds bachelors degree in management and production engineering from Krakow University of Economics. He is currently pursuing a master of science in technology-based business development from Department of Business Development and Technology at Aarhus University. Lukasz's main interests include operational development, industrial automation, and sustainable development.

Dmitry K. Shaytan is co-founder of innovationStudio, Lomonosov Moscow State University, Faculty of Economics, where he manages acceleration programs, and teaches entrepreneurial management courses. He is entrepreneur, founder and general manager of the innovation company "ETB" that designs software and hardware based innovative solutions. Educational background: MS in physics, and MBA.

Dr. Anna-Mari Simunaniemi (Food, nutrition and dietetics) works as post-doctoral researcher at the Microentrepreneurship group MicroENTRE at the University of Oulu in Finland. Her current research focuses on entrepreneurship as practice, microenterprises and growth management, entrepreneurs' work ability and discourses on entrepreneurship. She is processing her second doctoral degree on management at Oulu Business School.

Ass. Prof. Radoslav Škapa is the senior lecturer at Masaryk University, Faculty of Economics and Administration, Department of Corporate Economics, Czech Republic. He holds lectures in Operation Management, Logistics and Supply Chain Management and in Marketing Research. His research is focused on reverse logistics, product returns and efficiency and effectiveness of operations.

Angi Erastievich Skhvediani - assistant at Graduate School of Industrial economics of Peter the Great St. Petersburg Polytechnic University. I conduct the following courses: financial analysis, econometrics, corporate social responsibility.

Tale Skjølsvik is an Associate Professor at the Department of Computer Science, OsloMet – Oslo Metropolitan University. She holds a Ph.D. in Strategic Management from BI Norwegian Business School. Her research concentrates on the strategy, digitalization, design thinking and purchasing of knowledge intensive service firms. Tale has published papers in a number of leading international publications.

Iwona Skrodzka is Assistant Professor at the Faculty of Economics and Management at the University of Bialystok (Poland). She is teaching courses of mathematics, statistics, econometrics, and mathematical economics. She is engaged in research into application of multivariate analysis methods to study unobservable phenomena: human capital, social capital, intellectual capital, economic development, smart growth.

Inês Martins Soares was born on October 31, 1996, in Aveiro. She holds a degree in Management from the University of Aveiro. Currently, she attends the master's degree in Management at the Faculty of Economics of the University of Porto. Her interests include Commercial Management, Financial Management, and Corporate Social Responsibility.

Cristina Sousa is Assistant Professor at Universidade Portucalense and director and researcher at REMIT – Research on Economics, Management and Information Technologies. She is also Researcher at Dinâmia'CET-IUL (ISCTE-IUL). Her research interests include: innovation processes and their socio-economic effects; the dynamics of knowledge and innovation networks; entrepreneurship; and the transition to sustainable systems.

Dr. Inga Stankevice, Lecturer, represents School of Economics and Business, Kaunas University of Technology, Lithuania. Her research includes innovation structures, project management**.**

Lucia Štefaňáková I am currently studying at Masaryk University Master's degree programme, at Faculty of Business and Administration in Brno. My field of Study is Regional Development and Administration. I gained my Bachelor degree at Mendel University in Brno. I am part of the project named *Consumer Behaviour Research in Digital Environment* in which I did online user experience research of wine e-shop.

Audrey Stolze: Academic Researcher, currently researching Entrepreneurship Education and Digital Transformation through University-Industry interactions. Previously she managed International Projects at SCE. Audrey has over 10 years of work experience in Brazil and Europe as market researcher, international business developer and startup founder. Audrey holds a MA in International Business (Germany) and a BA in Business Administration (Brazil).

D.Sc. (Tech.) Kyllikki Taipale-Erävala is a Post-Doctoral Researcher in the MicroENTRE research team University of Oulu, Finland. Her research expertise is competencies enabling business survival in SMEs in changing business environments. Additionally, she is interested in developing micro enterprises, innovation, business models, knowledge management and servitization.

Anita E. Tobiassen is an associate professor at Oslo Business School, OsloMet – Oslo Metropolitan University. Her research has mainly focused on knowledge, innovation and internationalization of SMEs. She has published in journals such as International Small Business Journal, Journal of International Entrepreneurship, Journal of Knowledge Management, Baltic Journal of Management, Journal of Retailing and Consumer Services.

Dr Elizabeth Uruchurtu has worked in a variety of industrial, research and knowledge exchange projects ranging from the analysis and design of the user experience to the development of interactive content and applications. Her experience and expertise includes: Information Systems, Learning Management Systems, e-Commerce, Human Centred Design, and Interaction Design.

Dr. Shaili Vadera, Assistant Professor, Amity University Uttar Pradesh, Lucknow India. Dr. Shaili Vadera is a Faculty in Marketing and Entrepreneurship Area at Amity University Uttar Pradesh, Lucknow Campus. She has over 11 years of teaching experience including Doctoral programs. She earned her PhD in Economics from University of Lucknow in 2012She obtained her Post Graduate Diploma in Business Management from Institute of Productivity and Management, Lucknow. Her research interests include Entrepreneurship and New Venture Creation, Customer Relationship Management, Digital Marketing and Consumer Behavior.

Dr. Younos Vakil Alroaia has 20 years of work experience which is a bland of corporate and academics and specializes in the area of entrepreneurial development in small-scale industries. He has carried out consultancy work for the ministry of cooperative and commerce organization, as well as private company. He has published more than 85 research papers, articles and case studies in various international journals. Younos had done 18 research projects on entrepreneurship development in SSIs, Export target market, Industrial investment in Iran. Younos at the present is as a head of International center, Islamic Azad University.

Dr. Dave Valliere is Associate Professor of Entrepreneurship and Strategy at Ryerson University in Toronto, Canada. He holds a PhD in entrepreneurship, an MBA, and undergraduate and master's degrees in engineering. His research interests include culture and cognitive psychology in entrepreneurs and investors, effectiveness of information signalling in capital markets, and the economic and public-policy functions of entrepreneurship

Margarida Vicente, Ph.D. is Assistant Professor in the Department of Management at Higher School of Technology and Management of Viseu. Her research interests lie in the areas of exporting, innovation, and dynamic capabilities.

Zuzana Virglerová is an assistant professor at Tomas Bata University in Zlín, Faculty management of economics, Centre for Applied Economic Research. She is focused on business environment of small and medium enterprises, especially on risk management in this area. In addition she had worked as risk manager in real companies.

Aleksandra Wilczyńska, Associate Professor, Ph.D., D.Sc. Eng., is currently working as a lecturer at Gdynia Maritime University, Department of Commodity Science and Quality Management. She received her science degree from Krakow University of Economy with speciality in quality of food stuff. She has been conducting various research and project related to antioxidant activity of food products and raw materials, quality of regional and traditional food and other products, pro-ecological activities in the communes of the Pomerania province and recently she has engaged in the development of macro regions, including Baltic Sea Region.

Kazuko Yokoyama Professor Yokoyama is the Dean of the Graduate School of Business Administration, Toyo Gakuen University where she supervises research in the field of human resource management in Japanese companies by drawing comparisons between Japanese-style employment management and the merit-based systems. Her research is concerned with Japanese self-initiated expatriate entrepreneurs working in Southeast Asia.

Blaž Zupan, PhD, is an Assistant professor at the department for Entrepreneurship at the Faculty of Economics, University of Ljubljana. He is engaged in many entrepreneurship related courses and specializes in the field of new idea development. Alongside educational and research work he is also a co-founder of several companies and an active business consultant.

Invited Paper

Young University Spin-off Firms' Internationalization: The Influence of Founding Teams and Networks

Marina van Geenhuizen and Mozhdeh Taheri
Delft University of Technology, The Netherlands.
m.s.vangeenhuizen@tudelft.nl
mozhdehtaheri@yahoo.com

Abstract: Commercialization of inventions urges university spin-off firms to develop networks abroad, particularly if they are active in a small national economy. While it is recognized that young spin-offs are vulnerable due to lack of various resources and capabilities, support in internationalization from the university is rare. We investigate university spin-offs' internationalization using a sample of 105 of such firms in Northwest European countries. In early years, 62 per cent employ international networks, enhanced by capabilities gained in PhD education, participation in market training and innovation experience at practical level, but also (and strongly) by diversity among partners in domestic networks. Subsequent growth leads to a stronger internationalization, mainly derived from early patterns of internationalization, but a good 30 per cent of the spin-offs tend to face problematic situations, namely a shrinking pattern or persistent lack of internationalization. The paper concludes with some challenges for improvement.

Keywords: university spin-off firms, internationalization, global reach, capabilities, team and network.

1. Introduction

Universities have increasingly internationalized in the past decades, be-it in attracting students and staff from abroad, or in education through 'subsidiaries'. However, attention to internationalization of their spin-off firms has lagged behind. This is remarkable because aside from 'born globals', some segments of spin-offs are 'stuck in inertia' and not able to collaborate with partners abroad.

Various studies stress the importance of knowledge collaboration on a global level today (Bolzani et al, 2015; Heitor, 2015). A stronger specialization and importance of niche markets have limited the availability of specialized knowledge to a few places in the world, and these places are increasingly outside Europe. The OECD (2012) observes a growing role in international research activity in countries like China, Korea, Brazil and India. Today, South-Korea, the US and Japan have a lead in innovation performance over the European Union (EU) while innovation growth rates indicate that China is facing the strongest growth (8.1 per cent). This changing landscape of R&D and related innovative businesses may urge university spin-offs in Europe to establish international knowledge relationships quicker and with an increasing spatial reach. In addition, the world is also facing a massive urbanization (UN, 2014), calling for innovative infrastructural and construction solutions outside Europe and US, like practiced on-site in housing projects and port development, etc.

With regard to the larger class of high-tech SMEs, internationalization is clearly promoted as making firms growing stronger and becoming more profitable (EC, 2014); this e.g. through scale and scope advantages in specialized value chains, and benefits from collaboration with demanding R&D institutes, customers and suppliers overseas (Love and Ganotakis, 2012; Onkelinx et al, 2016). Internationalization among young high-tech SMEs has received attention for a long time, be-it as a stepwise path, the 'Uppsala model' and its revisions (e.g. Johanson and Vahlne, 2009) or more radically like among 'born-global' firms (e.g. Andersson and Wictor, 2003). More recently, attention has been drawn to a larger variation in paths of internationalization (e.g. Knight and Liesch, 2016).

Internationalization can take many forms, like collaboration with suppliers abroad, FDI investment, knowledge exchange, export activity, etc. Also, internationalization can take different modes of presence abroad, like an own sales office, representing agencies, or no presence but regular visits or electronic communication, all with different challenges and risks. No matter which type and mode, internationalization requires an appropriate level of resources and timely adjustments. The core concepts here are absorptive capacity and dynamic capabilities, in other words, the building, integration and reconfiguring of capabilities that are required to enable to deal with rapid external changes and adjust to new circumstances and challenges in technology and markets (Cohen and Levinthal, 1989; Escribano et al, 2009; Teece et al, 2007). There are two contrasting views on young high-tech firms and dynamic capabilities. In one view, young firms are facing a high vulnerability (liability of newness and foreignness) preventing an adequate responding to external changes, in particular to

opportunities of international knowledge relations. In a contrasting view, young firms benefit from a relatively large flexibility in decision-making, responsive learning and quick adjustment, and 'go abroad' immediately or short after firm establishment (Zaheer, 1995; Teixeira and Coimbra, 2014). How large such different segments would be among university spin-offs is however not known, also, it is not clear whether there is change over time.

As one of the first, we picture dynamics in internationalization. To our knowledge, there has been no research of larger samples that reveal international knowledge relationships of university spin-offs over time. Also, the attention for capability factors and resources is limited in research on spin-off firms (Bjørnali and Aspelund, 2012; Taheri and van Geenhuizen, 2011). Capabilities have two origins, team capabilities developed in the past, including pre-start years (Rasmussen et al, 2014), and external capabilities through networks (e.g. Milanov and Fernhaber, 2014). There is no consensus on which matters more in internationalization, the team or the network. Internationalization is conceived in this study as employing knowledge relationships abroad, which are rather stable and through which important knowledge about R&D and business activity is developed and exchanged.

Against this backdrop the research questions are as follows: 1) What are the patterns of international knowledge relationships and which changes have taken place over time? 2) To what extent is internationalization influenced by capabilities in the founding team and capabilities through networks? 3) What may be the implications for university support?

The study draws on interview data of 105 university spin-off firms in Northwest Europe in 2006 and an update ending in 2012, and various case studies in 2014. The paper unfolds as follows. Theoretical and empirical perspectives (Section 2) are followed by methodological steps (Section 3). Next is the analysis of the changing spatial pattern in knowledge relationships (Section 4) and the exploration of capability factors (Section 5). Implications and suggestions for support are in the Conclusion.

2. Capability factors

Firms with stronger capabilities are not only better equipped to identify and gain external knowledge that is valuable wherever in the world it is, but also to learn about barriers hindering the establishment of relationships, producing that valuable knowledge. Such barriers can be grouped into three categories: resource barriers, like shortages in investment capital, management skills, reputation; cultural barriers, like difficulty to adjust to language and cultural norms in doing business and in management practice; and institutional (legal) barriers, like in dealing with different financial and tax-related regulation and intellectual ownership (IO) issues. Firms' capabilities are not the core of the current study. We address capabilities not directly, but we address factors that are associated with increase/decrease of capabilities, like participation in training.

We develop a model as a set of capability factors influencing the reach (scale) in internationalization and changes herein between 2006 and 2012. We address nine capability factors below. First, a successful training of personnel in market potentials/marketing increases firm capabilities in identification and acquisition of new knowledge, while overcoming specific barriers, even in other continents (Escribano et al, 2009; Teixeira and Coimbra, 2014). Further, drawing on literature on accumulated knowledge within firms' founding teams, we assume that size of the founding team is an important factor in building and managing knowledge relationships, while smaller teams have limited absorptive capacity and capabilities in searching for the right partners and best matching knowledge domains (Colombo and Grilli, 2010; de Jong and Freel, 2010). We also assume that accumulated knowledge through working experience and main education of founding team members, as skills, expertise and understanding that have been gathered prior to the start, are important factors in spin-off firms' capabilities in acquiring new knowledge internationally (e.g. Visintin and Pittino, 2014). For example, Bjørnåli and Aspelund (2012) suggest that university spin-offs benefit from (industrial) experience of their founding teams in establishing international relationships through strategic alliances and sales. Moreover, a PhD education of a founder could provide firms with stronger capacity to overcome barriers like cultural (language) barriers and information barriers, and utilize pre-start networks (Bolzani et al, 2015; Taheri and Van Geenhuizen, 2011). Furthermore, some literature also points to innovation experience as a source of capabilities that enhance internationalization (Castellacci, 2010). We distinguish between two broad types of innovation, the one at practical level that is less novel and closer to market (as found at engineering

schools – civil engineering, architecture and spatial planning, etc.) and the one at advanced (basic) level requiring interaction with top research groups and highly specialized service providers.

In addition, employing domestic networks provides experience that is helpful in establishing relationships abroad, aside from resources that are directly useful, like the existing marketing organization of a domestic firm (Milanov and Fernhaber, 2014). In a similar vein, pre-existing networks abroad may make later international knowledge relationships more efficient and better to manage because spin-offs have already learned how to integrate internal knowledge with knowledge from foreign partners. Because the establishment of knowledge networks and the use of an office or agency abroad are resource-intensive, we expect no drastic changes in internationalization, only minor ones, after five years (Gilbert, 2005). Though there may always be spin-offs that make a jump ahead and increase internationalization.

To control for the influence of specialization in the regional economy of university spin-off, we include location as a control variable. Accordingly, spin-offs in clusters with a focus on international oil/gas production or in a small regional economy, are seen as activated to employ international knowledge relationships to a larger extent compared to spin-offs in more diversified and larger regional economies. Further, we include two factors on entrepreneurial orientation (EO) of firms. First, being engaged in science-based versus market-based industry, where science-based firms tend to be globally oriented in learning while in sectors pushed by market demand, adaptive learning is important which benefit more from local face-to-face interactions (Asheim et al, 2007). And secondly, the initial strategic vision on growth, in terms of becoming a large and international firm or remaining small and mainly domestically oriented (Lumpkin and Dess, 1996).

3. Data and methods

3.1 Data collection

We draw on data concerning two university cities, Delft (Netherlands) and Trondheim (Norway). The two countries share a similar, somewhat risk-avoiding entrepreneurship culture (GEM, 2010), have similar scores on the main European Innovation Scoreboard in years of this study (ProInno Europe, 2011) and face relatively small domestic markets, urging specialized firms to be export-orientated. Data-collection took place in two stages, in 2006 and 2012. In 2006 we constructed the database, with spin-offs active in commercializing knowledge created at university and survived to 2006 at an age not older than 10 years (150 spin-offs). Selection bias from not-surviving can be ruled out as simulation indicated that firms that failed in this period do not differ significantly from the ones that survived. Given an overall response rate of 70%, data were collected using a semi-structured questionnaire in personal face-to-face interviews with the principal manager, as member of the founding team. In 2006, we collected cross-sectional data on international knowledge relationships, and on several firm characteristics during the start-up phase and first years. Five years later we pictured their internationalization once more, using a short e-mail survey and/or telephone call.

3.2 Measurement

The dependent variable in this study, spatial patterns of international knowledge relationships, is measured as an ordinal variable in four categories (Table 1): (1) no international knowledge relationships, (2) only in Europe, (3) only in North/South America or Asia, and (4) in all relevant continents simultaneously (Europe, North/South America, Asia). We asked the respondents about the "most important organisation from which the firm acquires essential knowledge developed in the context of the firm's growth" and its location. Because many spin-offs were reluctant to mention a particular city – for sensitivity reasons in R&D and privacy reasons for foreign firm collaboration - the country level was adopted. Due to small numbers per country, we had to aggregate countries to the level of continents.

We include participation in market-related training in the model, as a dummy variable. The other variables connected to capabilities are measured as follows: founding team size as number of its members; working experience as the average number of working years prior to firm foundation (first three members); education as number of doctorate degrees in founding team; and experience with innovation by measuring an advanced level indicated by patents and breakthrough products/services, versus a relatively modest level, indicated by orientation towards practical market demand. Furthermore, experience with domestic social networks is measured through network size (number of social partner relations) and through diversity of partners. The last is measured as the product of diversity in socio-economic background (*Hs*) and spatial pattern of partners (local, regional or national) *(EI*):

$$Div = Hs\ (1 + \frac{EI}{2}) \quad (1)$$

and $$Hs = 1 - \sum_{k=1}^{8}(\frac{a_k}{N})^2 \quad (2)$$

where a_k is the number of partners with a different socio-economic background, and where k = 1 (large business), 2 (university), 3 (small business), 4 (government), 5 (family and friends), 6 (financial investors), 7 (lead customer), 8 (others). Note that a partner could be assigned to only one main partner type (identity) while N is the total number of partners with whom a university spin-off interacts. In addition, diversity in the spatial pattern of domestic partners is calculated as:

$$EI = \frac{E_p - I_p}{E_p + I_p} \quad (3)$$

where E_p is the number of external, non-local, partners, at more than 60 minutes by car, and I_p is the number of local partners ($E_p + I_p = N$).

As pre-existing internationalization in 2006, we take the spatial pattern and the presence abroad through office(s) or distributor(s) at that time, the last as a dummy variable. With regard to control factors, firm location is measured in two categories in 2006 as a dummy variable, Trondheim or Delft. Measuring category of industry as part of EO, we distinguish between science-based as involved in basics of chemistry, life-sciences, nanotechnology, etc., versus market-based as involved in specialized input to complex production systems or infrastructures systems, e.g., information processing and sustainable energy production. Furthermore, initial strategic intention is measured using the categories small and regional/national versus large and international.

3.3 Method of analysis

In the preparation to the modelling, we checked for multi-collinearity and looked at the endogeneity issue. As social networks correlate with internationalization in 2006, these are deleted from the model for 2012. Overall, there is no serious concern for multi-collinearity. With regard to endogeneity, capability factors have been measured in 2006 mainly as the situation of the firm at start or somewhat later and partially rooted in situations at university and faculty in the years before (Rasmussen et al, 2014). In contrast, demand for internationalization has increased more recently (OECD 2012; UN 2014). Therefore we can in part exclude reverse causality.

Table 1: Descriptive statistics

Variable	
Number of university spin-off firms (2006) Idem (2012)	105 97(a)
Dependent variable: international knowledge relationships in 2006 and 2012 (b)	Not internationalized (38.0%) (18.1%) Within Europe only (28.5%) (25.7%) North/South America or Asia only (5.8%) (16.2%) All above continents simultaneously (27.7%) (32.4%)
Control variables	
Location (dummy)	Trondheim (41.0%); Delft (59.0%)
EO-Industry (dummy)	Science-based: 26.7%;Market-based:73.3%
EO-Strategic intention (dummy)	International and large: 63.8%;Regional/national:36.2%
Capability factors	
Training (dummy)	Yes (31.4%); No (68.6%)
Size of founding team	Average:2.3; s.d.:1.16;Min-max:1-5
Working experience (years)	Average:2.6; s.d.:4.05;Min-max:0-21

Capability factors	
PhD education (number)	Average: 0.6; s.d.:0.86;Min-max:0-3
Innovation experience (level of newness)	Modest level (58%); Advanced level (42%)
Domestic network size	Average: 3.5; s.d.:0.95;Min-max:2-5
Domestic network diversity	Average: 0.33; s.d.:0.19;Min-max:0-0.88
Internationalization reach in 2006	See row above on dependent variable (2006)
2006's presence abroad	No presence abroad (75.5%); Office(s) or distributors/agents (24.5%)

Eight spin-offs failed in 2006-2012.
Aggregation to three was necessary for statistical reasons.

4. Changes in international knowledge relationships

A majority of the spin-off firms in our sample (62 per cent) employs international knowledge relationships in 2006. These relationships are often crossing continents, witness the spin-offs active outside of Europe outnumbering the ones active within Europe (33.5 versus 28.5 per cent) (Table 1). Importantly, using a similar definition for internationalization as in our study, a share of 60 per cent internationalization is found among 120 university spin-offs in Italy five years after start-up (Bolzani et al, 2015), which is close to our pattern as measured in 2006. Our sample in 2012 shows that 82 per cent employ international knowledge relationships, with an increase in relationships in merely Asia or North/South America (16 per cent), a change that may be influenced by increasing innovative activities and economic growth in BRICS countries.

Next, comparing knowledge relationships in 2006 and 2012 for each spin-off individually (Table 2) we observe the following trends.

Table 2: Change in reach in knowledge relationships on individual level (2006-2012)

Change	**Abs. and %share**
Shrinking pattern incl. failed firms	17 (16%)
No change (inertia)	52 (49.5%)
Remained similar to 2006: 'not internationalized'	16 (15.2%)
Remained similar to 2006: all other reach	36 (34.5%)
Increase: one step	20 (19%)
From 'not internationalized' to 'Europe only'	9 (8.4%)
Other one-steps	11 (10.6%)
Increase: two/three steps	16 (15.5%)
From 'not internationalized' to 'NA or SA, or Asia'	6 (5.5%)
Other two/three steps	10 (10%)
Total	105 (100%)

*NA: North America; SA: South America

A large group of spin-offs (50 per cent) has not changed spatial patterns, of which a good 30 per cent could have taken next step in spatial reach. In contrast, a similar part experienced some sort of expansion in internationalization patterns, of which 20 per cent have extended knowledge relationships to the America's or Asia, or to all relevant continents simultaneously. Remarkably, 16 per cent show a shrinking pattern of internationalization - also including firms that failed to survive. All-in all, though overall internationalization has increased, a good 30 per cent of all spin-offs tend to be problematic.

5. Factors influencing knowledge relationships

The procedure of modelling is as follows. We add variables to the basic model (controls) and determine the improvement for each new model (Table 3). The three control variables (Model 1) produce a rather weak result (Pseudo R^2 of 0.07) with two EO related variables found to be positive and significant. Next, we add five variables to the model, representing capability factors in the founding team, which increases the model power by 0.06 (Model 2). Three coefficients are positive and significant, namely, participation in training, PhD education, and innovation experience at practical level. In Model 3, by adding two variables on domestic social

networks, the model power increases somewhat stronger, by 0.08. The sign of diversity in domestic networks is positive and significant, indicating a varied and rich learning that is helpful in internationalization. In the full model, additionally, size of the domestic network is negative and significant. This result refers to limited search and connection capacity abroad if spin-offs manage relatively large domestic networks.

Table 3: Regression analysis of reach in knowledge relationships (2006)

	1	2	3	4
Control variables	Coefficient (s.e.)	Coefficient (s.e.)	Coefficient (s.e.)	Coefficient (s.e.)
Location (Trondheim=1)	0.50 (0.38)	0.88 (0.46) *	0.40 (0.40)	0.74 (0.48)
EO (science-based = 1)	0.82 (0.42) *	1.09 (0.46) **	0.90 (0.44)**	1.05 (0.49)**
EO (international = 1)	1.10 (0.41) ***	1.17 (0.45) **	0.74 (0.44)*	1.02 (0.50)**
Capability factors				
Training (yes=1)	-	1.13 (0.46)**	-	0.95 (0.50)*
Size of founding team	-	-0.16 (0.16)	-	-0.24 (0.17)
Working experience	-	-0.01 (0.05)	-	-0.01 (0.05)
PhD education	-	0.81 (0.37) **	-	0.76 (0.39)*
Innovation (practical =1)	-	1.01 (0.51)**	-	1.38 (0.55)**
Diversity in domestic network (2006)	-	-	4.60 (1.22) †	6.18 (1.51)***

Pseudo R^2	0.07	0.13	0.15	0.23
Log likelihood	-104.23	-97.18	-95.51	-86.33

* P<0.1, ** P<0.05, *** P<0.01, †P<0.005

Next, we focus on international knowledge relationships for the same spin-offs in 2012 (Table 4). For this year, we also explore influence of existing reach and being-present abroad in 2006. In the first step, three control variables are included and this again produces a weak result of Pseudo R^2 of 0.07 (Model 1). By including the five capability factors in the founding team, in Model 2, the model power increases only slightly by 0.02, without a significant beta-coefficient of these factors. This situation seems to be logically following from changes in founding teams towards more professional management teams. However, some early developed capabilities may become relevant, in particular working experience. In next step (Model 3), adding early knowledge relationships regarding spatial reach and presence abroad, gives a substantial increase in model power, namely to 0.25, with significance of both factors. And finally, the full model (Model 4) is slightly stronger, pseudo R^2 reaches 0.29, with significance of working experience and innovation level. The last indicates lost importance of practical innovation in favor of advanced innovation, most probably after maturation of advanced innovation.

And finally, we need to mention a consistent lack of influence of size of the founding team. Further, we may note that the most consistent factor influencing spatial reach in internationalization – for both 2006 and 2012 - is 'entrepreneurial orientation', indicating a positive influence of the early strategic vision of the spin-offs on their growth and how to achieve it. Also noteworthy is 'location' in the full model in 2012, with a negative sign.

Most probably, the economic downturn in the observation period (2006-2012) worked out negatively on Trondheim's economy and spin-offs, thereby reducing international knowledge relationships, e.g. related to activity in oil and gas fields in new areas, like Brazil and northern Russia.

Table 4: Regression analysis of reach in knowledge relationships (2012)

	1	2	3	4
Control variables	Coefficient (s.e.)	Coefficient (s.e.)	Coefficient (s.e.)	Coefficient (s.e.)

* P<0.1, ** P<0.05, *** P<0.01, †P<0.005

Finally, we present three case studies on management capability and dealing with (potential) problematic situations, like not internationalized - despite intentions, a shrinking pattern and consolidation:

1. Weak capabilities in management, including gaining financial resources: no internationalization. Three years after establishment, the spin-off, active in health care (hygienic products) and managed by two MSc graduates, attempted to increase importance of internationalization. However, it suffered from management overload in the preparation of internationalization, like identifying user-value of the product abroad and best mode of market entry. This while the domestic market was not yet sufficiently mature, causing lack of financial capital.
2. Management overload in a 'born global' situation, in part caused by pressure from refunding of investment capital: shrinking and bankruptcy. The firm was founded by university professors and MSc graduates, on the basis of a gearless solution for wind turbines, not yet accepted in the market. Being fully internationalized after start through scientific contacts at universities, a subsidiary in a cluster abroad, and a sales office in Asia, the firm could not handle all turbulence simultaneously.
3. Uncertainty in a 'born global' development and in taking next step in manufacturing: consolidation with a question mark. The firm, founded by a university professor and managed by MSc graduates, and fully internationalized through scientific contacts, prototype testing in Asia and a supplier subsidiary in Russia, is eager to start scaling up for manufacturing of its device (writing on silicon waver using multiple electron beams) in collaboration with a partner. It fails however to find such partner, while financial issues are becoming pressing. Advanced competences are needed in negotiation and entering into important contracts, including intellectual ownership, refunding of investment capital and eventually, acquisition of the spin-off.

The above case studies indicate strong importance of management in times of turbulence in different stages of internationalization.

6. Conclusion

We investigated changes in internationalization among university spin-off firms and influence of underlying (capability-related) factors. Positive influence derived from training and PhD-education, as well as innovation at practical level, gives way to positive influence from founders' working experience. Also, prior internationalization gains importance, causing partial inertia. Our results also suggest coexistence of three segments of spin-offs: (highly) dynamic in early internationalization and further steps; early internationalization but hesitation to take further steps; and remaining dealing with merely domestic knowledge relationships. Furthermore, a deeper look into (potential) problematic situations pointed to weakness in capabilities of founding teams. Starting or consolidation of internationalization often occurs in strong turbulence and financial uncertainty, in which teams need to be able to deal with multiple management

overload. This situation, but also the different segments of spin-offs, call for customized support, not for one model.

Founding teams preferably include members with a PhD education, or benefit from similar education/experience from external specialists, e.g. in an advisory board. Further, building large domestic networks needs to be avoided because such networks act as a managerial 'burden', instead, diversity needs to be enhanced as it tends to broaden horizons in spin-offs' cognitive domain. Results like these need to be clearly communicated in incubators, to increase awareness among spin-off firms. In addition, spin-offs themselves have indicated a solution to connecting with a trustworthy partner abroad, and that is starting a program by the university (or incubator) with foreign companies in the region, through which spin-offs can learn dealing with foreign companies and with cultural and institutional barriers (Van Geenhuizen et al, 2015). More importantly, internationalization can cause or trigger situations of serious management overload, in early steps but also in consolidation. For such situations, we would suggest universities in collaboration with regional authorities, development agencies or regional banks to provide professional 'crisis management' and temporary 'postponing' of financial claims (refunding) which serves to gain time to identify potential solutions.

Academic Research Papers

A Study of Enterprising Tendencies of Undergraduates of Different Fields of Study

Maha Hettige Ravini Abhayarathne and Sarath Sirilal Kodithuwakku
University of Peradeniya, Sri Lanka
ravzzrhi@gmail.com
sarathabc@gmail.com

Abstract: Entrepreneurship has gained much attention in the recent past with the recognition of its importance to a country's economic development. Enterprising tendency measures the psychological characters associated with tendency to set up and manage projects. Understanding the level of entrepreneurial tendencies of undergraduates will help to determine if they possess the required traits necessary to become entrepreneurs and will be immensely helpful to develop tailor-made approaches to teach and conduct capacity building programs to different groups of students. Therefore the main research objective was to identify whether students from various fields of study (Agricultural Technology and Management, Psychology, Civil Engineering, Management and Veterinary Medicine) exhibit different levels of overall enterprising tendency and the key enterprising attributes. In addition, to determine the differences across first and final year students and male and female students. A sample of 386 first and final year undergraduates from the University of Peradeniya was selected using stratified random sampling technique. A validated questionnaire; Caird's General Enterprising Tendency test (GET2 test) was used to assess the level of enterprising tendency, along with few other demographic and personal characters. ANOVA, t-test and chi square methods were used to test the hypotheses in the study. Results revealed that there is a significant difference ($p<0.05$) in the level of enterprising tendencies and four out of five enterprising attributes of students from different fields of study in first year students. Agricultural Technology and Management students and Psychology students showed higher tendency levels than Civil Engineering and Veterinary Medicine students. First-year students showed higher tendency levels than final years in most disciplines of study. However, there was no significant difference in the level enterprising among male and female students. Students of University of Peradeniya; irrespective of the field of study or year of study, on average all subjects showed medium enterprising tendency level.

Keywords: Enterprising tendency, Entrepreneurial characteristics, Entrepreneurship, Students, Different disciplines of study, need for achievement, need for autonomy, calculated risk taking and internal locus of control.

1. Introduction

Entrepreneurship plays an important role especially in developing countries throughout the world as it creates self-employment opportunities thereby reducing unemployment situations, increasing economic efficiencies, introducing innovation and contributing to the national economy (Nishantha, 2009; Hindle & Rushworth, 2000; Shane & Venkataraman, 2000). Youth unemployment is considered a serious concern in Sri Lanka. The interest in entrepreneurship among youth in Sri Lanka has been found to be low and the attitude youth have towards starting up their business ventures is also negative (Ibaraguen & Cader, 2005). Sri Lankan education system introduced a new entrepreneurial studies course to the school curriculum in 2007 with the intention of promoting and encouraging entrepreneurship in the country. However the effect of these studies after many years is yet an unanswered question (Weeratunge, 2010).

Past studies suggest that study of entrepreneurship among students in tertiary education is a field of research which has gained much attention. Entrepreneurship among youth is considered necessary as it is an alternative to professional occupation especially for graduates (Brenner, et al., 1991). Most graduates tend to seek paid jobs than starting their business soon after graduation. However, the increasing demand for limited paid jobs creates an unhealthy competition among graduates. The government, therefore, has taken many measures to enhance entrepreneurship in youth (Ariyawansa, 2011). Research has been carried out to find out to find the entrepreneurial career aspirations (Rosa et al., 1997; Gunawardena et al.,2018), entrepreneurial intentions and inclinations (Samantha Kumara, 2012), the effect of personality traits on entrepreneurial capacity (Denis, et al., 2016) and motivation for entrepreneurship career (Nishantha, 2009) of undergraduates in Sri Lanka. However, there is a dearth of studies on enterprising tendencies of undergraduates in Sri Lanka.

Entrepreneurial trait theory claims that entrepreneurs have distinct perceivable psychological characteristics that can be nurtured via education and training (Eken, 2017). Thus assessing of enterprising tendencies of undergraduates will enable understanding if undergraduates possess the traits necessary to become entrepreneurs, to develop tailor-made programmes for various students groups.

The study is timely because understanding the enterprising potential will enable developing more appropriate business education programs for school and university students. Because past research indicates that significant trait deficiencies may lead to possible business training opportunities for enterprising individuals (Johnston Jr, 2007). Recent research concludes that, although entrepreneurial traits needs to be developed at an early stage in life, understanding the enterprising potential of students could enable academics to develop course curriculum that can stimulate enterprising traits resulting in enhanced enterprising potential (Van der Lingen & Van Niekerk, 2015).

The following research questions were raised; whether students from different fields of study exhibit different levels of overall entrepreneurial tendencies and entrepreneurial attributes? Whether students from different fields of study exhibit different levels of entrepreneurial attributes? Whether there is a difference in the level of entrepreneurial tendencies of male and female students? Whether there is a difference in the level of the entrepreneurial tendency in the first year and the final year students of a given field of study?

1.1 Research objectives

1. To determine whether students from different fields of study exhibit different levels of overall entrepreneurial tendencies.
2. To determine whether students pursuing different fields of study exhibit different levels of entrepreneurial attributes.
3. To find if there is a difference in the level of entrepreneurial tendencies of male and female students.
4. To find if there is a difference in the level of the entrepreneurial tendency in the first year and the final year students of a given field of study.

2. Literature review

According to McClelland, an entrepreneur organizes a business and increases its productive capacity driven by the need for achievement. Gibb (1987) defines an entrepreneur as 'someone who demonstrates a marked use of enterprising attributes, such as initiative, persuasive powers, moderate risk-taking, flexibility, creativity, independence, problem solving, need for achievement, imagination, leadership, hard work and internal locus of control'. McStay (2008), based on past literature, identified three approaches to entrepreneurship, namely; the trait, behavioural and cognitive. Past research on entrepreneurial tendencies emphasises on identifying individuals with an inclination to behave entrepreneurially by considering personality characters which are similar to entrepreneurs (Cromie, 2000). The enterprising tendency is defined as the psychological characteristics associated with the tendency to set up and manage projects (Caird, 1991). However, this does not imply that all enterprising people are entrepreneurs, but a more substantial fraction of entrepreneurs may show psychological characteristics of enterprising people. People with higher levels of enterprising tendency tend to set up growth-oriented and innovative projects more frequently and good at utilising human, technological, physical and organisational resources. One's ability to develop enterprising potential may perhaps change depending on the changing constraints and context in life and career (Caird, 2013).

Enterprising tendencies can change over time and could be changed by many factors such as education, family, culture, social environment, technological environments. (Tiftik & Zincrikiran, 2014).

Caird (1991) states that most significant characteristics cited in many studies have been measured using psychological tests namely; a high need for autonomy, high need for achievement, calculated risk-taking, creative tendency and internal locus of control. Many studies in that past have considered high motivation levels as a unique characteristic for entrepreneurs (McClelland et al., 1953; Weber, 1930; Young, 1983). According to McClelland, "the arousal feeling an individual get when there is competition with a standard of excellence in situations where performance is assessed for success" is considered as the need for achievement (McClelland et al., 1953). Young (1983) states that individuals with high need for achievement are characterised as social entrepreneurs, who were enterprising to benefit the society. According to (Collins et al., 1964) entrepreneurs are not comfortable with authority figures, the determination and self-reliance are additional attributes related to need for autonomy. The high need for autonomy is related to one's independence and self-confidence (Johnson et al., 1987). Watkins (1976) in Caird, (1991) states that "the need for achievement is the strongest reason for entrepreneurs to start a business". Research by Caird (1991) and Cromie & O'Donoghue (1992) indicates that entrepreneurs tend to display a strong need for autonomy than

other occupational groups. Individuals who show a high need for autonomy often show dissatisfaction and discomfort when expected to work within boundaries and rules (Demirci, 2013).

According to Schumpeter entrepreneurial function involves revolutionary innovation of new products, and processes (Schumpeter, 1950). Caird (2013) argues that an enterprising individual is restless with ideas, can solve problems creatively and see the life differently. Innovative tendency makes individuals develop new technologies, businesses, projects, organisations, comedy and artistic outputs. Bessant & Tidd (2011) also argue that innovation is an essential element for starting new business as it allows to recognize opportunities and defines creativity as "making and communication of meaningful new connections to help us think of many possibilities; to help us think and experience in varied ways and using different point of view".

Risk-taking was first introduced as an essential entrepreneurial character by Richard Cantillon in 1755 and is considered one of the earliest defined characteristic in an entrepreneur. It is said that entrepreneurs are moderate risk takers (McClelland, 1961). A highly enterprising person always seeks for information and is opportunistic, they evaluate the worth of pursuing the opportunity with some risk. Caird (2013a) states that a risk taker as someone who is able to act on incomplete information and able to take decisions with minimum information, is self-aware of ones capabilities, set goals that are challenging but attainable and can grasp the probability that certain actions will be successful.

Weinstein (1969) stated that what matters for success is people's belief that they are responsible for their success, their ability and effort rather than luck. Internal locus of control is associated with attributes such as tolerance, dominance, achievement, well-being, assertion, independence, insight, initiative, effectiveness, sociability and intellectual efficiency (Joe, 1971). Enterprising people have an internal locus of control that makes them believe they have control over their destiny (Caird, 2013a).

The GET test measures the enterprising individuals and entrepreneurial characteristics which may have been nurtured via education and training over time (Caird, 2013a). The test was first developed in 1987-1988 by Sally Caird and Cliff Johnson at Durham University Business School (Caird, 2013a). The internal consistency of GET test was found to be acceptable by previous research (Stormer & Goldenberg, 1999). Both validity and reliability of GET2 were studied in many previous studies (Caird, 1990, 1993). Cromie (2000) states that some studies have found GET test has good internal consistency, criterion and convergent validity. Van Niekerk (2015) too states that GET test is an accurate tool to measure enterprising traits.

Enterprising tendency vary based on a person's gender, education level, family background and ethnicity (Aldrich & Waldinger, 1990). A study by (Henderson & Palm, 2012) in the European Union showed that there's a significant difference between students whose first degree is on business and whose first degree isn't business, where business students showed higher overall GET test scores thus indicating that business students had higher enterprising tendencies than non-business students. In another study to determine if management education affect entrepreneurial tendency in South Africa, it was found that students that are currently active with entrepreneurship studies have shown significantly higher enterprising tendency scores (Van Niekerk, 2015). A research by (Holienka & Holienkova , 2014) have found that there exists a significant difference in the overall GET test scores between management and psychology students, where management students scored higher than psychology students, also management students scored higher scores on four out of five enterprising attributes (namely need for achievement, calculated risk-taking, creative tendency and internal locus of control) than psychology students.

Enterprising tendency levels of university male students have shown to be more entrepreneurial than females (Gure, 2017). Another study on Indian University students by Sethu (2012) revealed that the overall scores for enterprising traits showed below average and those female students had significantly higher scores on enterprising traits than that of male students. Further, this study showed that students who came from more agricultural background possessed high tendency levels than business background.

A recent study claims that there are significant differences in general enterprising tendency levels of undergraduates who follow different fields of study. The study focused on students from different majors (business administration, applied informatics, psychology, and pedagogy) and study showed that students in different disciplines exhibit different rates of overall enterprising tendency as well as specific enterprising attributes such as need for achievement, calculated risk-taking and locus of control (Holienka, et al., 2015).

Studies on enterprising tendency by Caird provides the main framework for the study (Caird, 2013a) (Caird, 1990). The study is supported by a theoretical framework which focuses on the trait approach of studying enterprising individuals. Figure 1 shows the conceptual framework of the study.

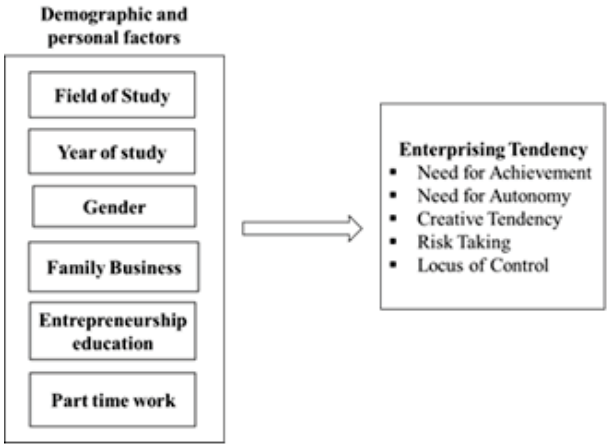

Figure 1: Conceptual Framework

2.1 Hypotheses

Based on the research question and the developed conceptual framework, the study was guided by the following hypotheses:

H1: There is a significant difference in the level of overall enterprising tendencies of students following different fields of study.

H2 - There is a significant difference in the level of key entrepreneurial attributes in students following different fields of study.

H3 – There is a significant difference in the level of entrepreneurial tendencies of male and female students.
H4 - There is a significant difference in the level of entrepreneurial tendencies of the first year and the final year students of a given field of study.

3. Methodology

The study took a deductive approach which used a cross-sectional survey research design and the research strategy used in the study was the quantitative approach. The entrepreneurial traits were quantified and measured using the GET test. The population of interest of the study comprised of first year and final year students of University of Peradeniya, Sri Lanka. The University of Peradeniya is the second largest state university in Sri Lanka based on the number of students enrolled each year (University Grants Commission Sri Lanka, 2015). The university comprises nine faculties namely; Agriculture, Allied Health Sciences, Arts, Dental Science, Engineering, Management, Medicine, Science, and Veterinary Medicine & Animal Science. First-year students are fresh undergraduates who have finished Advanced Level and just started their tertiary education in their respective field of studies whereas final year students have been studying in the university for four years and are about to make a career choice soon after finishing the degree. Thus taking students from two distinct years of studies will aid in finding if there's a difference in the tertiary education system on developing entrepreneurial tendencies among undergraduates.

The sample included students from five fields of study of the University, namely; Agricultural Technology and Management (ATM), Civil Engineering, Psychology, Management and Veterinary Science. Students who follow these fields of study are from different G.C.E Advanced Level streams of studies. However, students who follow ATM have taken either Bioscience stream with the subjects Physics or Agriculture (University Grants Commision, 2016). The individual undergraduate student was treated as the unit of analysis. Proportionate stratified random sampling techniques were used to collect the data which comprised of 386 students.

A self-administered questionnaire was used to gather necessary demographic and personal information and the enterprising tendency. A standard, validated test; General Enterprising Tendency (GET) test developed by Caird (2013) was used to measure the entrepreneurial tendency. GET test is licenced to be used in industry and it is used to measure the enterprising potential of business students (Burns, 2012). The enterprising tendency levels range from 0 to 100, 100 being the highest and similarly, to each of the traits the values range from 0 to 100 according to the online GET2test (Caird, 2013b).

The reliability analysis carried out using Cronbach's Alpha reliability tests showed that the Cronbach's alpha value (0.733) is greater than 0.7; thus the GET test has acceptable internal consistency and reliability. The first and second research questions were addressed using one-way Analysis of Variance (ANOVA) that was used to compare the overall enterprising tendency level scores as well as scores of each enterprising traits of students from five fields of study. Further, Analysis of Variance with interactions was used to check for the effect of demographic and personal characters on enterprising tendencies (faculty wise interactions). Two group mean comparison test (t-test) was used to compare the tendency levels of first and final year students of each of the study field and to compare the tendency levels of male and female students was used to address third and fourth research questions.

4. Results and discussion

The first hypothesis investigated whether there is a significant difference in enterprising tendency levels of students of different fields of study. The normality tests, Shapiro-Wilk and Skewness/Kurtosis were conducted, and the results showed significance values (p) greater than 0.05 in both the tests mentioned above thus proving that the tendency values are normally distributed. Table 1 shows the descriptive statistics of the overall entrepreneurial tendencies of students of University of Peradeniya. The overall enterprising tendency results, as well as the subscale scores, are given as percentage values (Caird, 2013b). Figure 2 below graphically depicts the overall mean GET test values of undergraduates across different study fields. One way analysis of variance was conducted to investigate whether the difference in the enterprising tendency levels of students from the five fields of study was significant. The level of significance of all statistical data analysis was set at $p<0.05$.

Table 1: Descriptive statistics of overall enterprising tendency

Field of study	Year of study	N	Min	Max	Mean	Std. Deviation
Agricultural Technology & Management	First	42	41	80	61.69	8.513
	Final	54	31	76	58.76	9.227
Civil Engineering	First	40	44	72	55.23	7.156
	Final	48	44	70	55.23	6.796
Management	First	30	44	70	59.93	6.523
	Final	31	31	76	55.13	9.106
Psychology	First	40	37	85	61.18	9.413
	Final	33	44	69	57.03	6.070
Veterinary Medicine	First	33	39	65	55.273	6.443
	Final	34	37	87	57.21	11.305

The results of Fisher's F-test one way analysis of variance suggest that there is a statistically significant difference between the overall enterprising tendency values of first year students from different fields of study ($F=6.29$, $p=0.0001$), thus accepting the first hypothesis. The findings suggest that students who pursue ATM and Psychology have a higher entrepreneurial tendency than students of other fields of study.

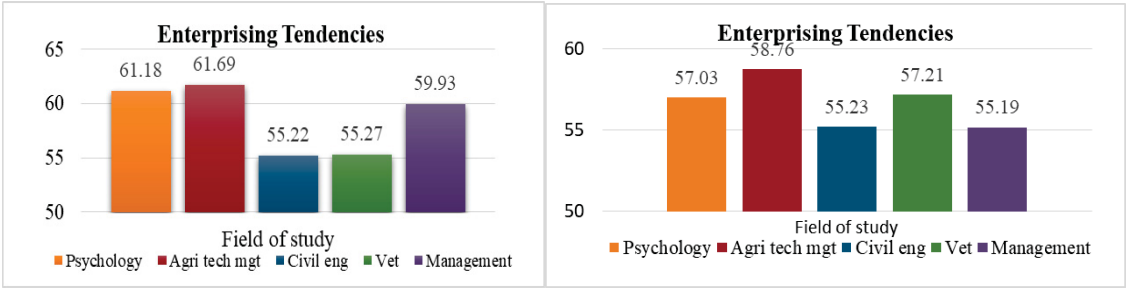

Figure 2: Overall mean GET test values of First Year Students (Left side) and Final Year Students (Right side)

Although previous studies have shown business or management students tend to have higher tendency levels (Holienka, et al., 2015), (Holienka & Holienkova , 2014) in the case of 1st year management students in University of Peradeniya, showed moderate enterprising tendency levels compared to other fields of study.

Both Veterinary Medicine and Engineering students showed the least enterprising potential. Interaction effects in the enterprising tendency scores with the field of study by demographic and other personal characters was tested using ANOVA with interactions. The table 2 below shows the effect of demographic and personal factors on enterprising tendency. Results suggested that out of all the variables considered, only the interaction of the variable; 'running their own businesses' with faculty was significant ($p<0.05$) at 95% significant level with respect to first year students.

Table 2: Interaction effect of demographic and other personal factors of first year students

Variable	Significance	(Variable)*study field Significance
Gender	0.828	0.415
Father self employed	0.933	0.142
Mother self employed	0.916	0.356
Entrepreneurship education	0.621	0.251
Family business	0.457	0.085
Role model	0.306	0.056
Involved in family business	0.141	0.330
Part time job	0.233	0.440
Running own business	0.953	0.006*

*Significant at $p<0.05$

Responses from a total of 201 final year students from the five fields of study were analysed. Although there exists a difference in the mean values of the tendency scores across fields of studies, the F-test of one way analysis of variance suggests that there is no statistically significant ($p<0.05$) difference between the overall enterprising tendency values of students from different fields of study ($F=1.40$, $p=0.2354$). Interaction effects result suggested that out of all the variables considered, only variable, 'entrepreneurship studies' was significant at 95% significant level, this showed that people who had followed entrepreneurship studies affect the enterprising tendency level. However, its interaction with the field of study was not significant.

According to the interpretation of GET2 test evaluation, average enterprising tendency values of the first year and final year students of all the five fields of study belong to the medium range. Although the average scores lied within medium scores, the overall scores were rather inclining to low levels. This suggests that the potential to start up and run a business is rather low in undergraduates of the selected streams of study.

According to (Caird, 2013a) a medium level enterprising person tend to have some enterprising characters, and they may be enterprising in some context also be able to express enterprising nature within employment as an intrapreneur or through voluntary community projects. However, Caird further states that a medium level enterprising person is highly unlikely to start up an innovative growth-oriented global business. The results of the study, therefore, agree with previous literature which suggests that there are significant differences in the general enterprising tendency levels between students in different fields of disciplines (Holienka et al., 2015; Holienka & Holienkova, 2014; Henderson & Palm, 2012; Sethu, 2012). Research suggests that different fields of study may attract various personalities of individuals and they tend to develop entrepreneurial tendencies in diverse ways, and this could be one of the causes for the difference among tendency level across different disciplines of study (Holienka et al., 2015).

An individual may be enterprising in many different ways based on the context. Caird (1990) argues that being enterprising does not necessarily mean that particular individual is starting up a business venture, but it means an enterprising person has the potential to set up and run a project in a wide range of different contexts. This can be applied to study findings, that is; ATM and Psychology students will have a better potential to set up and run a project when compared to students from other fields of study. This does not certainly mean they would start up a business but according to Holienka, higher tendency levels will help build and develop their professional careers while being innovative and may build their own professional identity. Therefore irrespective of the field of study a person pursues, investigating enterprising characters in diverse fields of study gives a better scope. Because the study itself verified that ATM, Psychology and Veterinary students showed higher entrepreneurial tendencies. From a view of entrepreneurship education perspective, it can be

reflected that different levels of enterprising tendency imply the necessity for entrepreneurship education to be employed in varied approaches (Holienka et al., 2015).

As for the second hypothesis the results showed that there is a significant difference in the key entrepreneurial attributes, results showed that need for achievement, need for autonomy, risk-taking and locus of control had significant ($p<0.05$) differences among study fields with respect to first-year students while the attributes, need for achievement and need for autonomy were significant with respect to final years. First year and final year ATM students have scored highest levels of need for achievement compared to other fields of study, while first years have scored highest in need for autonomy. Students who pursue Psychology showed higher levels of creative tendency as well as the higher internal locus of control. Final year Veterinary students showed higher levels of creative tendency and risk-taking. First-year Management students showed high levels of calculated risk-taking scores and higher internal locus of control. Engineering final years, however, had a high need for autonomy than other study streams. Although literature highlights that students who pursue business studies tend to show high levels of enterprising attributes (Henderson & Palm, 2012), in the case of this study, management students scored lower scores in need for achievement, need for autonomy and creative tendency. Engineering students too scored low in creative tendency, risk-taking and locus of control.

The third hypothesis test results indicated that although there are differences in the average scores for enterprising tendency between male and female students within each of the analysed fields of study, results of t-test suggests that there is no statistically significant difference in the overall enterprising tendency values of male and female students in any of the five fields of study at 95% significant level. The 4th hypothesis in the study was tested, and according to results, there exists a significant difference in the overall level of enterprising tendency values of first year and final year students who pursue Psychology and Management. In both fields, first-year students showed higher levels of average overall tendency levels than final year students.

Table 3 shows the paired t-test results; the t-test value and the two-tailed significance level. According to the results, there is a significant difference in the overall enterprising tendency levels of first year and final year Psychology and Management students. Although the difference was not significant in ATM students, first years showed higher tendency levels.

Table 3: Enterprising tendency levels between first year and final year students

Field of Study	Year of study	n	Mean	Paired t-test	Significance (Two-tailed)
Agricultural Technology & Management	First	42	61.69	1.613	0.110
	Final	54	58.75		
Civil Engineering	First	40	55.23	-0.028	0.997
	Final	48	55.23		
Management	First	30	59.93	2.337	0.021*
	Final	31	55.13		
Psychology	First	40	61.18	2.270	0.026*
	Final	33	57.03		
Veterinary Medicine	First	33	55.27	-0.863	0.392
	Final	34	57.21		

*Significant at $p<0.05$

There was no difference in the first and final year engineering students. However, students who pursue Veterinary Medicine showed a difference in the above pattern, where final years showed higher tendency levels than that of first years but this difference was not significant at 98% confidence level. This indicates that first-year students have higher enterprising potential than final year students.

Chi-Square test was conducted to test for significant associations of demographic and personal factors on the year of study. Results indicate that final year ATM students had followed more entrepreneurship studies than first year students and had higher involvement in family businesses. Although the overall enterprising tendency scores had no significant difference among first and final years, first years on average showed higher entrepreneurial potential despite the fact that first years had lower exposure to entrepreneurship studies and less involvement in family businesses than final year ATM students. Psychology students showed a significant difference in the level of overall enterprising tendency scores, where first-year students showed higher levels than final year students. Based on the test for associations, the first-year psychology students were involved in more part-time jobs than final year students. According to past literature, students who have part-time job

experience, tend to be more entrepreneurial. Therefore, the higher number of part-time job involvement in first-year students may have caused them to show higher enterprising potential. Concerning engineering students, final year students had followed more entrepreneurship studies than that of first years. However, there was no difference in their overall enterprising tendency levels between first year and final year students.

When it comes to the overall general enterprising tendency levels of the study sample, most of the students showed medium or low overall GET scores, with only a very few higher enterprising levels. The study, therefore, contributed toward new knowledge on the enterprising tendency levels of undergraduate students of the University of Peradeniya. Also, the research provided important evidence to show that enterprising tendency levels and enterprising attribute levels of students vary across the different field of studies.

5. Conclusion and recommendations

The study provided evidence on overall enterprising tendency levels being different among students of different study disciplines. Further evidence was found that there exist differences in the levels of important enterprising attributes across the analysed fields of study. ATM students showed the highest overall enterprising tendency levels in both final year and first year students while Engineering students and final year Management students showed the least enterprising tendency levels among the selected fields of study. Four out of five enterprising attributes showed significant differences among disciplines of study in first year students, namely; need for achievement, need for autonomy, calculated risk taking and internal locus of control whereas two out of five attributes had significant differences across the fields of study in final years, namely; need for achievement and need for autonomy. First year and final year ATM students showed higher levels of need for achievement in comparison to students of other analysed study fields.

First year students have higher overall enterprising tendency levels than final years in all the interested study fields except, Veterinary Medicine. Although the first years of the other four study streams showed higher tendency values the difference was only significant in Psychology and Management students. Although past literature suggests significant differences in enterprising potential between male and female students, in the case of this study, there was no significant difference in the enterprising levels between male and female students. Students of University of Peradeniya; irrespective of the field of study or year of study, all subjects on average showed medium enterprising tendency level, hence this research has provided insight into the enterprising traits prevalent over a cross section of students in the University of Peradeniya.

The study considered two separate samples of students from first and final years from the same discipline of study. However, if continuous data collection method is implemented, the change of enterprising tendencies of undergraduates over time can be studied. The study was only carried out in a single state university. If similar studies could be conducted for both private and government university students, it will provide a broader representation of undergraduates in Sri Lanka. Thus a more generalizable result could be obtained for the overall enterprising tendency levels of Sri Lankan undergraduates. Even though the study only identified differences in tendency levels of students pursuing different fields of study, the research does not answer the questions on how and why they differ. Therefore it is recommended to investigate further how and why students from different fields of studies show different enterprising potentials.

Sustainable Business Practices Among MSMEs: Evidence from four Metropolitan Areas in Ghana

Daniel Agyapong and Keren Naa Abeka Arthur

keren.arthur@ucc.edu.gh

Abstract: Pollution poses major health risks to man and other living creatures, especially in developing countries. Its sources include industrial emissions and improper waste by households and organisations. However, large firms have often been accused as the main actors of polluting water bodies, land and air. Despite this, some studies argue it is difficult to identify culprits for air and water pollution; hence, the need to analyse the business practices of MSMEs to determine their sustainability, since they contribute over 90% of businesses in developing countries. The study, therefore, looked at plastic pollutant, a major waste concern in Ghana. This is because, despite several government interventions in cleaning cities and towns of plastic waste; the problem still persists. Statistics indicate about 501,875 tons of plastic waste are generated annually, and it has created serious health and environmental risks such as the blocking of drains leading to flooding, the breeding of mosquitoes that spread malaria and the causing of severe aesthetic nuisance in terms of smell and appearance in communities. Using a mixed method, 500 MSMEs engaged in the production of Sachet Water in the Accra and Kumasi metropolis were sampled. Questionnaires and interviews were used to collect data. Data was analysed using descriptive and inferential statistics. The results showed that though MSMEs contribute significantly to plastic waste, they do not have any strategy for managing the waste generated. Furthermore, there is a map of complex network of actors in the plastic packaging chain, and therefore, it was concluded that the idea of plastic management policy should not target only sachet water producers. This study recommends that policy formulation aimed at dealing with this menace should target all actors in the plastic value chain including suppliers of plastic raw material, consumers of plastic packaged products, collectors of plastic waste as well as processors.

Keywords: Sustainability, Business Practices, Plastics, MSMEs, Metropolitan Areas

1. Introduction

For years, the issue of pollution has been considered a major issue in the environmental management literature. This is because, exposures to environmental pollution continue to pose major problems and health risks to society and its inhabitants; and these effects are said to be greatest in developing countries (Briggs 2013). Sources of pollution are reported to include industrial emissions, poor sanitation and contamination of air and water bodies (Briggs 2016) most of which are suggested to be generated by large companies (e.g. Anglogold, Exxon Mobile etc.). For example, carbon accountant Richard Heede apportions most of the blame for climate change to just 90 large companies (Starr 2016). Despite this, Blair and Hitchcock (2004) argue that identification of culprits for pollution especially that from air can be difficult; hence the question of whether micro, small and medium enterprises (MSMEs) play any major role in the whole pollution problem remains unanswered.

Perhaps the argument that MSMEs may in fact be worst polluters, at least in the case of developing countries like Ghana, can be made as these are found to contribute mostly to solid waste, specifically plastics. According to a study by Gambrah (2013) plastic waste as far back as 2010 constituted the second highest waste type (about 16.98% of solid waste) in the Accra metropolis and this is a worrying statistic considering the inability of plastic waste to decompose in comparison to the highest waste component in the region (i.e. organic waste).

Since 2010, news articles by Essien (2014), Kortei and Quansah (2016) and Lambert and Sabutey (2016) show that plastic waste not only continues to dominate the Ghanaian solid waste landscape (i.e. about 501,875 tons generated annually) but also has become a major challenge for government, policy makers. Although the plastic waste business has contributed to socio-economic development through job creation and the provision of household water security (Stoler et al. 2012), it also creates serious health and environmental risks such as the blocking of drains leading to flooding, the breeding of mosquitoes that spread malaria and the causing of severe aesthetic nuisance in terms of smell and appearance in communities (Gambrah 2012).

There is, therefore, a need to properly manage plastic waste so as to reduce its environmental impact. Efforts in this regard have focused on research into the use of policy making tools such as bans, the search for environmentally friendly alternatives and the engineering of genetically modified organisms to eat up

unwanted plastic wastes (Kotei and Quansah 2016) with limited understanding of who the culprits are and how MSMEs involved manage the situation through the value chain i.e. sourcing, usage, disposal and recycling. This identification of perpetrators among others is important to allow for targeted regulation and enforcement for effective results (Starr 2016).

The study, therefore, examined sustainable business practices in the management of plastic waste by MSMEs in the purified water industry in the selected metropolis in Ghana. Precisely, the study was to map out the plastic waste value chain in Ghana and identify key stakeholders involved and their role. Furthermore, it was to analyse the plastic waste value chain activities undertaken in-house by MSMEs in the purified water industry as well as analyse the sustainable business practices used by MSMEs in the plastic waste sector.

The rest of the paper is divided into five sections. Section two looks at the literature review, while the third section is devoted to the research methods used. Section four looks at the results and discussion and the conclusion and recommendations section are drawn in section five.

2. Literature Review

Corporate social responsibility maxim draws managers attention to the consequences of ignoring their environmental responsibility in this era of fierce global competition. The study was informed by the theoretical discussions on sustainable development and environmental management. Sustainable development operates on the principles of meeting present needs without compromising on the resources requirements of future generations. Sustainability has become the foundation for all socioeconomic and political development programmes at the local, national, regional and global levels. Indeed, the United Nations' Agenda 2030 provides the global framework for sustainable development as outlined in the 17 Sustainable Development Goals (SDGs). The subject of sustainable business practice is much more related to the targets in SDGs 3, 6 and 12. These targets emphasize on good health and wellbeing; clean water and sanitation as well as sustainable consumption and production. Sustainable business practices or the green business philosophy implies the organization engages in the production, distribution, consumption and post-consumption activities in an environmentally friendly manner. According to Rennie (2008), sustainable business is the process of assessing how to design products that will take advantage of the current environmental situation and how well a company's products perform with renewable resources.

At the country level, efforts have been made at integrating sustainability into development and how businesses carry out their operations. For instance, in 2016, a Harzardous and Electronic Waste Control and Management Act (Act 917) was passed by Parliament. The objective of Act 917 is to regulate and control electronic and other similar waste in Ghana. In 2013, the country introduced Environmental Excise Tax. The tax was intended raise funds to help in the recycling of plastic waste and collection in the country. Furthermore, there has been several forums and programmes in Ghana on waste in general and plastic waste in particular.

Yet the problem of plastic waste continuous to compound every year.

In their view, Jambeck et al. (2015) and Yang et al. (2018) posited that plastic waste pollution, particularly microplastics seem to have so much attention recently. Though this is true, plastic waste continuous to be the most common waste in countries like Ghana, despite all the effort at reducing it. Such efforts include collection and recycling of such waste. Amoako et al. (2018) explored a means of recycling sachet-water bags coco-nut hursk and found that it can be a good resource in the production of ceilings, partition boards and automobile interiors. Alemu and Dhanai (2018) found that cutting plastics into small strips and mixing with soil with different percentages, can help improve the properties of a problematic soil. Other studies that have explored the plastic waste menace include Jambeck (2017) who analysed the scale of plastic waste entering the coastal and oceanic waters around Africa. Furthermore, the issue that have been looked at in literature include quantifying both the volumes of packaged water consumed relative to household water requirements and associated plastic waste generated for three West African case study countries (Wardrop et al. 2017). In their study, Lineswala, Singh and Mishra (2017) focused on mass education and awareness generation on plastic waste management. Dzodzomenyo (2017) assessed the spatial distribution of regulated packaged water production in Ghana and found evidence to suggest that packaged water is transported shorter distances in Ghana.

From the previous works reviewed, there seem to be less attention focused on sustainable business practices and the role of the businesses involved in the production and the use of plastics in Ghana. Among the few studies that looked at sustainable business practices include Quartey et al. (2015). They looked at producer responsibility and management of products at end of life and proposed two theatrical recovery models that can be used to address the issue of sachet waste in Ghana. However, as a descriptive-qualitative research paper, they used only observation and existing literature on the subject matter. This is not adequate if one wants to understand the problem of plastic waste in Ghana. The current paper collects first hand data from the businesses in this sector.

Indeed, Quartey et al. (2015) raise a major issue of water quality and hence the growing number of MSMEs in the sachet and bottled water processing sector. Wardrop et al. (2017) opined that packaged water consumption is growing in lower and middle-income countries, but the magnitude of this phenomenon and its environmental consequences remain unclear. The packaged processing water sector is dominated by small and sometimes unformalized businesses. According to the National Association of Sachet and Packaged Water Producers (NASPAWAP), there are over 4,000 members, made up mainly of indigenous Ghanaian entrepreneurs (NASPAWAP 2016). However, given the widespread nature of their activities, especially in the towns and cities in Ghana, there is the possibility of the existence of many more unformalized businesses in the sector. This makes regulation of such entities difficult. Furthermore, the plastic waste problem is compounded by the mode of selling which is through the use of street vendors.

It must be noted that the problem of plastic waste in Ghana is not only created by sachet and bottled water, but also from plastic soft drink (soda) and carrier plastics (Arko-Achemfuor & Quan-Baffour 2015). According to Quartey et. al. (2015) plastics are used extensively in both food and water packaging industries because of their low bulk densities and inertness which make them convenient carrier materials with low risk of contamination. This has resulted in the large volumes of imports of plastics. It is estimated that over 10,000 metric tons of finished plastic products are imported annually into Ghana (Fobil 2000; Owusu-Sekyere, Osumanu & Abdul-Kadri 2013). However, the total volume of plastics in circulation at any point is largely influenced by the over 40 plastic manufacturing companies producing about 28,000 metric tons of assorted plastic products annually (Wardrop at al. 2017).

The paper focused on sachet and bottled water because it was observed that for every 10 pieces of plastics found in drains or on the street, between 7-8 pieces were from sachet or bottled water and in most instances, they were from small businesses.

From the review of literature, it was observed that there is a global effort at integrating sustainability in all socio-cultural, economic and political activities in line with the Sustainable Development Goals. Hence, this area has attracted a substantial research attention in recent times in developed countries. However, the situation is very different in some emerging countries like Ghana, where the issue of sustainability is yet to receive the attention of academics, researchers and policymakers. Furthermore, a survey of the literature has focused more on the problem of plastic waste and its impact and the issue of recycling by other actors. Such studies have not focus on the generators of such waste with respect to their knowledge of the problem and their extended producer responsibility. The paper helps fill this gap in the contest of Ghana.

3. Research Methods

The purpose of this study is to examine sustainable business practices in the management of plastic waste by MSMEs in the purified water industry. The study context was Ghana and in three metropolises (Accra, Cape Coast, Kumasi and Takoradi). These metropolises were selected because the MSMEs engaged in the water purification businesses in the country are concentrated in these cities. Due to the activities of illegal miners and other source of water pollutants in the country, majority of households consume sachet and bottled water. A 2015 Ghana Statistical Service(GSS) survey showed that packaged water in the form of 500ml filled bags or “sachets” is now widely consumed, with 43.1% of urban households reporting it as their main drinking water source in 2014 (GSS 2014 and Dzodzomenyo et al. 2017). This figure is expected to grow into the future.

Traditionally, Cape Coast have had water problem due to the effect of the sea and so people depend heavily on purified water. Furthermore, it is common to see on the streets and drains, plastic waste in these cities.

The paper employed mixed methods; the first objective that seeks to map out the plastic waste value chain in Ghana and identify key stakeholders is addressed primarily through a review of the theoretical and empirical literature on the topic. Secondly, the issue of analysing the plastic waste value chain activities undertaken in-house by MSMEs and that of assessing the sustainable business practices used by MSMEs were done based on primary data obtained from the field through the use of questionnaires.

The estimated population in Accra, Kumasi and Cape Coast Metropolis, according to Association of Sachet and Packaged Water Producers, was 2000 as at 2016. These are registered members. A sample of 322 MSMEs was selected for the study based on the Krejcie and Morgan (1970) sample size determination table. The questionnaire was made up both structured and unstructured questions. Some questions were on a rating scale of (1) least to (7) highest.

3.1 Measurement of variables

Variables used to measure sustainable business practices in MSMEs in the purified water industry were as follows:

Value chain analysis: Indicators used to measure this was extra levy on waste collection, plastic waste collection tax, designated collection centres, customer education on safe disposal, product packaging information, and alternative to plastic packaging.

Knowledge on sustainable business practices: Packaging of water, risk in take-back, going international, extended producer responsibility, socially responsible investment, and plastic waste processing business were the indictors used to measure this variable.

Knowledge on plastic waste: Waste as nuisance, waste decomposition, major sewage problem, presence of plastic waste, complain about plastic waste (exaggeration), and waste recycling and reuse were used to measure this variable.

Knowledge of regulations on plastic waste: Indicators such as plastic waste generation and disposal, registration of business, payment of penalty, tax on waste generation, and waste inspection were used.

3.2 Data collection and Analysis

Data was collected within a period of six months. Respondents were mainly owners or managers of MSMEs of Sachet and Bottled water businesses in the selected metropolis. Two hundred and three (203) questionnaires out of the 322 questionnaires were retrieved. This represents 63% response rate.

Data was analysed within the pragmatic philosophy using a mixed method approach. Issues on analysing stakeholders within the value chain was based on interpretative philosophy. Qualitative data was collected in the form of texts and images. This was analysed using themes. Means and percentages were used in analysing the quantitative data within the realism philosophy.

3.3 Ethical considerations

All the respondents were guaranteed anonymity and confidentiality in the reporting of the results of the study.

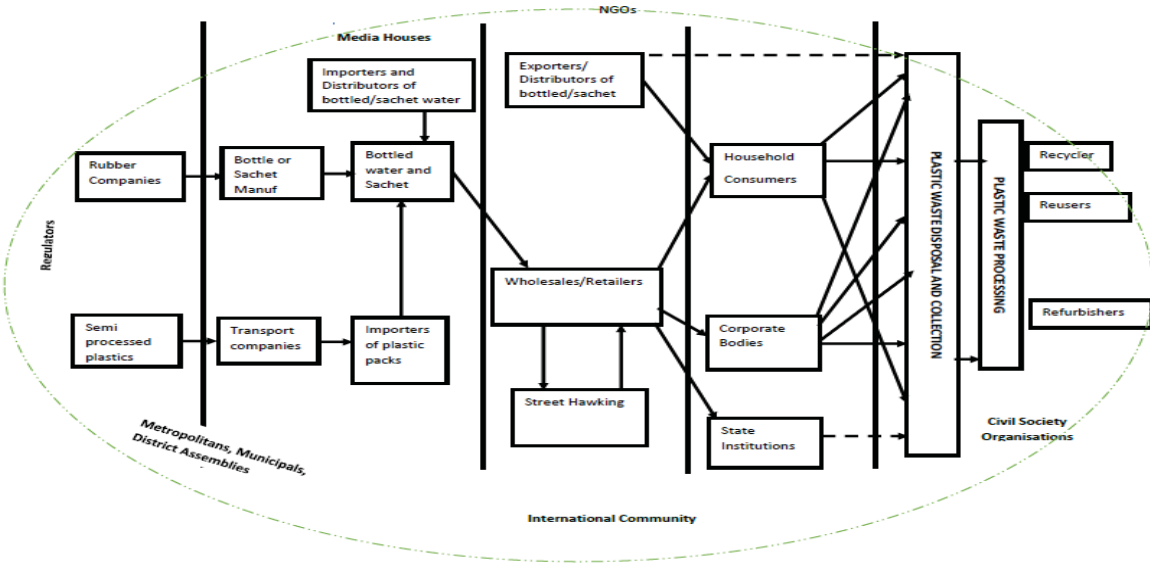
This was specified at the introductory part of the research instrument. Also, institutional policies and laws where the data were collected were adhered to and any governmental policy pertaining to this work was strictly obeyed. Finally, a strong respect for intellectual property was honoured. That is, both published and unpublished works were not used without permission and all references were credited and acknowledged accordingly.

4. Results and Discussion

4.1 Mapping the plastic waste value chain

The first research objective was to map out the plastic waste value chain, highlighting key stakeholders involved. To do this, existing literature on the subject matter was collected and analysed; and findings revealed that the plastic waste value chain comprised of complex web of activities which can be grouped into four main categories, namely; sourcing of raw materials, production of packaged purified water, distribution of packaged

purified water and plastic waste management. As shown in figure 1, the sourcing of raw materials category involves the processing and transporting of rubber and semi-processed plastics through transportation companies to plastic sachet and plastic bottle manufacturers well as importers of plastic packs for onward delivery to sachet and bottle water production companies. Once plastic packaging materials are received, production kicks off with the purification of water and its subsequent packaging by local packaged purified water manufacturers and importers and distributors of plastic sachet and bottled water. The distribution category of the plastic waste value chain involves the commercializing of purified packaged water which can be done either directly or indirectly through wholesalers and retailers (e.g. street vendor) to individuals, households, corporate bodies and state institutions. Further, the waste management category of the plastic waste value chain comprises the collection and disposal of plastic waste as well as its processing through channels such as recycling, reusing an refurbishing. While all of these activities take place, it is important to note that there are a host of other stakeholders such as regulators, metropolitans, municipals and district assemblies, international community, civil society, non-government organisations and media houses who influence or are influenced to practices within the industry.



4.2 Plastic Waste Activities Undertaken In-house

The second objective was to identify the plastic waste value chain activities carried out by MSMEs in the packaged purified water industry. To do this, responses were collected on the materials for packaging purified water and their sources, how packaged purified water is distributed and their strategies, if any, for waste management.

4.2.1 Material for packaging

Table 1 shows the frequencies and percentages of responses regarding materials used for packaging purified water among respondents. The results showed that 205 (82.0%) of the studied organisations used plastic sachets in packaging purified water for sale. This was followed by the use of plastic bottles as packaging material among 26 (10.4%) of the studied population. Additionally, glass jar and other materials were reported to be used by 5 (2.0%) and 14 (5.6%) MSMEs respectively for packaging purified water for sale. These results show that plastic sachets are a preferred packaging choice for MSMEs; thus, providing some explanation for why plastics constitutes the second highest waste type in some regions in Ghana (Gambrah 2013).

Table 1: Material for Packaging Water

	Frequency	Percent
Sachet	205	82.0
Plastic bottle	26	10.4
Glass jar	5	2.0
Others	14	5.6
TOTAL	250	100

4.2.2 Source of packaging material

Results in Table 2 show that 192 (89.9%) of responding institutions source their packaging materials from local companies while 15 (7.0%) of MSMEs imported packaging materials from manufacturers outside Ghana. Therefore, it can be argued that most of the businesses in the sample population were not actively involved in the sourcing of raw material category activities of the plastic value chain. Nevertheless, there is evidence that a small fraction i.e. 8 (3.7%) of MSMEs in the study did produce their packaging materials internally.

Table 2: Source of Product Packaging Material

	Frequency	Percentage
Imported	15	7.0
Locally Prod. (diff. firm)	192	89.9
Internally Produced	8	3.7
TOTAL	215	100

Table 3: Mode of Distribution

	Frequency	Percentage
Direct sale	188	44.2
Wholesalers	101	23.8
Retailers	136	32.0
TOTAL	425	100

4.2.3 Mode of distribution

Regarding mode of distribution, Table 3 indicates that while majority i.e. 188 (44.2%) of respondents reported to sell their products directly to their customers, 101% (23.8%) and 136 (32%) of responding institutions confirmed their use of wholesalers and retailers in commercializing their products. These results suggest consistent participation of studied MSMEs in the distribution stage of the plastic value chain and use of multiple modes of distribution as part of the process. Dzodzomenyo (2017) found evidence to suggest that packaged water is transported shorter distances in Ghana. This ensures effective distribution of sachet and bottled water.

4.2.4 Waste management strategy

As observed in Table 4, 159 (71.3%) of responding businesses did not have a strategy for managing their waste; thereby suggesting that majority of the studied MSMEs did not involve themselves actively in the waste management activities of the plastic value chain. Despite this, 22 (9.9%) and 17 (7.6%) of the studied institutions reported use of approaches such as recycling and take back systems respectively in managing their plastic waste. A further 8 (3.6%) mentioned use of practices such as waste collection for reuse and voluntary return through reward systems.

Table 4: Strategy for Managing Waste

	Freq	%
Reward for voluntary return of sachets/bottles	8	3.6
Collecting plastic waste for re-use	9	4.0
Own plastic waste management firm	8	3.6
Engagement in take-back of product pack	17	7.6
Recycling of plastic waste	22	9.9
Currently without a strategy	159	71.3
TOTAL	223	100

From the results, it could be deduced that a number of MSMEs within the sampled data, focused their efforts in the production and distribution stages of the plastic value chain with limited few undertaking all plastic value chain activities in-house. This partly explains why the problem of plastic waste persist in these metropolises.

4.3 Sustainable Business Practices of MSMEs

Furthermore, the paper examined sustainable business practices by MSMEs in the plastic waste sector. To do this, we collected responses on the knowledge and/or perception of owner managers on plastics, regulation, sustainable business practices, external support for plastic waste management and operational sustainability.

4.3.1 Nature of plastic waste

Table 5 gives the mean perception of respondents with regard to the nature of plastic waste. With a mean score of 3.08, it can be argued that respondents on average somewhat disagreed with the notion that plastic waste is not a nuisance. Similarly, the results revealed that respondents generally disagreed with arguments like the issue of plastic waste is an exaggeration, plastic waste are not everywhere as claimed and plastic waste does not constitute a major sewage problem; and these were evident with mean scores of 2.78, 2.42 and 2.31 for the arguments above respectively. Further, respondents, on average, strongly disagreed with statements posed regarding the decomposability and recyclability of plastic waste; thus showing that they knew that plastic waste did not easily decompose but could be recycled and reused. Overall, responses showed that respondents were knowledgeable about the nature of plastics and their impacts on society.

Table 5: Knowledge on Plastic Waste

Areas	N	Mean
Waste not a nuisance	203	3.01
Plastic waste Complaint (exaggeration)	203	2.65
Presence of plastic waste	203	2.32
Plastic waste not a major sewage problem	203	2.17
Plastic waste not recyclable	203	1.86
Plastic waste easily decomposes	203	1.61

4.3.2 Regulation of the plastic waste industry

Results summarized in Table 6 generally showed good understanding of regulations governing this industry among respondents. With means of 5.97 and 6.00, respondents confirmed their awareness of the need for their businesses to be registered and for waste inspectors to visit their business premises periodically.

Furthermore, respondents responded in much more affirmative with respect to their awareness of the existence of general regulation on plastic waste and disposal with a mean score of 4.66. The sanctions for poor waste management practices had a mean score of 4.14 and tax deductions for waste collection was 4.08.

Table 6: Knowledge of Regulations

Areas	N	Mean
Awareness of Registration of business	205	5.97
Visitation by Waste inspection	205	6.00
Awareness of Plastic waste generation and disposal	205	4.66
Familiar with Payment of penalty	205	4.14
Payment of Tax on waste generation	205	4.08

Table 7 provides two important issues on sustainable business practices with respect to going international and also plastics being the only means of packaging water. The analyses yielded mean scores of 4.62 and 4.67 respectively for two issues. This indicates the owner managers that participated in the study responded in the affirmative. From the results, it could be deduced that respondents had relatively little knowledge about alternative means of packaging water; and the fact that it is impossible to export sachet water to a number of countries.

Meanwhile, the question that if a business initiates a take-back schemes, it could negatively impact on the survival of a firm, had a mean score of 3.85. This implies the respondents perceived take back systems as inimical to their survival.

The question that sought to seek the understanding of the respondents with respect to their responsibility with respect to where their waste ends up had a mean score of 3.40. This score gives an indication that the respondents are not, overall, responsible to know where their waste ends up.

Table 7: Knowledge on Sustainable Business Practices

Area	N	Mean
Plastic as only means of Packaging water	205	4.67
Going international with plastic packs	205	4.62
Extended producer responsibility	205	3.85
Firms involved in take-back risk failing	205	3.40
Awareness of Social Responsible Investing	205	2.41
Awareness of plastic processing business	205	2.41

On respondents' awareness of plastic processing business and social responsible investing, the results showed a mean score of 2.41 for each of the constructs. The rather low mean value is an indication that respondents were aware of businesses that depended on waste plastic as main raw material. Secondly, the results showed, respondents were of the opinion that it is accurate for the perception of investors to shift towards business that are mindful of their environment.

4.3.3 External support for plastic waste management

From Table 8, respondents answered in the affirmative with respect to the question on the payment of extra levy to the assembly for waste collection. The analysis yielded a mean score of 4.16. The results imply respondents agreed paying extra to the assembly for plastic waste collection. This often comes in a form of levies and contributions. Furthermore, under the Environmental Excise Tax, businesses in this sector pay tax towards the management of plastic waste in the country. This is exemplified in the recognition of plastic waste collection tax by the respondents, although the mean score was low (3.20). Perhaps, this perception of respondents that they have paid funds to the assembly to manage their waste is the reason why they had little concern about where their waste ended up.

A mean score of 4.17 suggests a moderate agreement to the question of having adequate information on incentives for safe disposal of product pack. However, the respondents attested to the fact that not much is done by way of consumer education on safe disposal. This was confirmed by the low mean score (mean = 6.4) obtained in response to the question of whether they embark on campaigns to educate customers of safe disposal.

Table 8: External Support for Plastic Waste Management

Waste Management Actions	N	Mean
Extra levy on waste collection	205	4.16
Product packaging information	205	4.17
Plastic waste collection Tax	205	3.20
Customer education on safe disposal	205	2.64
Alternative to plastic packaging	205	1.94
Designated collection centres	205	1.54

With mean of 1.94, respondents were of the view they have not explored adequately, alternatives to plastic pack for water. This result confirms the earlier finding in Table 1, where it was observed that about 82% of respondents chose plastic as means of packaging water. Similarly, responses to the issue of designated collection centre attracted a mean score of 1.54.

4.3.4 Knowledge on operational sustainability

On knowledge of operational sustainability, respondents answered in the affirmative, indicating that their methods of operation were much more efficient and sustainable. This was shown in the higher mean score of 5.9. This suggests respondents were somewhat content with their current practices.

Table 9: Knowledge on Operational Sustainability

Areas	N	Mean
Anticipation of increasing demand	205	6.21
Operational efficiency and sustainability	205	5.90
Expect constant flow of raw material	205	5.51
Continuous profit with current processes	205	5.39
Introduction of stricter laws soon	205	4.02
Anticipate a little competition from abroad	205	4.02

Recording means of 6.21, 5.51 and 5.39, respondents in the main anticipate increasing demand for their products, constant flow of raw materials and continuous profits with current processes in the future respectively. The results showed respondents anticipation for future increased demand for sachet and bottled water. This is confirmed by a 2015 Ghana Statistical Service report that found 43.1% of urban households depended on sachet as their main drinking water source. Furthermore, the results showed respondents were certain about constant flow of raw materials. About 89% of respondents indicated they obtain their source of raw material locally. Moreover, respondents anticipate continuous profit with the current processes. The source of profit would come from the increased demand for purified water due to the high levels of contaminated drinking water in the country. However, this is only possible if the operational processes of these businesses are sustainable, especially as supply of sachet water increases with the increased number of businesses entering this least regulated sector.

Nevertheless, they acknowledge through mean scores of 4.02 and 4.02 respectively that competition with products from abroad and stricter regulation may be something they may have to deal with in the future, although their responds was not strong enough.

5. Conclusions and Recommendations

The plastic and plastic waste value chain is made up of complex network of actors. These actors include stakeholders within the primary and secondary environment of the sachet and bottled water businesses. These are made up of the relevant regulatory institutions, civil service organisations, international community, NGOs and the media constituting the players in the macroenvironment. The actors in the immediate environment include players in the down and up streams of the plastic value chain. From the current interactions as observed in the plastic ecosystem, there were much of open than closed loop or system.

The problem of plastic waste in the selected metropolis is as a result of massive utilisation of sachet and plastic bottle in the packaging of purified water. Furthermore, the source of product pack material is mainly from local manufacturers of plastics and from different firms.

Most MSMEs in the packaged water production industry employed mixed distribution strategy, although they did not have any clear strategy for managing waste generated as a result of their activities.

There was evidence that these MSMEs were knowledgeable about the nature of plastics and their impacts on society. They were aware of issues of sustainable business practices (including recycling and re-use) and aware of regulations in the sector. However, they did not feel responsible for the managing of plastic waste generated from their activities.

There is the need to introduce stricter laws that make businesses in this sector much more responsible for their waste. An extended producer responsibility policy should be introduced to make firms in the sector responsible for the end of life of their products in the society. Further, regulation should also be targeted at all the other stakeholders in the plastic waste value chain.

Revenue from taxes and levies collected from producers of plastics, sachet and bottled water should be used not only to clean-up these metropolises, but also to finance start-up projects in used plastics bags processing.

Through the use of their association, the sachet and bottled water producers should explore the options of packaging water using materials such as re-usable plastics and jars. They can also establish joint collection centre for plastics to provide adequate raw materials for businesses going into plastic waste processing.

There is the need to intensify the public education on proper disposal of plastic waste. This should involve all stakeholders in and around the value chain.

Micro-enterprises Supporting Regional Competitiveness in Post-mining Activities: The Case of Callio Pyhäjärvi, Finland

Katariina Ala-Rämi
MicroENTRE, Kerttu Saalasti Institute University of Oulu, Finland
katariina.ala-rami@oulu.fi

Abstract: Many mining towns have faced or are about to face challenges in sustaining their region economically and appearing attractive while their mineral resources are exhausted and mining activities are closing down. It can be difficult to create jobs to replace those lost in the industry, and as a result, these towns appear bleaker and economically unattractive. This case study is part of a larger project, exploring different innovative solutions for exploiting the operational environment of Finland's Pyhäsalmi mine after mining operations end in 2019. A closed mine causes large maintenance costs. If a mine is located in core regions, alternative operations are easier to find, but a peripheral location in Northern Finland requires even more effort to maintain or to increase regional competitiveness. This paper discusses a case study on the business potential of geothermal technologies. The Pyhäsalmi mine is one of the deepest (known) mines in Europe. Extending over 1445 metres underground, it is located in Pyhäjärvi, a small town (with 5500 inhabitants) in the middle of Finland that is relatively well located in terms of national infrastructure and accessible transport. Experiments involving its existing facilities and infrastructure are already underway in the proposed Callio concept aiming reuse of mine premises, but new businesses and innovative solutions are still needed to overcome the costs of maintaining the Pyhäsalmi mine's underground facilities and lost jobs after mining operations cease. This paper concentrates on the business potential of geothermal energy from the viewpoint of small companies. It is based on interviews with experts and the results of workshops with micro-enterprises from March to June of 2018. The research focus is small companies' interest in exploiting the business potential of geothermal energy and the necessary steps to makthe e this potential into a reality, thus enabling regional competitiveness.

Keywords: micro-enterprises, geothermal energy, regional competitiveness, case study, periphery

1. Introduction

The mining industry has long had a positive impact on local economies by creating jobs in locations that are often peripheral; thus, such regions' economic competitiveness has been strongly dependent on mining activities. In contrast, mining towns are often associated with negative images of environmental degradation, pollution and old-fashioned working practices. All regions facing structural changes need to find innovative solutions to overcome economic, social and environmental challenges, but these obstacles affect smaller towns in peripheral locations much more severely; here, lost jobs are relatively high and difficult to replace (Harfst 2015). Indeed, this is the case in Pyhäjärvi, where the Pyhäsalmi mine has been operating since 1962, but the mine's underground operations will cease completely by 2019. With 216 employees, the Pyhäsalmi mine is the biggest employer in the town, and its closure will lead to a loss of 400 jobs via its subcontractors and service providers; this amounts to more than 20% of the employed population of the town. Furthermore, if the indirect impacts of this closure, such as transportation, logistics and services, are taken into account, an additional estimated 200 provincial jobs and 200 national jobs will be lost.

In deep mines such as Pyhäsalmi, inflowing mine water requires active pumping. If pumping does not continue after Pyhäsalmi's mine closure, the mine will gradually fill with groundwater. Just pumping this water out will cost approximately one million euros per year; thus, innovative solutions to cover the maintenance costs are needed. Furthermore, closing a mine is expensive, with legal requirements for mining companies including dismantling buildings and equipment, undertaking earthworks and monitoring closure activities (see Luukkonen 2018). Furthermore, substantial job losses will threaten the region's competitiveness. However, Pyhäjärvi's existing infrastructure provides good facilities for several activities that could support the local economy and replace lost jobs by using local skilled labour and expertise in new lines of work. How to look after the mining infrastructure once its current activities are finished is both an economic and environmental question. Communicating and interacting with the local community about these issues is an important part of the corporate social responsibility (CSR) of the mining industry (see Jenkins & Yakovleva 2006). As part of its CSR, the mining company, First Quantum's mineral Ltd., has surveyed its current Pyhäsalmi mine employees and examined their plans after the closure; the company found that many of its employees are thinking of starting their own businesses (Figure 1).

Even though its location is not the most peripheral by Finnish standards, the mine's small town is rural and does not have any special features that would attract large amounts of tourists. Overall, the region's population is decreasing, with almost 8000 inhabitants in Pyhäjärvi during 1980 and under 6000 inhabitants in 2010. As mentioned, the mine is the largest local employer, and most of the other companies operating in the region are small firms. In a recent survey targeting small- and medium-sized enterprises (SMEs) in Northern Finland, Hänninen et al. (2018) found that these companies were seeking growth either in domestic business (43%) or in terms of employees (35%), with one out of seven companies focused on growth in exports. Thus, in spite of their peripheral location, many of these small companies are aiming for international success; these kinds of companies are important for towns such as Pyhäjärvi, especially in times of structural change.

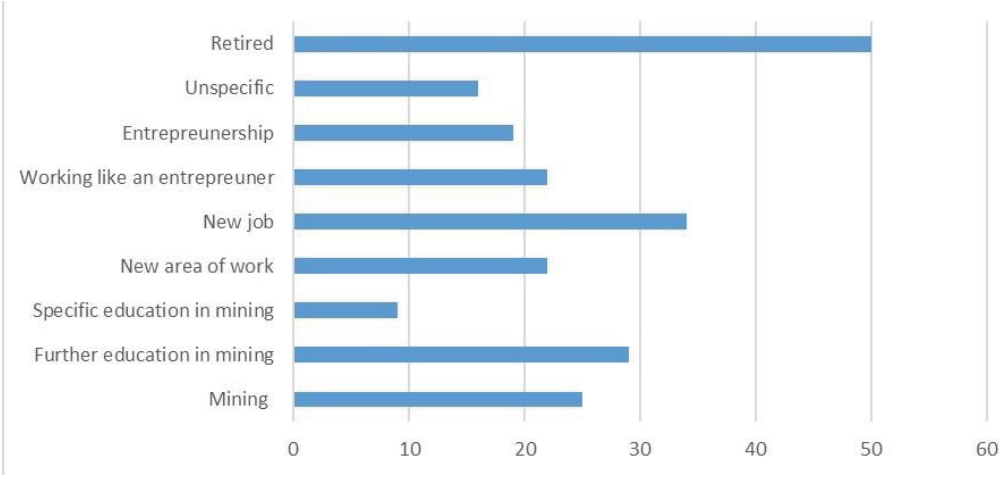

Figure 1: Future career plans of Pyhäsalmi mine employees as total number of answers (source: Luukkonen 2018)

The present research focus is on micro-enterprises' interest in exploiting the business potential of geothermal energy and the interventions required to make the potential a reality, thus supporting regional competitiveness. Regional competitiveness is defined here as 'the ability of a region to offer an attractive and sustainable environment for firms and residents to live and work' (European Commission 2018b). In this paper, a region is defined as a geographical area within a country and sharing common socio-economic and cultural elements. In this case, the region covers the town of Pyhäjärvi and its surrounding municipalities, all of which might benefit from using the mine facilities.

Previous studies in the region have pointed out that in the case of micro-enterprises, the entrepreneur's personal life and interests are the most significant factors when choosing a location; however, local demand and possibilities quide the entrepreneur's chosen line of business (Ala-Rämi 2007). Another study has found that a region's role in small companies is different from in larger firms; small companies are more likely to rely on tacit knowledge, local institutions and resources and to benefit from more complementarities in local networks and common learning (Tödtling & Kaufmann 2001). Becoming an entrepreneur is a significant opportunity to live in the most attractive region from a personal viewpoint, and, as can be assumed from the plans shown in Figure 1, is a way to stay in the region after the mining operations have finished. Those who aim to continue in mining are the ones who are willing to move because of work. The purpose of this paper is to discuss what kind of entrepreneurial opportunities geothermal energy can create in Pyhäjärvi but also what kind of interventions are needed to enable these opportunities.

2. Material and methods

This case study is part of a larger project, investigating different opportunities for innovative solutions and operations to exploit the operational environment of the Pyhäsalmi mine after mining operations cease in 2019. Callio is the name of a proposed new environment to replace the mine. The Pyhäsalmi mine is one of the deepest (known) mines in Europe with a temperature of +22°C year round. The present research is part of an on-going study about the business potential of geothermal technologies from the viewpoint of micro-enterprises, and it is based on interviews with experts, along with information gathered from workshops with firms during Spring and Summer of 2018. Future research includes business potential converted into numbers, but this paper concentrates on the regional aspects of exploiting geothermal energy. The research questions

are as follows: What kinds of business activities could exploit the possibilities created by geothermal energy? What else is needed to turn these possibilities into reality? These questions are explored through the competitiveness of the region, expressed in the following question: What are the actual and potential ways in which the micro-enterprise sector can take advantage of these business possibilities?

The town of Pyhäjärvi has a population of 5500. It is in the middle of Finland (see Figure 2) and is relatively well located in terms of national infrastructure and transport services, but the town in this sparsely populated region has suffered a decreasing population and increasing population age: the town's demographic dependency ratio (defined as the percentage of the working-age population) was 82% at the end of 2016. In the same year, the unemployment rate was 12.6%, which was less than in the county of Pohjois-Pohjanmaa (13.8%) but higher than the national average (8.1%) (Pyhäjärvi 2018). While the end to underground mining is inevitable, there has been a much effort to create a globally unique multidisciplinary operating environment, named Callio.

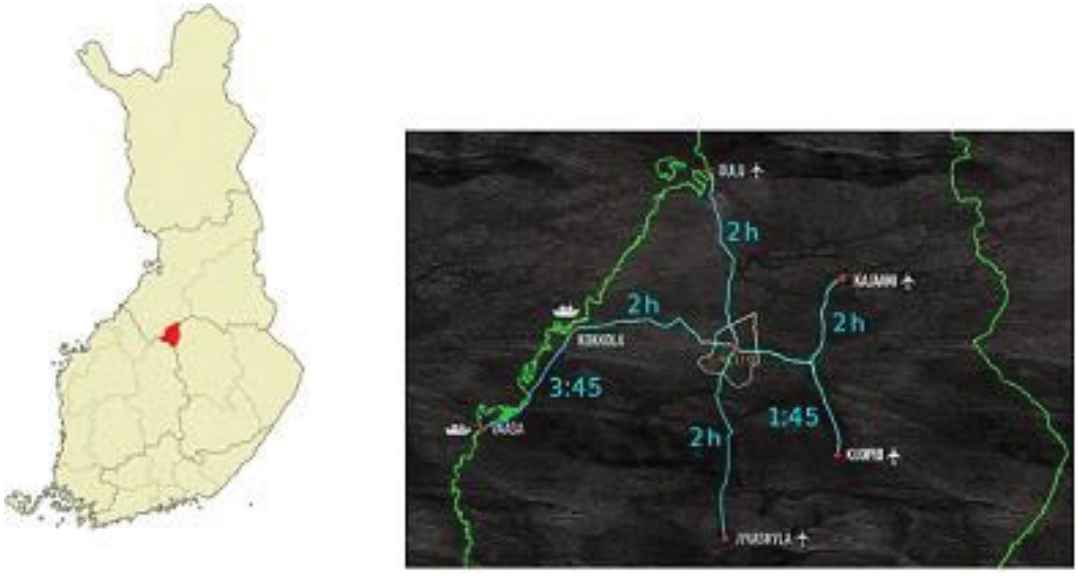

Figure 2: Location of Pyhäjärvi and driving distances to the closest towns (Callio 2018)

The mine and the surrounding brownfield area offer a diverse range of opportunities for both innovative projects and established operators. Experiments are already underway in Callio to use the existing mine facilities and infrastructure, but new businesses and innovative solutions are needed to overcome the costs of lost jobs and the maintenance of the underground facilities after mining operations cease. The Callio concepts (Callio 2018) include pursuing projects for business opportunities that could be partly put into practice by using geothermal energy:

1. Energy storage: pumped hydro energy storage located approximately 1400 metres underground;
2. Data centre: reliable and secured energy with the possibility for water cooling of the storage if needed;
3. Natural resources: bio energy terminal (i.e., forest biomass); growing plants, vegetables and mushrooms; raising fish; storing and aging cheese and liquors;
4. Research, development and innovation: a safe and stable operating environment for a diverse range of R&D and testing operations; new innovations in the fields of elementary particle physics, astrophysics/cosmology, geosciences and microbiology; mining, equipment service, rescue training and technology testing; conference facilities; leisure facilities.

The advantages of geothermal energy are manifold: 1) it is not dependent on the weather, so it provides warming and cooling energy year round; 2) the provided energy is 70–80% free of charge because the energy already exists in water; 3) it is produced near to where it is consumed, which is an advantage both economically but also ecologically; 4) it significantly decreases CO_2 emissions, although the amount varies a lot; 5) it can be formulated into efficient hybrids with bio and solar energy, as well as existing regional heating systems (Huusko 2016). In spite of the recognised advantages, geothermal energy technologies are still under development (Bleicher & Gross 2015). Furthermore, there are several regional patterns that have negative

effects on exploiting energy; some are geological, such as amount of energy sources and techniques possible to use, while some are more human-based, such as proximity to the end-users of energy. Nevertheless, technologies are an interplay of natural and technological elements, but even political conditions and organisational structures guide their development, applications and distribution (Bleicher & Gross 2015).

The data collected was via interviews and workshops that were carried out between February and August 2018; in this early phase of business potential mapping, the focus was on visioning and interest perception. There were five semi-structured interviews with key experts and policy makers, followed by the author's personal participation in one workshop on service design of underground laboratories, and one seminar with a specific focus on greenhouse experience in mine premises. Also, a benchmarking visit was made to Freiberg, where the geothermal energy use is more advanced; this visit enlightened and informed the context, possibilities and challenges in the Pyhäjärvi region for exploiting geothermal energy. This was followed by four workshops for companies or possible entrepreneurs who might be users or service or technology providers.

The participants of the workshops were told about potential and existing findings, but most of the time was used to discuss participants' ideas and questions. In this phase, when there are no exact amounts of energy and technique requirements, the collected information from needs of geothermal section in EU is important for motivation. It is not profitable to develop the required technological innovations or solutions for one location, but there is increasing interest in exploiting geothermal energy because of its eco-efficiency.

Concurrently, geological researchers are measuring and calculating existing amounts of energy and the best techniques for using it. After the geological researchers complete these estimations, the next phase of the project consists of calculating different business opportunities and how these may be translated into reality.

3. Results

There seems to be a large amount of ideas and interest in exploiting mine facilities, and there is even more interest in using geothermal energy, as the end use can take place just a few kilometres away from the mining location. Currently, pilot studies are investigating underground greenhouses (660 metres with a constant temperature of +18°C); even when it is -50°C outside, these facilities could be used for growing. However, UV light and choosing the right depths in terms of temperature and moisture are challenging. There are also plans to pilot fish farming; these are promising, since fish do not need light generation for growth.

Geothermal energy can also be used for cooling purposes and other condition optimisation such as moisture or light. Yet ideas on how to use the energy and the facilities vary from more traditional ideas, such as creating a testing environment for an ongoing neutrino experience, or mine rescue training, to more innovative ideas, such as using the facilities for spas, adventure parks, maturing areas for cheese or whisky, and housing of the elderly. Many stakeholders are awaiting the results of geothermal energy collection methods research, as these will not only guide which technologies are needed but reveal which methods for harnessing the energy are more cost-efficient. It is already known that the water temperature in the Pyhäsalmi mine is rather low (20–40 degrees), needing the pump to heat it before being used; therefore, companies offering heat pumps or water solutions are more interested in this phase than potential end users because it is not cost-efficient to pump the water to use in the town centre, four kilometres away from the mine. Furthermore, the mine premises are not considered an attractive environment, but it is possible to take water 500–1000 metres away from the mine location, close to the lake area, where the scenery is attractive.

Although geothermal energy cannot completely solve the problems involved with closing a mine, it can support large projects such as energy storage (based on pumped hydroelectric energy, closed water circulation and existing mine infrastructure) and a data centre (for keeping data safe). Geothermal energy provides possibilities for micro-enterprises by offering low-cost opportunities without requiring large investments—it could even help companies to break into global markets. The EU has recognised the potential of geothermal energy, as there is a great deal of interest in finding green solutions to replace coal power and other unrenewable power sources (European Commission 2018a). Therefore, it is important to find companies and individuals interested in starting businesses and to explore the advantages and limitations of these businesses using the mine's infrastructure and geothermal energy. Using the mine facilities by collecting existing geothermal energy with little cost is both an ecologically and economically sustainable solution. In spite of extensive ideas and expectations, most interviewed experts and entrepreneurs seem to be very timid in their

hopes, since several issues are creating uncertainty. It seems that all the different possibilities require either governmental support of the so-called key company to take the lead.

As mentioned, geothermal energy is a low-carbon and inexpensive form of energy, but its exploitation is in the very early stages in Finland. However, geothermal energy is already widely used with growing interest in the EU region for the reasons mentioned above. Internationally strong networks are essential to renovate and strengthen business in the region, and the innovation system of North Ostrobotnia is recognised in the Regional Strategic Plan (Council of Oulu Region 2018). Energy knowhow and technologies related to energy are defined as growth sectors. Increasing low-carbon production and distribution to control global change are the focus of regional strategy, and renewal energy sources in particular are not only seen as important for the task but also open up new business opportunities. In the regional energy strategy, the aim is to decrease greenhouse gases by 20% by 2021. Climate strategy aims for the region to be energy self-sufficient, but multipolar solutions and decentralisation are also priorities. In regional energy strategy, geothermal energy is increasing, especially in sparsely populated parts of the region. Furthermore, the Energy Ministers of Nordic Countries have agreed to strengthen Nordic global leadership on clean energy innovation and deployment (Government Offices of Sweden 2018).

If companies can recognise that the possibilities discussed in this paper are not only tied to energy resources from the mine but are pilot cases that open up possibilities to reach European markets and networks, this makes efforts in technological innovations more profitable. As part of this regional challenge and geothermal energy project, the region has joined in a larger European Smart Specialisation network collaboration, which has prepared a project aiming to improve policy instruments through new projects being supported, where the best practices with more advanced exploitation of geothermal energy would be exchanged with North Ostrobotnia's technologically strong knowledge. Such projects would be implemented as part of major international research and development centre activities of CallioLab, which ties regional authorities and policy makers, researchers and SMEs together.

Collaboration and learning from other partners' regions and their best practices would support management of local structural change programmes to support use of geothermal energy. The region of North Ostrobotnia aims at supporting successful business activities and international competitiveness and networking with research institutes and the private sector. Furthermore, this is an important means to tackle structural change in the Pyhäjärvi region, where many jobs and businesses are endangered due to the closing down of mine operations. One of the regional (RIS3) focus areas involves clean technologies, including energy, but also the ICT and software sector, including integration with businesses in different fields. The choices made in Oulu Region´s smart specialisation have taken into account the structure of the region´s enterprises and industry, areas of special expertise, research infrastructure, international position, national innovation policy and the region´s strengths and possibilities.

SMEs in the region of North Ostrobotnia are not well aware of the possibilities and challenges of geothermal energy, and the growing exploitation raises new social and environmental concerns, often closely linked to technological constraints. However, the preliminary numbers are promising: there is a large potential for renewable green energy, and around the mining infrastructure, pre-existing boreholes have already created an estimated ten cubic metres of reserve space. However, it is important to maintain communication between the researchers and the SMEs and individuals thinking of starting new businesses in the region, since they have differing viewpoints and their local and even tacit knowledge can open up new innovative solutions and technologies. Regarding technology, there is still a strong concentration of expertise in close proximity in the region of Northern Finland; thus, new technology, networks or knowledge could be the key to renewing the existing geothermal energy solutions, generating new business opportunities and contributing to regional competitiveness (Tödtling & Trippl 2013). Small firms might be more open to experiences and testing new solutions if they are supported by different funding possibilities and regional programmes, ensuring that regional projects play a large role in generating new information about future needs and possibilities.

There is no point in innovating if nobody is interested in putting these ideas into practice. One major challenge is the traditional perception associated with mining towns: that they are bleak and dirty. There is much work to be done to make these areas attractive to new inhabitants. Green and inexpensive energy is interesting to those who are already used to mine facilities, and a group of current mine workers are thinking of becoming entrepreneurs. Most of these people have been working for the mine for at least ten years; they live locally

and are willing to stay. They have good ideas about new uses for the facilities and might possess crucial information and ideas based on their experience. In relation to this, Roberts et al. (2006) concluded the following:

> *If the companies can find ways to ensure regional economies sustainable and competitive is a key challenge for business, communities and governments, at both the regional and national level. Business competitiveness is a major contributor to regional economic development. Firms can also have a significant impact on progress towards sustainable development. Whether this is positive or negative depends on how responsibly they operate.*

4. Discussion

This research aims to illustrate just some of the possibilities that geothermal energy creates, as well as the use of the Pyhäsalmi mine facilities and surroundings after underground mining operations end. Research into different techniques and energy potential is on-going, but possible sectors and interest of micro-enterprises have been mapped. The focus of this paper is not to give a detailed description of the potential of geothermal energy but to pinpoint possibilities that could attract micro-enterprises and elucidate why these companies are important for regional competitiveness.

Geothermal energy and its use inside mine facilities and the surrounding land create different kinds of business opportunities for micro-entrepreneurs. Therefore, geothermal energy should be seen as one of the strengths of Pyhäjärvi and the surrounding region. Supporting and encouraging current and future micro-entrepreneurs in the region can be regarded as a smart specialisation and an efficient way of supporting regional competitiveness. Low-carbon energy strategies should be implemented in collaboration with companies, local people and regional actors. Policies supporting SMEs and entrepreneurship should be developed to recognise the possibilities of geothermal resources, and geothermal energy should have more emphasis in the strategies and programmes providing funding to incentivise (i.e., developing innovative solutions, piloting or demonstrations).

Geothermal energy provides possibilities for micro-enterprises by offering low-cost opportunities without requiring large investments and could even help companies to break into global markets. The EU has recognised the potential of geothermal energy, as there is a great deal of interest in finding green solutions to replace coal power and other unrenewable power sources. Regarding technology, there is still a strong concentration of expertise in close proximity in the region of Northern Finland; thus, new technology, networks or knowledge could be the key to renewing the existing geothermal energy solutions, generating jobs and new business opportunities and contributing to the project.

Regional competitiveness is often measured in terms of economic outcomes and the potential means for enhancing it. In this case, the region is not globally innovative and will not be attractive to the capital or to creative talent. However, by identifying both the growth potentials and constraints of the region, it is possible to better utilise its existing resources—natural, historical, intellectual, cultural and social—to find innovative and entrepreneurial solutions, enabling those people attracted to the region to make a living. In the case of this peripheral, less favoured region, micro-entrepreneurs are already supporting regional competitiveness by slowing job loss and stabilising the population, turning structural change into a positive possibility both ecologically and economically.

There are clear challenges in the case of the Pyhäsalmi mine: the population in the region is sparse and less educated than the national average, and jobs provided by the mining company have been important. Rural municipalities surround the town, and there are no unique attractive features except for the mine facilities.

The geothermal energy potential from the mine is already known to differ from central European sites because of different bedrock and because the temperature is lower; however, the depth and extraordinary infrastructure, together with local tacit knowledge and inhabitants' commitment to stay in the region, provide the possibility for economic growth and innovative development. The potential for real business activities requires both out-of-the-box entrepreneurial thinking and the support of the public sector and regional authorities.

Declaration of interest statement

We the undersigned declare that this manuscript is original, has not been published before and is not currently being considered for publication elsewhere. We wish to confirm that there are no known conflicts of interest associated with this publication, and there has been no significant financial support for this work that could have influenced its outcome. We confirm that the manuscript has been read and approved by all named authors, and that there are no other persons who satisfied the criteria for authorship but are not listed. We further confirm that the order of authors listed in the manuscript has been approved by all of us.

Strategic Entrepreneurship in Enhancing Resources and Innovation in England – Case Revisited

Christos Apostolakis and Emre Arslan
Bournemouth University, UK
capostolakis@gmail.com
earslan@bournemouth.ac.uk

Abstract: This paper concerns the use of strategic entrepreneurship as a theory vehicle for making policy, but most importantly for supporting operational capacity of voluntary organisations in the South-West of England. Ten years ago, the voluntary sector was rich in cash, regulation was improving, fundraising had come to peak and the doors to public services were open. Today however, residents' welfare needs have increased in a rather desperate fashion and the anticipated public funds are not as high as they used to be. Consequently the voluntary sector needs to generate new ideas in competing for fundraising that can support current and future operational financial, human and other resources, as well as organisational innovation features that could potentially boost the sector's organisational capabilities again. The first objective of this paper is it is to identify and analyse how resources and innovation as core theory tools of strategic entrepreneurship can impact upon the entrepreneurial performance of voluntary organisations in the South West of England. Secondly, it is to describe and analyse the ability of the voluntary sector to work in an innovative manner and support consequent actual outcomes for those who are affected. Methodologically, an inductive approach has been adopted and qualitative research is implemented using semi-structure interviewing and collection of secondary data. The aim for using interviews is to explore and analyse the importance of the strategic entrepreneurship in practical terms, its application to every-day operational activities of voluntary organisations. Contribution-wise this is a really novel area of research that aims to provide both academic and empirical insights on the dynamism and usefulness of entrepreneurship for the strategic endeavours of organisations. Moreover, it is anticipated that the field of voluntary sector will help in providing appropriate findings that could serve significantly the purpose of this research.

Keywords: Strategic Entrepreneurship, Resources, Innovation, South West of England

1. Introduction

In recent years Strategic Entrepreneurship has been considered as the amalgamation of strategy with entrepreneurship, two subject areas differentiated from each other. Within the new subject area under construction a series of assorted elements could be considered: action motivation; common mind-set, shaped culture, leadership style and innovation. It could thus promote opportunity recognition, market positioning and resource allocation for the sake of wealth creation (Tsai and Lei, 2016). In this respect, the voluntary sector, as a potential field for applying strategic entrepreneurship, seems to have the prospect for exploring the above aspects in a manner that could contribute towards the support of local residents' well-being. Having said this, this is a formidable effort because of the multiple issues facing the sector. For example, the Indices of Deprivation Health Deprivation and Disability Domain (HDD) has indicated that there are some areas within Bournemouth Borough council – the geographical jurisdiction used in this paper - that are considered to be within the bottom 20% nationally in terms of residents' health. In addition to current health inequalities across the Borough, it is anticipated that Bournemouth will exceed the national average for its proportion of elderly residents. The proportion of people aged 65 and over in the UK is projected to rise from 16% to 23% between 2008 and 2033 as life expectancy increases. These are issues that need solutions in which strategic entrepreneurship could contribute in a fit-for-purpose manner.

One would argue that it is perhaps too complicated to synthesise a clear picture about implementation of strategic entrepreneurship into the field of the voluntary sector. Nevertheless, the objectives of this paper are twofold: a) The paper is a continuation of the one that was presented two years ago attempting to describe the narrative of a voluntary sector that has the ability to work in an innovative manner and support consequent actual outcomes for those who are affected. b) To identify and analyse how resources and innovation as core theory tools of strategic entrepreneurship can impact upon the entrepreneurial performance of voluntary organisations in the South West of England. To this extent some important research questions arise: a) what would define this process of entrepreneurship within the sector? b) In consequence, what type of entrepreneurial framework could be particularly applicable for the South West of England; and c) Is the voluntary sector really prepared to cope with these aspects that it has never really had the operational ability to undertake previously? Some difficult questions in here that need answers even those based upon initial research findings, as this paper explains in the next sections.

2. Theory

2.1 Strategic Entrepreneurship in leading the way

It has been very difficult to identify the intersection between strategy and entrepreneurship (Meyer et al, 2002) despite the fact that indirectly strategic management considers entrepreneurship as a subset of strategy (ibid.). In applying this assumption to current circumstances of the voluntary sector in England this is the underlying theoretical assumption of this paper: that evidence of application of strategic entrepreneurship can be found within it and not only this. Kantour (2016) contends that in terms of conceptualisation, strategic entrepreneurship involves alignment with other aspects such as sustained regeneration, organizational rejuvenation, and strategic renewal. Wickham (2006) goes a step further by arguing that strategy assists entrepreneurship by defining organisational heuristics that appear to be vital when an entrepreneur needs to analyse a situation and make decisions.

It comes as a consequence then that strategic entrepreneurship can contain opportunity and advantage-seeking actions and intends to achieve maximum organisation performance. Although small organisations are efficient in discovering opportunities they are not as effective in maintaining advantages from those opportunities because of operational inefficiencies related to their small range of abilities. On the other hand, large organisations are perhaps more successful in developing advantages (and furthermore competitive ones) compared to small organisations, but they are perhaps less able to explore new opportunities (Ireland et al, 2003). According to Chesbrough (2003). The overall opportunity-seeking actions' success depends on how an organisation integrates existing knowledge with new, more precisely; opportunity-seeking action is fundamentally a learning process, that the organisation gathers information from outside to increase its own knowledge base (March 1991). Thus creating an improved knowledge base allows an organisation to increase a competitive range important for operational success, (Ketchen et al, 2007). Ireland et al (2003) argue that strategic entrepreneurship has the distinctive and unique construct through which organisations are able to achieve advantages via learning. Entrepreneurship is linked with actions in generating newness and strategy is linked with long-term development of the organisation. This is a very important proposition for organisations of the likes of the voluntary sector which need learning desperately in order to innovate and succeed. The theoretical manner their performance is affected when seeking innovation and success will be explored in the next section.

2.2 Particular Performance Aspects Arising from Strategic Entrepreneurship

The impact of strategic entrepreneurship with respect to performance of entrepreneurial activities brings up some important issues. According to Kuratko and Audretsch (2009), when an entrepreneurial idea is first applied, it involves a higher level of risk. For this reason, risk, risk taking and/or risk management can be identified as core aspects for strategic entrepreneurship. Managers' propensity to take risks is inexorably connected to how they perceive it and deal with it. The decision maker such as managers, directors or the person who is in charge of a voluntary organisation form some beliefs about future outcomes while estimating riskiness of a decision. In this manner perceived risk of the situation can also be filtered based on the experience of the decision maker (Macko and Tyszka, 2009).

From an evaluation point of view, risk assessment could be seen as paramount for entrepreneurship because it allows for determining decisions that are normally vital for the future of entrepreneurial actions. It could be argued then that ranking risks could well work as method for measuring their worth once they have been identified. This can be done by considering the consequence and probability of each risk – as for example high, medium or low for their needs.

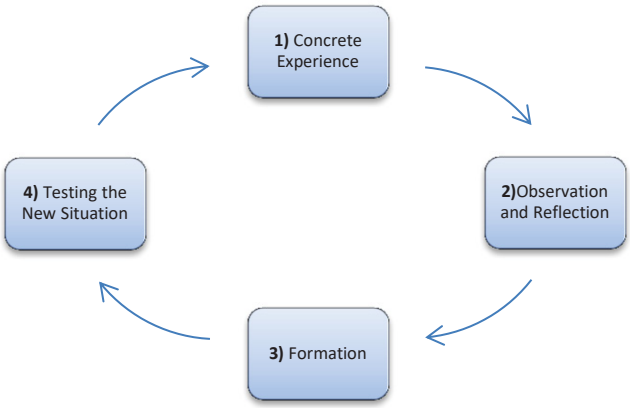

Figure 1: Learning organisation (Source: Lynch, 2015, p. 563 and adapted from: Kolb, 1984)

It has been argued that a way for estimating development of opportunities and thus attempting to decrease risk could be done via the approach of the *learning organisation*. A learning organisation is regarded as having the capacity to assess risks. This approach derives its importance from the ability to maintain constant entrepreneurial activity via a cycle of specific actions. It is an adaptation of David A. Kolb's "*Cycle of Experiential Learning*" analysis as it can be shown in Figure 1:

1. **Concrete experience:** The cycle starts with what could be called the concrete experience. This means that individuals or people who are involved with entrepreneurial activities such as researchers and other participating teams can start with some sort of prior knowledge such as technical entrepreneurial breakthrough (Kolb, 2014).
2. **Observation and Reflection:** The experience that has been discussed by the parties involved is then observed and reflected. At this stage plenty of questions can be asked for the sake of the observation and the communication channels are opened to the other members of the organisation (Kolb and Kolb, 2005).
3. **Formation:** It replaces abstract conceptualisation with formation by introducing routines in a particular structure (Kolb et al, 2001). The formation of the organisation is made based on experience acquired.
4. **Testing the new situation:** It involves active experimentation with testing the new situation, at this latest stage. This part can be the final stage for the learning organisation cycle which identifies how well developed the new structure is.

In a nutshell, identification of risks makes the entrepreneurial organisation able to confirm its performance effectiveness. Within this context, resources and innovation are regarded as important for making things happen (accepting that this is not an exhaustive list of elements). The theoretical underpinnings of these two terms are explored in the next section.

2.3 Areas for Enhancing Strategic Effectiveness

2.3.1 Resources

Resources can be identified as the organisation's assets which are tied semi-permanently to the organisation (Maijoor and Witteloostuijn 1996). They can comprise of: organisational, commercial, physical, financial, human and technological assets which are used by the organisations to produce, improve and deliver products or services for their customers (Barney, 1991). In resource-based view theory, the resources are classified as tangible, which are physical and financial and intangible which are knowledge, skills, experiences or the employees or volunteers and reputation, brand name procedures of the organisations (Wernerfelt, 1984).

Seeking competitive advantage that can come via exploitation of opportunities, as per the analysis above is its core contribution. Not every organisation though can reach competitive advantage, a point that can find its application to the voluntary organisations that do not normally possess capacity to deal with their resources effectively. It is entrepreneurship then that comes in, in order to support the creation of opportunities in which effective use of resources could make for the potential development of competitive advantage.

Entrepreneurship can then inform application of a resource-based view model by highlighting alternative uses of resources that are normally developed via primarily heterogeneous factors (Gries and Naude, 2011).

According to Acs and Szerb (2009), entrepreneurial attitudes, abilities and goals are also significant resourcing fundamentals. Moreover, it is the organisation's unique resources which are different from its competitors that contribute to the organisation's sustainable competitive advantage (Alvarez and Busenitz, 2001).

Heterogeneous resources are a common feature of both entrepreneurship and resource-based view. The main focus of heterogeneity in entrepreneurship is that belief that organisational resources can be of value no matter their quantity. In addition, the main focus of heterogeneity in resource-based view is the resources themselves. In other words, the resource-based view model and entrepreneurship adopt exactly the same unit of analysis which is the effective use of resources for an effective performance of an organisation (Alvarez and Busenitz, 2001; Barney, 1991).

2.3.2 Innovation

Innovation is identified as the application of new ideas or designs to the processes, products or other aspects of the activities of an organisation, that lead to increased value. This value can be explained in a broad way to include higher added value for the organisations themselves and also be beneficial for consumers or other organisations (Kuratko and Hodgetts, 2007). According to Schumpeter, "*carrying out innovations is the only function which is fundamental in history*". He also defined innovation as the motor of economic change that sets an important role of entrepreneurship in innovation (Schumpeter, 1939, p.102).

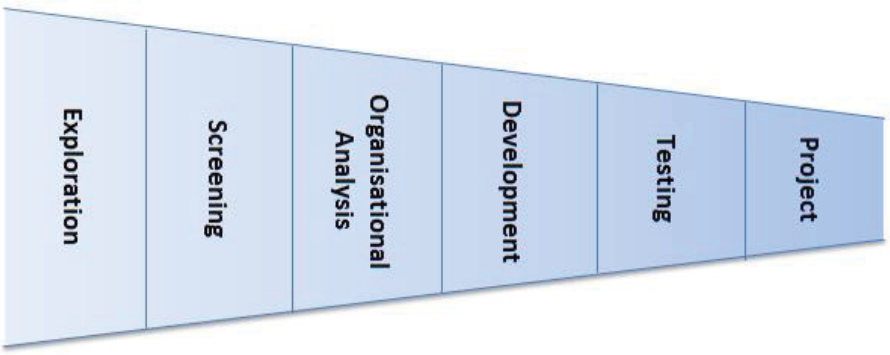

Figure 2: Evaluation of strategic entrepreneurship ideas (Source: Lynch 2015: p. 568)

There is a need to have a range of ideas in order to promote entrepreneurial innovation. Figure 2 shows the different stages to be followed in evaluating ideas that would lead to their actual "real-life" application and it seems that the voluntary sector fits within this context. It is not more than a "road map" on how an entrepreneurial idea can be presented in a way that reflects strategic purpose and of course produces "real life" outcomes. These parts are as it follows:

1. *Exploration*: The exploration part has close links with learning organisation cycle which was defined earlier. In this part, the idea which has been accepted as worth exploring will move into screening part.
2. *Screening*: Scrutiny takes place in here and potentially successful ideas will move into business analysis stage.
3. *Organisational Analysis*: Some good ideas which will not be able to generate adequate strategic opportunity or added value will be eliminated further (Lynch, 2015).
4. *Development:* Ideas that are favoured in the previous stage will be developed as experimental service or product for the organisation. Due to impossibility without practice, some ideas may still fail in this stage (Lynch, 2015).
5. *Testing*: The product or service which was developed in the previous stage will be tested against acceptance by potential customers/users.
6. *Project:* At this final stage, the idea that gained a status of attractiveness will be pursued as a strategic tool in the form of a project.

Innovation is dependent and constructed based upon criteria that determine usefulness of social activities within a sector such as the voluntary one. It is not suggested that by investigating entrepreneurial resources

and innovation no other elements of entrepreneurial work need to be looked at. The core reason relies upon their usefulness with respect to their role for shaping relationships between different actors in the sector such as funders, managers, staff and the other stakeholders (Chew and Lyon, 2012). These relationships and the way an effective organisational performance can be examined within the voluntary sector in the South West of England are the focus of the remainder of the paper.

3. Policy Context

3.1 The Voluntary Sector in the South West of England as a Context of Applying Aspects of Strategic Entrepreneurship

The voluntary sector in England has been paramount for re-evaluation of social policy in the last 20 years that gave it an emerging new role (Bussel and Forbes, 2002). In this context, it has an important role to play in supporting statutory services in the planning, response and recovery phases of emergent issues that reflect otherwise governmental policies (Cabinet Office, 2011). Delivery of services appears more and more as a way of increasing the organisational capacity of the sector. This capacity can provide an accessible and effective response to the community, the development of which voluntary organisations are formed to warrant (ibid.).

The voluntary sector in England became a considerable part of the economy with the income of £40.5 billion and spending with £39.3 billion, accounting for 97% of the sector's overall income (NCVO 2015). It has been estimated that 21.1 million people officially volunteered at least once in 2014 and 13.8 million officially volunteered regularly regarding voluntary community activities in 2014 (NCVO 2015). Consequently, voluntary sector particularly charities and foundations can play big part in the third sector. Horne (1998, p.156) suggests that cooperation between charities and businesses is important and needs to prevent potential conflict. He also stated that the mission of charities is "*to generate as more money as possible without compromising its charitable aims*". Nevertheless, charities' aim is not entirely to earn money but also to create correlated functions such as recycling of goods, raising awareness of charitable cause and fundraising (Horne, 1998).

In order to manage the variety of work for charitable cause, the numbers of voluntary organisations have significantly increased leading to larger competition for limited human and financial resources (Bussel and Forbes, 2002). The growing number of charities in the voluntary sector can be explained due to the removal of the direct public funding previously undertaken by the government: mainly in education, health care and social care (Chew, 2006). Current governmental strategic review about the voluntary and non-profit sector has been strengthening the compactness of relationships between voluntary and public sectors in delivery and shaping the policy of public services in the UK. However, those governmental changes have put massive pressures on the sector. This pressure has to do with managing operations as long-term strategy in conjunction with short-term survival needs for charitable causes (Chew 2006). Even though volunteering levels are high, there are signs that these levels may have reached a peak point, so for this reason, voluntary organisations struggle lately to employ from a decreasing pool of volunteers (Bussel and Forbes, 2002). Kendall and Knapp (1996, p.253) define the UK.'s voluntary sector changing competitive landscape as the '*new competitive climate*'. The growing number of voluntary organisations entering the sector combined with a blurring of the boundaries between public and private sectors are likely to increase the competition for further resources (NCVO 2015; Chew 2006). The issues mentioned above might fail to satisfy customers' needs in the future. This makes it very difficult to do in their move into commercialism. For instance, the 'trading up' of charity retailing can be off putting to some of these customer segments (Broadbridge and Parsons, 2003). Moreover, Whithear (1999) found some substantial differences between paid staff of voluntary organisations in comparison with those who work as volunteers.

In a nutshell, it could be argued that the sector appears to have offered appropriate space for entrepreneurial activities that could be implemented under the view of strategic planning and execution. In addition, it has been given a new role to play with regard to public services that traditionally the governmental sector was responsible for, as a new public service delivery' organisation. Having said this, the level of preparation for this role is not always adequate which creates a sense of lack of structure and inability for fit-for-purpose state.

4. Methodology

The methodology used in the present study is focused on an exhaustive kind of *secondary search* of experiments and entrepreneurial initiatives that take place in the context of South West of England, mainly via information available by governmental, voluntary and other relevant documents, the media, and academic

sources (electronic mainly but also hard copy ones). The number of sources of this kind has exceeded 100. This preliminary step is of particular importance in this study, firstly because so far there has not been a systematisation of major stakeholders involved in the academic context, regarding, for example, the number of entities, the statute assumed, the continuous mission, the focus of intervention regarding non-formal learning for entrepreneurship, existing partnerships, among others.

At the same time a number of *one-to-one semi-structured interviews* were used - 25 of them – with voluntary sector officials and activists. These took place between October 2017 to May 2018 in the conurbation of Bournemouth, Poole & Christchurch, Dorset in the South West of England. The primary data provided was analysed via *content* but also *discourse analysis*. The aim was to analyse the relationship between specific voluntary organisations and their key supporters as per the learning organisation framework presented in section 2.2. Finally, a *case study strategy* was employed that explored, but most importantly explained circumstances of impact of strategic entrepreneurship to the voluntary organisations in the South West of England.

5. Findings – Discussion

5.1 Evidence about Strategic Entrepreneurship' Application for the Voluntary Sector

The initial research findings refer almost exclusively to the voluntary organisations in the Bournemouth geographical jurisdiction, Dorset – which expands in the middle of the South West of England. The 2011 Census showed the population of Bournemouth to be around 183,500 residents. The mid-2013 estimate was 188,700 and it is predicted to reach 225,000 by 2037. The largest proportion of the population is White British 83.8% with a 16.2% minority ethnic population. Bournemouth has a relatively young population, with above national average proportions of adults under 34. In recent years the birth rate has risen which is leading to increasing numbers of under-fives (Bournemouth Council for Voluntary Service, 2016).

The voluntary sector in Bournemouth is very diverse; some of the facts are as follows:

- There are about 370 registered charities in the borough with a total income of more than £65 million a year;
- Two thirds of registered charities and 88% of all voluntary and community groups have an income of less than £100,000 a year;
- Nearly two thirds of registered charities do not receive any state funding;
- 8,500 volunteers work for registered charities delivering about 1.5 million hours of unpaid labour per year contributing about £20.5 million a year to the local economy (Bournemouth Council for Voluntary Service, 2016).

There is an increasing entrepreneurial activity in the area considering the economic and social situation of the town, especially in areas where voluntary work has been seen as thriving. Health is one of these areas of development within the voluntary sector. Improving the health of Bournemouth's residents has not only a social impact, but also an economic incentive: saving on the cost of treating preventable illness (Bournemouth Borough Council, 2012). Voluntary organisations that have been supported by the council such as Live Well Dorset or Drugs & Alcohol Action Team work in an entrepreneurial way which "*helps to make a difference and change lifestyle and habits for the better*" (LiveWell Dorset, 2016).

Most of all, it is this unique experience that an entrepreneurial education can offer. According to the representative of one of the most prominent social enterprises in the town:

> *"…I think our uniqueness is about the way we do it so I think that's unique quality about this organisation. I think that we are always as an organisation prepared to go the extra mile where as an organisation if you talk to all my teams, you will find people very committed to the work that they do"*

Table 1: Initial findings about application of strategic entrepreneurship in the South West of England

Strategic Entrepreneurship and Learning Organisation Process		
	General aspects	***Initial Evidence in the South West of England (Bournemouth jurisdiction)***
***Concrete experience*:**	Individuals or people who are involved with entrepreneurial activities can start with some sort of prior knowledge such as technical entrepreneurial breakthrough (Kolb 2014).	Increased ability by a wide number of voluntary organisations of all sizes that have been pursuing entrepreneurial activities with a strategic purpose and most of all uniqueness
	General aspects	***Initial Evidence in the South West of England (Bournemouth jurisdiction)***
***Observation and Reflection*:**	The experience that has been discussed by the parties involved is then observed and reflected (Kolb and Kolb 2005).	Not sufficient observations and reflections have been noted as this is a novel process for the Bournemouth Area
***Formation*:**	It replaces abstract conceptualisation with formation by introducing routines in a particular structure (Kolb et al. 2001). The formation of the organisation is made based on the experience.	Tentative attempts to promote conceptualisation of strategic entrepreneurship in a more formatted structure. The role of the borough council is still regarded as very significant
***Testing the new situation*:**	It involves active experimentation with testing the new situation. This part can be the final stage for the learning organisation cycle which identifies how well developed the new structure is.	An assorted number of entrepreneurial activities in certain areas such as health can be defined with a mixed rate of success.

Moreover, strategic identification becomes part of voluntary sector routine operations as one representative of a large-scale local voluntary organisation claimed:

> *"Our professional aims are clear. We're here to help re-invest the skills and experience of people used to dealing with life's challenges - and to open up opportunities they might otherwise miss. It is our mission to provide high quality services for the benefit of the community whilst finding new and innovative means of generating income"*

Furthermore, another representative contended regarding the value of the service provided:

> *"There is a social value act and any new sort of providers coming into an area need to meet that social value act requirement, so it is built into all of our tender processes and that is not about making a service better necessarily, it is also about the impact that, that service is going to have on the community"*

Aspects of strategic entrepreneurship are widely evident in Bournemouth and the whole South West of England, despite the fact that they appear not well connected in a strategically holistic manner, which could contribute to long-term standing and continuity. As a representative of a nation-wide voluntary name put it:

> *"…it this discrepancy of ideas within the sector that might enhance opportunities of learning and minimise risk existence, however it does not set conditions for effective performance".*

Having said this, according to another participant there is a realistic view about what are the parts of the voluntary organisations that need support more than others, with health being the prominent one because of the drug issues in the conurbation.

6. Conclusion – Case Revisited

The aim of this paper was to identify strategic entrepreneurship as a vehicle for supporting the operational capacity of the voluntary sector in the South West of England. Based on a revisited point of view about how

this works – about two years after - it could be argued that: a) no substantial change has been made however there is a more pragmatic view about the situation of the sector and what are the areas that really need support through directed funding; b) Governmental agencies and local authorities still play a significant role with regard to services which would otherwise be delivered by the voluntary sector; c) most importantly – according to a participant from the health sector – the voluntary sector by nature can "*produce innovation, as people there are good in coming up with innovative ideas and being able to implement them very quickly*". This perhaps indicates that voluntary organisations have been in a process of establishing processes of learning and minimising risks, which was not the case before. This might well indicate that strategic entrepreneurship, as the combination of pragmatism and innovation can have an effect in every-day life within a sector that increasingly demands its fair share in the policy arena.

Developing a Model of Film-Induced Slum Tourism Motivations: an Exploratory, Qualitative Approach

Arthur Filipe de Araújo, Armando Luís Vieira and Carlos Costa
University of Aveiro, Portugal
arthurfilipearaujo@gmail.com
aluisvieira@ua.pt
ccosta@ua.pt

Abstract: Film tourism encompasses visits to places whose attractiveness is related to audio-visual products (films, tv-series, soap operas…). There is a wide range of studies acknowledging those products' potential to influence destination image, visit motivations, and, consequently, tourist arrivals to the depicted places. Destination managers and tourism entrepreneurs have increasingly made efforts to capitalise on this potential. In academia, the phenomenon has motivated a growing body of work on the relationship between cinema and tourism. The literature suggests that even films that portray destinations under a bad light can increase motivations to visit them. Such conclusions, strengthened by several real-world cases, imply that films might play a special role in inducing motivations for slum tourism, which is described as tourism to which poverty is part of the attraction. Slum tourism has received little academic attention from the perspective of tourism studies, and research on film tourists' motivations is particularly scarce. The few indications available in the literature are either initial insights or assumptions and premises subjectively made by their authors. In this context, the present study aims at developing a model including the dimensions of slum tourism motivations, and the film elements that act as their determinants. To this end, an exploratory, qualitative approach was employed, based on the empirical data collected with the participation of tourists visiting the favelas of Rio de Janeiro. Results show that slum tourism motivations include Learning motivations and Experiential motivations as push factors, and that each of those dimensions is affected by two categories of film pull factors: Place & Personality, and Performance. The model is expected to work as an innovative tool for increasing destination attractiveness, and the effectiveness of managerial practices. In addition, it constitutes a first step towards a structural analysis of slum tourism motivations and their film determinants. The present investigation thus provides relevant theoretical and managerial insights, as well as important avenues for future research.

Keywords: favela, film tourism, innovation, Rio de Janeiro, slum tourism, tourist motivations.

1. Introduction

Tourist visits to destinations or attractions directly or indirectly motivated by audio-visual products, or including activities related to the cinema world, have been conceptualised as film tourism. Recent studies have shown that even films that portray destinations under what could be considered a bad light might awaken viewers' curiosity, and consequently, create or increase visit motivations (Loureiro & de Araujo, 2015; Shani, Wang, Hudson, & Gil, 2009). This suggests that films potentially fuel motivations to slum tourism, which is described as tourism to which poverty and associated signifiers are a central point and part of the attraction (Frenzel, 2017). Most of the extant literature on slum tourists' motivations comes from the fields of geography and social studies, while studies adopting a practical tourism management approach are still limited.

Moreover, the few indications regarding slum tourist's motivations in the literature lack empirical scrutiny.

Aiming at filling these gaps in the literature, the present study proposes a theoretical model of slum tourism motivations dimensions, and the elements of films that act as their determinants. To this end, an exploratory, qualitative approach was adopted, and the tourist activity carried out in the *favelas* (originally informal settlements mostly inhabited by the poor) of Rio de Janeiro was chosen as research setting. Such decision is justified by the *favelas* being one of the most expressive examples of slum tourism worldwide. Additionally, Rio's *favelas* are a slum tourism case in which audio-visual products, particularly feature films, allegedly play a significant role. Data was collected directly from tourists visiting the *favelas* via semi-structured interviews that covered topics regarding their motivations to visit such places and the potential role of audio-visual products.

Results show that slum tourism motivations can be conceptualised according to two main dimensions:

Experiential motivations and *Learning motivations*. The film determinants to those motivations fall into Macionis's (2004) 3 P's approach (*Place, Personality* and *Performance*), with the necessary adaptations to contextual nuances. Moreover, hypotheses have been developed regarding the effect of each film determinant on each slum tourism motivation dimension. These findings provide an original theoretical

contribution, since no previous attempt to structurally address slum tourism motivations has been found in the literature. Also, the role of cinema in creating or increasing those motivations has not been previously addressed either. In terms of managerial implications, the study's results provide useful insights to destinations where the slum-tourism phenomenon is a reality, especially those in which its attractiveness is associated with cinema. Moreover, tourism entrepreneurs involved in slum tourism activities, such as tour organisers and hostel managers, can also benefit from a better understanding of their target market's motivation. In order to provide more concrete guidelines, however, the model should be calibrated and tested from a quantitative approach in further studies.

2. Theoretical overview

2.1 Film tourism motivations

A seminal contribution to film tourism motivations was provided by Macionis (2004), who proposed a differentiation between *Place*, *Personality* and *Performance* (the 3 P's outline) as film elements potentially attracting viewers to the depicted destinations. In this context, *Place* refers to the location attributes, scenery and destination attributes; *Personality* relates to the film's cast, characters and celebrities; and *Performance* consists in the film's plot, theme and genre. This conceptualisation builds on the push-pull approach, originally proposed by Dann (1982), according to which, tourists' motivations are the sum of push factors, referring to their own needs and wishes; and pull factors, that is, destination attributes that potentially satisfy those needs and wishes. In this context, the 3 Ps are pull factors through which destinations portrayed in films might appeal to viewers. Accordingly, Macionis (2004) proposes a list of film tourists' internal drivers (push factors), which include: ego-enhancement; fantasy or escape; status/prestige; search for self-identity; or vicarious experience, which are potentially fulfilled by the film tourism experience.

This list of film tourism push factors was further refined by Macionis & Sparks (2009), and then employed, along with the 3 sets of pull factors, by most subsequent studies on film tourists' motivations (Meng & Tung, 2016; Oviedo-García, Castellanos-Verdugo, Trujillo-García, & Mallya, 2016; Rajaguru, 2013; Rittichainuwat & Rattanaphinanchai, 2015; Suni & Komppula, 2012), which also provided their contributions and adaptations to each particular context. Such body of literature is however still narrow, especially when considering the specific context of film-induced slum tourism, as, to our best knowledge, no study has addressed the role of films on viewers' motivations to this particular type of tourism. In this vein, the 3 Ps outline will be employed in the present study, alongside the context specific push factors of slum tourism motivations.

2.2 Slum tourism motivations

Slum tourism has been described as tourist visits to poor areas with the goal of experiencing the place where poor people live (Whyte, Selinger, & Outterson, 2011), or simply as tourism to which poverty and associated signifiers are a central point and part of the attraction (Frenzel, 2014). The practice is also commonly referred to as "poverty tourism". In academia, however, "slumming" and "slum tourism" are more broadly accepted, since, as suggested by studies in three major slum tourism destinations - Brazilian *favelas* (Freire-Medeiros 2011), Indian slums (Dyson 2012; Meschkank 2011), and South African Townships (Dyson 2012) - slum tours offer alternative observational schemes (Rolfes 2009), and typically aim at deconstructing poverty as the main association to such places.

Regarding the motivations of tourists engaging in such type of tourism, contributions in the literature are limited to some initial insights from studies with a different focus, typically from a sociological stance. For instance, Frisch (2012) and Dyson (2012) argue that authenticity is a central aspect of slum tourism motivations. A bolder statement is made by Mendes (2010), who links slum tourism in India to a fascination with the spectacle of poverty. Mendes' (2010) study, however, does not include any empirical component.

Freire-Medeiros (2007, 2009) conceptualises Rio de Janeiro's *favela* tours as reality tours, which can be viewed as "social tours" or "dark tours". In this context, social tours are based on participation and authenticity, and engaged in by tourists who are willing to help locals through their visit; while dark tours sell commoditised poverty and misery, attracting visitors with a voyeuristic desire to gaze upon the poor. Such classification, however, is not the result of empirical research on this topic. Instead, it is included as part of the characterisation of the object of research, which consequently, was conducted based on the subjective assumption that her conceptualisation was correct.

Analogous to Freire-Medeiros, (2007, 2009), Williams (2008) argues that *favelas* became a draw for foreign tourists due to the fascination with the drug culture as portrayed in *City of God* (2002), combined with a charitable, if not voyeuristic, desire to gaze upon disadvantaged communities. Such statement also implies a relevant role of cinema in generating slum-tourism motivations, which is also suggested by Freire-Medeiros (2006, 2007, 2011), Meschkank (2011), Privitera (2015), and Diekmann & Hannam (2012). In this context, the present work aims to further investigate this supposedly relevant connection.

3. Method

Bearing in mind the present study's goals, a qualitative approach was adopted. Impressions on slum tourism motivations, as well as the role of films and other audio-visual products on generating those motivations, were collected from tourists during their visits to the Rio de Janeiro's South Zone *favelas*, namely: Rocinha, Vidigal, Morro da Babilônia and Santa Marta. The selected favelas are the ones with the most relevant tourist activity.

Rocinha is the biggest favela in Rio, with over 700.000 inhabitants, and was the first to receive tourists, still in the 80's. Vidigal, its close neighbour, has a vibrant art community and is on the path to mountain trails, which attracts many visitors. Babilônia has a privileged location and many viewpoints, which attracted several favela-themed hostels. Finally, Santa Marta, the new, paradigmatic, touristic favela (Freire-medeiros, 2016), attracts tourists due to its favourable location and infrastructure, which includes a cable car and a tourist information office. Its attractiveness is also related to the shooting of Michael Jackson's 1996 video clip *They don't care about us*, and of the film *Fast Five* (*Fast and Furious Franchise* – 2011).

Data was collected through semi-structured interviews. The interview guide (see Appendix) aimed at serving as a general navigation tool, just to remind the researcher about key topics to be explored, while allowing for adaptations to each interviewee, such as changes is the order of questions, and the addition of new questions aiming at obtaining more details about particular topics. The guide was based on insights provided by previous studies and aimed at inviting tourists to talk about their motivations to visit the *favela,* as well as whether and how those were related to films. In order to generate additional insights, visitors were also asked about their previous image of the *favela* and their experiences during their visits.

The interview guide was pre-tested via video-conferences with tourists who had previously participated in favela tours. Participants were first contacted via *Facebook* groups, and then asked to participate in the interviews through *Skype*. The pre-test interviews were recorded and then re-listened in order to allow for the identification of points that should be restructured. During the field research, 54 tourists were interviewed amongst the four mentioned favelas. The interviews were also recorded, so they could be later analyzed in detail.

The collected material was examined through both within-case and cross-case analysis (Eisenhardt, 1989; Miles & Huberman, 1994), both carried out through categorical content analysis, which consists in the dismembering of the text in units, or categories, according to pre-established criteria (Bardin, 2000). Such technique was carried out with the aid of the *QSR NVivo 11* software, which allows the codification of content into categorical nodes. The coding resulted in nodes structures that helped with the process of analysing tourists' discourses with reference to the reviewed literature. The development of the proposed model was then based on such analysis.

4. Results

The analysis of tourists' impressions resulted in two main nodes: "Slum tourism motivations" and "Film determinants". In contrast with Freire-Medeiros's (2007, 2009) categorisation, according to which *favela* tours can be either *social* or *dark*, many other motivational items were found. *Dark* and *social* motivations were indeed present, however, rather than two major dimensions, they represented components within two bigger dimensions: *Experiential motivations* and *Learning motivations*.

Social motivations were mentioned significantly more often than dark motivations, and included a group of four items, which, alongside two additional items, account for the *Learning motivations* dimension.

Experiential Motivations, in turn, include nine items, amongst which, *Dark motivation*. It must be noted that assertive mentions to *Dark motivations* were rare within participants' answers, thus, the item's inclusion relies more heavily on previous literature. Slum tourism motivation items are detailed in

	Experiential motivations	
Novelty	A new or unfamiliar experience.	"… it seemed like something new and exciting, that I'd never done before…"
Film-induced specific (FIS)	Slum tourists' motivations related to specifically seeing something they saw on a film or other audio-visual product.	"the really stereotyped vision from like, the film "Cidade de Deus"".
Escape	The act of fleeing from one's routine.	"I really wanted to experience something else than what I'm used to in Belgium."
Artistic	Motivations related to music, graffiti, theatre and other art forms.	"… they have a lot of creativity here, a lot of art, artists, music, graffiti, theatre…
Experience a different environment (EDE)	Motivation related to physically being in a new and unfamiliar place with particular characteristics.	"…how the landscapes looked like, the structures the buildings…"
Culture and interaction (C&I)	Tourists' desire or need to interact and gain knowledge about the culture and way of life of locals.	"Being in touch with the community."
Search for authentic experiences (SAE)	Visitors' desire to experience something genuine and spontaneous, rather than planned and prepared for tourist consumption.	"the motivation was kind of, trying to (…) meet somebody and maybe find out what the actual real favela is like..."
Experience more than regular tourists (EMRT)	Tourists' desire to see and experience what most tourists, and often even the residents, do not.	"Because it was (…) a part of Brazil that not everyone sees, because normally they stay in Ipanema, *Copacabana*, Leblon."
Dark motivation (DM)	Tourists' desire to visit a slum due to the thrill achieved through being in a place associated with violence; or with a voyeuristic gaze upon the poor.	"Also, violence. (…) just, even being here (…) with, like, the police walking around with AK47s (…) it's quite… interesting."

.

Table 1: Slum tourism motivation dimensions' items

Item	**Definition**	**Examples of mentions by interviewees**
	Learning motivations	
Confronting media (CM)	Visitors' desire to confront the image portrayed by media with their first-hand experience.	"…because I don't trust what movies say, right? I don't trust what the news say, (…) I wanna go there myself and experience."
Gaining insight (GI)	Tourists' desire to learn about and understand broader social-economic issues of a city or a county through a visit to its slums.	"For me, to see where 20% of the population live in Rio."
Interest in reinvested profits (IRP)	Tourists' interest about whether the profits from tourism are reinvested in the community.	"… the money goes to people who live there which (…) is nice."
Interest in social projects (ISP)	Tourists willingness to learn about the social projects that aid dwellers.	"… because I know that there are a lot of social projects here and that's what I really want to do."
Improve inhabitants' life conditions (ILC)	Visitors willingness to learn about ways in which locals' life conditions could be improved.	"Just to see if they're not able to do it themselves (…) What could, maybe, other countries do to help as well."
Learning and empathy (L&E)	Visitors' desire to learn about locals' life and see things from their point of view.	"…the government doesn't care about people who live here, (…) I want to know how they survive. (…) some people are really suffering in the favela…"
	Experiential motivations	
Novelty	A new or unfamiliar experience.	"… it seemed like something new and exciting, that I'd never done before…"
Film-induced specific (FIS)	Slum tourists' motivations related to specifically seeing something they saw on a film or other audio-visual product.	"the really stereotyped vision from like, the film "Cidade de Deus"".
Escape	The act of fleeing from one's routine.	"I really wanted to experience something else than what I'm used to in Belgium."
Artistic	Motivations related to music, graffiti, theatre and other art forms.	"… they have a lot of creativity here, a lot of art, artists, music, graffiti, theatre…
Experience a different environment (EDE)	Motivation related to physically being in a new and unfamiliar place with particular characteristics.	"…how the landscapes looked like, the structures the buildings…"
Culture and interaction (C&I)	Tourists' desire or need to interact and gain knowledge about the culture and way of life of locals.	"Being in touch with the community."
Search for authentic experiences (SAE)	Visitors' desire to experience something genuine and spontaneous, rather than planned and prepared for tourist consumption.	"the motivation was kind of, trying to (…) meet somebody and maybe find out what the actual real favela is like..."

Experience more than regular tourists (EMRT)	Tourists' desire to see and experience what most tourists, and often even the residents, do not.	"Because it was (…) a part of Brazil that not everyone sees, because normally they stay in Ipanema, *Copacabana*, Leblon."
Dark motivation (DM)	Tourists' desire to visit a slum due to the thrill achieved through being in a place associated with violence; or with a voyeuristic gaze upon the poor.	"Also, violence. (…) just, even being here (…) with, like, the police walking around with AK47s (…) it's quite… interesting."

Regarding the role of films, the most frequently mentioned were *City of God* (2002), *Fast Five* (2011) and *Elite Squad* (2007 and 2010). Other audio-visual products mentioned were music videos, mainly Michael Jackson's *They don't care about us*, and Brazilian soap operas. Film determinants were conceptualised within Macionis's (2004) 3 Ps outline, with the necessary adaptations on the items, due to the specifications of films shot in *favelas*. Results suggest that, while *Place* and *Personality* attract visitors mostly through an hedonistic appeal, embeebed in contemplation and adventure, *Performance* elements tend to appeal to viewers by creating empathy with locals. Therefore, in order to adapt the original conceptualisation to the examined settings, *Place* and *Personality* were considered a single determinant (*Place & Personality*), while *Performance* alone represented a second one. Film determinants are detailed in Table 2.

Table 2: Film determinants' items

Item	**Definition**	**References**
	Place & Personality	
Landscapes	Landscapes portrayed in the film and other audio-visual products.	"…the image of the houses, on the hills, the Little streets."
Item	**Definition**	**References**
Scenery	Films' and another audio-visual products' scenery.	"I only remember *Fast and furious* (…) They jumping around the houses like (…) that's cool"
Cultural attractions (CA)	The cultural attractions portrayed in films and other audio-visual products.	"…the place, the typical parties of the favelas, for example"
Friendly characters (FC)	Characters in films and other audio-visual products who appeal to viewers due to their friendly personality.	"People were friendly, (…) it's kind of micro-economy, solidarity."
Way of life of characters (WLC)	Characters' appeal to viewers due to their different lifestyle.	"…portrays the every-day life, right? The routine (…) people going up and down, (…) the language, the slangs, people's clothes, the food they eat, the music to which they listen…".
Hard working characters (HWC)	Characters' appeal to viewers due to them being hard working.	"It is a community, right? Of people who work, of hard-working people."
	Performance	
The suffering and poor conditions faced by characters (SPC)	Films' and other audio/visual products' display of people submitted to suffering and poor living conditions	"…extreme poverty, (…) living just next to very wealthy people, but in (…) very poor conditions."
The violence portrayed by the films (VPF)	Films' display of violence, potentially instigating viewers to confront such reality with their first-hand experience	"lots of guns, that's what you see in the films, actually."
The experiences lived by characters (ELC)	Experiences in general portrayed in films	"(…) they live in such conditions (…) they pass through lots of things…)

Having the items of slum tourism motivation dimensions and their film determinants been addressed, the next chapter deals with the proposed relationships between those variables.

5. Model proposal

Experiential motivations include *SAE*, which refers to visitors' desire to experience something genuine and spontaneous, rather than planned and prepared for tourist consumption; and *EMT*, which refers to visitors' desire to see and experience what most tourists do not. The items of *Place & Personality* offer potential fulfilment for those desires, for example, through unique landscapes. Besides, *Cultural attractions*, which is also included in *Place*, potentially affects the *Artistic* motivation. Accordingly, character-related items can also potentially affect such motivations. For instance, *Friendly characters*, *WOL*, and *HWC* arguably influence viewers' desire or need to interact and gain knowledge about the culture and way of life of locals, on which consists the item *Culture/interaction*, included in *Experiential motivations*. In this context, H1: The effect of *Place & Personality* is positively associated with *Experiential motivations*.

Accordingly, the items included in *Performance* sensitise spectators to the life conditions faced by the characters, and consequently, by the population of *favelas*. This is particularly applicable to the *SPC*, as well as

to *ELC*, since those experiences are mainly related to suffering. This sensitising aspect is a relevant facet of many of the items encompassed by learning motivations, such as: *ISP*, *ILC*, *IRP,* and *Learning and empathy*.

These items refer to visitors' desire to contribute to the improvement of life conditions in the visited community, which is arguably affected by the sensitising effect of the mentioned *Performance* items. Therefore, H2: The effect of *Performance* is positively related to *Learning Motivations*.

The experiences of characters in films and soap operas also motivate viewers to visit the locations. In the case of the *favelas* as film locations and tourist attractions, those elements influence tourists' desire to experience the unique landscapes and cultural environment of such places; as well as to flee from their own routine and fulfil an adventurous endeavour, by experiencing what "regular tourists do not". In this context, the items *Novelty*, *Escape,* and *EDE* are probably affected by *Performance* in general. Moreover, *SAE* and *EMT* are arguably affected by *The experiences lived by the characters*, their life conditions and the context of violence, which contrasts with how Rio de Janeiro is promoted to conventional tourists, and awakens the desire for the authentic and "non-touristy", as expressed by many interviewees. Thus, H3: The effect of *Performance* is positively related to *Experiential motivations*.

Finally, although, for analysis purposes, *Experiential* and *Learning motivations* are conceptualised here as two distinct constructs, they are intrinsically connected, as the learning comes from the first-hand experience. The proposal of two distinct dimensions lies in the belief that some tourists are motivated by the experience *per se*, and thus are moved more by the items encompassed by *Experiential motivations*; while others are interested in those experiences as a way of gaining knowledge, and thus, are more affected by the items of *Learning motivations*. However, *Experiencing* and *Learning* are far from being two totally distinct motivations, and the latter is arguably affected by the former. Therefore, H4: *Experiential motivations* are positively related to *Learning motivations*.

Having the potential causal relationships between the observed variables been hypothesised, the proposed model, including the addressed hypotheses, is represented in Figure 1.

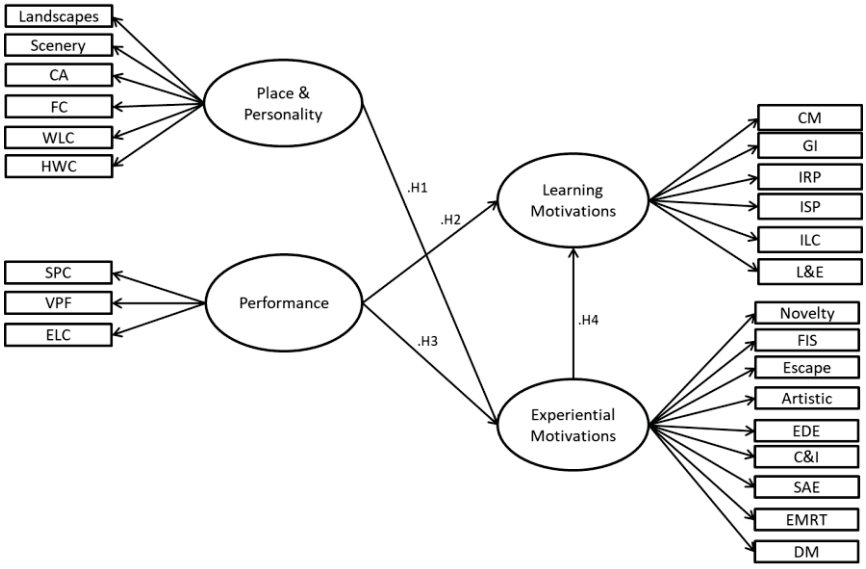

Figure 1: The proposed film-induced slum tourism motivations model

6. Conclusion

The present study's results suggest that slum tourism motivations are the sum of *Learning motivations* and *Experiential motivations*, while each of these dimensions is influenced by one or both of the following film determinants: *Place & Personality* and *Performance*. In this context, our results differ from Freire-Medeiros (2007, 2009), who categorises *favela* tours as reality tours, which can be either *social tours* or *dark tours*, according to participants' motivations. *Social* and *Dark* motivations were indeed found in the present study, but as part of bigger dimensions, rather than being dimensions themselves. Although Freire-Medeiros (2007, 2009) carried out field research, including interviews with tourists and participant observation, there are

several reasons why the present study's conclusions about slum tourists' motviations can be considered more accurate. First, Freire-Medeiros's (2007, 2009) goal was not to conceptualise slum-touists' motivations, but to observe how the *favela* became a touristic space, from a geographical point of view, focusing on spatial dynamics. Therefore, the data collection and analysis approach did not prioritise such variable. Moreover, the mentioned conceptualisation is not included in the study's results, but as part of the characterisation of the object of study. Thus, rather than providing the necessary empirical scrutiny, Freire-Medeiros' (2007, 2009) research was conducted based on the subjective premise that such conceptualisation was true.

Other previous indications in the literature regarding slum tourists' motivations are also subjectively made by their authors in the absence of empirical scrutiny, such as Mendes's (2010) statement regarding slum tourism and the fascination with the spectacle of poverty. The remaining are initial insights from studies with other main goals, such as those provided by Frisch (2012) and Dyson (2012), who suggest that authenticity is as a main element of slum tourism motivations, which has been reinforced by the present study. Therefore, this research's results provide a relevant theoretical contribution, as they represent a first step to achieve an in depth understanding of slum tourists' motivations, by identifying its dimensions. In addition, the present study is also a first attempt to assess the role of film determinants in slum tourism motivations.

From a practical standpoint, the results provide useful managerial implications for destinations where slum tourism is a reality, especially for those where movies play a relevant role, like the observed case of Brazilian *favelas,* as well as Indian slums. Aware of the film pull elements that effectively attract slum tourists, destination managers could work together with film makers in order to prioritise films that highlight them.

Depending on whether slum tourism is perceived as beneficial in a particular area, such partnerships could also be used to avoid the portrayal of those elements, or even try to depict specific ones, in order to attract a particular slum tourist profile, considered more in line with the destination's goals. For instance, a destination manager might consider slum tourists driven mostly by *Learning motivations* more suitable to the destination's goals, and thus, prioritise films that depict elements that attract this specific type of slum tourist. In the case of Brazil, such work could be done through communication and partnerships with the Ministry of Culture, since it works as the manager of tax wavier mechanisms that finance most national films that reach global audiences, including all the previously mentioned national movies.

An additional managerial implication refers to tourism entrepreneurs involved in slum tourism activities, especially in Rio de Janeiro, such as *favela* tours and hostels. Knowing what slum tourists are interested in, they will be able to innovate by tailoring the tours to visitors' motivations and promote accordingly. Moreover, the tour operationalisation can also be managed aiming at reflecting the values the study suggests slum tourists seek in such tours. In terms of *Experiential motivations*, the following actions are advisable: having partnerships with local guides (in the case of outsider companies – those that are not owned and managed by locals) in order to maintain tour authenticity; promoting and executing tours bearing in mind the visitors' desire to experience things that are not "touristy"; and featuring houses and landscapes on the promotional material. Implications from *Learning motivations* include: operationalising and promoting tours as educational; approaching broader socio-economic issues regarding the *favelas* during the tours; informing the fact that part of the profits is reinvested in the communities; and building tours' value chain in order to make it as local based as possible, that is: including local guides, meals in local restaurant or even locals' houses, and partnerships with local shops, NGOs and social projects.

Finally, the present work has some limitations, which in turn, present avenues for further research. The main shortcoming is inherent to the qualitative nature of the study, i. e., the proposed model results exclusively from the interpretation of tourists' discourses. In order to have an acceptable level of reliability, the model needs to be calibrated and tested, and this process should be grounded on quantitative data. In this context, applying a quantitative survey based on the proposed model in order to test it through techniques such as Structural Equations Modelling is a fertile task for further research.

Appendix – Interview guide

Name:
Nationality:
Profession/main occupation:

1. What motivated you to visit/stay in a favela?
2. What did you know about favelas before visiting one? From which sources do you believe this knowledge comes?
3. Was visiting a favela the main goal of your trip to Rio? If not, what was it?
4. What do you believe has contributed to your interest or curiosity regarding the favela?
5. What comes to your mind when you think about favela?
6. Please, talk about your experience in the favela. The positive negative points or anything else you want to share.
7. Do you remember having seen any film(s)/tv-series(s)/soap-opera(s)/video-clip(s) that takes place in a favela? If so, which one(s)?

If the interviewee does not remember having seen any audio-visual product that takes place in a favela, the interview must continue from question 10.

1. Would you say that having watched this(these) film(s)/tv-series(s)/soap-opera(s)/video-clip(s) has somehow influenced your motivations to visit a favela? (what about to visit Rio? And Brazil in general?)

In case the interviewee does not associate the audio-visual product to his/her motivations to visit the favela, the interview must end here.

1. Which elements of this(these) film(s)/tv-series(s)/soap-opera(s)/video-clip(s) motivated you to visit a favela or Rio de Janeiro?

For those who don't remember having watched any film(s)/tv-series(s)/soap opera(s)/video-clip(s) that takes place in a favela:

1. Do you know (have you ever heard) of any film(s)/tv-series(s)/soap-opera(s)/video-clip(s) that takes place in a favela? If so, which one(s)?
2. What do you know about this(these) film(s)?

Innovative Activity of Enterprises under the Condition of Financial Deficit

Yuliya Asaturova and Tatiana Khvatova
Peter the Great St. Petersburg Polytechnic University, Russia
asaturova_yum@spbstu.ru
khvatova.ty@spbstu.ru

Abstract: The successful development of innovation-active enterprises lies at the root of an effective market economy. However, according to the results of surveys on the entrepreneurship specifics in Russia, the innovative activity of enterprises is currently insufficient. The reasons for this are: lack of financial resources, caused by, among other things, economic sanctions; the high cost of innovation; insufficient capacity of organizations for innovation. Nowadays, enterprises have to withstand tough competition in attracting capital to finance business, which is especially hard for small enterprises. In this paper, the main factors influencing the innovation activity of an enterprise are investigated. The influence of financial and other types of constraints on a company's innovative and entrepreneurial activities is examined. As a result, the connection between the stable financial position of the company and its innovative activity is proven. The indicators of the financial and economic efficiency of the enterprise that influence the entrepreneurial and innovative activities of the company are revealed. It is demonstrated that the ability to correctly assess the economic benefit of using novelties is one of the key factors to the successful innovative activity of an enterprise. To analyze the financial constraints of enterprises that operate under the conditions of a capital deficit, the sources of financing the company's investment activities were considered. It is shown, in particular, that in order to attract loan capital, it is necessary to maintain a sufficient level of such limiting indicators such as solvency and financial stability. The paper considers modern methods of assessing and maintaining a sufficient level of these indicators at the enterprise. In addition to the financial component, the other internal and external factors of the innovative activity of an enterprise were considered in the paper. Based on the results of the study, a system of key performance indicators for the enterprise has been developed, which determines the relevance and scientific novelty of this work. Timely controlling and maintaining the required level of selected indicators will lead to an increase in the efficiency of the company's innovation and investment activities.

Keywords: Innovation, finance, constraints, entrepreneurship, solvency, financial stability, profitability, business activity, key performance indicators.

1. Introduction

The innovation activity of enterprises is one of the main factors of economic growth in contemporary societies (Ahlstrom, 2010, Steil, Victor and Nelson, 2002, Romer, 1990). Successfully functioning innovation-active enterprises are the basis of a developed market economy. The role of innovation is constantly increasing, occupying one of the priority directions in the development of world countries economics (Maradana et al, 2017). Today, investment in technological development is not only the main source of economic growth, but also the main anti-crisis measure (Zabolotskaya, 2015). Corporate finance greatly contributes to the development of entrepreneurial and innovative activities of companies, as they are characterized by flexibility and the ability to innovate (Neff, 2002). To enhance the innovative activity of enterprises, the basic institutions in the field of innovation have been created in Russia, including venture funds such as: Russian Venture Company, Russian Fund for Technological Development, Russian Development Bank, Bank for Development and Foreign Economic Affairs (Vnesheconombank) and others. However, despite the efforts made by the Government of the Russian Federation, the Russian economy has not succeeded in forming a stable trend of innovative development. According to the results of research on the specifics of entrepreneurial activity in the Russian market, it has been revealed that the innovative activity of enterprises is currently insufficient (Asaturova, 2015, Bek et al, 2013). According to the Federal State Statistics Service, in 2015, the share of organizations that implemented innovations in the total number of organizations surveyed was 9.3%, while technological innovation was introduced in 8.3% of enterprises (HSE Publishing, 2017). In the US this figure reaches 33% whereas in countries of the European Union it is 53%. For example, in countries such as Belgium, Switzerland, Germany and Iceland, more than half of the companies surveyed implemented technological innovations (52.9, 52.7, 52.6, 50.1%, respectively). The share of new or improved technologies, products and equipment in developed countries accounts for 70 to 85% of GDP growth, while in Russia, GDP growth is not caused by this factor. The share of research and development in the costs of technological innovation in Russia is 14-16%. The percentage of GDP expenditure on R&D is 0.53% in Russia, up to 2.5-3.0% in industrially developed countries (Zabuga and Vaisman, 2017).

Let us consider the reasons for the low innovative activity of Russian enterprises. Based on statistical data, according to the Statistical Handbooks "Indicators of innovation activity" for the years 2013-2017, three groups of factors negatively affecting the innovative activity of an enterprise can be identified: economic factors (the highest negative impact), internal factors and external factors (HSE Publishing, 2017).

The insufficient innovative activity of Russian companies is related, first of all, to such economic factors as the lack of own funds, the high costs of innovation and the lack of financial support from the State. The amount of funds for innovation in Russia remains low, while the economic sanctions increase difficulties in attracting external financing (Vertakova and Kulikov, 2014, Abramov, 2016). Modern enterprises have to withstand tough competition when attracting capital to finance business and innovation. This is especially true for small business enterprises. To solve this problem, in our opinion, it is important to provide a high level of financial standing of the enterprise, which will increase its attractiveness for investors and profitability.

The next two factors, included in the top five of the ranking - high economic risk and uncertainty of economic benefits of innovation results - are interrelated. The high economic risk of implementing innovative projects is typical for any economic system. Moreover, in addition to the traditional risk of any project associated with uncertainty about future scenarios for the development of certain events, innovative projects carry additional risks associated with uncertainty about the implementation of new ideas. The greater the positive effect expected from innovation is, the higher is risk. Therefore, an enterprise faces the task of determining an acceptable ratio of risk and return on investment (Litnitsky, 2014).

The last factor - low innovative potential of an enterprise - is associated with the lack of qualified personnel, as well as with the low experience of work with innovative projects. To eliminate these shortcomings, it is necessary to train staff, arrange project competitions and provide monetary incentives for implementing projects. These factors are more difficult to describe analytically, but the most important, from our point of view, in eliminating this shortcoming is the company's stable financial position, which has a huge impact on supporting the internal innovation climate in the company and providing the motivation to be the best.

Factors that negatively affect the innovation activity of an enterprise cause the constraints that impede innovative project implementation. This paper considers three types of such constraints: resource, productive and market constraints. Since the main problem limiting an enterprise’s innovative activity is the lack of financial resources, the main task is to increase the enterprise’s ability to attract funds for innovation.

Determining the connection between the financial position of an enterprise and its ability to innovate is the main feature of this work. The paper shows that financial stability and solvency indicators characterize the enterprise’s innovative attractiveness, which determines its ability to attract loan capital to finance innovation. Based on the revealed interrelations, a system of key performance indicators for the financial analysis of an enterprise is developed. It is justified that the timely controlling and maintenance of the required level of selected indicators will lead to an increase in the efficiency of the company's innovation and investment activities. This determines the relevance and scientific novelty of this work.

Thus, **the main objective of this work** is to find ways to enhance the innovation activity of companies operating under the conditions of financial deficit and to develop a system of key performance indicators that affect the innovation activity of the enterprise.

Achieving this goal implies resolving the following tasks: 1) analyse the factors hindering the enterprise’s innovative activity; 2) investigate the impact of constraints on innovative activity; 3) analyse possible sources of financing of innovative activity; 4) reveal the relationship between the stable financial position of the company and its ability to implement financing for innovation; 5) develop a system of key financial and economic indicators assessing the innovative activity of an enterprise.

The methodological basis of this research is the theory of innovation systems, theory of constraints and the theory of financial analysis. The paper uses analytical research methods based on normative models of financial analysis, such as the method of calculating analytical coefficients, comparative analysis and factor analysis.

2. Analysis of factors and constraints that affect an enterprise's innovative activity

Analysis of ways to increase the innovation activity of enterprises is based on a comprehensive research of factors and constraints that affect innovation. The term "innovation" was first introduced by the Austrian scientist J. Schumpeter, who interpreted innovation as a change in order to introduce and use new types of consumer goods, new production and transportation vehicles, markets and forms of organization in industry (Schumpeter and Opie, 1983). Even before introducing the concept of "innovation", he singled out five typical changes leading to a new quality of the production process emergence, namely: the use of new technology, new technological processes or new market support for production (purchase and sale); introduction of products with new properties; use of new raw materials; changes in the organization of production and its logistics; the emergence of new markets. However, innovation should not be limited only to the sphere of entrepreneurial activity. Innovations are possible in all spheres of human activity: innovation is an idea aiming to gain economic content and ~~to~~ be in demand in the society.

The innovation process (IP) is the process of transforming scientific knowledge into innovation, which can be presented as a succession of events, during which innovation ripens from an idea to a concrete product, technology or service and is distributed while being used in practice (Khvatova, 2009). This process is not interrupted even after an innovation is introduced, because as the distribution spreads, the innovation improves. The IP is aimed at creating the products, technologies and services required by the market.

The possibility of implementing the IP is associated with a certain concentration of an enterprise's resources, the innovative climate in the country and the enterprise's internal innovative potential. In the introduction of this paper, the factors impeding the IP were analysed. In scientific literature, factors are defined as conditions, causes and parameters that affect both the economic process and the outcome of this process (Asaturova, 2016, Litnitsky, 2014). However, in practice, the result itself can also be a factor hampering innovation. Factors and conditions that have a negative impact on innovation and entrepreneurial activity are called constraints (Krasnova, 2013). Therefore, together with an analysis of the factors that affect an enterprise's innovative activity, the effect of constraints on the feasibility of innovative projects is investigated. According to the theory of constraints (Goldratt and Cox, 1992), a constraint is understood as a factor that would contribute to a more successful achievement of the goal, if the company possessed a larger amount of it or used it more efficiently. Goldratt and Cox argued that in any economic system there are boundaries that do not allow it to develop further. There is also a system of constraints in the IP. The system of constraints in innovation means that the optimal combination of the minimum possible number of organisational resources should be found to create and promote an innovative product, in a limited market environment, in order to achieve the maximum possible financial result or other benefit. Let us analyze the main limitations within an innovation system. Based on the literature review, the following types of constraints can be identified: resource, result and market constraints (Krasnova, 2013).

1. *Resource constraints.* Under these constraints, the production or further development of an innovative product is only possible by creating a proper combination between the minimization of resources and the achievement of the desired result. These constraints include, first of all, financial resources, as well as production, technological and labor resources. At the moment, these are the most significant limitations. To overcome resource constraints (including financial ones), it is necessary to raise the company's productivity level, which is estimated by various indicators of the efficiency of the use of enterprise resources, as well as solvency and financial stability indicators, which affect the innovation attractiveness of an enterprise.
2. *Result constraints.* These constraints characterize the future profit of the implementation of the project. Under these constraints, the production and development of an innovative product is possible only in case the product's usefulness for the enterprise needs is proven. In order to take into account these constraints, it is necessary to evaluate the effectiveness of an innovative project implementation. The methods of the economic justification of an enterprise's investment and the innovation activity effectiveness are considered in the works by Asaturova (2015), Litnitsky (2014), Nikolenko and Tarasova (2016). In our opinion, the most important indicators are: net present value of investments (NPV); internal rate of return (IRR); payback period of investments (PP).
3. *Market constraints.* This type of constraint is based on the competitiveness of the innovative product and its brand awareness. Under these constraints, the production or development of an innovative product is only possible in the case of finding a correct concept of conquering a market. The economic

risk of introducing innovation is caused by the uncertainty in the innovative product's competitiveness. This fact is confirmed by the ranking of factors hampering the innovative development of Russian enterprises. According to this ranking, the fifth place among the reasons for low innovation development is the uncertainty of the economic benefit of the innovation result (see Table 1). In order to reduce uncertainty, it is necessary to predict the level of competitiveness of the innovative product. The problems of forecasting the competitiveness of innovative products are discussed in the paper by Zabuga and Vaisman (2017). One of the most important factors affecting the increase in the competitiveness of the company's products is the maintenance of a high level of productivity. Its level, characterized by the ratio of the obtained result divided by the volume of resources consumed, is measured by various profitability and business activity ratios.

When considering the external factors influencing the innovation activity of enterprises, it is also necessary to take into account the innovative and investment climate in the country, the presence of crisis phenomena, the current legislation in the investment sphere, the availability of the benefits for small and medium-sized businesses enterprises and other conditions for innovation. These parameters have a great influence on the entrepreneurial and investment activity of an enterprise, but as the enterprise itself cannot influence their optimization we will therefore not consider them when developing a system of indicators for assessing the effectiveness of the enterprise's activities that affect its innovative activity.

Thus, based on the previous analysis of factors and constraints, it can be concluded that the main problem for entrepreneurship at this current stage of the Russian economy is the resource deficit, including financial constraints. Modern enterprises have to withstand strong competition when attracting capital to finance business and develop innovation. In order to increase the effectiveness of innovation in a financial-deficit environment, it is necessary to increase the ability of an enterprise to attract the capital for innovation. In addition, in our view, the main way to do it is to maintain a company's strong financial and economic position.

As in the conditions of a financial deficit, it is the stable financial position of an enterprise that makes it possible to increase its investment attractiveness and to ensure the possibility of using the company's own capital to finance innovation (Asaturova, 2018).

However, based on the analysis of modern literature, it can be concluded that the financial component of increasing the innovation activity of an enterprise has not been sufficiently developed (Asaturova, 2016). For the moment, there is no developed system of key financial and economic indicators assessing the innovative activity of an enterprise. In this paper, we will trace the dependence of the company's innovative activity on its financial position and will develop a system of key indicators of the company's financial and economic performance, affecting the innovative activity of the enterprise. The theoretical basis for the development of the system of indicators are the works of Russian and foreign authors in the field of financial analysis, such as Brealey, Myers, and Marcus (2017), Garrison, Noreen and Brewer (2017), Sheremet (2011), Savitskaya (2012).

3. Analysis of the financial constraints' impact on financing innovation

As already noted earlier, the problem of financing innovative activity is the main factor restraining the innovative development of Russian enterprises. For an enterprise, financial constraints are primarily related to limiting the possibility of attracting own and borrowed capital to finance innovative activity. In order to identify indicators that increase innovation activity in the conditions of financial deficit, it is necessary to investigate the reasons for the financial constraints of the different types of financing. This will help to understand how an enterprise can influence and overcome them. To explore this question, we will analyze the sources of funding for innovation activities and the financial constraints connected with their use.

Based on the analysis of modern literature and the practice of Russian enterprises, it can be concluded that all sources of financing the company's innovation activity can be divided into 2 groups: external – loan sources of financing and internal sources - own sources of financing (Glukhov and Ostanin, 2013, Lee and Saen, 2012).

According to the present conditions in Russia, due to the reduction in state financing, the main type of *external financing* for the development of innovation in small and medium business enterprises has been bank credits and other types of loan financing in the financial and credit market. It is necessary to mention that the loan sources of funds have its advantages. The cash flows from the realization of the project are concentrated on

the accounts of the enterprise, providing the potentially profitable assets, which gives an opportunity to increase profitability. At the same time, control over the management of the company is not distributed to an unlimited number of individuals, as in the case of the use of share capital. In addition, financing through loans may be preferable for the development of new projects of enterprises that already exist because such enterprises are not required to pay higher fees for bank credit due to insignificant risk in the presence of material security for a loan covered by available assets.

However, at the moment, the use of bank loans is strongly limited in a view of high interest rates and its availability is severely limited by parameters such as the financial position of the enterprise. The objective reason for the insignificant use of foreign capital by Russian organizations is the low level of economic profitability of assets compared to the interest rate on loan capital in the Russian financial market. Therefore, bank loans are, as a rule, used to implement projects that have a high rate of return. Note that the rate of interest and the possibility of obtaining a loan at an enterprise primarily depend on the magnitude of the risk on the project and the characteristics of the company. Therefore, to ensure the possibility of attracting loan financing, it is necessary to increase the investment attractiveness of the company and the level of profitability of the company's assets.

Let us consider the other external forms of financing, such as state budget financing, foreign investment, venture capital and financial leasing. Note that the use of these forms of financing is strongly limited or has a specific nature. For example, financing using the state budget, as the main source of financing for large-scale scientific projects, is typical for large industrial enterprises. In addition, its availability is very limited. The state budget funds are given primarily to industries focused on the production of import-substituting products, competitive goods and services, on industries whose products will continue to be in high demand for a long time, as well as to industries developing new products or products of a higher class. Foreign investors in Russia mainly finance innovative projects related to the development of progressive foreign technologies. However, in view of the economic sanctions that are applied to Russia now, this type of financing is limited (Boboshko, 2014). The use of venture financing in the Russian market also has its limitations. One of the main factors hampering the development of venture capital investment is the lack of a legislative framework for the creation of private venture funds. Practice shows that a large part of venture companies working in the Russian market are organized by international organizations, or on the basis of intergovernmental agreements, which is again substantially limited in the face of economic sanctions. Financial leasing, as a form of a long-term loan to finance fixed assets, also has its limitations. Leasing schemes cannot be applied to all types of innovative projects. What is more, the cost of purchased equipment, together with the interest owed to the bank and insurance payments, can be extremely high, while the equipment market price during leasing can significantly decrease. Statistics show the limited use of this type of financing at Russian enterprises. In the Russian economy, leasing accounts for only 2-3% of investment into equipment.

The internal sources to finance innovation involve the use of own funds of organizations. These include the company's paid-in capital, retained earnings and the company's depreciation fund.

Self-financing by a company's internal funds is one of the main sources of financing the company's activities in conditions of limited capacity for obtaining loans. Internal financing sources include the accumulated capital profits, including the reserve fund, the depreciation fund of the enterprise and the expansion of the share capital of the enterprise. However, the use of these types of financing also has its limitations. The main limitation for most Russian enterprises is the low profitability and, as a consequence, the limit of net profit as the main internal source of financing. The share of depreciation charges in Russia as a source of financing of capital investments is also not high. At the moment, it is about 20% of the financing of capital investments, while in other countries their share reaches 70%. Therefore, in order to ensure the use of profit and depreciation fund to finance innovation, it is necessary to maintain profitability and business activity at a high level, and to improve the efficiency of the use of fixed assets of the enterprise.

Equity financing allows accumulating large financial resources by placing shares among an unlimited number of investors. The primary issue of shares is connected with the creation of new enterprises. For the development of an existing business, including the implementation of innovative projects, an additional issue of shares is made. The use of this form has some advantages over the loan sources of financing, since it allows enterprises to postpone the payment of liability for a later period, when the investing object starts to make a profit and the costs and results are more certain. However, collecting such funds for small and medium-sized companies

is more difficult than obtaining a bank loan. That is why in order to attract the capital through the issue of shares, it is necessary to ensure the stable financial position of the company, monitor the quotation of company shares and other indicators of the company's economic performance.

Thus, under modern conditions, which are characterized by limited budget financing, economic sanctions, high interest rates for lending and low profitability of the company's assets, the financing of the company's innovative activity is objectively limited. Overcoming these financial constraints is primarily related to raising the level of the financial position of the company. The stable financial position of the enterprise and monitoring such indicators as solvency and financial stability will allow the enterprise to provide a high level of investment attractiveness for increasing the possibility of attracting loan capital. Maintaining a high level of indicators such as profitability and business activity will make it possible to increase the efficiency of financing innovation with the company's own resources.

4. Developing a system of key performance indicators affecting the innovative activity of an enterprise

In the previous part of the study while analyzing the sources of financing innovation in modern conditions, we found that financing innovation is mainly carried out at the expense of the own funds of the organization and bank loans. Timely accounting of indicators of solvency and financial stability allows the company to respond to a possible shortage of cash in time, avoid bankruptcy and ensure the possibility of further borrowing for business expansion and development of innovations (Moiseeva and Scheulnikova, 2008).

In order to use its own sources of financing, an enterprise needs to monitor the status of indicators such as profitability and business activity. Ensuring a high level of productivity and asset turnover will overcome the company's resource limitations. Key financial and economic indicators from the sections of solvency, financial stability, business activity and profitability, contributing to the increase of the innovative activity of an enterprise, are summarized in Table 1. Let us justify the choice of specific indicators.

4.1.1 The solvency indicators.

The level of solvency indicators shows which part of the short-term debt can be repaid by the working capital available to the enterprise. These indicators differ by the level of liquidity (Asaturova, 2017). The most important indicator in assessing the company's investment attractiveness, in our opinion, is the *current asset ratio* indicator (CR), as it assesses the overall payment abilities of the enterprise, including the debts payment together with the opportunity of the further running of the business. In these conditions, the current assets should exceed the company's short-term debts by at least two times, as the most liquid assets can be used to pay debts. In order to analyze all the groups of debt of the company, the method of analyzing the liquidity of the balance is used (Asaturova, 2018). According to this method, the solvency assessment is carried out for all types of enterprise debts, grouped by maturity. If the own capital to ensure a sufficient level of solvency is not enough, the enterprise faces the task of increasing solvency. The solution of this task is connected with the replenishment of net working capital by the company profit (Biger, Gill and Mathur, 2010).

4.1.2 The financial stability indicators.

Analysis of financial stability implies an assessment of the possibility and appropriateness of borrowing funds to finance projects. The most important indicator characterizing the financial stability of the enterprise is the Equity to Total Assets indicator (EtTA). The level of the coefficient should exceed 50%. In this case, creditors realize that all loan capital can be compensated by the property of the enterprise. The financial solidity indicator characterizes the financial stability of an enterprise. The value of this coefficient shows the weight of those sources of financing that the enterprise can use in the business for a long time. The assets investment indicator characterizes the correctness of investing equity capital in the company's assets. The equity mobility indicator is very important for ensuring the flexibility of an enterprise in a constantly changing market environment. It shows the level of the net working capital in equity capital, characterizing the share of the equity capital, which is used in the working capital of an enterprise.

4.1.3 Profitability indicators.

Profitability indicators assess the level of capital return. The main purpose of profitability indicators is the overall assessment of the effectiveness of investing funds in the company. These figures are calculated as the ratio of the received for the investment base, with the help of which this profit was obtained (Garcia-Teruel

and Martínez-Solono, 2007). Under the base we can understand the invested capital, the resources expended and the sales of the production. The level of profitability characterizes the enterprise's ability to attract the company's own capital to finance innovation. The most preferred indicator for the possibility of influencing the innovative activity of the company is the Return on Equity indicator (ROE) which characterizes the profitability of the joint-stock or equity capital. The Return on Sales indicator (ROS) characterizes the profitability of sales.

The Return on Costs indicator (ROC) characterizes the profitability of production (recoupment of costs and expenses), characterizing the efficiency of the company resource use, which is important for overcoming resource constraints. The return on fixed assets indicator characterizes the return on property plant and equipment and values the efficiency of the use of the company's fixed capital.

4.1.4 Business activity indicators.

Indicators of business activity assess the effectiveness of the use of company resources by type, which is important in the presence of resource constraints. The high level of the business activity indicators characterizes the high level of company productivity, which measures the cost-benefit ratio of the company.

Business activity is calculated using indicators of turnover (turnover ratio and turnover period in days), which can be applied consistently to any type of analyzed resources in the enterprise (Asaturova, 2018). The concrete indicators are selected based on an analysis of the specifics of the enterprise. The most preferable indicators for the purpose of the overcoming of resource restrictions are turnover of fixed and working capital, inventory turnover and accounts receivable turnover. The growing level of these indicators allows companies to attract fewer resources to achieve the necessary results, which is important in the context of resource and financial constraints.

Thus, the selected key performance indicators that affect the increase of the innovative and investment activity of a company operating under financial constraints are presented in the Table 1.

Table 1: The system of key performance indicators assessing the innovative activity of an enterprise in the conditions of a capital deficit

Indicators	Principle of calculation	Comment
1. Solvency and financial stability indicators		
1. Current asset ratio indicator (CR)	Working capital / Current Liabilities > 2	It characterizes the ability of pre-acceptance to pay off short-term debts with simultaneous continuation of uninterrupted activity
2. Equity to Total Assets indicator (EtTA)	Equity capital / Total Assets > 0,5	Characterizes the independence of the enterprise from borrowed funds. It is the main criterion for the possibility of borrowing loan capital
3. Financial solidity indicator	(Equity capital + Long-term loan capital) / Total Assets > 0,5	Characterizes the share of capital of long-term use
4. Assets investment indicator	Equity capital / fixed assets capital > 1	Characterizes a share of equity in fixed assets of the enterprise
5. The equity mobility indicator	Net working capital / equity capital * 100 %	Characterizes flexibility in the use of a company's equity capital.
2.Profitability indicators		
1. Return on Equity indicator (ROE)	Net Profit / Equity capital * 100 %	Characterizes the efficiency of the equity capital. Promotes the valuation of stock quotes on the exchange.
2. Return on Sales indicator (ROS)	Net Profit / Sales of production * 100 %	Characterizes the profitability of the implementation, estimates the possibility of financing business by profit.
3. Return on Costs indicator (ROC)	Net Profit / Costs * 100 %	Characterizes the level of productivity and cost recovery level.
4. Return on fixed assets indicator	Net Profit / Fixed assets * 100 %	Characterizes the return on property plant and equipment, the efficiency of the use of fixed assets.

3. Business activity indicators		
1. Asset turnover indicators (by types)	Revenues from sales / cost of assets	Characterizes enterprise productivity, resource efficiency, by type
2. The period of assets turnover in days	Number of days per year / asset turnover	Characterizes the duration of one turnover of the assets in days

Timely accounting and maintaining the required level of these indicators allows companies to increase the opportunity of raising funds for the enterprise and thereby leads to an increase in the innovative activity of the enterprise. The proposed system of indicators can also serve as one of the methods for assessing the financial risk of working with the company (Nefediev and Suloyeva, 2014).

5. In Conclusion

In this paper, we have investigated the possible ways to activate innovative activity at Russian enterprises in the conditions of financial deficit. To solve this problem, the following tasks were performed:

1. The analysis of the factors interfering with the innovative activity of enterprises in the current conditions is made. It is shown that the main factors that negatively influence the innovation activity of enterprises are economic factors, such as the lack of financial resources, the high cost of innovation, the economic risk in the implementation of the project and the inability to determine the economic benefits of the project.
2. The impact of various types of constraints on the company's innovative and entrepreneurial activities were analyzed. Resource, performance and market constraints were considered. It was revealed that the most important constraints in the innovative activity of enterprises are the resource constraint and in particular, the financial constraints.
3. The influence of financial constraints on the possible ways of financing innovation is considered. It was revealed that the main sources of financing in modern conditions are loan capital on the financial and credit market, as well as the self-financing of the enterprise thanks to the profit of the enterprise and additional issue of shares. The ways of overcoming financial constraints by the use of various types of financing are considered.
4. The connection between the financial condition of an enterprise and its ability to attract funds for activating innovation activity under financial constraints is traced. It is shown that the provision of a stable financial position of a company is one of the most important conditions for increasing the investment attractiveness and innovative activity of the enterprise. Solvency and financial stability indicators will allow the company to provide a high level of investment attractiveness to increase the possibility of the loan capital rent. Maintaining a high level of profitability and the business activity indicators will increase the possibility of financing innovations by the company's equity.
5. Based on the results of the study, a system of performance indicators of the enterprise that have an impact on the innovation activity of companies was developed (Table 2). Timely accounting and maintenance of the required level of these indicators will lead to an increase in the effectiveness of the innovative and investment activities of an enterprise, which determines the relevance of this work.

Using the developed system of indicators in the business practice of the enterprise gives the entrepreneur an opportunity to identify the main shortcomings in the financial and economic activities of the company that negatively affect the innovation process. Correcting these shortcomings can significantly increase the possibility of attracting financial resources to finance innovative projects.

Abstract: This article is a description of a growing community and movement taking place in Portugal related to open innovation. The testimonies of two principal promoters as well as the views of two career academics were gathered. Herein, the process is described whereby real corporate problems felt in industry and requiring a solution are brought for discussion and resolution by a community of motivated problem-solvers, who were carefully chosen for their skills and capabilities. Can this initiative become a mass phenomenon and can it be built up to attract [paying and sponsoring] corporations across Europe and from different continents? How can the events evolve to become mainstream? What capabilities and promotion are necessary for that to occur? The promoters involved are entrepreneurs located in central Portugal and are seen to be forward-thinkers disrupting how innovation is seen and approached. In a society geared towards services and tourism the team is seeking to bring open innovation to the fore in a country also considered to be very creative and not lacking in creative talent – but which on the other hand is very traditional, collectivist, hierarchical, consensus-seeking, and where innovation may be resisted and change viewed with suspicion. In a 72-hour time frame where problem-solving participants are invited and gathered at a physical venue individuals surpass themselves and experience team work in a setting where all logistics issues are previously carefully thought out and taken care of – so as to provide for the best problem-solving environment possible. The open innovation initiatives (called Hackathons) involve the following: defining the challenges (we want challenges that define goals and purposes but that are open enough to let the team build something creative), defining the fit (each candidate can apply as a team or individually; candidates select their preferred area); building teams (the candidates are free to change teams and can even propose their own challenges; we encourage communication between the team elements and also the mentors). A three-day Hackathon involves: creating a team spirit; constant feedback; building an MVP (Minimum Viable Product); learning new things; sharing is caring.

Keywords: open innovation, traditional society, disruptive practices, disruptive thinking, problem-solving.

1. Introduction

This article is a manifest for action, given the situation in Portugal, and seeks to shed some light on which critical requirements should open innovation satisfy in order to be productive. "There is wide acknowledgement that inter-firm co-operative ties now play an important role in promoting innovation within firms […] The key idea is that through the exchange and co-ordination of resources and information in the value chain, firms can benefit from synergies in production, organisation and crucial knowledge transfer, which can lead to greater levels of both product and process innovations." (Tomlinson, 2010, p.762). Open innovation occurs along a closed-open continuum and is a new paradigm (Chesbrough, 2003). However, in traditional societies, such as Portugal, progress in this direction has been happening slower and change is imperative. Trust between open innovation partners is an important issue, and more study on the functioning of networks is necessary, in addition to the work done concerning transaction versus relationship societies.

Firms need also to release and dedicate funds to the pursuing of new innovative avenues in order to make, for example, open innovation Hackathon events financially rewarding for both parties – the organisers as well as the firms seeking solutions to their problems and challenges (Oliveira et al., 2012, 2013). This study is mainly an account by change agents who are implementing novel, cost-effective and carefully planned open innovation initiatives in Portugal. The ultimate objective is for the open innovation consortium to become an internationally sought out innovation partner, and to achieve this certain principles will have to be followed (Van Geenhuizen et al., 2015). As an exploratory initial effort this work is soon to be expanded upon with a more in-depth and specialized account, aimed at specific target groups. Open innovation is addressed as being a society-wide movement, going beyond companies and other organizations.

1.1 A definition of some key concepts related to innovation

Innovation may be defined as "new and useful products or procedures" (Rossberger and Krause, 2012, p.84).

This usefulness will depend on the region we are in and will also be dependent on the prevalent culture (Muslims and the Jewish will not eat pork, and people in India will not eat beef, for example). One hears tales of how in Africa older iPhone models are shipped there for sale, as in this region they lack the funds to buy the latest iPhone models. Thus, innovation adoption will also be dependent on economic factors. Additionally, certain countries do not have commercial relations with the USA, for example, and this limits the sort of products people have access to – again, an economic factor, as well, or even a political one, if political hostilities exist (Ghemawat, 2001).

Some authors have classified innovation as possibly concerning products / services – "product innovations involve significant changes in the capabilities of goods or services" (Oslo Manual, 2005, p.17); organisational practices – "the implementation of new organisational methods" (Oslo Manual, 2005, p.17); marketing practices – "the implementation of new marketing methods. These can include changes in product design and packaging, in product promotion and placement, and in methods for pricing goods and services" (Oslo Manual, 2005, p.17); as well as processes – "process innovations represent significant changes in production and delivery methods" (Oslo Manual, 2005, p.17). Nespresso was innovative in the way it worked with George Clooney to sell and promote Nespresso coffee as a capsule (marketing innovation). Having people work in an open space made people socialize more but also led to greater peer control (organizational innovation). Apple products have exceptional and innovative design and packaging (marketing innovation). Amazon and Farfetch innovated in the form concerning how products are delivered (in these cases, over the Internet, and via e-commerce) and have reaped tremendous rewards for that innovative effort (process innovation). Farfetch and Apple have also placed their products at the top end of the product spectrum, and this eliteness has also benefitted sales and the brand (marketing innovation). A lot of innovation today occurs linked to marketing practices.

Everdingen and Waarts (2003) did a study entitled "The effect of national culture on the adoption of innovations". Their results indicate "that variables describing national culture have a significant influence on the country adoption rates" (Everdingen and Waarts, 2003, p.217). They found that, still further, "while new products, systems or services are frequently launched in multiple countries, it is not uncommon for products to have high rates of adoption in particular countries but low rates in others. Even within Europe." (Everdingen and Waarts, 2003, p.217). So, the UK is different to Sweden, which is different to Portugal. Though not discussing Portugal in their article, they did mention our neighboring "cousin" Spain, and found that "the Nordic countries (Denmark, Sweden, Norway) have relatively high adoption rates, while the UK and southern countries like Spain score significantly lower" (Everdingen and Waarts, 2003, p.217).

Rossberger and Krause (2012, p.84) showed that "at the country level three cultural dimensions (uncertainty avoidance, in-group collectivism, and human orientation) are crucial for innovative outcomes in 55 countries".

Additionally, "diversity is expected to be positively related to innovation, which would make the inhomogeneity in cultural practices a cause of national innovation" (Rossberger and Krause, 2012, p.88).

According to Everdingen and Waarts (2003, p.228), "the higher the scores on UAI [uncertainty avoidance index], MAS [masculinity index] and PDI [power distance index], the lower the ERP adoption rate [ERP stands for Enterprise Resource Planning systems – which are an innovative and advanced type of software for controlling operations, promoting collaboration and the sharing of production knowledge for example in a manufacturing firm environment]. And, the higher the score on LTO [long term orientation], the higher the ERP adoption rate". Therefore, as Portugal scores very high on UAI (i.e. it is adverse to change, with only Greece scoring higher than Portugal, on this dimension, out of 62 countries) and high on PDI (i.e. organisations are very hierarchical and autocratic) (Hofstede, 2001), it is expected to have a lower adoption rate. Portugal also scores low on LTO (being short-term oriented) (Hofstede, 2001), leading, again, to a low adoption rate of innovations.

Chesbrough (2003) first coined the term "open innovation" as a paradigm assuming that innovation performs quicker and better if firms use external ideas as well as internal ideas, and internal and external paths to market. An example of successful open innovation is Hollywood, which for decades has innovated through a

network of partnerships and alliances between production studios, directors, talent agencies, actors, scriptwriters, independent producers and specialised subcontractors (such as the suppliers of special effects).

The mobility of this workforce is legendary: Every waitress is a budding actress; every parking attendant has a screenplay he is working on" (Chesbrough, 2003, p.37). While countries such as Portugal score high on uncertainty avoidance, and low on masculinity, meaning that they are not innovation-welcoming, but rather prefer harmony and good [even if superficial] relationships (innovation disrupts rather than unites, especially in its initial phases), the notion of open innovation may present itself as problematic. Furthermore, people strive for long-term employment with rock-solid contracts in Portugal and the idea of mobility does not generally have appeal in Portuguese society.

Baldwin and Hippel (2009, p.1), in relation to the open innovation topic, "conclude that innovation by individual users and also open collaborative innovation increasingly compete with – and may displace – producer innovation in many parts of the economy. We argue that a transition from producer innovation to open single user and open collaborative innovation is desirable in terms of social welfare, and so worthy of support by policymakers". Thus, we see the theme of this article as being important to the innovation community as, herein, we describe how we are witnessing the seeding of a new open and innovative mindset, in Portugal. Open innovation in such terms, and in a society with creative individuals such as Portugal, may spell new business opportunities for newly formed entrepreneurs who may appear as user-inventors; if the open innovation culture catches on.

However, open innovation also needs to be 'managed' such that benefits can be gained by all partners. We mention management of decision rights, bargaining power and – if new technology is involved - intellectual property rights (Gambardella and Panico, 2014). Management of the degree of openness and open knowledge relations is also important as the benefits on innovation or growth tend to stop increasing after a certain level and may even decrease (inverted U-shape relation) (Laursen and Salter, 2006; Taheri, Ye and Van Geenhuizen, 2018).

1.2 A discussion on open innovation

Open innovation is getting quite the attention from entities aiming to deliver creative and successful products to the market. Corporations need to move faster than ever and hard-working motivated employees are the fuel.

The ability to go through the whole process chain from Ideation to Production in a fast and controlled way shapes the market. Delivering quality products and reaching the market first are two key elements towards success. We've seen many big companies adopting Product Development methodologies such as Agile, which are built for fast adjustment and open communication. A prioritised backlog is shared with the whole team and is agreed with the customer, promoting openness, transparency through knowledge sharing and co-creation.

Instead of delivering a final product with a huge amount of features, it encourages delivery iterations of smaller feature sets so that feedback can be obtained earlier in order to allow early stage adjustments. That is today's reality: build fast, get feedback early, and adapt. Startups have also been employing these concepts.

Eric Ries in his Lean Startup Book - a manual for today's entrepreneurs defines the 3 key concepts that every startup should look into: Build > Measure > Learn. Building fast, getting feedback faster and taking lessons to adjust to that feedback. Startups worldwide have taken this approach starting with an MVP (Minimum Viable Product) and following this 3-step-cycle faster than ever. Alongside these methodologies new sets of tools started being accessible to everyone, such as electronics, 3D Printers, cheap computing machines for prototyping (such as Arduino and Raspberry Pi to name a few). This also allows to obtain faster prototypes of components at a much lower cost.

It is the consortium's mission to bring all of these concepts to everyone so that we can help shape the mindset towards a more open and innovative approach in work, specifically in product development. To do so we started idealising an open Hackathon and in the process we ourselves use all of the methodologies we want to put in practice at the said events.

2. Building a truly open event and shaping society's mindset

Some of the companies that participated were a little bit too shy about the challenges…

We have defined a process to allow people to fuel their brains by solving real problems in an open way. Each event creates its own culture, and we constantly promote communication between all parties through open platforms. We defined a model in which several companies and research organisations could share their real problems. We would open these challenges to the community for people to apply to solve them as teams within 72h.

Let us go through the process faced by our organisation:

1. Preparation
2. Three Day Hackathon
3. Post Hackathon

As an organisation we need to put some mechanisms in place. We follow the same methodologies we advocate within the organisation. We organise ourselves as if we were a set of Scrum Teams working on an Agile Project. We have a Product Owner who is responsible for defining the requirements and mapping them into the User Stories, which are then tracked in a backlog – we use Asana (Asana, 2018) for that. We defined a set of teams and a Scrum Master per team. We defined the following teams:

- Program
- Logistics
- Sponsors and Partnerships
- Marketing
- Multimedia Platforms
- Participants Support

The program is in charge of defining the rules of the game. This team defines what will happen and when. It defines the schedule and helps the Product Owner define the requirements for logistics. The program team sometimes acts as the customer for the Product, and because of that, it is in constant contact with the Product Owner during the construction of the backlog.

The logistics team is in charge of everything that concerns the venue. It needs to take into account the available space in order to feed the available slots for sponsors; it needs to think about video and audio, where to place the stage and its dimensions. All the details of how the event is going to play out and even support activities: social events, where to sleep, food, water, constant refreshing drinks, lights, etc.

The Sponsors and Partnerships team is in charge of ensuring that the event happens, they take care of conveying the vision towards companies that want to reshape the industry by taking advantage of these events. They are the word spreaders and go on Roadshows to present and promote the event in Universities, Research Institutes, Corporates, Schools. Not only do they talk about the event they also promote the values which the organisation represents as being basic to the next generation society.

The Marketing team designs the concept and all the content for media promotion. We use a theme that is matched with both the region and the type of challenges. This helps promote the local entities, and makes them act as partners as well. Marketing is all about delivering a message, and this team is key towards that goal. In the end everything we are working for sums up to delivering a message for the future. The brand is very important and it is born not only from beautiful graphics, but mainly from concepts, ideas worked from a group of creative people that take the local characteristics and the concept of the event and create a beautiful graphical representation of those same ideas. The creative team also decided to attribute a Creative Common Open Source license and shared all the sources of this brand. These simple parallel decisions also contribute to the Open Innovation mindset, inviting others to reuse and collaborate with these open minded creative teams.

The multimedia platform team acts as the support team, taking care of the digital platforms, streaming, website, registrations, communication platforms, etc. Basically everything that is digital. This team works in close collaboration with the Participants support team, which is responsible for selecting the participants,

onboarding them, and promoting conversation with the challengers. Throughout the event the participants will always have someone from this team to count on.

Each team is self-organised. It has its own features which each team member commits to and each team member is in constant communication with the Scrum Master. Once a week all the Scrum Masters gather with the Product Owner (and anyone else who wants to meet, provided they are primarily listeners) for a Sprint Grooming Session, in which for each iteration, all the Scrum Masters explain what was done, the problems faced, and what needs to be done next. Each problem is duly noted and the Product Owner identifies who can help solve it. Any delay impacting on other tasks is evaluated, and the project is updated accordingly. Each Scrum Master is given limited time to keep the meeting agile, but Action Items are taken to be followed up afterwards with only the required elements. The main focus is to highlight the Progress, the Problems encountered and the Planning to be done until the next meeting.

Each meeting is scheduled by sending an agenda beforehand stating the objectives of the meeting, the prerequisites for that meeting (e.g.: study a document, complete a form) and the expected outcomes.

3. The community

We thrive to create a community. None of this would be possible without the combination of several entities. Our goal is to bridge the gap between the Industry, the Startups and Academia, bringing Makers into the play.

The Maker movement is defined as a DIY (Do It Yourself) culture, and is composed of tech enthusiasts that thrive to solve problems on their own. It has gained quite a momentum with the ease to acquire electronic components that China offers nowadays. They are essential to the success of the event and the community we promote.

Regarding startups, in Thiel and Masters (2014) one may read that “positively defined, a startup is the largest group of people you can convince of a plan to build a different future. A new company’s most important strength is new thinking: even more important than nimbleness, small size affords space to think”. They are a key engine towards innovation these days, as they promote change at a faster pace in a riskier way.

The industry is the basis for everything. Usually coined to bigger corps, which needs to manage profits and shareholders, they are thought of as a big ship that is harder to maneuver. More resilient to faster changes and more difficult to adapt. We believe this has changed. More and more, big corporations are looking to do things the “Startup-up” way, creating innovation and intrapreneurs.

Academia contains all the engineering fuel. It is thinking ahead of time, usually less concerned with profit and more with the vision of the future, breaking the line between what is and what it could very well be in the future.

We want to combine all of these profiles to create a rich and positive community in which everyone can seek others to complement their knowledge and needs.

4. Event Preparation

There is a lot of work before the event.

It all starts with the definition of the challenges. We want challenges that define goals and purposes but that are open enough to let the team build something creative. For instance, one of the challenges proposed for a biomedical device (BITalino, 2018) was to create a musical instrument (virtual or physical) controlled by physiologic signals acquired through a wearable device. This kind of challenge allows the teams to have a common and shared goal but leaves a lot open for creativity and as regards the approach, since nothing is specified as to how it should be accomplished. Our organisation works closely with the entities providing the challenges to make them open, creative and executable within the span of the event. We focus on increasing the engagement of the mentors since an early stage to improve the quality of the preparation.

After having a set of challenges, we open the call to the candidates. Each candidate can apply as a team or individually. Candidates select their preferred area. When selecting the candidates we use their profile and

match them with other candidates to create multi-disciplinary teams in their preferred challenges. They are given some challenges to choose from which they can decide as a team.

The organisation selects teams taking into account the type of challenge and the candidates' profiles in order to create multi-disciplinary teams. When candidates apply as teams, other elements can be added to the team to complement their technological skills. As soon as a team is formed, they sign-in to our community – we use Slack(2018) – which is organised by channels, and where each team has its own channel, but can also communicate with all the other teams. Each challenge owner is also added to the team. This is usually someone within the challenge-proposing organisation that has been accompanying the challenge definition and will help out the team as mentor. The candidates are free to change teams and can even propose their own challenges. We encourage communication between the team elements and also the mentors.

5. Three Day Hackathon

Let the games begin.

We start the event with a short keynote to lay down some rules. We then show the place around to all the participants in groups and invite them to interact so that a true team spirit is built. We promote cooperation between teams and have social events for people to relax.

We believe that environment is key and to boost productivity and creativity we focus on having a venue with lots of natural light during the day, and good lighting during the night. We design social areas and a fun room with arcades and a lounge. We pick food that is light and nutritional to keep creativity standards high. All communications are short and concise to keep people working. We promote a casual and safe environment where everyone can be relaxed.

When the event starts we encourage teams to start talking about how they are going to solve the problem: their approach, what they need, planning and execution. It is expected that when the Hackathon starts teams already have an idea of what, how and when to build. We emphasize this by establishing two well defined times of the day in which each team is invited to share the following, with all the Mentors:

- Progress: what was done, what changed;
- Needs: roadblocks, necessities for the next stage;
- Goals: objectives for the upcoming hours.

We call this the PiNG (Progress, Needs, Goals), a concept we have reused from TOM Hackathon (TOM, 2018), and which reflects a short moment in which people basically do a Stand Up meeting such as a Scrum Meeting . We print out large boards (figure 1) for each stage, so that everyone can see their progress throughout the event and so that anyone can go and see what the needs of each team are.

We encourage the teams to think of each of these stages as an iteration, and all the mentors are invited to give feedback on the progress at the PiNG.

We advise the teams to think of the final result of their work as an MVP (Minimum Viable Product). Something that could actually represent what they are trying to achieve within the time constraints of 72 hours. The MVP should be iterable, meaning that, a working basis should be created with features / functionalities added as time goes by. We encourage people to build, and to that end we have over 12 mentors always available that cover several areas. We go the extra mile to have several 3D printers, electronic materials, large printers, as well as experts to explain and teach as to how to use them. Mentoring is key to help teams define what is really important, and what is not, for the goal of the project.

As mentioned above we bring top-class mentors to the event who are always ready to help everyone in their tasks. However, sometimes that isn't enough. For that end we also promote several workshops which people can attend, and which try to target the several challenges. Amongst the basic ones, we typically include a 3D Printing workshop, a fast prototyping workshop with small computing devices and sensors, a product design workshop and a data science 101 workshop. Hands-on is a "must", and we exclude all presentation-only formats.

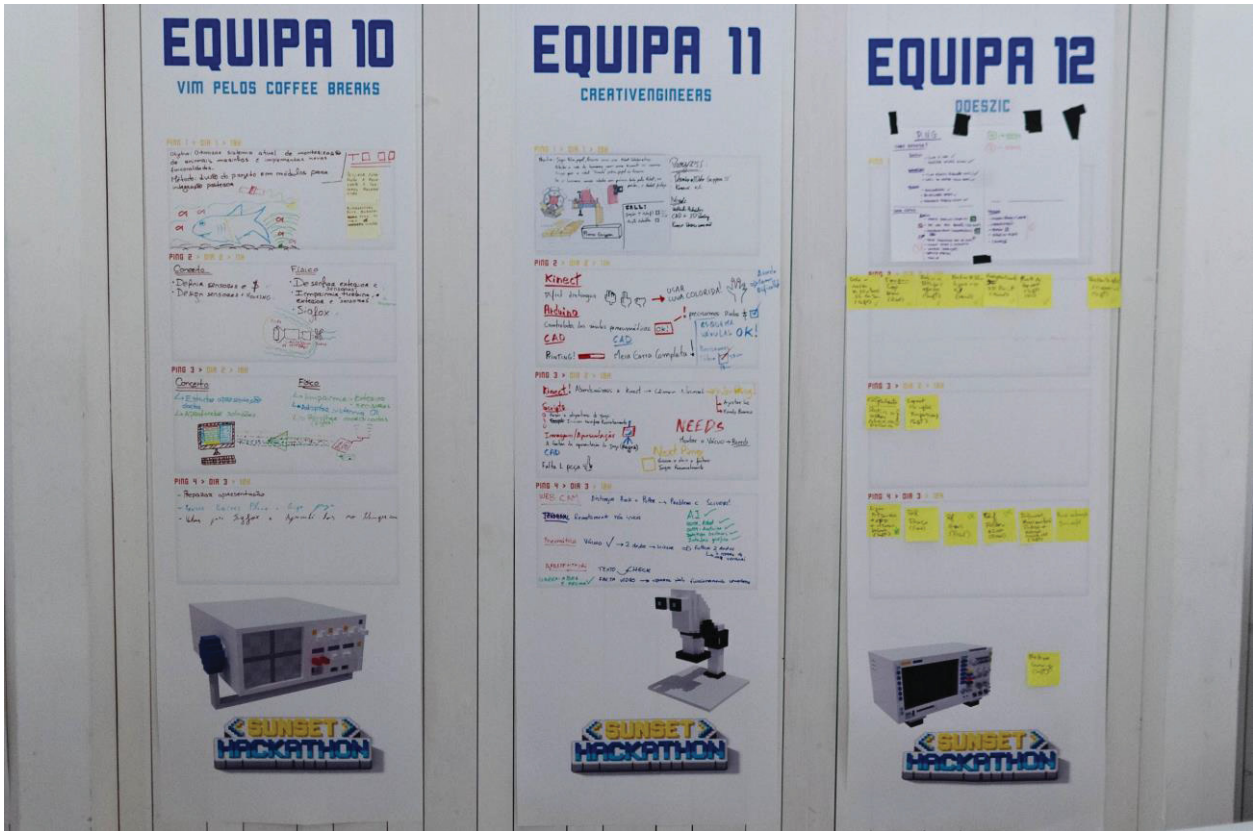

Figure 1: PiNG Wall

We want people to go back to their jobs with more tools than what they came in with. The first tool we focus on is the mindset of building something from scratch while rethinking an existing problem. Then comes the knowledge of using modern product development techniques. After that we focus on teamwork and organisational skills such as planning and work structuring. And, last but not least: openness by sharing.

Throughout the event we invite people to share their work on open platforms such as GitHub or Thingiverse.

As a team we also document everything in those platforms (information such as rules, guidelines, frequently asked questions, media formats, etc.). We always have someone available on the communication platforms to help and we promote teams to talk to each other through those channels as well as by stating what they need. Moreover we Live stream the workshops and talks to our community so that the knowledge is spread and people ask for more from us.

All the developed works are shared at the end with a broader audience, through a three minute pitch and showcase, in which the product is shown functioning. We invite mentors and challenge owners to join as a jury and ask the teams questions after each presentation. After that they will meet and choose the "best" three teams. We don't think that competition is the most important thing but it spices things up a little and everybody sees it as a friendly competition.

We don’t want the event to be inconsequent so beforehand we engage with the sponsors (challenge givers) to have internal presentations within their organisation. This has proven to be extremely successful. Interested teams go to the sponsors’ headquarters and present their work facing the employees who are interested. This always generates conversation and some works resulted in an interest to further develop the concepts, which for us represents a true twist on how innovation works. This is in fact one of the surprising outcomes of the event which we classify as a return on investment for challengers, as detailed below.

6. Return on Investment for challengers

Our hackathons produce instant results vertically. We help prepare innovative and interesting challenges while creating an ideal working environment that will stimulate trust, creativity and engagement. Some of the

expected results are of a qualitative nature and therefore difficult to quantify, but the simple fact of starting to talk about Open Innovation and the methodologies associated to the Hackathon inside a company already triggers a changing process that will shape mindsets to accept Open Innovation practices and make old processes more flexible. We firmly believe that our methodology helps the seeding of a new open and innovative mindset by just experiencing but also by revealing the need for the management of open innovation.

Our key outcomes are the following:

1. Developing new ideas
2. Training and building up on expertise
3. Promoting a culture of Open Innovation
4. Open Mindset

6.1.1 How much does it cost to kick-start a new concept? How much is lost by not testing a new idea?
Let us face it. Big corporations have complex processes. Because of quality control, management overheads, market fitting, requirements analysis, etc., asking a team to develop a new concept will probably lead to high budgets.

Sometimes the best way to deal with a new idea is to just start doing it. Hackathons are a great way to create a very early concept and to try it out. Sometimes we can instantly discover that it does not work, or that it is too complex. We like to think of hackathons as described in Knapp, Zeratsky and Kowitz (2016): "Sprint, how to solve big problems and test new ideas in just 5 days", except that we extend the final day (implementation and test day) into three days.

Moreover, teams are already so tangled up in their daily work that it is sometimes hard to fit in new products / ideas. Some concepts are just never implemented.

6.1.2 *How much is spent on training activities per person? Does it focus on multiple aspects?*
Different companies spend different budgets on training. Hackathons are also training activities. As mentioned above we feature hands-on workshops, but we will also guide the teams through the whole process: participants will actually be learning while on the job, but in a more open and creative way. They will be exposed to new tools, techniques and ways of working and thinking.

At the end of the day, the goal is for participants to develop new skills, knowledge and techniques that are relevant to their day-to-day jobs.

6.1.3 *How much is a brand worth?*
Building a brand is hard. In today's world we also need to make them shine and be attractive to buyers and employees. Hackathons are a way to connect with the community, thus helping to increase global awareness of brands as innovative and dynamic employers. They allow for exposure and, specifically, appeal to a market segment in which what drives people is the power to create with an open mind.

People will also have the opportunity to get to know other employees and further build upon the creation of a work culture / environment.

Open communication not only helps promote a new mindset within the company but it also helps in the transmitting of a powerful message to the external world. It reaches out to other corporations, universities, research institutes and tribes such as Makers.

A lot of companies already put out Open Source software which anyone can use and build upon. The idea is that if the community also contributes, products gain traction and can become better in a faster way. Some have started sharing their own internal tools with the community to take advantage of this, such as the Android OS (2018) launched by Google or React launched by Facebook.

Platforms that allow for the sharing of knowledge are proliferating. Open source already plays a major role in the industry and platforms such as GitHub (allows for the sharing of software) and Thingiverse (allows for the sharing of 3D models ready to be printed by anyone).

We promote the use of open source technologies and advise that projects are always shared with the community. We use open communication tools so that everyone can contribute to projects.

Universities fuel tech companies and, more and more, companies are starting to develop closer connections with the students to build awareness and pass the message of a great working environment. They also contain research institutes which hold some of the best experts and tech leaders in their departments.

Open events are crucial for any country to lead in fast society evolution. Open Innovation is about planting the seeds for companies to make the necessary quantum leap to get better at what they do (improve their efficiency) while contributing to a better society as a whole. It is a win-win situation for everybody in the ecosystem and the only losers are those not taking part in the revolution.

7. Conclusion

Innovation is never going to be easy as human beings in general are resistant to change. Innovation means the disruption of the present order of things, as Schumpeter acknowledged, and goes against the harmony so desired in Portuguese society where even our revolution, in 1974, occurred without any significant events; very unlike our neighbouring Spain, where hundreds of thousands, perhaps millions of people, were killed, during their civil war and revolution in the 20th century.

To have the ambition to change society in Portugal, which is very adverse to change, more so than the average European country, will indeed require Guerrilla Marketing (low-cost marketing albeit with a significant reach) (Almeida and Au-Yong-Oliveira, 2015) and a lot of positive word-of-mouth to spread the message and results of our initiatives. Funds are lacking and change normally requires a lot of capital; though start-ups do tend to lack financial backing, in general (Oliveira et al., 2012, 2013), and the best still manage to survive and grow.

Portugal needs to develop its internal and external marketing, investing in the creation of content about the best national case studies. We have to show, both nationally and internationally, the best case study results on new product development and on new business development. A new attitude needs to be publicized and new open innovation tools used.

We have described the process which we follow at our Hackathons. This article may also provide some additional visibility to our initiatives, which are all about innovation and entrepreneurship and so the intended audience for our work will gather and receive our work, at the ECIE 2018. We hope to attract the attention of enterprises which are perhaps at a loss as to what path they need to follow in order to increase their competitiveness. Our team is very adept at putting together events where all will benefit – those developing the innovations, and those on the receiving end of these innovations – the enterprises.

We thus hope with our study to have shown that change is indeed happening in Portugal, and in this case also linked to entrepreneurs and startups, as is normally often the case; and aided, somewhat by the academic community present in the region. To make the type of event described herein mainstream, and to be able to bring in corporations from different geographies, to solve their real problems in specialised environments, is perhaps an objective which may take some time, but which we dare to dream of.

If such events are possible in Portugal, which is not necessarily the most welcoming of environments for large scale innovation, then surely a lot may be accomplished also in other regions, with the right mindset and the right attitude and, above all, the right motivation for change. It would be interesting to research other environments (within Europe but also on other Continents) and their acceptability to open innovation efforts, such as those described in this article.

The Successful Implementation of Servant Leadership at a Factory in the USA

Abstract: This is a case study on leadership, a topic which has been much debated in the literature, as solutions for many diverse situations are still lacking and seem to escape us. The case describes how an entrepreneurial wood veneer factory operates, in the USA, with images included of a number of operations. The manager-owner took us on a guided tour from raw material (logs) to finished product (veneer wood). Waste is minimized at the factory in a very stream-lined operation which has a minimal amount of managers in place. Each worker is responsible for his or her job, done to perfection, as one task rolls on to the next, without stopping. The attitude of the innovative servant-type leadership in place is that "win-win" situations are better for all, and there is enough profit to go around. Servant-leadership-type leaders exist to serve employees and exercise minimal management control. At this firm there are no self-serving managers. Rather, mature and great working relationships are developed. Being greedy would mean that unions would have to be brought in. At this firm that was not necessary, by request of the employees themselves. Hispanic workers are very good and are cherished at this firm, in the heart of the USA. As leadership is dependent on culture, the discussion also includes references to cultural aspects relevant to management. The story is thus of a positive firm with positive leadership and subordinates. We conclude that employees who have emigrated from poorer countries in search of a better lifestyle may indeed make excellent workers, despite what some political leaders have announced in the media. We have found evidence that Spanish-speaking individuals do not only work well under autocratic leadership, as portrayed by the literature. Our study is thus revealing of a new cultural-type involving workers working outside their home countries. Under different leaders, in different countries and environments, certain workers are prepared to go the "extra mile" and behave in a completely different way as to what is expected from them in their home countries. This is surprising and may have important implications for multinational firms worldwide.

Keywords: cooperation, collaboration, leadership, win-win, wood veneer, production

1. Introduction

The finished product at the wood veneer factory analysed herein is used to make floors, furniture and doors, among others. One might think that furniture, for example, is made of solid wood. However, this is not the case. Slim slices of wood veneer will go on the outside and be filled up to make finished products, such as chairs and tables. We feel that this information is important as wood is very much cherished (for many purposes), however many people are not aware of the process followed in order to get wood-based products to market.

The case is about leadership, the discussion of which is far from resolved, though there are certain practices which are recognized as being more appropriate in certain situations and geographies. For example, in an emergency, or in a crisis, if there is no time to waste, if time is of essence, then a more autocratic leadership style is seen to be best. On the other hand, if there is more time and if the participants in the decision making process, and those affected by the decision, are highly qualified, and there is time for discussion, then a more democratic approach will lead to the best results. Furthermore, certain countries are seen to have a particular culture which will favour more autocratic versus more democratic leadership styles, depending on the case in hand. For example, the USA and other Anglo-Saxon countries are naturally more democratic environments than, for example, Hispanic countries, in general (Hofstede, 2001; Hofstede et al., 2010).

This study shows how the firm analysed uses a servant leadership style, with minimal management control being exercised. Employees are fully responsible for their tasks and do not require what has been termed

"micro-management", whereby production line supervisors are very close to each operation, interfering constantly to optimize production output. This form of micro-management might be acceptable in a paternalistic country such as Portugal where there is a large power distance index (PDI = 63 – see Hofstede, 2001, for a discussion of this) registered between leaders and managers and their subordinate employees.

Employees who are micro-managed are seen to lack the capacity to perform work tasks by themselves, which may actually become a self-fulfilling prophecy over time as employees become more and more dependent on their managers for decision-making. In contrast, servant leadership seeks to make employees independent and able to decide and navigate corporations by themselves. It is argued that, for example, in Portuguese speaking countries, that such a leadership style is not effective and is not desirable.

The article, in the following section, provides some background notes on leadership; which is then followed by a description of the methodology used in the study; after which the case itself is presented and discussed; finally, the contribution of the article is set forth, as are suggestions for future research.

2. Background - Some notes on leadership

Perhaps due to a greater democratization in society which is also, in turn, due to the advent and evolution of information and communication technologies (ICT), and online social networks in particular, "the subject of authoritarianism and how it influences leadership and leadership processes has been neglected in recent decades." (Harms et al., 2018, p.105). Portugal, a high power distance country, has seen many changes including in higher education, whereby lecturers now share their personal cell phone numbers with their students, who they have perhaps befriended on Facebook and / or on Instagram and WhatsApp – in what is no longer a distant and estranged working relationship. "However, recent global events make it clear that a better understanding of authoritarianism is needed and that leadership researchers would benefit from a renewed interest in studying why followers embrace autocratic leaders." (Harms et al., 2018, p.105). Though a number of Portuguese university professors are now closer to their students, this does not mean that they are respected more than they were in the past. Harms et al. (2018, p.105) actually state that: "Specifically, we will begin by addressing a fundamental question that has driven research for over 70 years: "Why do free people willingly choose leaders who will restrict their liberty?"".

Our study, in fact, is a little different, if not the opposite. We have chosen to do research on a firm where the leader is not autocratic and who rather defends, as indeed works alongside, his employees – making their jobs easier, instead of more difficult. In addition, these same people who have chosen to follow their leader's judgement, and management philosophy, when at home, in their Hispanic countries, have inevitably done the opposite – that is, they have chosen autocratic leaders in government and choose also to follow autocratic leaders in firms – one may just imagine the kind of chaos that might occur if leaders were not authoritarian in Mexico or in Guatemala – where participative and democratic leaders are seen to be weak (Irving, 2010).

"The emergence of the democratic-leadership is one of the most humane styles of leadership. Democratic leadership positioned people as the most important factor in the leadership exercised by the orientation and emphasis on relationships with members of the organization." (Lestari et al., 2018, abstract). Why is this form of leadership not more popular, and indeed not more successful, given its emphasis on the treating of human beings as being central to the success of organizations? Financial needs, of emigrants, and being outside one's own environment and comfort zone,, without a "safety net" to fall back on, may make people more cooperative and indeed more hardworking. However, the evidence gathered on the case study herein is quite clear – the employees at the firm acted responsibly and productively, even in the absence of constant supervision by an autocratic leader – which would have been the case had they been at home, in their home countries.

3. Methodology

In order to get to know the firm better, the authors were taken on a factory tour, by the owner-manager. The whole interaction lasted for one whole working day. During the company visit the authors were accompanied by a main (international) customer of the firm. The owner-manager of the firm took great care in explaining the whole manufacturing and transformation process to his visitors. A lot of organizational pride could be noted as we took the tour and as we realised that the firm had come a long way in its history (it was founded

in the 19th century). Observation – "seeing, hearing or sensing data relevant to the research" (Remenyi, 2014, p.123) played a major role in the writing of this case study.

During the visit a number of photos were taken (some of which are shown herein). Despite no restrictions having been imposed, as concerned the photography, and as concerned, for that matter, the material learned and observed – the firm studied herein remains anonymous and no mentioning of anything which might otherwise help single them out is present in the text.

A description of how the work flows fluidly at the factory is essential to the essence of the story, as in so doing the simplicity of the operation, free of major bottlenecks, becomes evident.

4. Discussion and presentation of the case

After a tour of a factory in the USA (in late March, 2018, for a couple of hours), we must say that the whole complexity of the operation of preparing wood veneer (for floors, furniture, doors, among others) was astounding. The rules are clearly laid down, at the firm, and the value chain must not be broken. This is how this German-owned firm is managed (it has had German ownership since the 1960s).

We started off by seeing logs of wood outside, in storage, in the car park. Nice big, long and wide logs. Of different varieties (image 1). The next step involved taking the bark off the logs (images 2 and 3).

Image 1: Logs of wood outside - in storage

Images 2 and 3: Taking the bark off the logs

Then the logs were soaked in water, of increasing temperature (the water increases in temperature 5ºC, per hour, automatically). If soaked straight into hot water the logs would split, making them useless; thus the care of soaking logs initially in cold water and then making the water gradually heat up – so that they would become soft enough to cut. The smell of heated wood was very peculiar (images 4, 5 and 6).

Images 4 and 5: Logs soaked in water

Image 6: Logs soaked in water

Then the logs went to one of two places, to be cut. If they were big enough they would be cut vertically. Sliced into wafer thin pieces of wood. If the log was smaller, it would be cut in a circular fashion, around its perimeter. To make the slices longer and larger (images 7 and 8).

Images 7 and 8: Logs ready for cutting

After being sliced into thin pieces of wood veneer [*folheado de madeira*] (image 9), the wood would then go into a drying machine (image 10).

Images 9 and 10: Wood veneer and a drying machine

After being dried, the wood would be cut (finished). Unattractive edges would be cut off. Places in the wood from which branches had grown out would also be singled out (with white chalk) for elimination (images 11-13). Customers will often aid in deciding which parts of the finished wood veneer they want to buy.

Images 11 and 12: Wood veneer ready for finishing (ready for cutting unattractive pieces off)

Image 13: Wood veneer ready for finishing (ready for cutting unattractive pieces off)

After tying the finished wood together, the wood would go to be classified (image 14). Depending on the type of wood (white oak, red oak, walnut, etc.) the classification could involve from 30 to 100 different levels (of quality). The length of the wood is also classified. White oak sorting is a nightmare and goes up to 100 different classifications. An important employee (very senior in the operation and trusted by management) would do the wood classification – a task that machines were definitely not able to perform. The objective is that the wood classification be always the same, so as to avoid customer complaints.

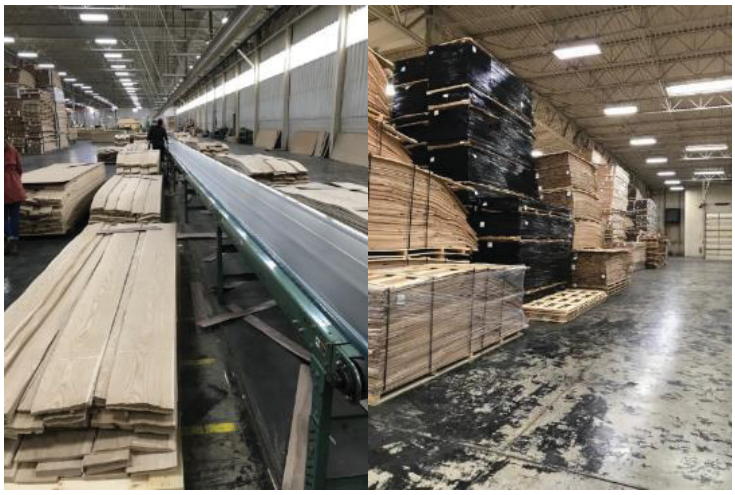

Image 14 (on the left): Wood classified for customers

Image 15 (on the right): Wood veneer in storage – to later be shipped off to customers

The wood veneer would then go into storage, to later be shipped off to customers (images 15 and 16).

Image 16: Wood veneer in storage – to later be shipped off to customers

Of note is that a highly paid employee (image 17) will sharpen the knives that cut the wood. Each knife costs around 3 thousand dollars and lasts up to 3 months. The knives are then replaced. A sharpened knife will cut into paper just be laying the paper on top of it and by gently bringing the paper down. This job is thus quite dangerous and requires extra care. The sharpening of the knives may be done using a Japanese (high quality grade) stone, for example (image 18).

Image 17 (on the left): The division which sharpens the knives

Image 18 (on the right): The sharpening of the knives may be done using a Japanese (high quality grade) stone

The factory, very well laid out, with the material going from one step to another, further and further into the heart of the factory, employed mainly South American (Hispanic) workers. Workers from Guatemala, the Honduras, El Salvador, Mexico, among others. These people are very good workers as they work out of necessity and in order to upkeep their families. Most of the workers are women. This may be a problem when heavier-duty tasks need to be done. Instead of one man doing the task, two women would be required. Other than in these cases, women are tremendous workers. They work fast and keep costs down as being mothers and raising families they are well aware of the cost of living. They also do not miss work. Men, on the other hand, mainly work to not default on their child support payments. If, in the USA, they default such family support payments they will go to jail.

The only manager in the factory is the owner (or son of the owner, who is close to retirement). He will spend his time in production, solving problems as they appear. He will not stay "hidden" in his office but will "manage by walking around", as the literature likes to call it. "Management-by-walking-around (MBWA) is a widely adopted technique in hospitals that involves senior managers directly observing frontline work" (Tucker and Singer, 2015, p.253). At the factory an objective was to actively solve easy problems as they arose, which leads to improved performance (Tucker and Singer, 2015). With managers at a minimum in the factory, certain setbacks of MBWA were also not to be felt – such as making situations more complicated, rather than

simplifying them (Tucker and Singer, 2015). The owner-manager is also responsible for buying the wood. There is no place in the factory for numerous "pure" managers who just oversee operations and add no value; except for the owner-manager himself, who will manage the 140 people in the factory.

Absenteeism is a problem and being at around 8% this means that additional workers need to be employed (around 10% extra staff) (please see Oliveira, 2005, for a discussion of how absenteeism should be at, or below, 2%). North Americans do not make the best factory workers and tend to be unreliable. North Americans, at this level, work to make some money; then perhaps they will stop for a day or two; only to return to work when they are again lacking money for their daily necessities.

The reason for having a supplier in the USA (with high salaries in comparison to most countries) to make wood veneer is that certain geographies have certain types of wood, which may then be shipped all around the world (to Europe, Brazil, Africa, among many others), to customers who want, for example, white oak.

Of note is that this firm does not deal with unions. Unions did come round at one stage, and there would be a lot of shouting – mainly at management – as the unions treated the firm very badly. However, the employees did not like that, they did not feel comfortable with this situation. Therefore, it was jointly and collectively decided (employees and management) and agreed to not have unions at the firm.

The owner-manager wanted to go from eight hour days to nine hour work days. However, this was turned down by the employees, mainly the women, as they had to go and tend to their families after eight hours of work. An agreement was arrived at though – and that was to work for five hours on a Saturday. Therefore, management was pleased to get the equivalent of 5 x 9 hours per week. Every week.

This is a case of servant leadership in action. Leaders exist to serve the employees and to make them better at what they do, aiding their operations. There are no self-serving managers who expect things to be done while they are being served. Rather, mature and great working relationships are developed. Hispanic workers are very good and are cherished at this wood veneer firm, in the heart of the USA.

At this servant leadership firm employees "look to their organizational leaders for vision and direction" (Blanchard, 2018, p.9), much as with traditional leadership. Furthermore, the purpose of servant leaders is "to help your people become eagles rather than ducks and soar above the crowd – accomplishing goals, solving problems, and living according to the vision" (Blanchard, 2018, p.11). Therefore, servant leaders are, in a first instance, responsible (for creating an image of the path to be followed, onwards towards the future; for showing the firm where they want to go, and the results that are intended to be achieved) and then, in a second instance, responsive (gearing the team towards superior implementation – and, in the meantime, turning the traditional hierarchical pyramid upside down). As a consequence of the above, firm collaborators are first responsive (to the visionary senior leadership) and then responsible for what they do (capable of implementation, aided by a responsive senior leadership team).

5. Contribution

We discuss an entrepreneurial company which has implemented the controversial and [still] novel "servant leadership" style. The stage is unique, in the USA, involving a German firm with mainly Hispanic employees. Intuitively, one may be led to think that an autocratic leadership style would be best – as Hispanic countries register a high power distance culture – Colombia scored 67, Ecuador 78, Guatemala 96, Mexico 81, Panama 95, and Salvador 66, for example, for Power Distance (Hofstede, 2001; Hofstede et al., 2010) – and thus would seemingly respond badly to a leadership style where the leader exists to serve his or her employees (servant leadership). The case study reveals, however, that the opposite is true. The firm's Hispanic employees come to work and do not waste time or energy with "internal political games" and with unions and do not constantly need to be told what to do – which might have favoured them in the short-term but certainly would have damaged the prospects of the company in the long-term. We thus tell the story of a positive firm with positive leadership and collaborators.

We also suggest that certain employees who emigrate from certain poorer countries and seeking an improved life style abroad may make excellent employees, contrary to what some political leaders have announced on the media and as regards immigrant workers. This is a case of senior leadership accomplishing the perfect

match with its workforce – despite what the literature says about Spanish-speaking individuals and them preferring and working well only under autocratic leadership. "We highlight Anderson's (2006) exploration of barriers that impede the effective implementation of servant leadership in Latin America […] Anderson identified ten primary barriers and three central strategies for overcoming these servant leadership barriers" (Irving, 2010, p.123).

Our study is thus revealing of a new cultural-type by workers working outside their home countries – which goes contrary to what the literature says about them. Under different leaders, in different countries and environments, certain workers are prepared to go the "extra mile" and behave in a completely different way as to what is expected from them in their home countries. This is surprising and may have important implications for multinational firms worldwide.

6. Future research

It would be interesting to research how Portuguese emigrants perceive their environments when they emigrate to work in other countries. Portuguese emigrants have been noted to work very hard, in extreme conditions and often under considerable personal hardship, when abroad and when working for foreign bosses. Portuguese workers are renowned for their dedication to work, for avoiding conflict, and for being innovative and for blending in with the locals – when working in another country. It would be interesting to study their mindsets in these situations and why, at home, in Portugal, with such a capable workforce, Portugal has gone bankrupt three times, in its modern democratic history (since 1974), and is incapable of supplying jobs to its qualified youth population who are even encouraged to emigrate by successive governments in power – in order to find more worthy tasks in the workforce when abroad.

Just like the Hispanic workers focused on in this case study – who often also come from impoverished backgrounds and countries, and who emigrate to the USA to become highly cherished and highly valued employees – the Portuguese seem to "go into a higher gear" when abroad.

This is a phenomenon which needs to be researched further so that lessons may be learned and applied in their home countries and when aiming for greater economic development.

Management of innovation – Constraints on commercialization of University Innovation: Evidence from SA

Ramika Bansi
Durban University of Technology, South Africa
rbansi@dut.ac.za

Abstract: Globally, commercialization of university innovation has increased and gained in interest by universities, industry and politicians. The idea of marketing innovation produced by universities is the practice embraced in most advanced economies. However, government's investment in R&D have not generated the anticipated return. A gap has been identified between innovation developed from publicly financed research and the failure to convert these findings into tangible outcomes. Research undertaken without the ambition to commercialize or to be profitable, lacks market focus. The study reports on an investigation that explored reasons for the current low commercialization rate of university innovation in South Africa, with a view to increasing this rate. The qualitative data enquiry discovered that the key challenges in commercialization were perceived to be: lack of entrepreneurial skills, lack of adequate infrastructure and funding opportunity to commercialize research, commercialization not regarded as a high priority to senior university management, institutional bureaucratic regulations and an inefficient system of decision making with regards to intellectual property, research lacks market focus, research is not undertaken with commercialization in mind and lack of local industry receptors to induce engagement. **Design:** This paper adopted the mixed survey method, which utilized a questionnaire survey to collect data from the 23 university IP managers, and a semi-structured interview schedule was used to collect data from innovators affiliated to one of 23 universities. **Value:** This study outlines key factors that could, if implemented improve level of commercialization of university innovation. Innovation and entrepreneurship changes our lives, work and contributes to our future. Has contributed to improved standard of living, creates job opportunities and generation of income, which forms conditions for prosperous societies. Creates social change. Breaks away from tradition, produces unique offerings that generates new wealth. All resulting in greater morale and economic freedom with profound, long-lasting impact on human race.

Keywords: innovation; entrepreneurship; innovation management; entrepreneurial innovator; intellectual property rights; publicly-funded research; technology transfer; commercialization.

1. Introduction

Innovation is frequently described as the lifeblood of organizations, and within a corporate setting, the true value of innovation is manifested in outcomes such as the success of commercialization (Schendel and Hill 2007: 1). Universities need to equip their researches with entrepreneurial skills in order to implement their innovations (Lakovleva 2011). Entrepreneurialism at universities is epitomized by the rise in patenting, licensing and the creation of spin-off companies by academic researchers (Wright et al 2007).

Innovators with entrepreneurial ability is of vital importance since most innovation are sold at an embryonic stage and further development requires inventor participation (Thursby and Thursby 2003). This view is supported by Spilling (2010), who argued that commercial activity relates to the key driving force, which is "the entrepreneur and their ability to identify and develop business opportunities". Clark (2004) also highlighted the entrepreneurial transformation of universities requiring collective entrepreneurial action. This view is further reinforced by D'Estea et al (2013) who advocates the importance of prior experience in innovation-related activities would greatly impact on continued success in academic entrepreneurship.

A key driver for economic growth is knowledge and investment in research and development (R&D). To realize benefits as return on investment, an innovation's inherent value is only acknowledged within its environment when the public utilizes the manifested outcome (such as a commercial product) (Bansi 2016). Tahvanainen and Nikulainen, (2010) maintains that commercialization is certainly a significant provider to economic growth, which is further supported by Bansi (2016) affirming that accessibility and utilization by the public contributes to ultimate economic growth. In principle, commercialization is an exchange of know-how for financial return (Speser 2008), which can be apparent in diverse ways that include:

- impact of entrepreneurship on innovation success
- activity that converts innovation into tangible products or service
- route of transferring R&D outcomes from a university research laboratory to industry

- identification of a commercial prospect for scientific or engineering invention and consequent steps to design, develop, and to further enhance the innovation for usefulness
- adoption of a innovation or service by customers
- arrangement that allows innovators to receive economic gain from their efforts, which includes patent licensing, R&D funding, and joint ventures

Further, as identified by Natsheh et al (2015), commercialization is not always a straightforward process; many challenges requires to be overcome for its success. Especially so, innovation in its embryonic stage may face challenges simply because it lacks familiarity and public validation.

This paper presents findings of results of study on commercialization of university innovation. The results attempts to add value to both universities and innovators, by firstly providing awareness to potential challenges, and secondly offers possible solutions to overcome challenges. The review of literature on challenges experienced by international universities is discussed, followed by the survey description and interview methodology of the study. Results are presented on key findings followed by a conclusion.

2. Literature Review

Variation of commercialization systems are found amongst the different countries. Prior to 1980, the lack of a uniform IP policy governing ownership and the lack of incentives to commercialize innovation presented challenges for US universities. The situation was corrected by the introduction of the Bayh-Dole Act, as opposed to Australia where the university commercialization environment imposed limitations and controls in activity that satisfied national standards.

Ultimately, the Bayh-Dole Act gave US universities the opportunity of ownership on innovations, removed Government from the process, and provided incentives for commercialization to occur. Through revenue sharing between university and researcher, the Bayh-Dole Act strengthened incentives for researchers to actively participate in commercialization activity. This was also the experience in countries such as, the United Kingdom, Japan, Germany, Austria, France, Denmark, China, and the Republic of Korea. However, this practice is not imperative for successful technology transfer, since in some leading innovative countries of Europe (such as Finland and Sweden) researchers own their IP. Some believed that the Bayh-Dole Act could adversely affect the quality of university research, nonetheless there is limited empirical evidence to prove this effect.

Innovation activity based on university-generated IP has been on the increase in the US, Western Europe and Canada, however literature suggests that the European Union has been lagging behind. It was also found that older knowledge transfer offices produced fewer innovation disclosures, patent applications and grants as compared with younger offices. As knowledge transfer offices gain in experience, it becomes easier to weed out research results with weak commercial potential thereby contributing greater focus of attention on commercially promising technology.

Each country's IP policy, procedure and regulations has its own strengths and weaknesses that result in challenges and successes. For example, the higher education sector of Australia has a well-developed system that is subsidized by Government and focuses on adding value to key primary products in the mining and agricultural sector.

A case study of Japan, Finland, Canada, and the Flanders region of Belgium found that these nations changed their national innovation strategies to increase R&D spending, collaboration between industry and academia, and new technology start-ups (Wessner 2013).

Germany's ability to remain globally competitive in advanced manufacturing exports, despite wage and other costs being higher in comparison with the US is possible through being a mature industrialized nation. Although the German patent system was known to be similar to the US system, it was considered more stringent, thereby resulting in a lower number of patent grants although likely higher in average value. Their patent examination process requires the patent to be new, non-obvious, and capable of producing greater efficiency. As with the US system, the courts adopt a liberal attitude in interpreting and enforcing existing patent rights once granted. Penalties for wilful infringement include not only fines but also the possibility of imprisonment. Unlike the US policy, German patents were also subjected to working requirements. Meaning

the grant of a patent could be revoked after the first three years if not commercialized, if the owner refused to grant licence use of innovation deemed for public interest, or if the innovation was primarily being exploited outside Germany.

Canada and the United Kingdom have similar IP systems to that of the Bayh-Dole Act style approach. Failure of research institutions to take responsibility for IP management stems from the Canadian system, which arises out of the laissez-faire approach to IP ownership. Both the Canadian and the UK experience may therefore find the solution of research bodies being the most conducive owners of IP.

Although the Finnish system was not investigated in detail, it was found to be comparatively different from countries that emphasize funding instruments to promote research collaboration between higher education and the business sector. Strong emphasis focused on human capital and areas for industrial innovation. Canada proposes research bodies give priority to local industry and small business when licensing IP, while the UK on the other hand considers such an obligation unrealistic and inconsistent with the global nature of industry. Although the Chinese IP system was not evaluated in detail for this study, it is known to have similar ideas to India. Both nations have innovation agendas for improving living standards and moving into high-tech knowledge-intensive industries. Their systems attract foreign investment from industries that are found to develop global competitive corporations. According to Breitwieser and Foster (2012) empirical literature suggests that the effectiveness of patent protection in India varies from industry to industry, and inventive activity is sensitive to protection only in selected spheres such as the chemical and pharmaceutical sectors.

Countries have fine-tuned their intellectual property right regimes as per their developmental requirements. Against this backdrop, there is an ongoing attempt to harmonize and strengthen intellectual property protection regimes worldwide.

It is difficult to assess which country's strategy and policy will continue with success. Policy options found appropriate in one country may be completely challenging for another country, yet all responsibility is aimed at encouraging strategies and systems to identify, protect, manage and exploit valuable IP in the best interest of each country. Literature suggested that strong IP regimes may inhibit the diffusion of knowledge and technology development in countries that are technology followers. Valuable insights for decision-makers and policy-makers have been discussed, which presents a holistic picture of the continually changing global context.

To validate these challenges experienced by IP&TTO managers, a series of interviews were undertaken with innovators whom agreed that the above-mentioned factors could affect commercialization success. Likewise, the survey revealed that technical development, entrepreneurship and a lack of adequate infrastructure hindered success in commercialization of university innovation. The IP Act, which is based on the US Bayh-Dole Act, recognizes the importance of publicly funded institutions such as universities. The objective of the IP Act is to ensure that IP from publicly financed research and development is identified, protected, utilized and commercialized for the benefit the people of South Africa.

3. Experience of South African Universities

In compliance with the IP Act, a number of universities in South Africa have sought to establish intellectual property and commercialization departments that are responsible for generating revenue from research. However, despite the potential, there is minimal in the way of innovation, patenting and commercialization at present at South African universities. Cloete, Nel and Theron (2006) are of the view that a contributing factor to low patenting activity by South African scientists may result from "research not conducted with commercialization in mind, and therefore lacks market focus."

University inadequacies range from the absence of emphasis on commercialization, to a low to non-existent entrepreneurial culture. Deficiencies in commercialization knowledge among researchers was emphasized as another barrier. Results revealed not all barriers are common between universities and some barriers may be more excessive than others. It is likely that the impediments vary between universities based on an individual's overall knowledge of the commercialization process.

The study contributes to understanding the impediment to societal progress and provides a starting point for further research. It shows that a lack of market focus and related issues are key challenges to commercialization which are similar to previous studies. It has also been confirmed that industry partners ought to encourage the building of a supply chain which will require enhanced university-industry collaboration.

It is difficult to assess which country's strategy and policy will continue with success. Policy options found appropriateness in one country may be completely challenging for other countries, yet all responsibilities are aimed at encouraging strategies and systems to identify, protect, manage and exploit valuable IP in the best interests of each country. The literature also suggested that a strong IP regime may also inhibit the diffusion of knowledge and technology development, especially in countries that are technology followers. Valuable insights for decision-makers and policy-makers have been discussed, which presents a holistic picture of the continually changing global context.

Presently, South African universities are found to be lagging behind in creating an IP culture, thereby reflecting low disclosure rates. University IP&TTO's should encourage disclosure internally instead of directly to industry. Increased disclosure results in greater patent applications with commercial possibilities. This hypothesis is consistent with the findings of Mellon (2011) who argued that a large patent portfolio impacts on the greater probability of positive commercialization activity. It can therefore be assumed that the extent of a patent portfolio in relation to commercialization activity is an influential element in defining the commercialization performance gap.

The university environment and culture have a profound impact on the probability of commercialization success. Factors within the control of universities include conducive IP policies and practices; incentives for participation in IP activity, e.g. promotion prospects; unbiased decision making on innovation; and, entrepreneurial skill with focus on issues of risk management in the context of commercialization. While the IPR Act was envisioned to accelerate commercialization, Government did not adequately plan for research output in the form of innovation to be transferred from academia to the commercial market. It was anticipated that the IP&TTO's at universities would facilitate the transfer of innovation to the marketplace; instead, they have become gatekeepers constraining the flow of innovation, which frustrates researchers and industry.

Governments ought to enhance university-industry collaboration via their part in funding universities. A decent reward system for researchers would provide incentives to participate in commercialization activity. Concomitantly, collaboration with industry must be encouraged. IP transformation and commercialization energy cannot make up for a country's weak national innovation system. Appropriate technological capabilities and linkages are required prior to relevant returns appear in the form of commercially successful spin-off companies or licensing. Thus, low technological capacities in terms of both human capital and infrastructure, limited awareness on the benefits of IP among researchers, university management and industry, still require reform for success in innovation commercialization to become apparent.

4. Results

The idea of granting universities the title of ownership of IP from publicly funded research was brought about with the expectation of increased commercialization. Further, it was felt that IP would contribute to increased economic development by affording the country the opportunity to participate in global trade and industry activity. However, not all stakeholders have seen the provisions of the IP Act 51 of 2008 as favourable. For the period 2008-2013, eight universities reported to have registered more than ten patents, five universities registered between six and ten, four registered one or two and two registered none. Two universities reported having commercialized nine or more innovations, ten had commercialized between one and five and nine had commercialized none. Seven universities experienced unsuccessful attempts at commercialization. This is a very modest level of performance; even those universities, which have commercialized a patent during the six-year period averaged only around one per annum.

This study established strong evidence that possibly contributes to the low commercialization rate, which is made up by: the lack of support from university management, insufficient incentives for innovators, absence of access to funding opportunity, research undertaken without commercialization in mind which indicates lack

of entrepreneurial thought/skill; and, institutional bureaucratic regulations with and unfair system of decision making with regards to IP.

University, government and industry executives need to demonstrate genuine support for research and innovation development activity over the long term, allocate the necessary resources required for its success, and implement long-term plans and strategy for innovation. Researchers, innovators, entrepreneurs and government officials ought to aware of potential challenges in commercialization prior to investment in R&D for return income generation.

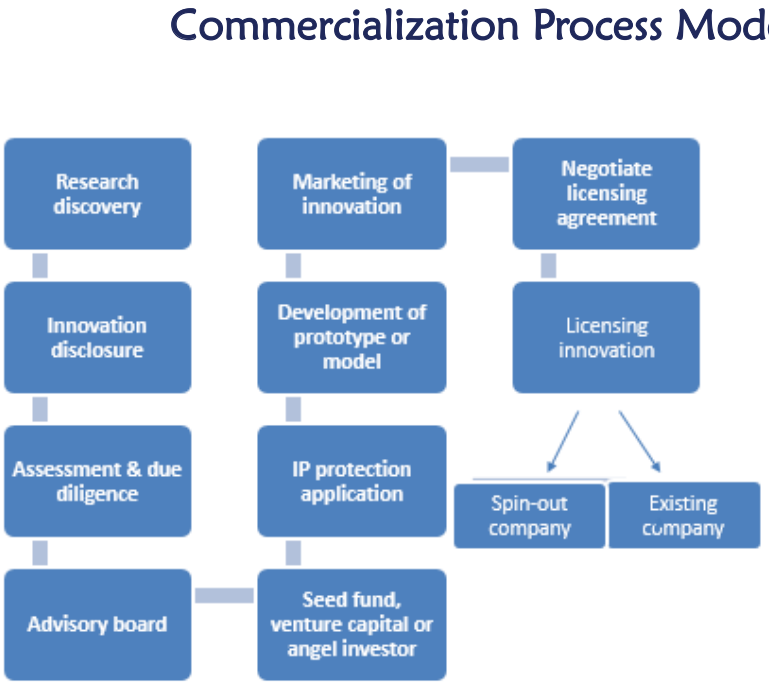
Results identified that universities with clearly defined IP policy, sound structured IP&TTO and the support of senior management are likely to enjoy success in commercialization performance. The absence of an attractive incentive system, both financially and in terms of career advancement, may have driven innovators to identify private industry collaborations outside their universities, which at times includes international engagement. Stronger university/industry collaboration ought to be cultivated for South Africans to reap the benefit of investment in R&D thereby consequently strengthen economic competitiveness.

5. Recommendations

Studies on commercialization have produced lengthy dos and don'ts, identifying qualities and characteristics of university IP&TTOs, and lists of resources that Governments ought to provide for success to be achieved. At best, these merely serve as guides that provide insight to varying extent that may contribute towards success.

The complexities involved in commercialization makes it difficult for a proposed model to effectively work in different environments, therefore a 'one size fits all' approach will not be feasible. Some of the models include activities to be undertaken simultaneously in order to increase the chance of commercialization. With the combination of data that emerged from the questionnaire, interview sessions and reviewed literature, a linear model of commercialization does not seem sufficient. Bradley *et al.* (2013: 2) identified shortcomings of the traditional linear model which include inaccuracies such as strict linearity and oversimplified processes; a one-size- fits-all approach; emphasis on patents; inadequate account of informal commercialization; failing to recognize the influence of institutional culture; and the absence of a university reward system within the model.

With the identified shortcomings in mind, the following commercialization model is proposed:



Diagrammatic representation of commercialization model

The proposed model would operate as follows:

- Research discovery

Research activity frequently lead to discoveries and innovation with the potential of commercial applicability.

- Innovation disclosure

Innovator to disclose innovation to university IP&TTO within specified timeframe.

- Assessment and due diligence

To ascertain competing products and whether the product satisfies a market need or creates a new market product. Decision on whether to proceed with innovation or not. On assessment of potential commercial value, a preliminary commercialization strategy drawn by IP&TTO.

- Advisory board

Based on submitted strategy, an advisory committee comprising of the university faculty, university IP&TTO, Government, legal adviser, innovator and industry experts in the field of the identified innovation review disclosure and advise on a potential commercialization route.

- Seed fund/venture capital/ angel investor

Application for seed funding to a potential investor or venture capital required to fund commercialization.

- IP protection

The IP&TTO engage legal counsel for appropriate IP protection that acts as a deterrent from infringement and affords potential investors with security from an investment standpoint.

- Prototype or model

A model or prototype developed to demonstrate proposed working product.

- Marketing of innovation

Once IP protection filed, market innovation to potential industry partners

- Negotiate and licensing agreement

When a commercialization partner is identified, the decision to licence the innovation to an existing company or establish a spinout company is decided upon. Royalty distribution or equity stake is negotiated. In-depth examination of innovation may involve signing of a non-disclosure agreement.

The above process may not necessarily flow in an entirely linear direction, although components illustrate overview of commercialization route.

6. Conclusion

Presently, South African universities are lagging behind in creating an IP culture, thereby reflecting low disclosure rates. University IP&TTO's ought to encourage internal disclosures instead of directly to industry. Increased disclosure results in greater number of patent applications with possibility of commercialization. This hypothesis is consistent with the findings of Mellon (2011: 23) who argued that a large patent portfolio impacts on the greater probability of positive commercialization activity. It can therefore be assumed that the extent of a patent portfolio in relation to commercialization activity is an influential element in defining the commercialization performance gap.

Abstract: A high-quality business environment shapes a country's economic system in a significant way, motivates people to start a business, and creates favorable conditions for remaining on the market and for the growth of small and medium-sized enterprises (SMEs). The aim of this paper is to define important economic factors influencing the quality of the business environment and their impact on the economic system. In regards to this aim, an empirical research was conducted in 2018, using a survey in the SME sector in the Czech and the Slovak Republic. These countries, given their common history, share a very similar economic structure and development. The research was done on a sample of 641 respondents. They were business owners and managers active in small and medium-sized enterprises. As a part of the research, important factors were defined in the following areas: macroeconomics, currency policy and interest rates, SME financing and population consumption. The respondents had the option to express their agreement using the Likert scale: strongly agree, agree, neutral, disagree and strongly disagree. The results of the research were processed via the method of regression analysis. It was discovered that the defined economic factors significantly influence the perception of the quality of the SMEs' business environment. A positive perception of the state of the macroeconomic environment motivates people to start a business. Entrepreneurs in both countries rated the current state of the macroeconomic environment as favorable and supportive of their entrepreneurial activities. They also confirmed that the current situation supports the enterprises' innovation activities. Based on the respondents' statements, the current level of basic macroeconomic parameters, such as the gross domestic product, employment, and inflation, supports entrepreneurship and creates interesting business opportunities in the SME sector. Similarly, the Central bank currency policy stabilizes the business environment in both countries. The research yielded a finding that in the current economic situation, small and medium-sized enterprises have a good access to bank loans. On the contrary, economic factors such as population consumption, changes in income and the structure of consumer spending are not statistically important factors that could influence the quality of the SMEs' business environment in the Czech and the Slovak Republic.

Keywords: access to finance, economic factors, macroeconomic environment, monetary policy, quality of business environment, small and medium-sized enterprises

1. Introduction

A high-quality business environment shapes a country's economic system in a significant way, motivates people to start a business, and creates favorable conditions for the growth of small and medium-sized enterprises (SMEs).

The quality of business environment in the SME sector is shaped by an array of economic and non-economic factors. Macroeconomic environment, monetary policy of Central bank, access to finance and consumer behavior significantly influence the quality of business environment in the small and medium-sized enteprises (SMEs) segment.

This paper examines the influence of significant economic factors on shaping the quality of business environment in the SME sector. The originality of this paper lies in the presentation of entrepreneurs' and top management's notions about the way economic factors influence the overall quality of the business environment in the Czech and the Slovak Republic.

The structure of the paper is as follows: The introduction presents views of several authors on the influence of selected economic factors on the quality of business environment. The second part defines the aim of the research, methodology and the description of the data used. The Results and Discussion part presents the results of own empirical research in the Czech and the Slovak Republic. The conclusion offers a final summary of the research.

2. Theoretical background

The influence of economic factors on the quality of business environment is examined by many authors. According to Bekeris (2012), macro-economic factors are important determinants of business conditions in the country (similarly Kadocsa & Francsovics, 2011), and hence, the factors can have a significant impact on profitability. Macroeconomic factors such as imports, exports, competition in the market, population, wage rate, FDI, GDP, unemployment, infatuation rate, business tax rates and inter-bank interest rates were examined. The authors discovered that most of the macro economic factors do not affect the profitability of SMEs except for unemployment and interbank interest rates. The result shows that increasing unemployment has a negative effect on profitability. The authors argue that higher unemployment may induce less demand for products and services and thus it has a negative effect on SMEs' profitability. With respect to interest rates, it is also found that lower interbank interest rates have a positive effect on profitability. This means that when the interest rate is lower, SMEs can borrow more from banks and hence they can invest in profitability projects that may lead to a higher profitability for SMEs. In this context, Kadocsa and Francsovics (2011) state that the monetary policy should be considered as a macroeconomic factor that influences SMEs' competitiveness.

Thai and Turkina (2014) found that economic opportunities and resources influence entrepreneurship. More recently, Ipinnaiye, Dineen and Lenihan (2017) examined the drivers of SMEs' performance and they provided evidence that firm growth is influenced by the macroeconomic environment both directly and indirectly.

One of frequently discussed topics is the access of small and medium-sized enterprises to external financing via bank loans.

Ahmedova (2015) states that access to finance is the most important factor for SMEs to be competitive in the market. She found that 86% of the SMEs in the survey (in Bulgaria) do not have a bank finance facility and thus need to give up profitable projects. It was also discovered that 62% of the firms' investments came from their owner, 24% from friends and family members, and bank loans were only about 15%. Another finding was that innovative firms can be more competitive than the non-innovative ones, as by innovating new products and services, they can reach out to new groups of customers. It was also found that technological advancements can help the firms to be competitive in the market because by using technology, a firm can be more efficient and that can create competitive advantage. Also, high competition in the market is driving SMEs' profit level to fall which is creating a survival problem.

Dajcman (2016) states that macro-economic shocks restrict banks to providing less bank loans to businesses. Banks tighten bank loans when they face a period of economic downturn. Specifically, during the World financial crisis, bank loans to firms were reduced by nearly 30% in the examined European countries. However, credit tightening is more pronounced for the SMEs than for larger firms. Another finding is that increased inflation rates negatively affected bank loans to SMEs, as due to inflation, banks need to charge higher bank loan price which reduces the tendency for firms to borrow from banks. Thus, macroeconomic factors are important determinants for SME bank loans.

Steinerowska-Sterb and Steiner (2014) analyzed the differences in the decision making process of Polish firms who have received bank finance and those who did not during the period of 2010. First, it was discovered that the lack of access to finance negatively affected the firms' growth which led to a reduction of the number of employees to cut the costs. Second, due to the lack of external bank finance, SMEs needed to cut their ongoing business projects which had a severe impact on their profitability and sustainability. Third, SMEs without bank finance had to cut their product prices in order to be able to sell them quickly and to get their money back. By doing so, credit constrained firms maintained their working capital. Finally, they found that credit constrained firms reduced the investment in R&D activities. Hence, the innovation ability of the firms was also hampered by the lack of bank finance.

O'Toole, Gerlach-Kristen, and O'Connell (2013) examined credit constraint problems for SMEs in Ireland by using the SAFE survey during the period of 2009-2011. The paper finds that the lack of access to finance is the third most important barrier for the SMEs to grow and develop. Finding customers and high competition in the market was the first and second key issues faced by the SMEs. Lack of customers was making it difficult for the SMEs to sell their products, which was creating liquidity problems. Similarly, high competition was reducing

their sales, putting pressure on SMEs to maintain their profitability. In the survey, about 61% of firms did not apply for bank loans and 39% of the firms did. Among the 39% that did apply for bank loans, 20% got rejected by banks because they could not meet the bank loan criteria. Authors argue that since the survey was done during the financial crisis and after the financial crisis period, it was still difficult for banks to lend SMEs. As a result, banks were applying strict rules and credit criteria on SMEs to access bank loans.

High lack of demand for products had a negative effect on the growth of SMEs. The paper shows that SMEs faced high competition from unregistered SMEs which was creating a problem for SMEs to sell products to their target customers (Dragnic, 2014).

3. Aim, methodology and data

The aim of this paper is to define significant economic factors influencing the quality of the business environment and quantify their power in the economic system. In regards to this aim, an empirical research was conducted in 2018, using a survey in the SME sector in the Czech and the Slovak Republic. These countries, given their common history, share a very similar economic structure and development. The research was done on a sample of 641 respondents. They were business owners and managers active in small and medium-sized enterprises.

The statistical unit of research was one enterprise. The survey was carried out on a sample of 9400 enterprises from Slovak Republic (SR) and 7800 enterprises from Czech Republic (CR). Entrepreneurs were selected from the database "Albertina" (CR) and "Cribis" (SR) randomized numbers using mathematical functions "RANDBETWEEN". The extent required for the function was always determined by the number of businesses in the region. Individual companies were directly addressed by email or phone, but also via personal meeting.

641 responses from enterprises were collected (312 enterprises in CR and 329 enterprises in SR). The percentage of completed questionnaires in form of positive feedback reactions was 4%. Examined socio-demographic data were gender, education and age of the entrepreneur (two qualitative and one quantitative statistical code), the size of the enterprise, and the length of operating on the market (two qualitative statistical codes).

The structure of the sample according to the size of firms was as follows (CR/SR): micro (258/234), small (43/71), and medium (11/24). The questionnaires was answered by (CR/SR): 236/251 men and 76/78 women.

One of the factors was also the age of the company. Most respondents had been operating their businesses for more than 10 years (CR/SR: 208/147), 48/78 of entrepreneurs 5-10 years, and the rest (56/104) of the entrepreneurs 1-5 years. The survey involved all regions of the Czech Republic and Slovak Republic. Education (CR/SR): university education (127/224), higher education (135/95), and higher education without graduation (50/10). Questionnaires were addressed to entrepreneurs from different areas of the economy (CR/SR): 109/122 were from service companies, 73/69 were from commercial companies, 53/51 from manufacturing companies, 29/39 from construction, 19/11 from transportation, 9/20 from agriculture, and the rest were labeled "Other" (industry not mentioned in the questionnaire).

Significant factors of the macroeconomic environment (EF1), monetary policy and interest rates (EF2), financing SMEs (EF3), and population consumption (EF4) were defined within the research, using the following statements:

3.1 EF1: Macroeconomic environment

EF11: I consider the macroeconomic environment of my country to be favorable for doing business.
EF12: The state of macroeconomic environment of my country supports starting a business.
EF13: The present macroeconomic environment supports enterprises' innovation activities.
EF14: The present level of basic macroeconomic factors (GDP, employment, inflation) supports business and creates interesting business opportunities.

3.2 EF2: Monetary policy and interest rates

EF21: The Central Bank's monetary policy has a positive impact on the business environment.
EF22: Banks' interest rates have a positive impact on the business environment.
EF23: Banks' interest rates have a positive impact on enterprises' innovation activities.

EF24: The Central Bank's monetary policy stabilizes the business environment.

3.3 EF3 Financing enterprises:
EF31: Enterprises have easy access to bank loans.
EF32: Banks' credit conditions for entrepreneurs are acceptable.
EF33: The cost of loans for enterprises is acceptable.
EF34: Banks have a positive impact on the quality of the business environment.

3.4 EF4 Population consumption, changes in income and the structure of consumer expenditure
EF41: The growing consumer consumption positively influences the quality of the business environment.
EF42: People can afford to buy more products and services.
EF43: The growing consumer consumption positively impacts my business.
EF44: People purchase more, compared to the past.

3.5 QBI41: The business environment in my country is of high quality and suitable for starting a business.
The respondents had the option to express their agreement using the Likert scale: strongly agree, agree, neutral, disagree, and strongly disagree.

The research results were processed using the method of regression analysis.

The following statistic hypotheses were evaluated to fulfil the main objective of the paper:

H1: Economic factors EF1 (macroeconomic environment), EF2 (monetary policy), EF3 (financing of companies) and EF4 (Population consumption, changes in income and the structure of consumer expenditure) are statistically significant and determine the quality of business environment in the Czech and the Slovak Republic.
The following statistical tools of descriptive statistics (tables, descriptive characteristics - sum) were used in addressing the above hypotheses of partial research. Methods such as absolute frequency and sorting the responses in evaluating statements were applied. The number of variations of each statement was 5 (strongly agree, agree, neutral, disagree, strongly disagree). The method of simple sorting was used to express the relative frequency of positive responses of a statement. Another used method was the relationship between qualitative variable statistical characteristics (statement, type of country) utilizing contingency table and contingency intensity. Contingency intensity was measured using the Pearson coefficient of contingency, which is based on the square contingency. Z-score was used to determine significant statistical differences in the evaluation of statements of students' answers by country of study.

To verify hypothesis H1, the regression analysis is used to quantify the relationship between variables, not with an aim of its forecasting. The dependent variable (QBE) and independent variables (EF_1, EF_2, EF_3, EF_4) with indicators are metrics, so the regression analysis is one of the appropriate statistical methods. Independent variables must satisfy the assumptions of linearity, homoscedasticity, and normal distribution of data to be statistically sound regression model parameters. The assumption of linearity was verified by a graphical analysis of data using the scatter plot. The homoscedasticity assumption has been verified using the Bartlett's test in which the p-value must be greater than the level of significance to meet the requirements. The assumption of a normal distribution of the number of students' evaluations of statements was verified by:

graphical analysis (comparing the histogram with normal distribution curve) testing, and descriptive characteristics (skewness and kurtosis), using a z-score. If the value of the skewness or kurtosis of the z-test was greater than the significance level, then the premise was rejected. A correlation matrix was used to verify the relationship between dependent and independent variables. T-test was used to verify the significance of the parameters in the regression model. The basic linear multiple regression model which defines the relationship between the dependent and independent variables, has the following general form for the Czech Republic and Slovakia:

$$QBE = \beta 0 + \beta 1 * EF1 + \beta 2 * EF2 + \beta 3\ EF3 + \beta 4\ EF4 + \varepsilon t\ , \qquad (1)$$

where *QBE* – dependent variable (Quality of business environment); β_0 – constant, $\beta_1; \beta_2, \beta_3; \beta_4$ – parameters of independent variables EF_i; EF_i – independent variables (EF_1 – macroeconomic environment, EF_2 – monetary policy and interest rates, EF_3 – financing companies, EF_4 – Population consumption, changes in income and the structure of consumer expenditure); ε_t – error term.

The coefficient of determination indicates the percentage of variability of propensity for entrepreneurship of students that is explained by the chosen regression model. Then the coefficient of determination was compared with the adjusted coefficient of determination. The F – test was used to verify the significance of the entire regression model. The presumption of multicollinearity was verified by using variance inflation factor (VIF – test). If the value of the VIF test for the independent variable is less than 5, then the parameter is not affected by multicollinearity (Hair et al., 2010). The desired p-value of the F – test must be lower than the level of significance. The level of significance is 0.05. The calculations were done using sophisticated statistic software SPSS Statistics.

4. Results and Discussion

To test hypothesis H1, regression analysis of data was used. Linear trends between the dependent variable (QBE) and independent variables (**EF_1, EF_2, EF_3, EF_4**) can be seen in the results of a graphical analysis (scatter plot). The graphic analysis of normal distribution of data shows divergences from normal distribution in the EF_4 independent variable. The results of the assumption of normal data distribution are given in Table 1.

Table 1: Skewness, kurtosis and z- value of independent variables

Independent variable	Skewness	z- value	Kurtosis	z-value	Bartlett's test
EF_1	0.1693	0.6154	-0.7504	0.1445	0.5541
EF_2	0.2318	0.2565	-0.8667	0.8751	0.8421
EF_3	0.0171	1.9217	-0.5085	0.2111	1.4777
EF_4	-0.0429	0.1799	-0.0429	0.3598	2.0209

Source: Authors' results.

The results confirmed that the EF_1 and EF_2 independent variables fulfil the conditions of normal data distribution as well as homogeneity of variances (Bartlett's test EF_1, $EF_2 > 0.05$). The independent EF_3 and EF_4 variables do not fulfil the condition of normal data distribution (z - values of skewness EF_3 and z – value of kurtosis $EF_4 > 2.000$). These independent variables can be inserted into the regression model with the aid of the t-test. The results are shown in Table 2.

Table 2: Characteristics of the variables not included in the model in the first phase

Independent variable	Partial correlation	t- value
EF_3	0.3398	2.8254
EF_4	0.3315	2.2121

Source: Authors' results.

In Table 2 the calculated test characteristic of student distribution in the independent variables (EF_3 and EF_4) are higher than the critical test value. EF_3 and EF_4 are accepted as an independent variable in the linear regression model. The intensity of dependence between the dependent and independent variables is illustrated in Table 3.

Table 3: Correlation matrix of variables in the model of quality business environment

	QBE	EF_1	EF_2	EF_3	EF_4
QBE	1				
2	0.4021	1			
EF_2	0.4127	0.3609	1		
EF_3	0.3270	0.2768	0.3642	1	
EF_4	0.3055	0.3130	0.3559	0.3057	1

Source: Authors' results.

From the results of the z-test (see Table 1), the t-test (see Table 2) and the correlation matrix (see Table 3), independent variables EF_1, EF_2, EF_3 and EF_4 are accepted as statistically significant parameters of the linear

regression model. The results of testing the significance of the thus designed regression model with three independent variables are shown in Table 4.

Table 4: Characteristics of quality business environment of regression model

Least squares multiple regression					
R^2					0.2737
Adjusted R^2					0.2691
Multiple correlation coefficient					0.5231
Residual standard deviation					0.7759
Regression equation					
Independent variables	Coefficient	Std. Error	t- Stat	p-value	VIF
(Constant)	0.5185	-	-	-	-
EF_1	0.2357	0.0358	6.5743	<0,001	3.6515
EF_2	0.2442	0.0402	6.0786	<0,001	2.8765
EF_3	0.0159	0.0419	3.7991	<0,001	4.3211
EF_4	0.1010	0.0375	2.6918	0,002	3.1897
Analysis of variance					
F-ratio					59.9078
Significant level					<0.0001

Source: Authors' results

Graphic analysis of the entire model confirmed the conditions of linearity, homoscedascity and independence of deviations. The conditions of normality were also fulfilled by the results of the normal distribution graph.

The Variance Inflation Factor results demonstrated the absence of the effect of multicollinearity (VIF independent variables are less than the critical value 5 (Hair, 2010): EF_1 = 3.6515; EF_2 = 2.8765; EF_3 = 4.3211; EF_4 = 3.1897). The differences between the determination coefficient and the adjusted determination coefficient are minimal (R^2 - 0.2737 and Adjusted R^2 - 0.2691). The p-value of the F-ratio of the entire regression model is less than 0.005.

The above calculations of the characteristics of regression analysis (see Table 4) lead to the formulation of the shape of the linear regression function of regression model of propensity for entrepreneurship of university students as follows:

$$QBE = 0.5185 + 0.2357*EF1 + 0.2357* EF2 + 0.0159 EF3+ 0.1010 EF4 + \varepsilon t , \quad (2)$$

where *QBE* – dependent variable (Quality of business environment); β_0 – constant, $\beta_1; \beta_2, \beta_3; \beta_4$ – parameters of independent variables EF_i; EF_i – independent variables (EF_1 – macroeconomic environment, EF_2 – monetary policy and interest rates, EF_3 – financing companies, EF_4 – population consumption, changes in income and the structure of consumer expenditure); ε_t – error term.

The hypothesis that the designed regression model is statistically significant at a 0.05 significance level is accepted. The variability of selected independent variables (EF_1, EF_2, EF_3 and EF_4) explains up to 27.37 % of the variability of intensity of the quality of business environment in the SME segment in the Czech and Slovak Republic. The determinant Macroeconomic environment has the greatest influence on the quality of business environment from all selected economic factors. Contrariwise, the smallest influence, if statistically significant, is the determinant population consumption, changes in income and the structure of consumer expenditure. The economic factors had an influence on QBE of SMEs.

Hypothesis was confirmed. The results showed that statistically significant indicators are: I consider the macroeconomic environment of my country to be favorable for doing business (EF_{11}), the state of macroeconomic environment of my country supports starting a business (EF_{12}), The present macroeconomic environment supports enterprises' innovation activities (EF_{13}), The Central Bank's monetary policy stabilizes

the business environment (EF_{24}), enterprises have easy access to bank loans (EF_{31}) and People purchase more, compared to the past (EF_{44}). Other indicators are not statistically significant.

Other authors also examine the quality of the business environment in the analyzed countries, and present interesting inputs in this field.

The results of the survey by Virglerova et al. (2017) "have demonstrated that four groups of key determinants can be identified in the business environment studied among SMEs in the Czech Republic. The first and most global determinant is "State and public perception" which includes both the country's legislative background and the general public's perception of entrepreneurs. The second is "Banks and their approach to business" which includes the most important external source of finance for SMEs in the Czech Republic. The third area is "Knowledge of rules and principles" which determines the activities of business owners especially on the financial market. The last determinant is "Financial risks and their increase in post-crisis times", comprising the awareness of financial risks, risk management, and the changes in risk perception during the crisis and after it.

The state plays a very important role within its business environment. Three areas of the state's influence on the business environment were selected: the state's help with entrepreneurship, administrative burden related to entrepreneurship, and corruption and clientelism. These areas were moreover examined in terms of the age of the business and company size. It was found that SMEs perceive the help of the state more than micro businesses. More than 53% of entrepreneurs encountered clientelism. Furthermore, the results confirm that the problem of corruption increases with company size. Encountering corruption and clientelism may be significantly more influenced by the length of entrepreneurship than by the company size (Virglerová et al., 2016).

Ključnikov et al. (2016) define and quantify important factors of the quality of the business environment for small and medium-sized enterprises (SMEs) in the Czech Republic. They found that only 10% of the entrepreneurs positively evaluated the applicable forms of state financial support. 64% of Czech entrepreneurs feel the support of their surroundings while doing business, 45% think that SMEs have restricted access to external sources of financing, and over half note the intensive influence of market risk. It was also determined that there are statistically significant differences in the pattern of responses between micro-enterprises and small and medium-sized enterprises.

The payment discipline represents a major problem in SMEs in Slovakia. While 83% of them noted the existence of problems with overdue receivables, 30% of the respondents acknowledged problems with their own payment discipline and identified secondary insolvency as the most important reason for it (Ključnikov et al., 2017).
Results by Ključnikov and Popesko (2017) suggest that Slovak entrepreneurs primarily supply their products and services on the domestic market, while their export potential is limited. The assessment of the state support of export activities is rather negative. An alarming finding is that Slovak entrepreneurs in the SME segment do not use even basic tools of financial risk reduction to a higher extent, and that the use of services of the state export bank Eximbank is negligible.

5. Conclusion

The aim of this paper is to define significant economic factors influencing the quality of the business environment and quantify their power in the economic system.

In was discovered in this research that macroeconomic factors play an important role in shaping the quality of the business environment. Among the most significant factors influencing the quality of SMES' business environments are: the state of the macroeconomic environment, Central Bank's monetary policy, access to external financing, and population consumption. Factors most influencing the perception of the quality of SMEs' business environment in the Czech and the Slovak Republic are: EF_{11} (I consider the macroeconomic environment of my country to be favorable for doing business), EF_{12} (the state of macroeconomic environment of my country supports starting a business), EF_{13} (The present macroeconomic environment supports enterprises' innovation activities), EF_{24} (The Central Bank's monetary policy stabilizes the business environment, EF_{31} (enterprises have easy access to bank loans and EF_{44} (People purchase more, compared to the past).

The research has its limitations, but also brought interesting findings and a potential inspiration for further research of the quality of the business environment in the SME segment. Next research will be oriented on defining not only economic, but also non-economic factors influencing the quality of the business environment in the SME segment.

What is the Role of Networks and Geography in Reward - Based Crowdfunding Success?

José Jacinto Bilau and Jorge Pires
Polytechnic Institute of Beja, Portugal
jose.bilau@ipbeja.pt
jorge.pires@ipbeja.pt

Abstract: The crowdfunding phenomenon attracted considerable academic and professional attention in recent years. Research on the determinants of performance in rewards-based crowdfunding campaigns is developing at a fast pace and had essentially wide in its focus, allowing us to learned generically about what works and what does not work in this type of crowdfunding. In our paper we deepen this research by analysing the role of networks and geography in reward-crowdfunding success and examining potential differences according project goal. Using the most popular crowdfunding platform in Portugal (PPL crowdfunding), we followed 340 campaigns initiated and ended in 2017 and constructed a data set to capture campaign characteristics and funding outcomes. A binary logistic regression model was used to investigate networks and geography factors driving a campaign's success. Our results highlight the role of social networks and project region on funding success rewards-based crowdfunding. With our study, we contribute to the literature on crowdfunding and funding success. We provide comprehensive view on the role of networks and geography explaining in rewards-based crowdfunding success. We extend the previous knowledge by the fact that both networks specific aspects and geography specific aspects have an influence on the question of whether a project is successfully funded and can thus be realized. We also found a different role of these variables according to the size of the project. From a practical point of view, the results of our study are highly relevant for stakeholders on crowdfunding platforms. Project founders can make use of the results in order to improve the information related to their projects to increase the chance to have a project successfully funded. Our results are also relevant for crowdfunding platforms itself. These platforms might automatically assess the chance of successful funding of projects. Furthermore, platform operators could also suggest changes to founders whose project have been evaluated as potentially less successful.

Keywords: rewards-based crowdfunding; success prediction; networks; geography

1. Introduction

In the summer of 1885, the Statue of Liberty was in pieces in New York, with no funding to stand on a pedestal. So Joseph Pulitzer, The New York World editor, decided to launch a fundraising campaign in his newspaper. The newspaper kept readers up-to-date with the crowdfunding campaign, listing donors and amounts on a regular basis. The campaign raised money from more than 160 000 donors with more than three quarters of the donations, totalling less than a dollar. In just five months, The New York World grossed $101091 - enough to cover the last $ 100 000 to complete the pedestal. If launched today, this campaign would be a classic crowdfunding project, such as those run online by existing platforms around the world.

Joseph Pulitzer used the newspaper to raise money from a very large group of donors, each promising only a small money exchange. Those who donated a dollar or more received a mini 12-inch model of the statue. In a similar vein, artists, musicians, small entrepreneurs, and others have long relied upon funding from various backers to produce new works. Rewards-based crowdfunding enables funders to obtain financial resources from the general public, via internet-based platforms, in exchange for some level of non-financial reward (Davis et al. 2017).

While the crowdfunding phenomenon has attracted considerable practitioner and scholarly attention, existing research does not allow us to fully understand the determinants of crowdfunding campaigns performance (McKenny et al, 2017).This is a key question within crowdfunding research to date.

Research on the determinants of performance in rewards-based crowdfunding campaigns had essentially wide in its focus, allowing us to learned generically about what works and what does not work in this type of crowdfunding (see Kuppuswamy and Bayus, 2017 for a review). Two perspectives that deserved some attention refer to the possible influence of networks and geography on successful rewards-based crowdfunding. Networks are important channels through which can access financial resources (Ahlers et al, 2015; Brüderl & Preisendörfer, 1998). In rewards-based crowdfunding an exploratory study made by Mollick (2014) suggested that there are connections between social networking sites of a founder and their ventures with funding success. A body of literature also has examined and identified negative effect of geographic

distance in different contexts (Sorenson and Stuart, 2001; Seasholes and Zhu, 2005; Nieuwerburgh and Veldkamp, 2009). However in rewards-based crowdfunding Agrawal et al (2011; 2015) suggests that online mechanisms seem to diminish many distance-sensitive costs.

To deepen the role of networks and geography in rewards-based crowdfunding success we narrowly focused research question: what is the role of networks and geography in rewards-based crowdfunding success? Additionally, we questioned whether the influence of networks and geography changes with the project goal? To answer these questions we followed 340 campaigns initiated and ended in 2017 in the most popular crowdfunding platform in Portugal (PPL crowdfunding), and constructed a data set to capture campaign characteristics and funding outcomes. This platform uses a rewards-based model where founders receive tangible, nonmonetary rewards for their contributions, often in the form of products /services, or tokens of appreciation such as thank you notes.

The paper is structured as follows: Section 2 provides a brief overview of the study context. Section 3 presents a review of literature and the hypotheses to be tested. The data used, the statistical model and measurements of the variables are detailed in Section 4. The univariate and multivariate results of our data analysis are presented in Section 5. Section 6 provides conclusions.

2. Study context

Important steps have been taken to introduce regulation of crowdfunding into Portuguese legal system. First, with the publication of Law nº 102/2015, of August 24, that defined the legal regime for crowdfunding (LRC). In this law, crowdfunding is referred as the type of financing of entities (or their activities and projects) through which any natural or legal person, national or foreign, obtains investment from one or more individual investors, using a crowdfunding platform. In LRC four modalities of crowdfunding were established and regulated, namely: (i) Donation-based crowdfunding (ii) Reward-based crowdfunding; (iii) Equity-based crowdfunding; (iv) Lending - based crowdfunding. Law no. 102/2015 was subsequently supplemented by Administrative Rule no. 344/2015, of October 12, which established the rules applicable to the prior notification procedure for the start of activity of crowdfunding platforms through the means of Donation and Reward. The Portuguese Securities Market Commission approved CMVM Regulation No. 1/2016 where it defined the regime applicable to Equity-based crowdfunding and Lending-based crowdfunding.

This progress in building the legal framework for crowdfunding has only recently been completed with the publication of Law nº 3/2018, of 9 February 2018. This law defines the applicable sanctioning to the development of crowdfunding activities in Portugal. The law also makes the first amendment to Law 102/2015 of 24 August, which approves the crowdfunding.

3. Literature review and hypotheses derivation

3.1 Networks and reward - based crowdfunding

Networks are important channels through which can access financial resources (Ahlers et al, 2015). In crowdfunding there is the social network as a result of community crowdfunding platform where the entrepreneur is embedded in. This social network can help entrepreneur to find backers for his projet (Nahapiet and Ghoshal, 1998; Zheng et al, 2014). Belleflammea et al (2015) states that 'social buzz' or 'eWOM (electronic word-of-mouth), in the form of support, that a particular campaign would receive on social networks (e.g., shares on Facebook, or tweets on Twitter) may be critical for the campaign success. They consider que some funders put more weight on recommendations they receive from friends in a social network than on general information of campaign. According this author "social buzz" may supplement adequately the campaign description that a founder would give on crowdfunding platform. Agrawal et al (2014) suggest that the evolution of a fundraising campaign depends on founder social ties. Mollick (2014) found that a fundraisers number of Facebook connections (taken as a proxy for the size of a founder's social network) are a good predictor of successful fundraising. Thies et al (2014) analysed the effects of "social buzz" on the likelihood of success of crowdfunded campaigns. Their data set combines information about projects proposed on Indiegogo platform and number of shares and tweets that these campaigns received, respectively on Facebook and Twitter. Their results show that "social buzz" (especially Facebook shares) positively influences project backing. Others author's also agrees on the importance of social networks to collecting funds in crowdfunding models (Agrawal et al 2011; 2014; Kuppuswamy and Bayus, 2013; Lin et al, 2013).

Consequently, we hypothesize that:

H1: Crowdfunding projects with largest number of facebook shares are more likely to be successfully funded than projects with fewest facebook shares.

Throughout campaign some projects receive comments on the platform that can stimulate (new) funders to invest (Mollick, 2014). Antonenko et al (2014) found that the number of comments or founders updates on the project matter and point out that intensive communication positively impacts successful projects. Based on these previous results the following hypotheses will be tested:

H2: Crowdfunding projects that received comments on the platform are more likely to be successfully funded than those who have not commented.

Social networks can help disseminate knowledge about the organization's existence and can also be a sign of reputation (Coleman, 1988). So, the institutions those promote crowdfunding campaigns may seem more trustworthy in the eyes of the backers than the individual founders. Members of an organization can also use their individual social networks to accelerate the dissemination of rewards-based crowdfunding campaigns.

Networks with members of social organizations and associations have attracted relatively less attention in the literature. Members of social organizations helps small private firms have better access to venture capital (Ahlstrom and Bruton, 2006) and business angels (Wong and Ho, 2007). In this sense, an organization's social networks rather than individual networks can facilitate access to finance. We believe that Institutions are more likely to succeed in a crowdfunding campaign, thus we propose the following hypothesis:

H3: Crowdfunding projects in which founders are organizations are more likely to be successfully funded than projects promoted by individuals ones.

3.2 Geography and reward - based crowdfunding

The theory predicts that investors in entrepreneurial ventures in the early stage will tend to be local, to compensate costs of collecting information and monitoring progress (Florida and Smith, 1993; Lerner, 1995; Mason, 2007). Likewise crowdfunding backers tend to support campaigns that are geographically close to them (Lin and Viswanathan, 2015). Mollick (2014) concluded that early contributions from local investors (e.g. family and friends) can determine the pattern of subsequent contributions by more distant funders. However some authors devalue this geographic variable because online mechanisms can reduce economic frictions associated with financing in early-stage projects over long distances (Agrawal et al, 2011; Vulkan et al, 2016).

Consequently, we hypothesize that:

H4: Crowdfunding campaigns developed in Continental Portugal are more likely to be successfully funded than campaigns located out of Continental Portugal.

For some people supporting rural economy is essential to maintain the viability of rural populations. Rewards-based crowdfunding can be seen by some potential funders as valuable means of promoting the development of rural areas (Kim and De Moor, 2017). Crowdfunding can contribute to inclusion if is used for financing social projects (Austin et al, 2006; Gerber et al, 2012). However rural campaigns also can exacerbate the doubts of funders as they cannot easily follow the development of projects.

We distinguish between projects carried out in urban areas and projects carried out in rural areas based on the legal-administrative criterion in force in Portugal (Law No. 11/82, of 2 June). The category of city is conferred to towns that combine more than 8000 voters with a certain set of equipment and infrastructures.
Based on this distinction the following hypotheses will be tested:

H5: Crowdfunding projects developed in urban areas are more likely to be successfully funded than projects located in low population density regions.

3.3 Network and geography and project goal campaign

Literature suggests that influence of funding target on crowdfunding campaign success differs with model of crowdfunding. In reward-based crowdfunding most studies indicate that higher funding goals are negatively associated with success (Belleflamme et al, 2014; Cordova et al, 2015; Cumming et al, 2014; Kuppuswamy and Bayus, 2013; Mollick, 2014; Zheng et al, 2014). We believe that our networks variables can contribute positively to mitigating this impact in campaigns with higher projected goals. On the contrary the negative impact of our geography variables should be more pronounced with higher projected goals.

Consequently, we hypothesize that:

H6: Social networks variables have a greater positive impact on the success of rewards-crowdfunding campaigns with project goal ≥ €2000.

H7: Geography variables have a greater negative impact on the success of rewards-crowdfunding campaigns with project goal ≥ €2000.

3.4 Additional controls

We include two additional variables in our analysis to account other factors that might be driving success in rewards-based crowdfunding. We control for duration and communication quality of campaign.

The duration of crowdfunding campaigns is determined in advance. Typically long campaigns durations are associated with greater visibility of the project and consequently better performance. However also may argue that very long campaign duration may be perceived as lacking trust of founders. Results of empirical studies give reason for these two in perspectives. Zheng et al (2014) found that the duration of the campaign is positive related to success in rewards-based campaigns in China, while no significant relationship was confirmed for the United States. Other studies also found that larger project duration increases the chances of success in reward-based campaigns (Cordova et al, 2015, Burtch et al, 2014). On the other hand, the duration of the campaign is negatively related to success in studies conducted by Cumming et al (2014), Kuppuswamy and Bayus (2013) and Mollick (2014).

When starting a crowdfunding campaign on platform founders need to create project profile including a title, project description, target funding, campaign duration and rewards. Communication on the platform can be improved by inserting photos and video. Theories of communication have been employed to understand entrepreneurial fundraising (Ahlers et al, 2015; Plummer et al, 2015). In crowdfunding, producing a video demonstrates an indicator of a higher-quality project, since it signals at least minimal preparation (Mollick, 2014). Zheng et al (2014) indicated that the shared meaning of a crowdfunding project also has a positive influence on the success of the project. The shared meaning can be enhanced through a video project.

Parhankangas and Renko (2017) consider that key part of any crowdfunding proposal is a video pitch, in which the entrepreneurs present the project to be funded. By communicating effectively, founders can convince funders about their legitimacy and potential (Lounsbury and Glynn, 2001).

4. Data and model description

Data for the analysis is derived from the most popular crowdfunding platform in Portugal: PPL crowdfunding (https://ppl.com.pt/). This platform was founded in 2011 in Lisbon by four MBA students of different nationalities. PPL crowdfunding uses a rewards-based model where funders receive tangible, nonmonetary rewards for their contributions, often in the form of products / services, or tokens of appreciation such as thank you notes. The terms of funding follow an “all-or-nothing” model and its activity is accredited by crowdsourcing.org, the benchmark in the crowdsourcing and crowdfunding industry, according to CAPS (Crowdfunding Accreditation for Platform Standards). PPL is a founding member of the European Crowdfunding Network, whose main objective is to join efforts to promote this new tool at European level. In March 2018 the PPL crowdfunding website stated that since its inception €2731738 has been raised with 73805 individual contributions (€ 37 average support). In 1800 projects launched since its inception, 830 campaigns were funded in an average period of 49 days. The success rate in PPL is approximately 45%. On average, the projects financed raised € 2818. Until March 2018, the categories of initiatives that had raised a greater volume of funding were “Music” and “Social”.

The final dataset contains information on 340 PPL campaigns initiated and ended in 2017. Data were compiled from initial campaign descriptions and result appearing on the PPL platform after expiration of campaign deadline. In 340 campaigns 52.2% obtained the intended financing while 47.8% did not reach the project goal.

Using a binary logistic regression model our study investigates the factors driving a campaign's success. The dependent binary variable (1/0) is represented by the campaign crowdfunding status (success/failure). The classification of "success" was assigned in cases where the intended financing was obtained (or passed on).

They were classified as "failure" if the intended funding was not achieved. The independent variables used in this study are a mix of continuous and categorical variables. The definitions of the individual level model variables are given in Table 1.

The binary logistic regression model to test our hypotheses related to the factors driving a campaign's success given by:

$$\text{Ln}\ \frac{p}{1-p} = \beta\, 0 + \beta\, 1\, X1 + \beta\, 2\, X2 + \ldots + \beta\, k\, Xk$$

Where *p* stands for the campaign's success probability; $\beta\, 0$ is the intercept and $\beta\, i$ is the regression coefficient. In logistic regression the coefficients derived from the model (e.g., $\beta\, 1$) indicate the change in the expected log odds relative to a one unit change in X1, holding all other predictors constant. The beta coefficients are estimated through the method of maximum-likelihood method. Version 23.0 of the Statistical Package for the Social Sciences (SPSS) was used to analyze the logistic regression.

Table 1: Definitions of individual variables

Variables		Description	
Dependent variable	Campaign Status	Whether or not the campaign succeeded in getting the funding	= 1 denoting intended financing was obtained (or passed on); 0= stands not obtaining the intended financing
Independent variables (Networks)	Facebook Shares	Campaign Facebook shares	= Number of campaign shares made via Facebook (Log10)
	Project Comments	Comments about campaign	= 0 not receive comments; 1= receive comments
	Founders	Type of founder	= 0 Individual; 1= Organization
Independent variables (Geographic)	Geographic Distance	Project location	= 0 Out of Continental Portugal ; 1= Continental Portugal
	Project Region	Type of Region	= 0 Rural Area ; = 1 Urban Area
Independent variables (Control)	Duration	Campaign duration	= Number of months
	Communication Quality	Media used in communication	= 0 communication with just videos or photos; 1= communication with videos and photos

5. Results

5.1 Descriptive statistics

Table 2 shows some of the characteristics of the sample. Campaigns that received comments during the active period were on average more successful (75.8%) while those that did not receive comments only 34.2% achieved the amount funding goal (Chi2=56.774; p=.000).

Table 2: Descriptive statistics of categorical independent variables

Variable	Value	Successful	Unsuccessful	Total	
		Percentage	Percentage	Percentage	Frequency
Project Comments	Without Comments	34.2	65.8	55.0	187
	Receive comments	75.8	24.2	45.0	153
		Chi2= 56.774 p=.000			
Founders	Individual	48.4	51.6	45.6	155
	Organization	56.8	43.2	54.4	185
		Chi2= 2.047 p=.152			
Geographic	Out of Continental Portugal	47.8	52.2	20.3	69

Distance	Continental Portugal	54.2	45.8	79.7	271
		Chi2=.670 p=.413			
Project Region	Rural areas	59.3	40.7	50.6	172
	Urban areas	46.4	53.6	49.4	168
		Chi2=5.149 p=.023			
Communication Quality	Video(s) or foto(s)	46.4	53.4	39.1	133
	Video(s)+foto(s)	57.0	43.0	60.9	207
		Chi2= 3.103 p= .078			

The campaigns originated in individual founders (45.6%) and in diverse organizations (54.4%). The initiatives of individual founders had more failure than success (51.6% versus 48.4%). In the organizations the situation found is different: 56.8% of the initiatives were successful and 43.2% failed to obtain the target funding.

In the 340 crowdfunding campaigns of the sample, 79.7% were destined to projects located in continental Portugal, while a little more than 20% were intended to be carried out of continental Portugal. Half of the campaigns included in the sample were for rural areas and the other half for urban areas. However, 59.3% of projects targeting rural areas were more successful, compared to 46.4% of the counterpart (Chi2 = 5,149 p = .023). In terms of "communication quality" it is noted that about 60.9% of the campaigns on the platform were supported in images and videos. The use of only one of these means of communication is minority in the sample (39.1%). Campaigns that only used photos or video recorded a higher failure rate (53.4%) compared to campaigns that used a strategy of communication with videos and photos together (43.0%).

Table 3 shows several continuous independent variables that potentially differentiate the campaigns with the highest probability of success. We found that the most shared campaigns on Facebook achieved, on average, greater success than those that were less shared (Anova F 40.759; Anova p = 0.000). Unsuccessful campaigns also had a longer duration. The average duration of successful campaigns was 1.55 months versus 1.67 months of unsuccessful campaigns.

Table 3: Descriptive statistics of continuous independent variables

Value	Total	Successful	Unsuccessful	Successful	Unsuccessful	Anova-F	Anova-p
	Means	Means	Means	Std dev.	Std dev.		
Facebook Shares (Number Log 10)	1.8613	2.2071	1.4724	1.062213	1.05570	40.759	.000
Duration (months)	1.6123	1.5516	1.6806	.61598	.57334	3.965	.047

When the sample is split according to the project goal (cut 2000€), we get N1 subsample with 185 observations for Project Goal < €2000 and N2 subsample with 155 observations for Project Goal ≥ €2000.To be noted, the level of successful is significantly higher with project goals ≥ €2000 (Table 4).

Table 4: Descriptive statistics of dependent variable

(Crowdfunding campaign status)

	Frequency		Percentage	
	N1 Project Goal (< €2000)	N2 Project Goal (≥ €2000)	N1 Project Goal (< €2000)	N2 Project Goal (≥ €2000)
Successful	90	90	48.6	58.1
Unsuccessful	95	65	51.4	41.9
Total	185	155	100.0	100.0

5.2 Multivariate analysis

We obtained the matrix of correlations between the independent variables used in the model. Although some of the correlations are significant they are not high enough (none is higher than 0.5) to conduct to multicollinearity problems (Hair et al 1998; Sharma,1996). We also did not check values of VIF and Tolerance that indicated multicollineraty.

The logistic regression analysis proved to be a statistically significant model (difference test/chi square = 107.022, df = 7, p = 0.000). The result of the Hosmer-Lemeshow test (chi square = 12.173; df = 8; p = 0.144) confirmed that the model fits the data. The classification table indicates that the model correctly classifies 71.5% of cases. According to the Nagelkerke R Square, the dependent variable variance explained by the model is 36%.

Analysis of Table 5 enables identification of the significant Wald coefficients in four variables (p<0.05): Facebook Shares (H1), Project Comments (H2), Founders (H3) and Project Region (H5). These four variables (and control variable "Duration") are able to predict the success of reward-based crowdfunding campaigns.

Geographic Distance (H4) and Communication Quality also used in the model, are not significant determinants of the probability of the success of crowdfunding campaigns at the usual statistical significance (p<0.05).

Table 5: Determinants of campaign's success

Variable	Coefficient (B)	Wald Chi-Square	Exp(B)	p-value
Intercept	-1,324	5,318	,266	,021
Facebook Shares (Log number)	,600	23,276	1,823	,000(*)
Project Comments (yes)	1,929	49,092	6,886	,000(*)
Founders (Institution)	,611	5,027	1,842	,025(*)
Geographic Distance (Portugal)	,464	2,006	1,591	,157
Project Region (Urban areas)	-,701	6,855	,496	,009(*)
Duration (months)	-,531	4,477	,588	,034(*)
Communication Quality (vídeo+photo)	-,011	,002	,989	,967

(*) (p<0.01) (**) (p<0.05)

Prior to performing logistic regression of each of the subsamples, we carried out the previous procedures to eliminate the question of multicollinearity among the variables of the models used. Although some of the correlations are significant they are not high enough (none is higher than 0.6 in N1 and 0.5 in N2). We also did not check values of VIF and Tolerance that indicated multicollinearity. These results lead us to conclude that the question of multicollinearity does not arise among the variables of the models.

The logistic regression proved to be a significant model statistically in both subsamples (N1: difference test/chi square = 47.701, df = 7, p = 0.000; N2: difference test/chi square = 79.400, df = 7, p = 0.000). The result of the Hosmer-Lemeshow test (N1: chi square = 15.390; df = 8, p = 0.052; N2: chi square = 8.246, df = 8, p = 0.410) confirmed in both situations that the model fit the data. The classification tables indicate that the model correctly classifies in 69% of cases in N1 and in 76.8% of cases in N2. According to the Nagelkerke R Square, the dependent variable variance explained by the model is 35.6% and 46.5% respectively in N1 and N2.

We predict that networks (facebook shares, project comments and type of founders) would have the greatest positive impact in higher projects goal. Relative to geography variables (geographic distance and project region) our expectation was greater negative impact in higher projects goal. These assumptions would be supported if there was a positive relation and an increase in the explanatory power of each variable for Model 2 in relation to Model 1 (networks) and if there was a negative relation and an increase in the explanatory power of each variable for Model 2 in Model 1 (geography).

Table 6 presents the results of the logistic regression used to identify the factors that influence the probability of campaign success according Project Goal. It is clear that facebook shares have increased positive and significant effect on the probability of success when project goal ≥ €2000 (p= 0.001 to p= .000). When we looking at project comments, the results indicate that variable has same positive influence in two subsamples (p-value = .000). Unlike ours expectation, the results show that type of founders is important and significant just in projects with target < 2000 €. Our sixth hypothesis (H6) is therefore partially supported by these results.

It has not been confirmed that negative influence of geography increases in larger projects. On the contrary, project region variable loses its significance when the project goal is higher than 2000 €. These results suggest that hypothesis 7 should be rejected.

Finally, in relation to control variables, the quality of communication plays a significant role only in campaigns ≥ €2000 (p=.039). A cut in campaign target at 2000 € makes the duration of the campaign stop being significant in any of the subsamples.

Table 6: Determinants of campaign's success according Project Goal

Variable	Project Goal (< €2000)				Project Goal(≥ €2000)			
	Coefficient (B)	Wald Chi-Square	Exp(B)	p-value	Coefficient (B)	Wald Chi-Square	Exp(B)	p-value
Intercept	-1,195	2,627	,303	,105	-2,419	5,339	,089	,021
Facebook Shares (Number Log 10)	,697	11,113	2,007	,001(*)	,623	13,519	1,864	,000(*)

6. Conclusions

Previous studies investigated the success determinants of rewards-based crowdfunding campaigns were conducted mostly in the US and based on the world's largest crowdfunding reward platforms such as Kickstarter or Indiegogo. This research is developing at a fast pace and had essentially wide in its focus, allowing us to learned generically about what works and what does not work in this type of crowdfunding. Our study focused on less studied context (Portugal) and deepens this research by analysing the role of networks and geography in reward-crowdfunding success and examining potential differences according project goal.

First of all is important emphasize the high level of success found in the study. More than half the campaigns (52.2%) have achieved the project goal.

Our analysis confirms that the number of facebook shares correlates with the success of the project. This allows us to conclude that projects can be driven to success through social network. According results social networks can adequately complement the description of the campaign that a founder would give on a crowdfunding platform. As predicted in hypothesis 1 we have confirmed that crowdfunding projects with largest number of facebook shares are more likely to be successfully funded than projects with lowest number of shares. The influence of this variable is significant regardless of the campaign project goal but is even more relevant in smaller campaigns.

We also looked at the 'comments' on the success of the campaign. Comments received on the platform seem to have very significance in the success of the crowdfunding campaign, regardless of the project goal.

In hypothesis 3, we have tested if crowdfunding projects that were promoted by organizations are more likely to be successfully funded than projects whose founders were individual. Our hypothesis was confirmed. However the result showed that this is only true in campaigns with project goal < €2000.

Our results also found no correlation between geographic distance and successful financing. Crowdfunding campaigns relating to projects outside continental Portugal do not seem to exacerbate funders' doubts, perhaps because the nature of the campaigns leads them to believe in project development. The fourth hypothesis, which predicts that crowdfunding projects developed in Continental Portugal are more likely to be

successfully financed than projects located outside mainland Portugal, has not been confirmed. This conclusion is valid independently of the project goal.

We find that campaigns targeting rural areas are more successful than campaigns targeting urban areas, confirming our fifth hypothesis. This finding is new because this variable had not been tested before. However the influence of this variable is significant just in smaller crowdfunding projects.

Finally, we also looked at two controls variables on the success of the campaign. Our study found that duration of crowdfunding campaign is negatively correlated with its success. This significance was not confirmed when split the sample with cut-off at € 2000.The communication quality variable used in the study (video and photos) is not always correlated with success of the funding, contrary to what is found in other studies cited in the literature section. This variable predicts success only in the largest dimension campaigns.

With our study, we contribute to the literature on crowdfunding and funding success. We provide comprehensive view on the role of networks and geography explaining in rewards-based crowdfunding success. We extend the previous knowledge by the fact that both networks specific aspects and geography specific aspects have an influence on the question of whether a project is successfully funded and can thus be realized. We also found a different role of these variables according to the size of the project.

Taking together insights from the related literature and our findings, we put forward three conjectures: 1) the importance of networks for crowdfunding success suggests that founders need to build their networks before committing to campaigns; 2) In reward-based crowdfunding smaller projects carried out in less developed regions have a greater attractiveness of funders; 3) In larger projects communication quality is instrumental for crowdfunding success.

From a practical point of view, the results of our study are highly relevant for stakeholders on crowdfunding platforms. Project founders can make use of the results in order to improve the information related to their projects to increase the chance to have a project successfully funded. Our results are also relevant for crowdfunding platforms itself. These platforms might automatically assess the chance of successful funding of projects. Furthermore, platform operators could also suggest changes to founders whose project have been evaluated as potentially less successful.

More research is surely needed to assess the determinants successful of rewards-based crowdfunding. We present two suggestions: First, how do characteristics of the individual launching the crowdfunding campaign influence crowdfunding outcomes? Second, Founders generally broadcast crowdfunding appeals to potential investors using an online narrative. These narratives use a variety of media to encourage investment. How the content presented and media used interact to influence crowdfunding outcomes?

Abstract: Entrepreneurship was and is still one of the main pillars to address real economic changes in nations, especially in developing nations characterized by (1) the government inability to achieve remarkable growth in various areas(economic, social, technological, political… etc) , and (2) the high level of uncertainty and risk of investment in this still-growing economies. Firms and entrepreneurs thus face numerous challenges and are expected to be equipped with particular types of capabilities to survive and maintain competitiveness which is what Teece et al. (1997) labeled as "Dynamic Capabilities". Additionally, the entrepreneur must exhibit distinct ability to deal with these changes. This distinct ability could be attributed to numerous factors, but entrepreneurship cognition remains the dominant. Entrepreneurs implement many cognitive processes, yet, in dynamic market settings (characterized with high risk and uncertainty) specific cognitive processes remains more important than others. This current study accordingly will try to link between both firms' capabilities to deal with environmental challenges and entrepreneurs' cognitive abilities required in this process. It will shade light on the type of dynamic capabilities firms' need to deal with market dynamism and the role of the entrepreneurs' cognition in shaping these capabilities. It will provide a conceptual framework to identify the cognitive processes required by each type of the dynamic capabilities. It could be concluded that this paper will provide a link between the field of strategic management by focusing on capability development and the field of cognitive psychology and entrepreneurship by identifying the entrepreneur's relevant cognitive and mental processes contributing as a micro-foundation to the capability development.

Keywords: The Resource Based View, Dynamic Capabilities, Entrepreneurship Cognition, Entrepreneurial alertness, Cognitive Adaptability, Entrepreneurial Judgment

1. Introduction

Instability, new players, government inefficiencies, changes in consumer preferences, technological advancement and the need for innovation are just some of the numerous challenges entrepreneurial firms face in today's business world. This imposes risk and uncertainty on their operations (Teece et al., 2016; Teece and Leih, 2016).

Accordingly, firms are continuously adjusting and re-adjusting their business models, operations and practices to match, lead and benefit from these environment hostile conditions. In entrepreneurial context, this calls for further focus on continuous opportunity exploration and exploitation (Stevenson and Jarillo, 1990; Cuervo, 2005) to achieve long-term competitiveness.

In the field of strategic management, researchers have been always trying to answer the question of how firms could achieve a sustainable competitive advantage (Teece et al., 1997; Ambrosini and Bowman, 2009). The Resource Based View (RBV) is among the contributing views to this issue (Barney, 1991). Competitiveness is viewed as a factor of organizational resources and capabilities of specific characteristics (Barney 1991, 1995).

With the increased market evolution, resources are not enough to maintain competitiveness but the use of these resources is what differentiates between firms. The use, shaping and reshaping of resources is referred to as "Capabilities" (Penrose, 1959; Amit and Schoemaker, 1993; Eisenhardt and Martin, 2000; Felin et al., 2012). In hyper dynamic environment organizations tend to depend on a specific type of capabilities labeled as "Dynamic Capabilities" (Teece et al., 1997).

Due to their increased importance, scholars have been interested in understanding how these dynamic capabilities are developed in a firm and what could be the potential pillars affecting their existence. In general, capabilities are implicit and embedded firms' routines or practices (Harreld et al., 2007; Grewal & Slotegraaf, 2007), resulting from collective and teamwork (Helfat and Peteraf, 2003; Pandza et al., 2003) and they are

developed over time not over a single point of time (Amit and Schoemaker, 1993). Historical decisions and choices of the firm typically affect the path of capabilities development (Schreyogg and Kliesch-Eberl, 2007). The main decision makers in entrepreneurial firms are the entrepreneurs. Many entrepreneurial aspects affect entrepreneurial decisions but their cognition stands as one of the leading aspects. Research in entrepreneurship cognition has gained momentum over time trying to answer the question of "why" entrepreneurs pursue non-traditional cognitive paths (Mitchell et al., 2002).

Accordingly, the following paper provides an in-depth analysis of dynamic capabilities, their foundation and development, and explores the role of cognition in this process. It also contributes to the literature by providing an interdisciplinary approach that explains the phenomenon from different perspectives of neighboring disciplines which are strategic management, entrepreneurship and cognitive psychology. This paper further highlights the cognitive abilities required in the process of capability development in entrepreneurial firms. More substantially, this paper contributes to advancement in the research of dynamic capabilities and cognition by framing them into types (opportunity recognition and capitalizing capabilities for dynamic capabilities) and processes (alertness, cognitive adaptability, judgment for cognition). Additionally, the selected categorization of dynamic capabilities and the cognitive processes are relatively novel in the relevant management research agenda. For instance, cognitive adaptability is among the cognitive variables related to the study of dynamic capabilities, yet, still scholars have not yet tackled it from this perspective.

Additionally, the paper is proposing that cognitive adaptability with a specific type of dynamic capability could be a separate independent variable affecting its development and with another type, it could have a moderating effect.

2. The Theoretical Foundation

Dynamic environment usually imposes pressure on organization to alter its business practices and recently to redefine the main sources of its competitiveness. Many management practices and theories articulated firms' competitiveness among which is the Resource Based View (RBV). The RBV articulated by Barney (1991) assumes that competitiveness lies in both resources and capabilities (Penrose 1959, Wernfelt, 1984, Barney, 1991).

Cordially, firms started shifting their focus from being market and product oriented to strategizing for resources its acquisition, development and use (Wernerfelt, 1984). However, resources on its own are not enough for sustainable competitive advantage. Organizations should always consider their capabilities to better explore, use, re-use their resources (Penrose, 1959).

Organizational capabilities have had different labels across literature; some refer to it as collective skills, work routines (Winter, 2003) or firms' best practices. Working on defining capability was very generic in the early years, were some referred to as superior capacities or abilities (Wernerfelt, 1984), others described it as a "Process" that results from interaction between different resources over a period of time (Amit and Schoemaker, 1993). In 2000, Winter used "routines" a building block for capabilities (Felin et al., 2012).

Routines are "repetitive, recognizable patterns of interdependent actions, carried out by multiple actors" (Feldman and Pentland, 2003: 95). For him, capabilities are accumulated "routines" resulting from firms' inputs and management decisions. These routines result in capabilities, which lead to competitive outputs by the firm.

It worth mentioning that organizations' capabilities have different types, deployed based on the context.

Environmental Dynamism is among the contextual variables that call for a specific type of capabilities labeled as Dynamic Capabilities (Helfat and Winter, 2011). In 1997, Teece, Pisano and Shuen introduced the "Dynamic Capability Framework". This framework emerged to examine how competitiveness could be maintained or improved given the changing, "hypercompetitive" or "high-velocity" environment (Barreto, 2010). They defined dynamic capabilities as "ability" with the purpose to "integrate, build and reconfigure internal and external competences to address rapidly changing environment" (Teece et al., 1997: 510).

After Teece et al. (1997), Eisenhardt and Martin (2000) described these dynamic capabilities as "processes" and "routines" with the purpose to adapt to or even initiate environmental changes. These capabilities are different than other capabilities added that dynamic capabilities enable firms to modify its stock of resources and capabilities either through configuring and integrating the current base or adding new ones (Winter, 2003; Zahra et al., 2006). In 2007 Teece developed the comprehensive approach to define dynamic capabilities through its functions. He claimed that dynamic capabilities enable firm to *sense* new opportunities, *seize* and capitalize them and also *reconfigure* and orchestrate its resources and assets. Many categorizations for dynamic capabilities followed the work of Teece (2007). Among the recent are the one adopted by Wu et al. (2016). Embarking from focus on innovation, knowledge management and to match the entrepreneurial cycle, they divided dynamic capabilities into opportunity recognition and opportunity capitalizing capabilities.

Opportunity recognizing capabilities in the recent strategic literature are labeled as the "externally oriented" capabilities since they help organizations sense, scan and search the external environment for opportunities.

These capabilities result from the ability to detect and gain knowledge from the firms' external environment.

Accurate knowledge acquisition and gain depend on the firms' great effort and optimal speed in collecting and accumulating the knowledge (Zahra and George, 2002) which on its turn will allow firms to filter opportunities to select which to pursue. Additionally, like any other capabilities, when opportunity recognizing capabilities are shared among different departments, the more information is gathered which increase the probability of new innovations within the entire firm (Wu et al., 2016). Managerial process, organizational structure and managerial abilities should facilitate the integration of new knowledge in the firm to enhance firms' ability to sense the environment for new opportunities (Liao et al., 2009).

On the other hand opportunity capitalizing are "internally oriented" capabilities, because once the opportunity had been identified, organizations should do the necessary changes in terms or configuring reconfiguring resources to match the opportunity and the environmental changes (Teece, 2007) and this will eventually result in market acceptance of the opportunity. This could be done by altering organization structure, applying new management techniques and reshaping firms' networks (Wu et al., 2016). Additionally, Opportunity capitalizing capabilities are also related to knowledge management inside the organization, more specifically to knowledge integration from the external to within the organization and transfer of knowledge within the different parts of the firm (Wu et al., 2016; Liao et al., 2009).

3. Foundation of Dynamic Capabilities from an Entrepreneurship Cognition Perspective

Understanding dynamic capabilities as a phenomenon and its dimensions call for a "progressive scientific reduction" approach by examining its layers, components and what beneath. This is what scholars call analyzing the "micro-foundations" (Felin et al., 2012). It is claimed that dynamic capabilities are the outcome of different organizational routines (e.g. R&D, new product development) (Nelson and Winter, 1982).

Analyzing routines is found to be "vague" in the field of management (Felin and Foss, 2005). Consequently, to clearly define routines different views should be combined to reach a comprehensive understanding. Zollo and Winter (1999:12) defined routines as "stable patterns" for firms' ways to deal with "stimuli" whether internal or external. The pattern is the outcome of a systematic "organization-specific" ways of reaching a decision (Abell et al., 2008). This means that routines are formed by repetition (Pentland et al., 2012) and that is why it tends to be stable (Nelson and Winter, 1982). However, routines change, evolve or improve by time as continuous adoption of routines produce knowledge and a subsequent learning (Levitt and March, 1988). The change in routines and the ability to change the routines leads to the formation of capabilities and more specifically the dynamic capabilities (Pentland et al., 2012). Organizational ability to learn (which is necessary for capability and routines development) and integrate this learning is dependent on numerous micro factors, yet managers and their abilities to learn remain among the leading factors. On its turn, to acquire new knowledge and improve learning, individuals should possess certain skills and abilities referred to as "cognitive abilities".

The need to analyze the relationship between cognition and capabilities rise from the strategic nature of both concepts. Traditionally, it was assumed that capabilities are outcome of path dependent decision. This implicitly states that how people think and their cognition is the one of the mechanisms by which capabilities

are developed (Eggers and Kaplan, 2013). To link between both capability development and cognition, learning and knowledge must be tackled.

Entrepreneurs tend to develop mental modules to interpret, perceive and understand the surrounding environment (Porac, et al., 1989). These modules accordingly, serve as a filter for the type and genre of information managers or entrepreneurs collect, noting that this information serve as the input for decision making (Grewatsch and Kleindienst, 2017). The changes in this modules and structures result in individual learning (Easterby-Smith et al., 2000). Organizational learning is produced when the resulting learning from individual or group cognition becomes rigidly embedded in the organization. This embedment will be vividly viewed and illustrated in many organizational aspects such as its routines, policies, processes and strategies (Vera et al., 2011).

It is worth mentioning that organizational capabilities and especially dynamic capabilities allow the iteration of the learning process. Dynamic capabilities are the result of changes in routines. Changes in routines result from learning which was initiated by changes in cognition. Additionally, the changes in routines and the development of new capabilities help in the production of new knowledge which on its turn result in learning by allowing for the development of new routines (Easterby-Smith et al., 2000, Easterby-Smith and Prieto, 2008).

This could be concluded by claiming that (1)The study of micro-foundation of capabilities and especially the dynamic capabilities is fundamental for organizations as it shapes their strategic direction; (2) cognition; among other factors; stand as an essential micro-foundation for capability; (3) to better explore the relationship between cognition and dynamic capabilities, both constructs must be broke down into more illustrative aspects. Cordially, the upcoming conceptual model will analyze the micro-foundation of dynamic capabilities from a cognitive perspective and to be more specific cognition will be analyzed in terms of its processes and dynamic capabilities in terms of its types.

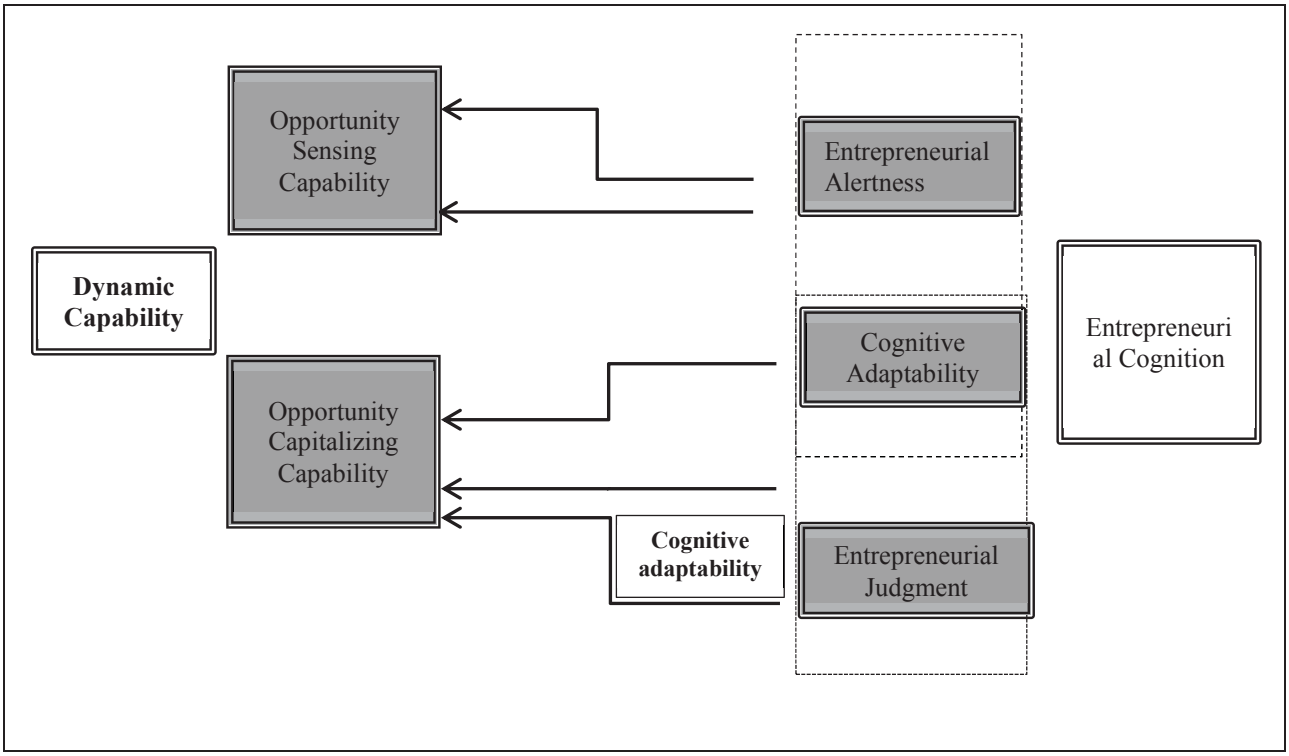

Figure 1: The Conceptual Framework

(Developed by the researchers)

The framework identifies the dynamic capabilities in terms of two types: opportunity recognizing capabilities and opportunity capitalizing capabilities. For the opportunity recognizing capabilities, the cognitive variables

claimed to have a role in its development are: entrepreneurial alertness and cognitive adaptability. First is *entrepreneurial alertness*. Opportunities are usually recognized through constant scan of the environment and industry structure (Dong et al., 2016, Teece, 2007; Helfat and Petraf, 2015). It requires entrepreneurs to actively search for information, interpret, make sense, build connection and recognize patterns within this information to shape and identify value creating opportunities (Helfat and Peteraf, 2015). Entrepreneurial alertness guides this sensing (Helfat and Peteraf, 2015), information search and recognition process (Kirzner, 1979). It was the answer to the question of how entrepreneurs interpret and schematize market event, what do they see that other do not and how do they see it (Gaglio and Katz, 2001). As cited in Gaglio and Katz (2001: 96) that alertness is "a distinctive set of perceptual and cognitive processing skills that direct the opportunity identification process". Accordingly, it could be proposed that High level of alertness as a cognitive process leads to the development of opportunity recognizing capabilities.

Alertness is the most comprehensive cognitive foundation for opportunity recognizing capabilities. in 2015 Helfat and Peteraf argued that perception and attention are the cognitive drivers for opportunity recognizing capabilities.

First for perception as a variable, it was tackled as function of perceiving something, for example, risk perception, self-perception…etc. in the field of entrepreneurship; the common function was perception of opportunity. As for attention, by examining the explanation of Helfat and Peteraf (2015) of attention, it was implied that the meant attention was to information, whether search of information, or the ability to be selective and pay attention to particular information. It is worth noting that the search also revealed that cognitive functions for opportunity recognizing capabilities revolve around: interpretation, perception, pattern recognition, sense making, schemas. These are all embedded in entrepreneurial alertness as defined by Tang et al. (2012). For them alertness is a cognitive ability, including three phases: alert scanning, alert association and alert judgment

Second is *cognitive adaptability*. Uncertainty is constant in today's business environment. It is how entrepreneurs learn, think and adapt and cope with this uncertainty that differentiate organizations. The field of entrepreneurship cognition had been pointing to this side of the entrepreneurs naming it "Cognitive Adaptability".

It is defined as "the ability to be dynamic, flexible and self-regulating in one's cognitions given dynamic and uncertain task environments". Cognitive adaptability allows entrepreneurs to adjust their learning and decisions based on feedback received from the environment (Haynie and Shepherd, 2009). Haynie and Shepherd (2009) tried to capture the main aspects of cognitive adaptability and claimed that it is the outcome of five main metacognitive mental activities which are: goal orientation, metacognitive knowledge, metacognitive experience, metacognitive choice and monitoring.

Metacognition represents the mental strategies individuals employ to think. It is considered as "high order" cognitive processes through which individuals self-regulate what they know about themselves, others and the environment to employ the appropriate cognitive functions. Cognitive adaptability process begins with analyzing an individual goal orientation and whether his cognition will be directed by personal or environmental goals (Haynie and Shepherd, 2009).

Then selecting which cognitive strategies (which provide the base for entrepreneurial decision) is a factor of metacognitive awareness, knowledge and experience. In a dynamic environment context, these metacognitive processes assist in rapidly and accurately evaluate opportunities and pursue the right ones. This is because entrepreneurs with high metacognitive awareness, knowledge and experience, knows their strength and the competence of their venture, understand the environment and its dynamics will deploy the correct cognitive strategies and cordially is more likely to pursue the valuable opportunities (Nambisan and Baron, 2012).

Furthermore, within each of these metacognitive processes, monitoring occurs for the individual cognitions during all previous phases (knowledge, experience and goal orientation) to re-evaluate the decisions and re-assess personal motivation for better cognitive adaptability to the environmental changes (Haynie and Shepherd, 2009).

In general, metacognition and the subsequent cognitive adaptability enhance opportunity spotting and recognition whether inside or outside the firm ecosystem. Accordingly, as clarified in the conceptual framework, it is proposed that high cognitive adaptability leads to the development of opportunity recognizing dynamic capabilities

Additionally, it could be claimed that entrepreneurial alertness and cognitive adaptability are complementary cognitive processes enabling opportunity recognition. On one hand, ,entrepreneurial alertness guides opportunity recognition (Helfat and Peteraf, 2015) by enabling entrepreneur to actively search for information, interpret them and recognizing patterns (Gaglio and Katz, 2001). On the other hand, cognitive adaptability provides the base and guide for these cognitive activities (information search, interpretation, and pattern recognition) by guiding entrepreneurial initial thinking strategies (Haynie and Shepherd, 2009). Subsequently it could be claimed that high cognitive adaptability accompanied with high alertness leads to the development of opportunity recognizing dynamic capabilities

As for the opportunities capitalizing capabilities, the relevant cognitive processes ought to have a role in their development are: entrepreneurial judgment and cognitive adaptability. First is *entrepreneurial judgment*. Once opportunities worth pursuing had been identified, entrepreneurs should decide on some internal or external changes needed to capture these opportunities (Teece, 2007; Wu et al., 2016). Entrepreneurial judgment is what guides the selection of these decisions and their prioritizing (Teece, 2007; Uygur and Kim, 2016)

The presence of opportunity capitalizing capabilities in firms leads to actual strategic change by undertaking strategic investment decisions and/or potential changes in firms' business model (Helfat and Peteraf, 2015).

Examples for those decisions could be new product development (Teece, 2007), restructuring and orchestration in firms' resources (Helfat and Peteraf, 2015) or structure or enhancing organizational learning (Wu et al., 2016). This induces that the cognitive processes employed by the entrepreneur within the development of these capabilities are decision making oriented. Literature had been narrow in clearly identifying these processes. Teece. (2007) stressed that the cognitive requirements for the capitalizing capabilities are entrepreneurs' ability to reach non-biased decision through his judgment. Uygur and Kim (2016) defined judgment as "the cognitive process in minds of the entrepreneurs that operates on the causal model, i.e. a knowledge structure concerning what factors they believe will help the chance of profitability under uncertainty". Entrepreneurial judgment guides decisions such as resource allocation (Casson, 1982; Foss and Klein, 2012) or reaching profitable investment decisions. Making these decisions especially in uncertainty is not guided only by rationalism and knowledge but rather by entrepreneurs' opinion and beliefs; which is labeled by entrepreneurial judgment. So as illustrated in the conceptual, entrepreneurial judgment; as a cognitive process; leads to the development of opportunity capitalizing dynamic capabilities framework.

Second is *cognitive adaptability*. Cognitive adaptability allows entrepreneurs to better understand themselves, the others and the environment to take the appropriate decisions. it helps them employ the right thinking strategies, collect the accurate needed information and cordially guide their selection and decision making process (Haynie and Shepherd, 2009; Mitchell et al., 2011; Nambisan and Baron, 2012). The opportunity capitalizing phase, entrepreneurs are left with many decisions to make to seize the opportunity. He needs to be selective and accurate in his selection of which changes to undertake and in which order. Entrepreneurs who are cognitively adaptable are claimed to be more selective and more confident (convicted) in the changes they undergo. That is why it is claimed that high cognitive adaptability leads to the development of opportunity recognizing dynamic capabilities

Finally, it could be claimed that cognitive adaptability leads to better judgment which results in the development of opportunity capitalizing capabilities in the firm. For entrepreneurs' judgments to be constantly accurate, and since the environment firms' operate in nowadays is complex and dynamic, entrepreneurs must have the cognitive ability to adapt their thinking based on feedback received from the environment. This cognitive ability is cognitive adaptability. Accordingly, high cognitive adaptability along with high entrepreneurial judgment leads to the development of opportunity capitalizing dynamic capabilities.

4. Conclusion

This paper tried to broaden understanding of the dynamic capabilities often labeled in management literature a black box. it shed light on its nature as organizational routines nurtured by organizational learning. Organizational learning is an outcome of applied entrepreneurial cognition. Accordingly, it could be claimed that entrepreneurship cognition is among the main contributors in founding those dynamic capabilities. Yet, in entrepreneurial firms, these capabilities could be classified based on nature and function. Some capabilities help in opportunity recognition and other in opportunity capitalizing. Each type implies different organizational routines and work practices and cordially are nurtured with different cognitive processes. Entrepreneurial alertness and cognitive adaptability are claimed to be related to opportunity recognition capabilities. This is because alertness allows entrepreneurs to see what other over looked and cognitive adaptability provide them with the flexibility to alter their mental models based on environmental changes and thus clearly see opportunities. Furthermore, opportunity capitalizing capabilities are affected by entrepreneurial judgment as it helps entrepreneurs in deciding on many crucial aspects and changes required to seize the opportunities. Additionally, it could be claimed that judgment is enhanced with the existence of cognitive adaptability, leading to the development of opportunity capitalizing capabilities. For future research, it recommended to enlighten this research area through testing the above developed model to test its validity and the accuracy of its assumptions.

Abstract: Innovation in tourism has been receiving increased attention in the last decades, especially in what concerns networked innovation processes. This has gained increased relevance in tourism, an industry made of SMEs that resort to networks to obtain competitive advantages when developing new products and services. Thus, it is fundamental to analyse the networks' structure and how it can improve innovation performance. While social capital theories mainly address how it can be used to improve the whole network, other theories focus on how individuals can use social capital to obtain better competitive positions, or how the absence of ties between nodes defines the network structure and the opportunity to build social capital. Structural holes theory analyses the absence of ties between nodes in a network and how they can be connected by a broker, who will gain control over resources and highly increase his social capital. This paper aims at identifying and comparing the different types of brokers in two tourism destinations' innovation networks (Douro and Aveiro, Portugal). In addition, it relates both the network structure and the individual position of tourism organisations, to the innovation performance of those destinations. This is accomplished by applying sociometric analysis to the innovation networks. Results demonstrate that different social structures and patterns of cooperation bring diverse impact on the innovative performance of tourism destinations. Conclusions advance recommendations for tourism organisations to increasingly contribute to tourism regions' innovative performance.

Keywords: Innovation networks; tourism; structural holes; innovation performance; Portugal

1. Introduction

Innovation in tourism has been receiving increased attention in the last decades, especially in what concerns networked innovation processes. It is widely acknowledged that, nowadays, innovation emerges mainly within collaborative arrangements, instead of being developed in an atomist way by organisations. If this is relevant for most industries, it gains increased relevance in those made entirely of SMEs that resort to networks to gain resources and competitive advantages when developing new and integrated products and services (Costa et al., 2008, Acs and Audretsch, 1988, Fernandes et al., 2017, Vonortas, 2011).

However, not all network dynamics and structures foster a positive innovation performance. Different configurations will result in distinct tourism innovations, whether in its nature, or impact (Brandão et al., 2018, Scott, 2013). Bearing this in mind, several streams of research have been analysing the most 'innovation-friendly' network structures. Social capital theory (Coleman, 1988, Putnam, 2000) focuses on how it can be used to benefit the entire network. Other lines of thought concern with how individuals can use that social capital to obtain better competitive individual positions, or how the absence of ties between nodes defines the network structure and the opportunity to build social capital. This is the case of structural holes theory (Burt, 1992, Burt et al., 2013), on which this research is based. Structural holes refer to the absence of connections between actors in a network. If these gaps are filled by an actor (broker), in theory, he will have a better and more powerful competitive position, controlling resources, knowledge, and information. Being these the basis of the development of innovation (Lundvall, 1992), it may be concluded that these actors play a significant role in the development of innovative ideas in tourism destinations. This paper aims at identifying and comparing the different types of brokers existing in two tourism networks (Douro and Aveiro, Portugal), and relating both the network structure and the individual position of tourism organisations, to the innovation performance of the destinations. This is accomplished by applying sociometric analysis, namely centrality, structural holes, and brokerage measures, to the networks of tourism organisations. Results demonstrate that different social structures and structural positions bring diverse impact on the innovative performance of tourism regions. This allows to advance recommendations for tourism organisations to increasingly contribute to destinations' innovation and competitiveness.

2. Networks in tourism innovation

The evolution of innovation models demonstrate that the practice of innovation in firms started from linear, sequential and atomistic processes developed entirely within the scope of the firm, towards the most recent models in which firms, in order to be successful, develop their innovation in a networked environment, with strong patterns of cooperation not only with other businesses, but also suppliers, customers, universities, research centres, etc. (Rothwell, 1994, Chaminade and Roberts, 2002). Nowadays, *"(…) more and more of the innovation process takes place through networking rather than through hierarchies and markets. (…) only a small minority of firms and organisations innovate alone, and that most innovations involve a multitude of organisations"* (Lundvall and Borrás, 1997:106). In tourism, both theory and practice acknowledge the same phenomenon. As Sundbo et al. (2007) argue, innovation in tourism *"requires networks and co-operative systems*" and, in this context, territories assume a paramount role, as tourists arrive to a destination to consume an integrated experience, which makes firms mutually dependant when developing common destination innovations.

Networks may be defined as *(…)*

> *organisational structures whose operating philosophy may be placed between Weber's bureaucratic model and the neoliberal or market philosophy. Networks are based on two or more (usually administrative independent) organisations which decide, by a formal or informal commitment, to engage in a medium- or long-term cooperation process involving the exchange of products and services (…). A network is, therefore, underpinned by the premises that every organisation depends on the success of others and also that competition must be viewed beyond the region where an organisation is located*" (Costa, 1996:148).

Tourism is fragmented in its nature, comprising distinct, but complementary activities, creating integrated experiences in destinations. It is geographically dispersed, because origin and destination areas are distant, and resources are used jointly as they are 'free'. In this context, networks provide important benefits, as they compensate this segmentation in bringing together tourism stakeholders and providing tourist with comprehensive experiences. Moreover, tourism business environment is turbulent and very competitive, meaning that growth or even survival of firms might depend on collective action (Scott et al., 2008). This comes in line with the thoughts of Porter (1990), who insists that it is competition associated to cooperation (and not monopoly) that fosters growth and innovation. However, he agrees on the specialisation argument: knowledge spillovers will favour innovation in specialised and geographically concentrated industries, such as tourism. The cluster approach advocated by Porter emphasises market and competition above networking and social interaction as success factors for innovation in clusters. This concept is strongly linked to Porter's "diamond model" of competitive advantage, which can be used to assess the overall quality of a business cluster. The diamond encompasses the determinants that influence competitive advantage: (i) factor conditions (production), (ii) firm strategy, structure, and rivalry; (iii) demand conditions; (iv) related and supporting industries; (v) government and chance (as additional determinants). The intensity of interaction within the diamond is increased if firms are also clustered or geographically localised (Porter, 1990). Tinsley and Lynch (2001) acknowledge that networks are the frameworks that bind the place and people together, going beyond the destination to regional, national, or even international levels.

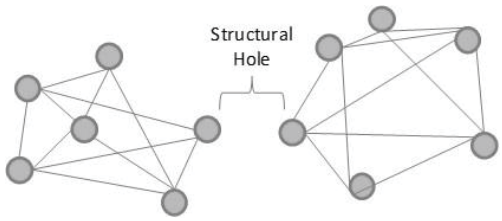
2.1 Structural Holes

The social network approach to organisations embraces several concepts and streams of study. *Social capital* is a growing research stream in organisational network studies (Borgatti and Foster, 2003). Popularised by Coleman (1988), it addresses the advantages and benefits that individuals get from the relationships established within a network, improving the entire structure. Burt (1992) concerns with how individuals can use social capital to obtain better competitive positions within the social structure. Kilduff and Tsai (2012) refer that one of the most fascinating streams of research within social networks is that of how the absence of ties between nodes defines the network structure and the opportunity to build social capital. This leads to the analysis of a fundamental concept within social networks: *structural holes*.

Structural holes are gaps in a social structure, or the absence of ties between nodes in a network (figure 1).

These nodes can be connected by a broker, who will gain control over the flow of resources across the gaps.

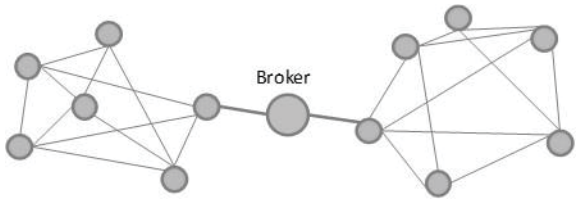
Brokers highly increase their social capital by linking two otherwise disconnected nodes, cliques, or even entire networks. In this line of thought, social capital is created within a network by structural holes, as actors can broker connections between formerly disconnected nodes (figure 2), having privileged access to information and control over the projects that bring together actors from different sides of the hole (Burt, 1992, Burt et. al, 2013).



Source: own elaboration

Figure 1: Representation of a Structural Hole

These individuals leverage their investment in social relations by connecting with different groups, achieving a powerful and competitive position (Burt, 1992, 2001). Conversely to Coleman's (1988) understanding on the most fruitful network structure for the creation of social capital (which relies on network closure), Burt considers that it is rather a function of brokerage opportunities that emerge from structural holes. Thus, structural holes are defined as *"the separation between nonredundant contacts. (…) is the relationship of nonredundancy between two contacts. (…) As a result of the hole between them, the two contacts provide network benefits that are in some degree additive rather than overlapping"* (Burt, 1992:18).

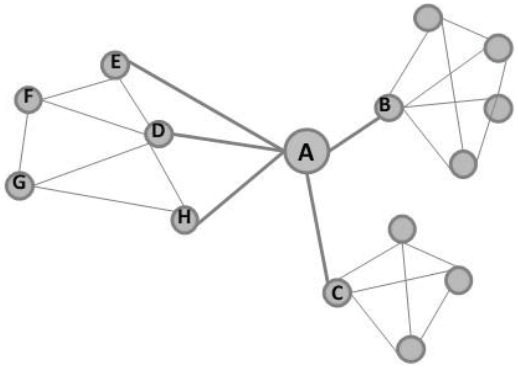


Source: own elaboration

Figure 2: Representation of a Broker

Brokers bridge structural holes, recognised by the lack of cohesion or of equivalence among actors. Brokers achieve a unique combination of information fostering innovative potential that is difficult to imitate because it emerges from social ties, rather than from training or position.

This theory embraces two categories of benefits that individuals fulfilling structural holes can achieve: information and control benefits. These individuals profit from the disunion of others. Brokers have greater access to information, improved response time to opportunities, access to novel information earlier, control and ability to negotiate the social relations because they are placed between two players who seek for the same information or between two players in two or more relations with conflicting demands (Burt, 1992:30-31).



Source: own elaboration

Figure 3: Structural advantage of a node within a network

In Burt's perspective, the more structurally constrained actors (those having small, dense, and closed networks with few or indirect ties) are less likely to attract new partners, as they offer lower returns, have reduced

access to new information and are engaged in a routine behaviour that does not favour innovation. Large, diversified, sparse and open networks stimulate creativity and innovation as they provide the access to varied information and do not constrain members, thus fostering innovative practices. As exemplified in figure 3, node A's bridging role in the social structure provides it with structural advantage over node D, despite it is in the centre of a tightly-knit clique.

Following these ideas, Burt argues that the spanning of structural holes provides the mechanism that relates weak ties to positive outcomes in Granovetter's *Strength of Weak Ties* theory (Granovetter, 1973). The strength of a tie is a function of the "*amount of time, the emotional intensity, the intimacy (mutual confiding), and the reciprocal services which characterise the tie*" (Granovetter, 1973:1361). The underlying argument is that someone's acquaintances (weak ties) are less likely to be socially connected with one another than his close friends (strong ties). The actor's set of acquaintances comprise a low-density network (where many of the possible ties are absent, i.e. presence of structural holes) because it is unlikely that they know each other.

Conversely, the same actor's network of close friends is densely connected. Weak ties between a node and his acquaintances are crucial bridges between two dense cliques of close friends that would otherwise be disconnected. Granovetter's theory asserts that individuals with few weak ties will be deprived of information from distant parts of the social system and are thus confined to marginal information from their strong ties (Granovetter, 1973). This has significant impacts on innovation, as it diverts those nodes away from new knowledge underlying innovation. The geographic location is important to this discussion. Considering that different locations originate cultural differences, the ideas created and shared by a specific group will probably be entirely new for a network located elsewhere (Granovetter, 1983). Bearing this in mind, the author argues that weak ties between networks from different regions or countries perform an important mediating role by providing the necessary channels to knowledge and innovation diffusion, preventing the lock-in effect.

2.2 Brokerage

Brokers are bridges that fill in gaps or structural holes in a network, i.e. they connect nodes that would otherwise be disconnected. Thus, they have higher control and power over other nodes, as well as access to several types of resources, information, and knowledge. According to Burt (2004:349), "*people who stand near the holes in a social structure are at higher risk of having good ideas*" and therefore have a crucial role in the development of regional level innovation.

Individuals that act as brokers may play different roles types. Depending on where the actor lies on the path between two other actors and the type of relations with its neighbourhood, there are five possible combinations that resulting in different types of brokers, as presented in table 1. The existence of structural holes provides the opportunity to access to new and wider sources of knowledge and to control its flow within the network. Brokers are thus in powerful positions, despite having high or low centrality. They have rapid access to resources, fast dissemination of information regarding opportunities and threats, they benefit from cooperation, and are able to identify possible exchange partners and allies (Burt, 1992, Uzzi, 1996).

Table 1: Types of Brokers

Type of Broker	Characteristics	Graphic
Coordinator	Connects actors from the same group.	Consultant	Connects members of the same group, but he does not belong to that group.	Gatekeeper	Member of a group who is at its boundary and controls access of outsiders to the group.	Representative	Controls access of his group to outside actors. He is the contact point of his group to outsiders.	Liaison	Mediates the relation between two groups and does not belong to either of them.

3. Research Methods

This research aims to unveil the structure underlying tourism innovation networks, specifically the dynamics related to structural roles and brokerage positions occupied by tourism organisations, within tourism networked innovation processes. To achieve this, an empirical study was conducted, di8rected at regional organisations that are on the interface of tourism innovation.

The study was conducted in two destinations (Aveiro and Douro, Portugal), so that a comparative analysis can be made. The selected destinations are in different development stages, offer distinct tourism products, and attract different markets. Resorting to Malerba's (2005) definition of regional innovation systems and the legal composition of Portuguese Regional Tourism Boards, fifteen organisations were identified in each destination.

Data was collected by a questionnaire with the objective of gathering relational information, i.e., which organisations establish mutual ties within tourism innovation processes.

A set of metrics developed by Burt (1992) allows to understand how and why an actor's connections affect his constraints and opportunities, namely: i) the *effective size* of the network, or the number of non-redundant contacts.; ii) the *efficiency*, or the effective size divided by the number of alters in ego's network, informing whether the proportion of ego's ties to its neighbourhood is "non-redundant"; and iii) the *constraint*, which measures the extent to which ego has invested in people who have invested in other of ego's alters (Hanneman and Riddle, 2005). These metrics were computed using the software UCINET 6.

4. Results

In order to fulfil the research objectives, it was important to know the innovation performance of both regions.

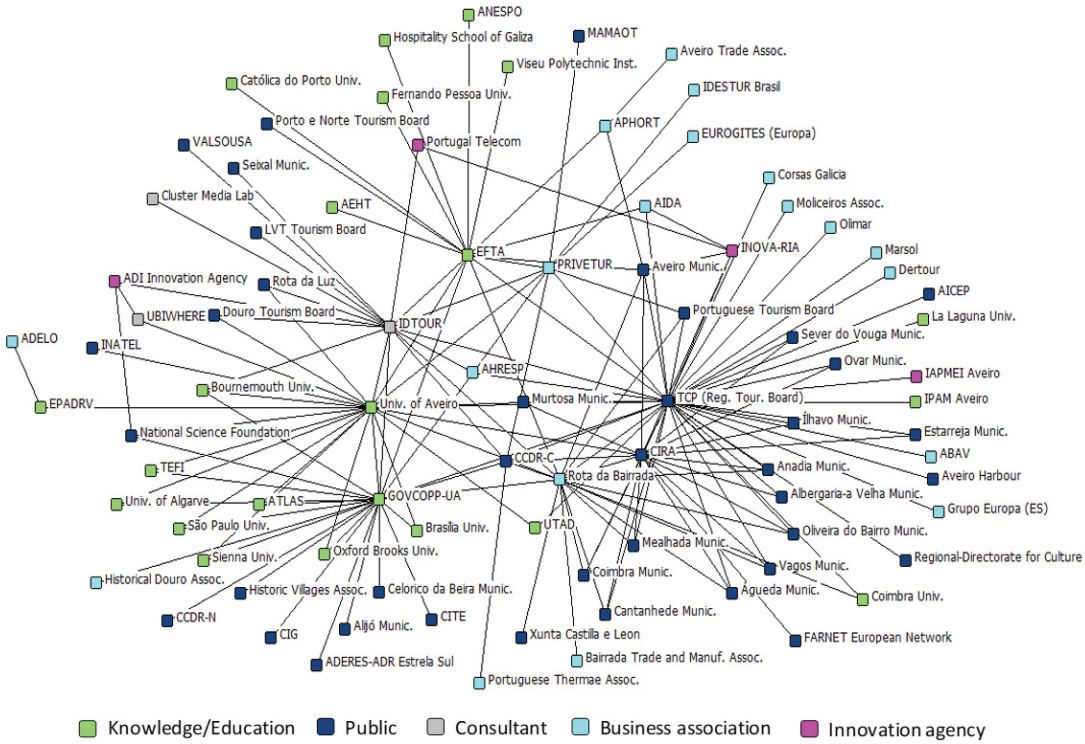
In a complementary study, the number and type of innovations introduced by tourism firms was surveyed.

Results demonstrate that Aveiro presents a higher innovation performance, as 84.4% of the firms are innovative, against 77% in Douro. Aveiro has also a higher rate of firms developing tourism products that are entirely new to the market (56% in Aveiro; 43.7% in Douro). In the light of these findings, further conclusions regarding the structural roles and positions can be drawn.

4.1 Structural holes

The analysed networks present very different structures. Aveiro's network comprises 87 actors connected by 314 ties. It has a density of 4.2% and a centralisation degree of 44.5%. It is characterised by the diversity of its actors, regarding both their geographical scope, and the type of organisations. The most central actors (those with a higher number of ties) are public organisations: the Central Portugal Regional Tourism Board (RTB), the Association of Municipalities of Aveiro (AMA), and knowledge organisations, namely the University, its Research Centre (RC), and IDTOUR (tourism spin-off), as represented in figure 4. Being the most central nodes, these actors are the most prominent in regional tourism innovation. The network of Douro includes 55 actors and 127 ties, resulting in a density of 9.2% and a centralisation of 69.2%, meaning that power is more concentrated in a few actors (those with higher centrality), which are public organisations, namely the Douro Tourism Board (DTB), the Association of Municipalities of Douro (AMD) and the North Coordination and Development Commission (decentralised body of central government for regional planning), as depicted in figure 5.

Figure 4: Sociogram of Aveiro's Tourism Innovation Network



In the innovation network of Aveiro, ten actors stand out due to their higher number of nonredundant contacts (table 2 and figure 4). The RTB, the RC and the University of Aveiro are simultaneously the most central, and the most efficient actors, which means that the impact that they are getting for each unit invested in using ties is high. Efficiency is large to the extent that an actor's alters are connected to different third parties. The efficiency of RTB is of 93%, followed by the RC with 91% and the University of Aveiro with 89%.

These ten organisations are also the less constrained actors, that is, they are endowed with a higher freedom of action within the network and lower dependence on their alters. This metric ranges from zero when the node has numerous disconnected, readily replaceable links, to one when the actor has only one effective link and hence is highly constrained. Results demonstrate that the RTB, the vocational school, RC, IDTOUR and the University of Aveiro are the less constrained actors in the network. It is also worth highlighting that there are actors that, despite not being central, have a significant role in filling structural holes and thus have important roles in the generation of regional level innovation in tourism, which are the Bairrada Wine Route, Privetur, the CCDR-C and INOVA-RIA.

In Douro, there are fewer actors presenting relevant structural holes measures when compared to Aveiro (table 3 and figure 5). Eight organisations stand out for their effectiveness. The first one is CCDR-N, with 37.2 nonredundant contacts. This actor's counterpart in Aveiro's network (CCDR-C) has a significantly lower value, with only 4.1 nonredundant contacts. These results confirm the importance of this public agency in the development of Douro as a tourism destination, especially in what relates to the support of tourism innovation based on collaboration patterns. DTB has an effective size of 34.5. However, it is more efficient than CCDR-N (0.93 against 0.91) and less constrained (0.10 for the DTB and 0.13 for CCDR-N). In the third place, with an efficiency of 0.9 and 21.7 nonredundant contacts, appears the Association of Municipalities of Douro, followed by Douro Hospitality School (effective size of 11.9 and efficiency of 0.8).

Table 2: Structural holes' measures for the tourism innovation network of Aveiro

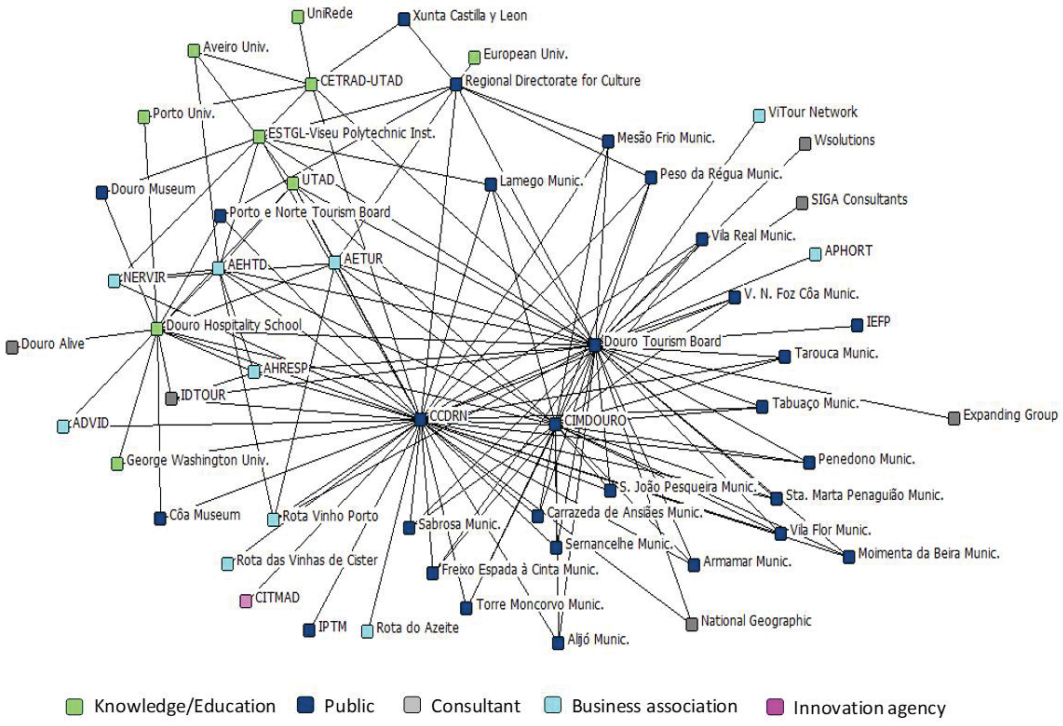
Actors	Degree	Effective size	Efficiency	Constraint
Centre Regional Tourism Board (RTB)	41	38,3	0,93	0,08
Research Centre (GOVCOPP-UA)	24	21,9	0,91	0,10
University of Aveiro	23	20,4	0,89	0,12

Association of Municipalities of Aveiro (AMA)	20	17	0,85	0,20
Actors	**Degree**	**Effective size**	**Efficiency**	**Constraint**
Bairrada Wine Route	19	15,3	0,80	0,16
IDTOUR (spin-off)	17	14,2	0,83	0,11
Vocational School	16	13,9	0,87	0,09
PRIVETUR (Rural Tourism Association)	10	7,8	0,78	0,15
Centre Coordination and Development Commission (CCDR-C)	7	4,1	0,59	0,19
INOVA-RIA (Innovation agency)	5	3,4	0,68	0,29
Whole network	*87*	*245*	*0,79*	*0,69*

The remaining organisations present inferior values, especially when compared to the actors placed at the lower places of Aveiro's ranking. The knowledge organisations do not stand out in Douro. The exception is the research unit that, despite not being very effective is, in fact, efficient, reaching 0.92 (it is important to note that an actor can be efficient without being effective, and the opposite is also true). In Aveiro, knowledge producers are within the most relevant organisations bridging structural holes.

Another interesting conclusion relates to the fact that two private business associations, namely AEHTD and AETUR seem to perform an important role at this level. Despite their lower effective size due to the reduced number of nonredundant contacts, they present an acceptable level of efficiency (respectively, 0.64 and 0.63) and of constraint (0.20 and 0.22).

Figure 5: Sociogram of Douro's Tourism Innovation Network



In addition to the organisations ranked as the most significant, one should highlight the role of the University of Aveiro also in the Douro network since it presents an efficiency of 0.78, which places it at the fifth position of the efficiency ranking, although it comprises a different network and plays a central role in the innovation network of a different region. Even though the analysis is not made to both networks together, it may be concluded that the University of Aveiro is at a privileged position as a broker, as it connects both networks.

Table 3: Structural holes measures for the Douro tourism innovation network

Actors	Degree	Effective size	Efficiency	Constraint
CCDR-N	41	37.2	0.91	0.13
Douro Tourism Board (DTB)	37	34.5	0.93	0.10
Association of Municipalities of Douro (AMD)	24	21.7	0.90	0.14
Douro Hospitality School	15	11.9	0.80	0.16
Regional Directorate for Culture	9	6.8	0.75	0.19
CETRAD-UTAD (research unit)	7	6.4	0.92	0.16
AEHTD (Association of Hotels)	10	6.4	0.64	0.20
AETUR (Tourism Firms Association)	8	4.5	0.63	0.22
Whole network	*55*	*202*	*0.70*	*0.49*

If the whole network structure is considered, the average results demonstrate that Aveiro is more efficient that Douro, with 79%, against 70%, respectively. This also occurs due to the effective size of both networks: Aveiro has a total of 245 nonredundant contacts, while Douro presents only 202. However, Douro is less constrained (0.49) than Aveiro (0.69), endowed with a higher freedom of action and less dependent on other actors (tables 2 and 3).

When highly connected actors present a significant effective size, they will have privileged access to new and diverse knowledge and information, which may improve innovation performance at destination level.

Subsequently, their efficiency will also reflect these conclusions, as they are probably the most efficient actors.

It is demonstrated that they are also the less constrained. These organisations have an important position and thus should play an important role in the network's innovation performance: they should assume the responsibility of disseminating the information, knowledge, and resources that they receive throughout the network, or at least assure that it flows through the proper channels until reaching the adequate receivers. For that to happen, there should be a strong internal cohesion and collaboration towards the development of innovative tourism products and services.

4.2 Brokerage roles

To analyse the brokerage roles, actors should first be classified into different groups. For the purpose of this work, and considering the relevance of the territory and the embeddedness of relationships in tourism innovation, brokerage among actors from different geographical levels is analysed. Therefore, actors were classified as local; regional; national/other Portuguese regions; and international.

The local actors of the Aveiro network comprise mainly municipalities, which have a minor importance as brokers, except for the municipality of Aveiro which acts 14 times as consultant (connecting members of the same group, other than the one it belongs to). However, the most important local broker is IDTOUR (spin-off), not only for the total number of times it performs this role (224), but also because it acts as a liaison (122 times), mediating the relations between two groups and not belonging to either one of them, as a consultant (66 times), as a representative, and as gatekeeper (16 times for each). This performance places the firm as the 6^{th} most important broker in the network.

Regional organisations comprise the most dynamic group and the most important brokers. The RTB is the most relevant, playing the five different types of brokerage, 1530 times, mainly as a liaison (428 times). Despite presenting a high value as coordinator (linking regional members), it is where it is less relevant (128 times).

The research unit and the University of Aveiro stand at second and third places acting, respectively, 502 times and 446 times as brokers. They are brokers at all five levels, being the liaison role the most relevant for both. It is, however, worth to observe that being both knowledge producers, the research unit assumes a higher importance as consultant, and the university both as gatekeeper and as representative, with 102 times for each role. Despite creating new knowledge, it is also a vehicle for the access of local and regional actors to

knowledge from outside the system. When analysing the brokerage roles of actors at national level or from other Portuguese regions, one may conclude that the majority is irrelevant. The only one that stands out is PRIVETUR, acting as liaison. Finally, international actors do not perform any role as brokers

Even though the innovation network of Aveiro includes less brokers than Douro. Douro has three or four actors that are the most relevant brokers, while in Aveiro there at least seven nodes with high importance in linking otherwise disconnected actors. Concerning the connection of actors from different geographical locations, the Central Portugal Regional Tourism Board is especially relevant in establishing relationships among local organisations and between local and regional, and local and international ones. It may be considered as the main gateway for providing new links for local tourism organisations. The research unit mainly brokers the relations among national actors and between national and international tourism organisations. On the other hand, the University of Aveiro mediates important links of regional to international actors and it also links international nodes among themselves, which places it as a very important element of access to new international knowledge and resources. AMA and the Bairrada wine route, due to their nature of association of local municipalities and firms, intermediate the relations among these actors. The spin off performs its brokerage role by connecting regional with national actors and national among themselves. The proportion of brokers in the tourism innovation network of Aveiro is lower than Douro's, as only 23% of its actors perform this role (20 nodes out of 87).

In Douro, local actors do not perform significant roles as brokers. The local group mainly comprises municipalities, which act exclusively as consultants. This means that they connect actors from regional, national, or international levels. They are in advantageous positions, as they can access new knowledge and resources from different locations, which may increase innovation levels. However, the number of connections is very low for all actors, as each one only acts as broker 2 times, except for a few municipalities that have a significant importance as tourism destinations in Douro, when compared to the overall region.

The most relevant dynamics in terms of brokerage occurs within the regional group. CCDR-N plays the five different types of brokerage 1484 times, especially as gatekeeper (368), representative (368) and consultant (346). This public agency can connect members from other geographical levels, controls the access of "foreigner" actors to regional actors and acts as the contact point of regional actors to local, national, and international actors. This organisation is, thus, at an extremely powerful position within the tourism innovation dynamics of Douro. The DTB presents a similar position by performing all five types of brokerage 1238 times. Although, the consultant role is the one that stands out (428 times), followed by the gatekeeper (260) and representative (260). It is also worth referring, at regional level, that the AMD acts as broker 496 times, mainly as consultant. The Regional Directorate for Culture, AEHTD, CETRAD, AETUR, the Polytechnic Institute and the University are also relevant brokers within the regional group.

Considering the actors that play the most relevant roles as brokers, it is interesting to understand at which geographical levels their action is more significant. DTB is especially important for the connection among local actors, between local and regional actors and between local and regional actors with international ones. CCRDN presents a very similar pattern, though it has a higher intervention in connecting regional actors among themselves. AMD acts mostly at local and regional levels, and Douro-Lamego Hospitality and Tourism Training School stands out for acting as a broker among regional actors, and of these with national and international ones.

Out of the total of 55 nodes that comprise the tourism innovation network of Douro, 37 (67, 3%) are brokers.

The brokerage type that is more played in Douro is the consultant (1178 times). It is also interesting to analyse this from a geographical perspective. Despite the lower importance of national and international nodes, they should not be despised, as they may introduce novelty and fresh knowledge in the network which, when considering the internal cohesion and density of this region, will rapidly and efficiently spread throughout the entire social structure and promote tourism innovation processes developed in cooperation.

5. Conclusion

The purpose of this paper was to analyse structural holes in tourism innovation networks, to identify and compare the different types of brokers, and to relate both the network structure and the individual position of tourism organisations, to the innovation performance of the destinations.

In order to do so, two distinct Portuguese destinations were studied (Aveiro and Douro). The main findings reveal that, in general, the most central actors, i.e., those assuming higher prominence in regional tourism innovation processes, are also those who perform the most significant brokerage roles. They have access to more information, knowledge, resources and exert more control and influence over other actors, as they can reach a larger number of individuals. They are also less dependent on a few specific actors. Therefore, they are in an advantageous position for knowledge acquisition and sharing and to promote collective learning, which are fundamental processes underlying innovation. It may be thus concluded that in Douro, regional tourism innovation is mainly supported by public organisations, while in Aveiro, beyond them, knowledge producers play an equally significant part.

Results also demonstrate that Aveiro is a more efficient social network as it is endowed with less redundant contacts. The investment of time and energy in creating and nurturing relations is thus well directed. This type of structure creates space for the emergence of structural holes that are occupied by brokers that inject new and fresh knowledge in the network, which reveals to be more advantageous for the development of innovation. Considering that Aveiro has a higher performance in terms of tourism innovation, it may be concluded that a larger number of non-redundant contacts and the existence of different types of brokers mediating the knowledge and information has a positive impact on the innovation performance of the destination, but also on the prominent role of these brokers that are simultaneously the most central actors. In addition, the brokerage with a significant number of international actors also brings a positive impact to networked innovation, a scenario that is particularly relevant in Aveiro when compared to Douro.

Abstract: When a small business focuses on growth the one of its main topics is to find personnel who will enhance the growth. Earlier studies indicate that in many fast growing small to medium enterprises the main problem is finding and retaining high quality employees (e.g. Atkinson and Storey, 1994; Fraza, 1998; Hornsby and Kuratko, 1990). Knowledge of HR and leadership might help owner in personnel issues, because growth entrepreneurs must begin to increase their staff and learn how to develop and implement human resource management (HRM) policies. The faster the growth is facing the small firm, the more likely it will experience HR problems. This empirical study focuses on 29 Finnish growth-oriented entrepreneurs' views about HR related issues. They were asked about challenges of growth, what kind of skills they would need, and also what kind of HRM they are using in order to retain their personnel. The entrepreneurs were mostly interviewed at face-to-face and couple of them via Skype or phone. One interview took approximately one hour and the method of interview was half-structured. The interviews were transcribed and then read thru several times. Results supported earlier studies when indicating that there are many problems about finding right personnel. Especially when working at international market the internationally experienced people were highly valued. Additionally, the changing requirements towards personnel was one of the challenging issues. When company is growing, the needed skills are changing as well, and this long-term orientation could be better taken into account when hiring personnel. In order to retain personnel, entrepreneurs had mainly modern leadership skills with good benefits for employees. In order to support growth entrepreneurs, it is important to recognize personnel's needs in different stages of growth.

Keywords: Growth entrepreneurs, HR, recruiting, leadership

1. Introduction

When a small business focuses on growth the one of its main topics is to find personnel who will enhance the growth. This means that owners of such growth companies must learn to communicate their vision, mission and values to their employees along with a clear understanding of how the firm is to achieve these goals (Barrier 1999). Earlier studies indicate that recruiting and retaining high quality staff is a major challenge for fast growing small to medium enterprises (e.g. Atkinson & Storey 1994; Fraza 1998; Hornsby & Kuratko 1990).

Growth in small firms usually involves increasing the number of employees engaged within the business, as well as the overall complexity of the enterprise (e.g. multiple sites, multiple product lines and increasingly complex marketing environments). As the scale and scope of the enterprise increases the owner-manager will experience pressures to delegate responsibility within the firm and build an effective team (Heneman et al, 2000). An educated and skilled labour force is considered to be essential to the success and growth of small business and for businesses to gain some competitive advantage in the global economy (Cosh et al, 1998; Huang 2001). The influence of the human resource capabilities of the small business owner-manager is therefore critical in this process.

The small businesses find usually difficulties when there is competition for new staff and in retaining existing skilled staff (Walker et al, 2007). Small businesses compete for attracting and retaining skilled staff with their larger counterparts, but are easily in a defendant position. Because of the limited resources, it is typical for small firms to focus on short-term needs in their HRM-activities (Anderson et al, 2002). Both their financial and human resources are restricted, which force them to live for the moment. Recruiting in larger business is easier because they usually have the ability to pay more and offer financial and non-financial incentives that are difficult for small businesses to match; uncertainty regarding continuous workflow; perceived difficulty of finding appropriate staff; ability to manage staff and not knowing how to terminate unsuitable staff (Barrett & Mayson 2004; Klass et al, 2000; McElwee & Warren 2000; Storey 2004). These may be hard issues for small business if the owner-manager is not skilled in human resource management.

Additional challenges identified include: time and resources (Klass et al.2000); firm size (Heneman et al., 2000); and cost (Arthur, 1995). More significantly, according to Klass et al. (2000) small businesses may not recognise the complexity of human resource training and expertise, and therefore rely on what they have vicariously learnt from previous work experience. Previous studies indicate that poor managerial competencies have often been linked to small business failure (Gaskillet al., 1993; Jennings and Beaver, 1997; Perry, 2001), so the importance of modern leadership skills and HRM-related knowledge would be helpful when targeting growth of the company.

It has been found that small business owner-managers are reluctant to participate in formal training and development, they do acknowledge that HRM is important to their businesses (Webster et al, 2005). To facilitate greater participation by owner-managers in training activities Ehrich and Billett (2004) have recommended the development of pedagogic principles that are suited to the changing skills development needs of small businesses. Of particular interest to the business owner-manager will be the impact that training will have on the business, not just in terms of the bottom-line, but also for its relevance and application to day-to-day operations. Storey (2004) and Westhead and Storey (1996) have also highlighted that there is not enough emphasis placed on the link between management training of small business owner-managers and business performance. This is despite owner-managers recognizing the importance of developing and maintaining management skills (Loan-Clarke et al, 1999; Smith & Whittaker 1996).

2. HRM models of small enterprises

Despite the growing research interest in small business human resource management (HRM) issues during the past years (Kok & Uhlaner 2001), most HRM models are designed from large companies' point of view (Hornsby & Kuratko 1990; Cassell et al, 2002; Mazzarol 2003). It is not self-evident that the models would be directly transferable to the small business context, which is generally characterized by informality and flexibility (Kok & Uhlaner 2001). The results of HRM would, at least, be unexpected if the HRM models are applied as such without taking the context into account (Storey 2004). However, it is commonly established notion that the formality of HRM practices increases alongside the size of firm's grows (Hornsby & Kuratko 1990; Mazzarol 2003). However, there are still among the biggest companies in the Finland those one which do not have any HR-managers, thus it may depend of the owners education and skills and also field if there will be any formal HRM practices (and still the company may work very well).

The model of "Growth-HR-Management" by Mazzarol (2003) presents of founder-owner entrepreneurs who seek to grow the companies. In the model, the direct and indirect influencing factors of are presented. It is having negative or positive outcomes relating to employee turnover, productivity and commitment. Directly influencing factors are HRM policy and practices such as informal to formal recruitment and incentives, and low to high team building and appointment of managers (Mazzarol 2003). In other words, when the goal is to grow and build HRM policy and practices to support it, and further to ensure the commitment and productivity of employees, the formal HR practices would be very helpful.

There are three things that affect the HR policies and practices directly: 1) owner-manager's commitment to employee partnering, 2) company structure (e.g. ownership, complexity and number of sites) and 3) nature of work environment (e.g. level of specialization, worker skill level) (Mazzarol 2003). Owner-manager's commitment to employee partnering is influenced his/hers personal characteristics which are management style, management education and level of experience as well as personality. In addition, all the indirect influencers are affected by external market conditions. (Mazzarol 2003.)

The important aspect is the role of entrepreneurs' characteristics and level of commitment to employee partnering which has a great influence in HR policies and practices. However, Mazzarol (2003) suggests the process in not straightforward, but will include trial and error process, in which the working policies and wanted growth HR outcomes are sought. Based on this model, it could be suggested that management training focusing on leadership styles and HRD and HRM would be highly recommended and would result on those needed policies and finally in the growth HR management. Mazzarol points out that it crucial for the entrepreneur to let go of micro-management and learn how to delegate responsibilities.

Also Mitchelmore and Rowley (2013) have proposed a entrepreneurial competence model, which is in their case female entrepreneur competence model. It includes four factors; personal and relationship

competencies, business and management competencies, entrepreneurial competencies and human relations competencies. They point out that the first and the last are especially important because of their focus on relationship building and communication. In their study, human relation competencies also "include hiring, staff development, leadership, employee relations and motivating staff" (Mitchelmore & Rowley 2013: 137).

In this study we focus on growth entrepreneurs' experiences of HR, especially related to recruiting and retaining personnel.

3. Method

This empirical study focuses on 29 Finnish growth-oriented entrepreneurs' views about HR. They were representing different fields but common to them was that they were experiencing very fast growth. They were asked about challenges of growth, what kind of skills they would need, and also what kind of HRM they are using in order to retain their personnel. The entrepreneurs were mostly interviewed at face-to-face and couple of them via Skype or phone. One interview took approximately one hour and the method of interview was half-structured. The interviews were transcribed and then read thru several times and using content analyzing methods the results were formed.

4. Results

Using content analyzing method the following themes were found: Recruiting, changing needs related to personnel and how to keep the personnel.

4.1 Recruiting difficulties finding the right people with right attitude

4.1.1 Finding the right know-how

Results indicate that many problems of growth were concerned about finding right personnel and especially when working at international market the internationally experienced people were highly valued. Additionally, mistakes with recruitments were hard to handle. According to Mazzarol (2003) and Fraza (1998) the faster the growth, the more likely the business is to experience human resource problems and one of the main problems is finding and retaining high quality employees.

> *"Last year we went four months without sales, because we did not get enough right kind of people in. Recruiting, recruiting, recruiting. And now we are at that point that we cannot get skilled people to international unit from Finland. There's not enough people. Not enough excellence. It is a bit sad situation but there's nothing we do about it, we just have to look outside the borders." Firm A*

> *"At this point we are not publicly recruiting for the marketing management's position. And how we are going to get the right person for that job, I really can't say how." Firm B*

> *"That is a really tough, recruiting, we have done several mistake recruitments in every market. And just that especially in sales and sales management it is very difficult. But then, if there is any doubts, you just have to put an end to it, admit the mistake and go on from there." Firm C*

4.1.2 Finding people with right attitude

Fast growing enterprises have high expectations for their personnel and some admit that if growth is difficult for themselves as entrepreneurs, so they admit that what can you then expect from the subordinates.

There may be problems with growth when employees have to adapt all the time, and some people cannot handle that.

> *"The founders have been able to handle this deal, but not all employees can adapt. And there is no blame at all, because it looks quite mysterious to us too, but at least we equity tight to this so it's a strong incentive. But it's hard to understand what it is like to come to work for a year that is different each day." Firm D*

> *"But then again, you must be able to handle uncertainty and this constant change and that all these new people come in, and they also have to learn." Firm B*

Other qualities mentioned were right attitude, commitment, interest of own work, and fitting in the firm's culture, entrepreneurial attitude, commitment, independence. For example entrepreneurs were reasoning the importance on fitting in the firm's culture and growing in his/her role the leadership will be easier

> *"I can't hire in my company even one person who doesn't have that fire in their eyes and within them." Firm E*

> *"It's really important that people who we take in, kind of fit into our culture, procedures and thinking, and the can in their own role develop and contribute. Which makes management a bit easier." Firm F*

> *"When we hire people, it is this entrepreneurial attitude that we look for. In a way that is the perhaps the most import thing to get those skills." Firm F*

4.2 Amount of personnel grows – changes are needed

4.2.1 Leadership style should be modified

When firms are growing then entrepreneurs were experiencing difficulties to update leadership, organizing overall and processes.

> *"And then we had this challenge when the number of staff is suddenly increasing, the importance of management so that we can organize all the jobs and we have clear processes described and clear job descriptions… that has taken a lot of time and has caused a lot of sick leaves like in the recent years." Firm G*

4.2.2 Hiring should be done in long term purpose

Additionally, the changing demands towards personnel was one of the challenging issues. When company is growing, certain skills are not needed anymore, and this should be taken into account when hiring personnel for long-term purpose. It has been noted that small firms typically appreciate informal, work-based learning and flexibility and adaptability are more important than explicitly formulated job descriptions and skill specifications. The transmission of tacit knowledge through ad hoc and/or hand-or training is fundamental (Hill and Stewart, 2000).

> *"Many time we have to forecast the growth. Looking back we could have been more brave in the beginning. We kept doing those things we knew how to do and did the in a small way and with care, which of course is also good too." Firm H*

4.2.3 Always too little or too much employees

Also the speed of growth is not appropriate, there are too many or too few employees.

> *"Growth is never just right. Especially in the firm like ours, the production is never the same size as growth, and the number of staff is never in line either. It is a step ahead, behind or totally in the wrong place. So it's such a continuing thing since we have such a long value chain in our possession." Firm D*

4.3 Importance of personnel and keeping them

4.3.1 *Role of personnel at growth*

All the answers here referred the right people, growing those people, keeping those people and focusing on the personnel issues.

> *"In international growth, it really is about the same thing, it depends on the right team and patience." Firm A*
>
> *"It is probably by far the most important lesson, that if a company wants to grow you as a manager have to use your time to help people grow. "Firm A*

"We have structured this and it's our first principle, that for us to grow, the staff needs to grow faster." Firm C

4.3.2 *Retaining personnel with high quality leadership style*

In order to retain personnel, entrepreneurs had mainly very modern leadership skills with good benefits for employees. Entrepreneurs tried hard to keep their employers happy and committed. Several comments were mentioned about doing things together, feeling like a family, empathic spirit, teamwork, growing together.

Everything was concentrated on good feelings and togetherness, openness, discussions and coaching. Hierarchies were not wanted in modern organizations.

"I don't believe in, even in entrepreneurship, in dictatorship or my-way-thinking, making the calls and saying what is done. I believe there needs to be a vision and one has to open so people can challenge it and have the discussions." Firm I

"Our way of working and what I have tried to do is that we always have to act humanely, act according to our values, and respecting others. And I see and at least hope that time of these brilliant pissheads is over." Firm D

"And then that we hire for life, so in a way we try and support each person in their own life so that they are motivated and enjoy this like a home, and that way that long term…" Sales C.

4.3.3 Money was also one way to gain commitment

"And then we have made the business model so that for example our mechanics are satisfied, they earn really well and so on, since they do such a hard job. And then we have created this training system for them that involves wealth planning so that we they start making the money they wouldn't go right away and spend on that…" Firm K

"And it has been clear that we want our people to be part of this. We want offer them a change to subscibe our stocks and in that way engage them but also to give them a feeling that I work for my own company. I think it is for many people, even if they own just a small share, very cool thought that I own some of this place where I work. "Firm L

5. Conclusions

This paper indicates that the Finnish growth oriented entrepreneurs understand the role and importance of personnel at their business, and they have very modern ways to retain their personnel. In many interviews it was clear that personnel are clearly more than only the people who are hired to do some work at their company. Entrepreneurs were sincerely attached to their personnel and wanted that their personnel would feel like to be almost like at home at the enterprise. To give that feeling, they were ready to give many freedoms and monetary assets. However, finding the right personnel with right attitude was not easy, and in some cases the finding the right personnel was so slow that it prevented or did slow down the growth. One possible solution could be that entrepreneurs could be more active with universities and students, so universities could send their students to do e.g. trainee programs at growth enterprises. These start-up enterprises could be great opportunity for young students who would like to want get most out of future possibilities. They could also gain very specialized knowledge and thus gain competitive advantage in the career markets.

Important aspect of entrepreneurship is self-directed learning (Rae & Carswell 2000). According Rae & Carswell (2000), the previous business and commercial experience of the owner or senior managers contributes significantly to the development of 'mental models' that form the basis for action and decisions.

The principal influences on this process are the personal values, self-efficacy and goals of key individuals, as well as their ability to learn to develop their existing capabilities in an active manner. It may be that those people with active learning ways and longer working experience may cope better with demands of growth

entreprise. So active advisory board or mentors could be very helpful when entrepreneurs are trying to solve their e.g. recruiting problems, HR-related issues when their enterprise is growing.

Role of Trust in Building a Business Network by Entrepreneurs in Russia

Natalia Bukhshtaber
Lomonosov Moscow State University, Russia
bukhshtaber@mgubs.ru

Abstract: The literature suggests that interpersonal trust is essential for building effective entrepreneurial networks. According to the 2011 World Values Survey and recent national surveys, more than 60% of Russians believe that caution is warranted when dealing with others. Low levels of social trust may affect entrepreneurs' readiness to build networks based on trust, which is defined as a psychological state comprising a willingness to act based upon positive expectations of other person's intentions or behaviour. This paper addresses the role trust plays in the building of business networks by Russian entrepreneurs. It also considers how trust between network participants changes over time. The findings are based on qualitative data gathered from in-depth interviews of 59 entrepreneurs from traditional, low, medium, and highly innovative SMEs. The paper identifies and compares the mechanisms that Russian entrepreneurs representing SMEs in four innovativeness categories use to build trust in their business networks, especially in terms of the cognitive, affective, and behavioural aspects of trust. It also highlights differences in how entrepreneurs representing SMEs in various innovativeness categories use mechanisms of trust to build and govern their business networks. The derived understanding can help entrepreneurial network participants be more effective, especially in terms of avoiding mistakes associated with the underestimation of the importance of trust in building long-term business relations.

Keywords: trust, business network, entrepreneurship, innovativeness, business relationship management, Russia

1. Introduction

The literature accentuates the importance of trust as a driver of networking, where it is seen as a medium through which entrepreneurs gain access to a variety of resources. The essence of networking lies in finding partners and establishing effective ties, thereby allowing companies to achieve their aims in each stage of their development. From this point of view, entrepreneurs' willingness to trust their partners determines how they establish and manage relationships to develop their business. A low level of trust increases operational costs owing to the need to manage threats, verify information, monitor processes and track partners' performance in relation to contractual commitments. A more trusting relationship allows for greater focus on the strategic level and on the opportunities that arise from the relationship. Trust is particularly important for new ventures – in the absence of positive experiences that can serve as a basis for cognitive trust, entrepreneurs must build affective trust with their partners in order to establish good relationships. They can do so by demonstrating a high degree of commitment or by using referrals. Moreover, the literature suggests that trust can develop as a relationship progresses.

However, the extant research does not examine whether the mechanisms of trust vary depending on certain characteristics of the business, such as its innovativeness, or the extent to which the uncertainty associated with the nature of the business affects entrepreneurs' willingness to trust and to accept unstructured, less formal relationships. These issues are particularly interesting in the context of Russia, which is a fast-developing economy. In the span of 26 years, a modest number of small and medium-sized enterprises (SMEs) operating in different markets and with varying degrees of innovation have emerged in Russia, where the economy was previously characterised by a lack of private businesses. The literature emphasises that in developing countries characterised by unstable economic and political situations and by underdeveloped entrepreneurial frameworks, the level of trust in business is generally low. The question is whether it is equally low for various types of business. In other words, does the perceived uncertainty of doing business related to such factors as innovation cause entrepreneurs to treat trust issues differently?

2. Conceptual background

As an entrepreneur's business network is a free association of actors, trust is widely assumed to be essential (Hoang and Antoncic, 2003; Glanville, 2016). Trust is understood as a psychological state comprising a willingness to act based on positive expectations of the other person's intentions or behaviour (Weber et al., 2004; Kucharska, 2017). Trust allows network participants to assume that each party will behave in a predictable and mutually acceptable manner, and that they will act with honesty and integrity (Turyakira and Mbidde, 2014). These expectations reduce transaction costs (Dyer and Chu, 2003). For example, they make the

monitoring and renegotiating of mutual arrangements unnecessary, which is important when faced with time constraints and implied conventions (Młokosiewicz and Misiak-Kwit, 2017). This is particularly true given the highly complex tasks usually solved within an innovative entrepreneurial network, as not all aspects of these tasks can be codified.

The literature views trust as an important social mechanism in networking governance that often relies on "implicit and open-ended contracts" (Hoang and Antoncic, 2003; Glanville, 2016). Trust and a commitment to meeting obligations and keeping promises are important mediating factors that may lead to successful networking. A lack of these elements may lead to a loss of reputation and ostracism (Turyakira and Mbidde, 2014). When an open relationship exists among network actors, a loss of reputation has serious consequences for the likelihood of establishing connections in the future (Newell and Swan, 2000). Smith and Lohrke (2008) distinguish between two dimensions of trust: affective and cognitive. The former, which resides at the interpersonal level in the emotional relationship domain, develops when network partners emotionally invest in relationships. Those investments result in genuine concern for the welfare of network members and a belief in the intrinsic value of those relationships. Moreover, affective trust refers to an expectation of a positive network outcome based on the network partners' constructive attitudes. In contrast, cognitive trust can develop at the interpersonal and organisational levels, and is based on evidence of trustworthiness. This type of trust results from the positive outcomes of repeated interactions.

Trust and commitment should be proactively pursued by all parties concerned in order to ensure the sustainable development of relationships (Turyakira and Mbidde, 2014). When parties trust each other, they are likely to be more willing to engage in network activities through which additional trust may be generated understood as behavioural trust (Newell and Swan, 2000; Gillespie and Mann, 2004). This is particularly applicable in the context of entrepreneurship, where trust serves as an important driver of relationship establishment between entrepreneurs and resource providers because information and evidence regarding new ventures is lacking. Moreover, both parties fear the possibility of risk realisation: entrepreneurs risk losing a viable idea, while resource providers risk wasting resources (Newell and Swan, 2000). However, if relationships are established and go through repetitive stages of negotiation, commitment, and execution, then behavioural trust develops, which then drives the evolution of those relationships (Newell and Swan, 2000). If these interactions occur under the influence of trust and commitment, one could hypothesise that networking evolves due to the entrepreneur's ability to build relationships based on feedback from previously developed networks. This supposition is supported by research showing that serial entrepreneurs build their networks differently than novices (e.g., Aarstad et al., 2015).

In Russia, which has a long history of state dominance in the economy, trust in entrepreneurship and private initiative are lacking (Kharchilava, 2014). According to the 2011 World Values Survey and more recent national surveys, more than 60% of Russians believe that caution is warranted when dealing with others (Krivopuskov, 2013; Public Opinion Foundation, 2013). Low levels of social trust may affect entrepreneurs' readiness to build networks based on trust (Trapkova, 2004). Notably, the formation and development of trustful relations in Russia is poorly understood. The literature indicates that the practice of choosing counterparties on the basis of personal ties is still widespread in Russia (Gudkov, 2012). Contacts are sought out based on the recommendations of relatives, friends, classmates and ex-colleagues. In other words, the source of trust lies in close ties rather than in the business reputation of a person or firm (Kharchilava, 2014). According to Kharchilava (2014), when making decisions about establishing relationships with others, most Russian entrepreneurs rely on the recommendations of people whom they trust. However, the basis for the development of trust is personal business experience. If the entrepreneur has positive experiences of cooperation with a person or organisation, he will prefer to continue that relationship even if someone else offers him more favourable terms (Kharchilava, 2014). This paper's author believes that use of trust by Russian entrepreneurs as a mechanism for establishing and managing business relations is highly complex and largely depends on the type of business and its innovativeness.

3. Research method

To contribute to our understanding of the role of trust as a determinant of the ability and willingness of entrepreneurs to build and manage their networks in Russia, the aim of this research was to identify whether the nature of a business activity (innovative versus conventional) affects the role of trust in creating business networks. To achieve this aim, the following proposition was investigated: entrepreneurs in different

innovativeness categories have different understandings of trust and the mechanisms through which trust can be used as a network-building tool.

Our knowledge of the role of trust in business networks is mainly based on literature focused on Europe and the US. As such, it might be irrelevant in the Russian context, which is characterised by a historically low level of social trust. Therefore, this study started without a clear picture of Russian entrepreneurs' use of trust to build business networks. It was based on a desire to test the proposition using qualitative data collected during in-depth interviews with entrepreneurs. Given this study's interpretive nature, the grounded theory method (Corbin and Strauss, 1998) was chosen. This approach best fits this study, as it allows for insights to be drawn from the data to build an understanding, which then serves as a meaningful guide for additional research-related actions.

The analysis of the qualitative data gathered from about 30 interviews allowed for identification of four patterns of entrepreneurial behaviour (Table 1) based on such criteria as business-model logic, market features, and the scope and characteristics of operating activities. The criteria were adapted from Aulet and Murray (2013), who proposed a set of characteristics differentiating between innovation-driven enterprises from traditional small-business enterprises. Patterns were revealed by comparing the respondents' answers and assigning their firms to the appropriate groups. Notably, each pattern corresponded to a certain level of innovativeness inherent to a particular group's type of business. Thus, four company-innovativeness categories (IC) were identified: very low (pattern 1), low (pattern 2), medium (pattern 3) and high (pattern 4). In the course of additional data collection, interviews were conducted to have at least 10 entrepreneurs in each group.

Table 1: General characteristics of business enterprises, by innovativeness category (IC)

Parameter	**Pattern 1 (IC-very low)**	**Pattern 2 (IC-low)**	**Pattern 3 (IC-medium)**	**Pattern 4 (IC-high)**
Starting point for building a business model	Clients' needs related to the traditional product/service; suppliers or partners selected to address clients' needs	An existing product, and existing relationships with suppliers and partners; value added to augment the quality of the product/service, segment of interested customers is identified later	The company's technological ability to significantly improve the product/service; the segment of interested customers is identified and relevant communication channels are built	A new idea about satisfying clients' (unconscious) needs; leads to the creation of a new product/service; discovery, development and education of the market
Basis of business model	Customer loyalty	Strength of relations with partners	Progressive technologies	Innovation
Degree of novelty	Existing business model to satisfy a particular segment's needs	Incremental innovations	Adaptation of an existing technology, or an architectural or modular innovation; in rare cases, holds a patent for design or useful application	Radical innovation or combination of more than two innovations; holds different patents, sometimes more than one type
Attitude toward technology	Present due to the supplier	Company mostly carries out minor refinements of technology present due to the supplier and partner	Company carries out independent improvements/ adaptations of the technology to create the product/service	Company independently develops the technology and creates the product/service
Market	Traditional, stable market; goods or services for mass consumption, or a niche market requiring customisation	Traditional, stable or weakly growing market; standardised product or service with slightly improved characteristics	Niche market, developing due to technological solutions	Market for a new or highly modified product or service, often accompanied by a new consumption model
Market's geographical range	Local	Regional	Regional, global	Global
Stage of customer-base evolution	Majority; serves customers directly	Majority; a distribution channel for partners	Early adopters and early majority; conducts sales through partners or online	Customer discovery or start of sales
Competitive advantage	Customer loyalty, convenience, quality, individual approach	High-quality services, competitive price, convenient consumption model	Heavily modified, more efficient technology for solving customers' problems	New or radically improved technology

Parameter	Pattern 1 (IC-very low)	Pattern 2 (IC-low)	Pattern 3 (IC-medium)	Pattern 4 (IC-high)
Firm's role in the consumer's value chain	Serves the needs of customers	Links producers of goods/services to clients	Integrates the efforts of a few participants to bring adapted or improved technologies to an existing market	Integrates the efforts of many participants to bring radically improved or new technologies to a new market

As this study was located in the interpretative paradigm, the author was interested in deriving detailed, in-depth answers to the research questions. Thus, in-depth interviews were used as the main data-collection tool.

However, as the study's framework required interviews of a large number of entrepreneurs, a strategy was needed that would reduce the potential for error due to variability in the words used by interviewees, especially in relation to the parameters used for categorisation (column 1, Table 1). Therefore, an interview guide consisting of two parts was developed (Table 2).

Table 2: Interview guide structure

	Section 1	Section 2
Aim	Collect data related to control variables to be used for grouping SMEs and understanding the common features of companies in these groups.	Collect qualitative information related to the research questions.
Question type	Semi-structured.	Open-ended.
Content	Factual information about the SME, its products/services, market, development trajectory, perceived innovativeness.	Qualitative information about networking behaviour and perceived role of trust in building business relationships.

The interviews, which took place from April to September 2017, covered 59 Moscow-based SMEs that launched business activities from 2009 to 2017. A snowball sampling approach was used to find respondents.

The author's personal connections with Russian organisations of innovative development, technoparks and accelerators helped in the data-collection process. Although this technique is prone to bias that is beyond the control of the researcher, it is still suitable for answering qualitative research questions in exploratory research. The data characteristics are described in Table 3.

Table 3: Data characteristics

Degree of novelty	Total SMEs	Interviewees		Sector				
		Male	Female	Production	B2C services*	IT sector	B2B/B2G services**	Wholesale and retail trade
Very low	**20**	9	11	4	8	0	3	5
Low	**17**	13	4	6	5	3	2	1
Medium	**12**	12	0	6	1	5	0	0
High	**10**	10	0	7	1	2	0	0
	59 (100%)	44 (75%)	15 (25%)	23 (39%)	15 (25%)	10 (17%)	5 (8%)	6 (10%)

* Hotel, tourism, education, dental care, restaurant, hookah salon
** Transportation, logistics, legal and accounting, construction, real-estate services

92% of SMEs in the sample were in a "start-of-sales", "market-penetration", "sales-growth" or "scaling and diffusion" stage. In other words, these companies had passed through the initial period of development and were, therefore, able to characterise their networking experiences in various developmental stages. As such, these companies were relevant objects for the purposes of this study.

4. Study results

The study results were obtained by identifying common behaviour patterns in each innovativeness category.

The results of the analysis of respondents' answers regarding proposition are presented in Table 4.

Table 4: The role and mechanisms of trust in building a business network

Parameter	IC-very low	IC-low	IC-medium	IC-high
Role of trust	A basic value and a tool for building relationships with customers, suppliers and partners. Needed to simplify the resolution of problems	Organic part of long-term relationships – without trust, there is no relationship. Trust is subject to continuous re-evaluation based on feedback and experience	Measure of perceived risk in building relationships. Trust is a consequence of honest, successful, long-term cooperation	A relationship's intrinsic binding substance through which energy is transferred between partners. Readiness to start building trusting relations as a result of affective trust
Basis of trust	Experience of conducting similar activities, business practice	Aligned, time-tested relationships and partnerships between organisations along the entire vertical of value creation	Proven professionalism of the partnering companies and the people working in them	Personality of people engaged in the relationship; priority given to building personal relations
Trust in relationships at the personal level	Recommendation is key. Quick establishment of a close, highly trusting relationship is risky. Development of trust is based on positive experience with cooperation	Reliability is key; includes the ability to always consider the interests of the other party in interactions and compliance with agreements Informal relations are less important than formalised relations	Professionalism is key; includes reputation in the professional community, history of personal and professional achievements, positive experience with cooperation in terms of results and ease of communication	Coincidence of personal values is key; includes mutual gravitation in interactions and emerging rapport. Strong personal business reputation and recommendations from trusted people help
Trust in relationships at the organisational level	"Trust, but check" – relations with an organisation are only possible on the basis of reliable information that has been checked through friends and other sources All statements should be supported by documentation	Formalisation of relations and conclusion of contracts serve as the basis for trust Honesty in implementation of contractual agreements, reliability and dependability of compliance with obligations are important	Reputation as a reliable partner and professionalism in conducting business are important. Portfolio of contracts concluded with other organisations in the industry indicates trustworthiness	Recommendations, reputation in the market and previous positive experiences are important. Conclusion of a detailed contract to protect against claims of failing to fulfil expectations Acceptance of the fact that contracts do not always work
Key principles in building relationships	Based on verification by people with whom trust already exists. Trust is a consequence of fair, non-deceiving behaviour of the other party	Based on the calculation and evaluation of benefits. Trust is a consequence of compliance with agreements, which are usually formalised	Based on expectations of long-term synergetic development. Verification through known channels to reduce risk. Agreements not always completely formalised	Based on coincidence of values and attitudes Willingness to trust even if relations are not formalised Observing the balance between how much you are trusted and how much you trust
Expectations from partners	Compliance with timing and financial commitments, and verbal promises; respect the interests of the other party	Legal settlement of relations; absence of deceit; honesty, openness; sincerity; symmetry and equivalence of benefits in relationships	Professional, mutually enriching cooperation; respectful symmetrical, honest and open attitude to work; some readiness to go beyond formal agreements	Involvement and synergy in relationships; mutual consideration of partners' interests; honesty; openness and the absence of hidden intent; compliance with obligations and verbal agreements
Willingness to act based on trust	Medium	Low	High	Extremely high
Evolution of trust	Initially cautious; trust grows over time; easily lost if promises and commitments are not met	Rational selection of a partner; strive to build long-term, trustful relationships; relations either become reliable and trustworthy, or cease due to a loss of trust	Initially prefer to check, but ready to take risks given perceived value of relations; some tolerance of the complexities of interactions, provided that the partner wishes to solve problems	Initial sympathy for a person; relations built on the "person-to-person" level; readiness to build friendly business relations; trust gradually grows due to business achievements; if expectations are not met, the relationship is interrupted

When answering the interview questions, respondents in all categories indicated that trust played a key role in building networks and establishing business relationships. Some respondents noted that trust was important in terms of both the external (e.g., clients, partners) and internal networks (e.g., employees, co-founders):

> *I think that trust plays a paramount role. For us, this is a basic value in relations with suppliers and with customers. (Vladislav, IC-very low)*

> *Trust – it should be part of everything. ... If you have business partners, then you must be sure that the relationships are honest. Employees must be trusted because otherwise you have to do everything yourself... In interactions with co-founders, everything in principle is built on trust. (Vladimir, IC-low)*

> *Trust is very important. To be trusted, you must inspire trust. It is not enough to say, "We have installed our equipment everywhere. We already have a reputation in the industry and, therefore, you must work with us". If partners or customers feel that you are not professional, they will never cooperate with you or order from you. (Andrey, IC-medium)*

> *In principle, I do not communicate with people that I do not trust. In my opinion, common values lie at the heart of trust. When I think about whether I should communicate with a person, I just look at his value system. (Arthur, IC-high).*

These quotes show that trust is perceived as a fundamental value by non-innovative (IC-very low) and highly innovative (IC-high) companies. These companies believe that it is impossible to interact with members of their networks without trust. Although this attitude toward trust reflects the uncertainty associated with the specifics of doing business, the reasons for its existence differ for the two categories. In the IC-very low category, the uncertainty is likely to be explained by the small scale of the business, where most issues are dealt with in an informal way for the sake of simplicity. IC-very low companies need to be sure that they will not be deceived and that any problems that might arise can be resolved through negotiations. In the IC-high category, the uncertainty primarily reflects the high degree of complexity of the company's tasks. Sometimes clear expectations for the partner's contribution or the likely costs of these tasks cannot be formalised in a contract. In such situations, there is no fair assessment because the innovative activity is new. Notably, the dependence of entrepreneurs on other participants of their business network is very high in both cases.

Moreover, the transaction and coordination costs associated with finding the right partner and quickly integrating it into the project to unleash business opportunities are perceived as high. Thus, trust acts as a guarantor in terms of optimising costs and minimising the risks associated with opportunistic behaviour, even if the entrepreneur is not aware of this factor. As entrepreneurs in these two categories are accustomed to relying on their own intuitions in making decisions, their answers reveal that affective trust is highly significant for them:

> *Trust is very important because it is often necessary to negotiate without signing contracts. Accordingly, it is important to understand that you can trust people and to know that you will not be deceived.* (Tatiana, IC-very low)

> *Innovative projects and processes require diverse, multidirectional efforts. We need people who are able to almost instantly integrate into the project, and diverse tasks need to be attacked from different angles. Some type of metaphysical energy should emerge among people if they are to become engaged in something innovative and unpredictable. Trust is a prerequisite for people to exist together in an innovative project.* (Dmitry, IC-high)

For companies in the IC-low and IC-medium segments, trust is necessary for ensuring the effectiveness of key business processes. At the same time, of all of the innovativeness categories, the IC-low segment demonstrated the most rational and prudent approach to all issues, including questions of what constitutes the basis of trust. This type relies mainly on behavioural trust, which suggests that interdependence is not high and that there is a pool of potential partners from which to choose (i.e., transaction costs are not perceived as

very high). However, the reliability and trustworthiness of the partner allow for economising on coordination costs in the long term:

> *Trust always plays a role in establishing contacts and building business relations. However, you cannot just trust everyone and everything. Neither intuition nor emotions work. I would say that you must base all of your decisions on rational considerations and calculations.* (Pavel, IC-low)

As technology companies often enter zones of uncertainty and undertake projects that are not always amenable to detailed planning, they are more willing to enter into new relationships based on trust even though they know that they are taking certain risks. While dependence on a business partner can be assessed as average, the high degree of specificity of complementary competencies that the entrepreneur seeks from the relation is an issue. This explains why it is perceived as appropriate to accept risk. An analysis of the generalised answers of entrepreneurs in this category (see Table 4) suggests that they tend to build business relations by relying on cognitive trust (i.e., before entering into relations), and that they try to find some evidence of trustworthiness to minimise risks and costs:

> *Trust is a risk that you accept. To manage this risk, you should try to assess how much you can trust the partner*. (David, IC-medium)

Respondents in all categories noted the importance of recommendations and information sources, which allowed for assessments of the possibility of establishing a trusting relationship. At the same time, the more high-tech a company was, the more often the respondents found it difficult to find the necessary recommendations given the novelty of the projects. In general, innovative companies demonstrated a higher degree of openness to building trusting relationships with new partners:

> *The most important thing is openness and trust. Without these elements, it is impossible to work in an innovative business.* (Artem, IC-high)

Respondents in all categories indicated that trust grows as relations develop, which emphasizes the role of behavioural trust. In particular, trust grows with the joint acquisition of experience, especially if that experience is gained in difficult situations that can only be solved through the joint efforts of the company and its partners:

> *In my opinion, overly close and trusting relations should not emerge immediately. Finally, trust must be based on positive interactions*. (Elena, IC-very low)

If the experience of working together is positive, the degree of trust is enhanced over time. (Yuri, IC-medium)
If we talk about relationships with new partners that are just joining a project, some kind of sympathy may initially arise, but trust grows gradually and it needs to be won. You have to look at people and try to assess how much you can trust them. There must be a balance between how much you are trusted and how much you trust. I believe that the level of trust in a partner is as high, as the problem that brought the two of you together was important and then you successfully solved it through joint efforts. (Andrey, IC-high)

Respondents in all categories noted that building trusting relationships takes time and that doing so is hard to plan. Not only is a trusting relationship difficult to build, but trust is also easily lost, which can ruin the relationship. Respondents noted that the concept of trust in business includes such factors as fulfilment of obligations, reliability, honesty, openness, sincerity and symmetrical relations. The respondents pointed to deliberate, fraudulent actions as the main reason for loss of trust in a partner. They also highlighted dishonest, unsymmetrical attitudes and a failure to take the mutual interests of participants in the partnership into account:

> *If you have a business partner, he should have an honest attitude towards you and should not put his interests above your interests. Your partner must take your interests into account and treat you fairly, equally and symmetrically.* (Vladimir, IC-low)

Interestingly, while non-technological companies viewed the emergence of mutual, material benefits as the main reason for building trusting relationships, innovative companies pointed to possibilities for the mutual enrichment of ideas and mutual development in the innovation space:

> *I strongly advise you to carefully plan everything when you intend to build a trusting relationship. Consider in advance what you can give in material terms to someone from whom you want something.* (Anna, IC-very low)

> *In general, I build all business relationships as friendly relationships, which, I believe, reflect a higher level of trust – you trust a person unselfishly. There must be some kind of internal chemistry for this to occur. I try to surround myself with people with whom I feel comfortable and who do certain things better than I can. I am better in other ways. We exchange ideas and grow together.* (Dmitry, IC-high)

Non-innovative and low-innovative companies viewed the formalisation of relations in contracts as an important factor in the development of trust:

> *You must trust people. However, in business relationships, I do not advise anyone to negotiate verbally. All words must be backed up by signed agreements*. (Vyacheslav, IC-very low)

> *In addition to verbal agreements and promises, always sign a contract. This will make your trusting relationship even more solid. (Alena, IC-low)*

In contrast, highly innovative companies felt that formal channels and contractual relations would not work unless contact was established with the right people at the right level. Respondents in highly innovative companies pointed out that business relationships had to be built on personal grounds in order to increase trust. In other words, contact with partners should be established at the person-to-person level. According to innovative entrepreneurs, purely formal relationships do not work in business. This behaviour can be explained by the desire to minimise risks and reduce uncertainty. Personal contacts allow partners to bring relationships that have been created on paper to life:

> *We consciously try to transfer communications onto a personal plane*. *(Arthur, IC-high)*

> *A personal component always has a favourable effect on business relations because it helps increase the level of trust. (Andrey, IC-high)*

All respondents pointed out that trust should expand over the course of a relationship through the shared experience of doing business. At the same time, for the overwhelming majority of entrepreneurs, a loss of trust meant the cessation of both personal and business contact.

5. Conclusion

The novelty of this study emerged from the grouping of start-ups into innovativeness categories, and from the identification of common patterns of trust-related networking behaviour in each category and differences among those patterns. This study highlighted the differences in how entrepreneurs in these categories used trust mechanisms to build and govern their business networks.

This paper confirmed the main propositions found in the literature. For entrepreneurs who participated in the study, trust is an important mediating factor that influences networking behaviour. Trust between business participants changes over time, but it does not necessarily *develop* over time. The data analysis also revealed that companies in different categories perceived the basis of trust in different ways and that they had different dynamics when forming trusting relationships. Nevertheless, trustful relations often developed due to interactions aimed at providing mutual assistance, especially in difficult periods. Moreover, relations often faded as a result of a party's failure to live up to obligations. It can be concluded that the level of trust grows when repeated interactions have positive outcomes, thus proving that the behavioural aspect of building trust is important.

The data analysis not only leads to the conclusion that trust is an integral part of professional networking for Russian entrepreneurs, but also highlights different patterns of networking behaviour backed by different attitudes towards trust in the various innovative categories. The highest degrees of readiness to trust and openness to building friendly business relations were demonstrated by innovative companies. For entrepreneurs from this category, the rapport between participants in the relationship, which was based on common values and interests, was of particular importance. These common values and interests related not only to material elements but also to creating something new through joint efforts. The respondents' answers also showed that building trust on the basis of personal relationships was of the utmost importance for innovative entrepreneurs. However, the behaviour of innovative start-ups differed significantly from what is described in the literature. In view of the technological complexity of these businesses, network building cannot be based on recommendations from an individual's close circle. Moreover, professional relations sometimes developed into friendly relations. Thus, for innovative entrepreneurs, the key element in decisions to establish business relations is affective trust.

In contrast, less innovative entrepreneurs are mostly guided by the model described in the literature when establishing and governing new business relations. They rely on the recommendations of those in their close circle as evidence of partner's reliability, try to formalise contractual relations and attempt to rationally assess the benefits of cooperation. In other words, they approach network building from the cognitive side.

The conceptual understanding of the mechanisms of trust used by different types of SMEs developed in this study should be of interest to managers. The discussion of differences in companies' understandings of the appropriateness of trust mechanisms, which give rise to different networking behaviours, should allow managers to avoid common mistakes. Such mistakes often occur because managers fail to consider the possibility that their business partners might be in a different innovativeness category and, therefore, may value different aspects of trust (affective, cognitive or behavioural). As shown in this study, an inability to understand the interests of the other side often creates problems in otherwise trusting relationships. For example, a number of companies belonging to the IC-low category are likely to simultaneously be suppliers for companies in the IC-very low category and distributors for companies in the IC-medium and IC-high categories.

Therefore, an understanding of differences in the mechanisms for building and managing business relationships in all categories can make all value-chain participants more effective.

The Small BusinessResponsible Entrepreneurship and Stakeholder Engagement through Digital Media

Mark Anthony Camilleri[1] and Rui Augusto Costa[2]
[1]University of Malta, Malta
[2]University of Aveiro, Portugal
Mark.A.Camilleri@um.edu.mt
Rui.Costa@ua.pt

Abstract: This research explored the owner-managers' attitudes toward digital media and stakeholder engagement. Its research methodology integrated measures from the technological acceptance model, the pace of technological innovation and corporate social responsibility (CSR), to better understand their rationale for using technology to communicate about commercial, ethical and social responsibility issues. A factor analysis indicated that the respondents were perceiving the usefulness of digital media to engage with marketplace stakeholders. Whilst, a stepwise regression analysis reported positive and significant relationships between the pace of technological innovation and the owner-managers' perceived usefulness of digital media for communication purposes. The results also revealed that young owner-managers from the large SMEs were more likely to utilize digital media than their smaller counterparts. This contribution implies that small and micro businesses are increasingly using digital media to improve their stakeholder engagement. This study indicates that the pace of technological innovation, the SMEs' perceived ease of use of digital media, as well as their commercial responsibility were significant antecedents for the SMEs' online communication.

Keywords: Responsible Entrepreneurship, CSR, Corporate Social Responsibility, Digital Media, Online CSR reporting, Technology Acceptance Model, Pace of Technological Innovation, CSR measures.

1. Introduction

Many corporations are increasingly reporting comprehensive content on their corporate social responsibility (CSR), environmental sustainability and corporate governance issues for the benefit of their stakeholders.

Firms are better able to address, balance, coordinate, and prioritize multiple stakeholder demands through social engagement; all of which help it become more efficient, reputable and successful, in terms of financial performance (Panwar, Nybakk, Hansen and Pinkse, 2017). Therefore, businesses are encouraged to promote their responsible entrepreneurship and to nurture relationships with stakeholders. This contribution posits that online communication enables businesses, including small enterprises to reach wider audiences. The stakeholder engagement through digital media could translate into tangible benefits for a company's reputation, brand image, customer loyalty and investor confidence (Camilleri, 2017), among other benefits.

The corporate communications may be intended to improve their reputation and standing among stakeholders and to lower the criticisms from the public (Camilleri, 2017). Nevertheless, little is known about the small businesses' responsible entrepreneurial practices and on their stakeholder engagement (Panwar et al., 2017; Baumann Pauly, Wickert, Spence and Scherer, 2013). Therefore, this paper builds on previous theoretical underpinnings and addresses a knowledge gap in academic literature as it examines the small firms' owner-managers' perceptions on the 'use' and 'ease of use' of online technology, that could be utilized for the promotion of their enterprises' responsible behaviors among stakeholders.

1.1 The Research Question

The purpose of this study is to examine the SME owner-managers' attitudes toward digital media as they may use it as a vehicle to promote their responsible practices. Specifically, this study integrates the 'pace of technological innovativeness' (Greenhow and Robelia, 2009; Grewal, Mehta, and Kardes, 2004; Garcia and Calantone, 2002), 'the technological acceptance model' (Rauniar, Rawski, Yang and Johnson, 2014; Davis, 1989), and 'technological anxiety' (Garcia and Calantone, 2002) measures to explore the respondents' attitudes toward online media. In addition, it also uses the CSR measures that relate to commercial, ethical and social responsibility (Singh and Del Bosque, 2008). Therefore, this contribution examines the SME owner-managers' stance on technological innovation; as well as their perceived "ease of use" and "use" of digital media. At the same time, it extends the results of previous theoretical underpinnings and prior empirical studies on the related subjects appertaining to the use of digital media for stakeholder interaction, including the communication of commercial, ethical information and social responsibility reporting.

2. Theoretical Background and the Formulation of Hypotheses

2.1 Responsible Entrepreneurship and Stakeholder Engagement

Storey, Emberson, Godsell and Harrison (2006) presumed that a significant factor for the SMEs' engagement in responsible behaviors was that good practices were becoming embedded in their supply chain relationships. In addition, there was mounting pressure from third parties which demanded that SMEs should also follow online and offline networking behaviors of their larger counterparts (see Costa, Breda, Costa and Miguéns, 2008).

However, SMEs possess distinctive characteristics of informality (Daniel, Costa, Pita and Costa, 2017; Russo and Perrini, 2010), the processes which are used to trigger employee involvement in such enterprises may need to be identified against other factors which may be relevant to particular organizational contexts. For instance, the nature of the SMEs small social setting can provide them with an opportunity for enhanced flows of communication, more face-to-face involvement and flexibility in managing human resources. The smaller firms and their practices are usually portrayed contextually, subjectively and/or in interpretational ways. Small businesses may be opposed to the extra administrative burdens in their daily routines. Baumann Pauly et al. (2013) maintained that the consistent handling of CSR in MNCs required them to draft formal CSR policies and procedures. However, the reality is that CSR is different for SMEs than it is for the larger firms (Camilleri, 2018, Russo and Perrini, 2010). Although, the large firms are more likely to address environmental management, employment, local communities and controlling and reporting strategies (Camilleri, 2017: 2015), SMEs often demonstrate a genuine commitment towards the community and society, at large (Russo & Perrini, 2010). The enterprises' owners-managers may conduct their business activities with a conscience, as they are truly concerned of responsible and sustainable behaviors (Jenkins, 2006). They frequently do this without referring to the CSR concept at all, and without communicating what they do (Nielsen and Thomsen, 2009; Fassin, 2008). The SMEs are subject to a number of distinctive and intrinsic characteristics that set them apart from the larger firms (Daniel et al., 2017). Recent studies have indicated that communication of social responsibility practices among SMEs is generally unsystematic and handled in an ad-hoc manner (Nielsen and Thomsen, 2009). Yet, it may be presumptuous to generalise that all SMEs are not communicating their responsible behaviors in an effective way. Arguably, SMEs may enhance their reputation and standing if they disclose their good practices to stakeholders. There are opportunities for them to create good publicity, as they can also raise awareness of their brand and products. Therefore, there is scope for SMEs to formalize their social and environmental behaviours (Camilleri, 2015; Fassin, 2008) through digital media (Penwar et al., 2017).

2.2 The Technological Innovation, Perceived Use and Ease of Use of Digital Media

Digital media has reshaped communication at different levels (Lamberton and Stephen, 2016; McCarthy and Silvestre, 2011). It enabled the emergence of a new participatory public sphere where everybody could dialogically and publicly interact and collaborate in the creation of content. The engagement between the public and the organization is one of the main characteristics of the internet. The public is continuously being presented with the companies' content marketing as the global diffusion of social software like blogs, RSS feeds, wikis, electronic fora, webinars and social media networks have facilitated the organizations' engagement with stakeholders (Camilleri, 2017). Many corporate websites already possess a high degree of interactivity; including their ability to disseminate information and to generate relationships between the different publics and the organization. In this case, the use of the Internet is unidirectional; as its essential objective is to diffuse information. However, in social media platforms, the degree of interactivity is high, and the Internet is used to facilitate conversations between the organization and its stakeholders (Camilleri, 2017).

For this reason, interactive communication is changing the social dynamics (Fieseler and Fleck, 2013). Web-based co-operation and data exchanges have empowered the communication between many businesses and their stakeholders (Fleck and Meckel, 2010). It enables them to engage with online users and to take advantage of the positive publicity arising from real-time word-of-mouth marketing (Camilleri, 2017).

Communication through social media is dynamic in relation to traditional media (Fieseler and Fleck, 2013).

Social media have the technological potential to speed up communication processes, and to increase direct interaction, dialogue and participation across organizations and various audiences. Such interactive communications are referred to as "viral" because ideas and opinions spread like epidemic diseases through the network via word-of-mouth. Hence, the SME owner-managers are encouraged to acquaint themselves with the use of online media to increase their impact of their communications. They can amplify the

effectiveness of their responsible entrepreneurship efforts, whilst engaging with stakeholders through digital media. Yet, recent contributions suggest that the implementation of the businesses' online engagement is neither automatic nor easy (Fieseler and Fleck, 2013). The dialogic features that are enabled by web pages, blogs, and other social media may prove difficult to apply (Moreno and Capriotti, 2009). Although recent research is discussing about the dialogic level of online stakeholder engagement (Camilleri, 2017; Nielsen and Thomsen 2009; Moreno and Capriotti, 2009), little empirical research has measured the enterprises owner-managers' stance on responsible entrepreneurship and CSR communication through digital technologies.

2.3 The Formulation of Hypotheses

This study has investigated the owner-managers' "technology acceptance" (Davis, 1989; Greenhow and Robelia, 2009; Grewal et al., 2004; Garcia and Calantone, 2002). The respondents were expected to indicate their behavioral intention on the "use" and "ease of use" of digital media, including the Internet and social media. This study has also adapted "the pace of technological innovativeness" measure to examine the respondents' engagement with ubiquitous technologies for stakeholder engagement. This argumentation leads to the first two hypotheses:

1. There is a positive relationship between 'the pace of technological innovation' and 'the technological acceptance' of digital media.
2. There is a positive relationship between the pace of technological innovation of digital media and the owner-managers' stakeholder engagement through online reporting of CSR (or responsible entrepreneurial practices).

The technology acceptance model (TAM) has often explained the users' adoption behaviors of technology (Rauniar et al., 2014). This model suggests that there is a causal relationship between the users' internal beliefs, attitudes, intentions and their use of technology. In this light, this model has been purposely chosen to determine why SMEs were accepting or rejecting the use of digital media for stakeholder engagement and CSR disclosures. The perceived usefulness (variable) of digital media is the degree to which a person believes that using this technology would enhance his or her job performance in marketing communications (Davis, 1989).

From the outset, the researcher presumed that the owner-managers would perceive the usefulness and the ease of use of digital media (to communicate their CSR credentials to stakeholders). The technology acceptance model also comprises the perceived ease of use variable, which is the degree to which a person believes that using a system (including websites, search engine optimization, social media, blogs et cetera) would be free of effort. The usage of such online technologies is influenced by the perceived ease of use (Davis, 1989). Therefore, the researcher has investigated the owner-managers' digital skills. Hence, this study hypothesized;

1. There is a positive relationship between perceived usefulness and the perceived ease of use of digital media for CSR reporting (or responsible entrepreneurial practices).

Although potential users may believe that a given innovation is useful; they may, at the same time be wary of digital media. The owner-managers may not be proficient enough or may not possess adequate digital skills and competencies. They may perceive that online technologies may be too hard to use and that the performance benefits of usage are outweighed by the effort of using such applications (Meuter, Bitner, Ostrom and Brown, 2005). Alternatively, they could not dedicate sufficient time and resources to use web technologies. As a result, companies may not always report enough information on their social, ethical and environment-related activities (Singh and Del Bosque, 2008). On the other hand, the literature review suggested that there is scope for the companies of all sizes to engage with stakeholders through digital media.

This leads to the fourth hypothesis that aims to identify the possible antecedents (by using a stepwise regression analysis) of CSR reporting through digital media.

1. The pace of technological innovation, the owner-managers' perceived usefulness and ease of use of digital media, and their ethos on responsible entrepreneurial behaviors are the antecedents for their businesses' stakeholder engagement through digital media.

This research has adopted the digital media measures of technological innovativeness, technology acceptance, technological anxiety as well as CSR items that examined the owner-managers' attitudes toward commercial, ethical and social responsibility.

3. Methodology

The survey questionnaires were distributed by email to business owner-managers who were members in a trade union representing SMEs in the retail and hospitality industries. The respondents' informed consent was obtained after they were informed in writing about the surveys' content, uses of the data, voluntary nature of participation, and confidentiality of identifiable survey information. There was a response rate of 51% (*n* = 202) from all the targeted enterprises in Malta, the smallest European Union country. The rationale behind the selection of the designated profile of owner-managers was to gain a good insight into their ability to make evaluative judgements in taking decisions regarding online communications and on their responsible entrepreneurship. Table 1 presents the socio-demographic profile of the sample:

Table 1: The socio demographic profile of the survey participants

Age		**Gender**		**Education**	
Less than 19 years	2	Male	87	Secondary	13
Between 20 to 29 years	47	Female	115	Post-Secondary / Vocational	123
		(n=202)		Undergraduate	45
Between 30 to 39 years	57			Post Graduate	18
Between 40 to 49 years	43			(*n=199*)	
Between 50 to 59 years	27				
Between 60 to 69 years	17			**Firm Size**	
Over 70 years	8			1 to 10 Employees	71
				11-50 Employees	92
mean:	*37.1 years*			51-250 Employees	39
(n=201)				*(n=202)*	

3.1 The Measures for Digital Media

The researcher has adapted six items from the 'pace of technological innovation' that were intended to measure the practitioners' attitude toward technological change in marketing. This study has also used the 12 items from the technology acceptance model to explore the respondents' attitudes on web technologies (Davis, 1989). Four items were used to examine the respondents' 'technological anxiety'. (Lamberton and Stephen, 2016; Meuter et al. 2005).

3.2 The Measures for Responsible Entrepreneurship

This study has adapted Singh and Del Bosque's 'commercial', 'ethical', 'social' and 'support' dimensions that consisted of 16 items. The 'commercial' dimension measured the owner-managers' perceptions about their economic strategy. The 'ethical' dimension featured items on ethics and regulatory matters as it explored the respondents' attitudes about honesty, integrity and moral principles. The 'social' dimension referred to environmental protection and to discretionary investments in the community at large. The 'support' dimension sought to discover how the respondents perceived corporate communications on commercial, ethical and social issues (Singh and Del Bosque, 2008).

4. Data Analysis

Firstly, the descriptive statistics illustrated the means, standard deviations for all variables. Secondly, a principal component analysis (PCA) has been chosen to obtain a factor solution of a smaller set of salient variables. Thirdly, a multivariate regression analysis has investigated the hypothesized associations by using the stepwise method.

4.1 Descriptive Statistics

All responses were coded using a five-point Likert scaling mechanism. The values ranged from 1 (strongly disagree) to 5 (strongly agree) whereas 3 signaled an indecision. The scale items that were used in this study included; 'the pace of technological innovativeness', 'perceived ease of use', 'perceived usefulness', 'technological anxiety', 'commercial responsibility', 'ethical responsibility', 'social responsibility' and 'support'.

This study is consistent with the extant literature on the 'technology acceptance model' (Davis, 1989, Meuter et al., 2005). As a matter of fact, there were high mean scores of near 4, which reflected the respondents' stance on the use of digital media. The survey participants have indicated their strong agreement with the 'pace of technological innovativeness' (Grewal et al., 2004). Moreover, this study investigated how 'gender' and 'age' could influence the frequency of use of digital media. The results suggested that gender did not influence this choice as there was no statistically significant difference between the groups' means as determined by the Chi square tests. Pearson's Chi-Square $\chi 2$: was 1.150, Df 2. $p = 0.563$. This finding suggested that gender did not significantly influence the frequency of use of digital media. There were no statistically significant differences between different age groups and the frequency of use of digital technology. However, the results showed that the survey participants who were between 30 to 39 years of age (where n=57), who were followed by those who were between 20 to 29 years old (where n=47) were more likely to use their digital media than other groups. Pearson's Chi-Square $\chi 2$ was 3.803, Df 6 and $p = 0.703$. Surprisingly, there were also a few owner-managers who have never used digital media in the past (n=5).

4.2 Data Reduction

Bartlett's test of sphericity also revealed sufficient correlation in the dataset to run a principal component analysis (PCA) since $p < 0.001$. PCA has identified the patterns within the data and expressed it by highlighting the relevant similarities (and differences) in every component. In the process, the data has been compressed as it was reduced in a number of dimensions without much loss of information. PCA has produced a table which illustrated the amount of variance in the original variables (with their respective initial eigenvalues) which were accounted for by each component. A varimax rotation method was used to spread variability more evenly amongst the constructs. There was a percentage of variance column which indicated the expressed ratio as a percentage of the variance (accounted for by each component in all of the variables). Only principal components with eigenvalues greater than 1 were extracted. Table 2 illustrates the number of extracted components from the original number of variables and presents the resulting cumulative percentage of variance for the group of variables (and also reports the related 'loss of information').

Table 2: Data Reduction through Principal Component Analysis

Original Number of Variables		Cumulative Percentage of Variance %	Loss of Information %	Components Extracted
Digital Media	22	62	38	6
Responsible Entrepreneurship and Stakeholder Engagement	12	74	26	4

All constructs were analyzed for internal consistency by using Cronbach's alpha. There were excellent measures that exceeded the recommended reliability estimates. The value of the Kaiser Meyer Olkin (KMO) measure of sampling adequacy was also very acceptable at 0.8. The factors accounted for more than 62% variance before rotation for the digital media variables. Whereas, there was 74% of the variance explained before rotation for the CSR measure. There were ten extracted components from the original thirty-nine variables for the digital media and CSR variables. A brief description of the extracted factor components, together with their eigenvalue and their respective percentage of variance is provided hereunder in Tables 3 and 4.

Table 3: The Extracted Factor Components from the Digital Media Variables

	Use of Digital Media			
		Initial Eigenvalues	% of Var.	Alpha
1	Perceived Usefulness of Digital Media	5.533	25.152	0.812
2	Pace of Technological Innovation	2.378	10.809	0.832
3	Technological Anxiety	1.846	8.391	0.845
4	Easy Interaction with Digital Media	1.662	7.553	0.901
5	Perceived Ease of Use of Digital Media	1.192	5.418	0.874
6	Effective Digital Media	1.119	5.085	0.877

Extraction Method: PCA, KMO = 0.792; Sig:000

Table 4: The Extracted Factor Components from the Responsible Entrepreneurship and Stakeholder Engagement Variables

	CSR Reporting			
		Initial Eigenvalues Total	**% of Var.**	**Alpha**
1	Engagement with Marketplace Stakeholders	8.874	35.024	0.841
2	Valuing Online Reporting of Responsible Entrepreneurship	4.654	20.119	0.784
3	Valuing Online Environmental Sustainability Reporting	1.846	13.454	0.911
4	Engagement with Human Resources	1.162	5.403	0.825

Extraction Method: PCA, KMO = 0.812; Sig: .000

The factor components were labelled following a cross-examination of the variables with the higher loadings.

Typically, the variables with the highest correlation scores had mostly contributed towards the make-up of the respective component. The underlying scope of combining the variables by using component analysis was to reduce the data and to make it more adaptable for the regression analysis.

4.3 Regression Analysis

A stepwise procedure was chosen to select the most significant predictive variables in the regression equations. Therefore, the *p*-value was less than the 0.05 benchmark. This also resulted in adequate F-ratios, implying that only the significant amounts of variation in regression were accounted for. More importantly, in the stepwise procedure the insignificant variables were excluded without appreciably increasing the residual sum of squares. The regression models produced the regression coefficients which represented the strength and the significance of the relationships. Moreover, the socio-demographic control variables were also entered into the regression equations.

H1: The first hypothesis indicated that there was a relationship between 'the pace of technological innovation' and 'technological acceptance' on the use of digital media. The results indicated that there was a positive and significant relationship between perceived usefulness of digital media and the pace of technological innovation where Spearman's rho, adj r2 = 0.173. This relationship was significant at (p <0.05). It transpired that the 'perceived usefulness' was dependent on the pace of technological innovation (t-value = 4.457).

H2: The second hypothesis explored the correlation between the "technological innovation of digital media" with the factor component; namely, "online reporting of responsible entrepreneurship". The results indicated that there were positive and very significant relationships (p <0.01); where Spearman's rho, adj r2 = 0.296. It transpired that small businesses' online disclosures on their social engagement were correlated with the technological innovation of digital media (t-value = 2.53) and also with firm size (t-value = 1.87).

H3: The third hypothesis explored the correlation between the owner-managers' perceived "use" with their "ease of use" of digital media. The results indicated that there were positive and very significant relationships (p <0.01); where Spearman's rho, adj r2 = 0.296. It transpired that the owner-managers were using interactive technology to communicate with their stakeholders, and they were proficient in it (t-value = 2.53). The findings also from the stepwise regression analysis also suggested that the larger firms were more likely to utilize digital media than their smaller counterparts (t-value = 1.87).

H4: The last hypothesis investigated whether the technology acceptance of digital media and the companies' ethos on responsible behaviors would have an effect on their stakeholder engagement. Therefore, the perceived usefulness, perceived ease of use, the pace of technological innovation and technological anxiety; as well as commercial responsibility, ethical responsibility and social responsibility variables were all considered as plausible independent variables in the regression equation. The factor component, 'online reporting of responsible entrepreneurship' was inserted as the outcome variable. There was a positive and significant relationship where Spearman's rho, adj r2 was 0.230. The regression equation indicated that the small businesses' online engagement was dependent on the easy interaction with digital media (Perceived Ease of Use) where t = 6.501; the users' digital skills (Pace of Technological Innovativeness) where t = 4.022; stakeholder relationships (Commercial Responsibility) where t = 1.855; firm size, where t = 0.877; apprehension of digital media (Technological Anxiety) where t = -0.126 and age, where t = -0.114.

5. Discussion and Conclusions

This contribution provides a snapshot of the investigated SME owner-managers' attitudes toward digital media. At the same time, it raises awareness of responsible entrepreneurial initiatives that could be promoted through corporate websites, and other digital channels including social media and blogs. The quantitative results have clearly indicated that the survey participants recognized that digital media could help them promote their social and environmental behaviors. This research reported that the owner-managers perceived the usefulness of digital media, as this technological innovation has helped them to better engage with stakeholders. Previous literature also pointed out that the SMEs owner-managers prefer to learn through networking and from their peers (Costa et al., 2008; Jenkins, 2006). However, the owner-managers of the larger businesses were more capable of using digital media to interact with stakeholders, when compared with their smaller counterparts. Another finding has indicated that the younger owner-managers were more proficient in their use of innovative technologies. This study suggests that many owner-managers were already using the web, and they even perceived its usefulness. Yet there were a few participants who were still apprehensive toward this technological innovation.

The principal component analysis revealed that the businesses' online communications were primarily directed at marketplace stakeholders, including; consumers, suppliers and other businesses. However, their communications on their businesses' social responsibility and environmentally-sound practices also served to engage with other interested groups; including human resources, shareholders and investors, among others.

In conclusion, the regression analysis reported positive and significant relationships between the SMEs' online stakeholder engagement and the pace of technological innovation; and between the SMEs' online engagement and the owner-managers' perceived usefulness of digital media. This study has shown that the pace of technological innovation, the owner-managers' perceived ease of use of the digital media, as well as their commercial responsibility were significant antecedents for their online communication of their responsible entrepreneurship. Arguably, the use of technology is facilitated when individuals will perceive its usefulness and its ease of use (Davis, 1989). In fact, he findings from the second, third and fourth regression equations indicated that the small and micro businesses were using digital media to improve their stakeholder engagement and to communicate about their responsible entrepreneurship issues.

6. Limitations of Study and Future Research Avenues

Previous studies have considered different sampling frames, research designs, methodologies and analyses which have produced different outcomes. Although the number of survey participants were sufficient in drawing conclusions about their attitudes; this study is not amenable in drawing general conclusions in other contexts. The researcher believes that there is scope in undertaking qualitative studies to explore the participants' in-depth opinions and perceptions on the subject. The businesses' overall vision is to a large extent driven by its owner-managers and then trickled down to the mind-sets of the employees. Further research is necessary to identify the organizational aspects that facilitate or hinder the organizational implementation of responsible entrepreneurship and its communication. Abn longitudinal study in this area of research could possibly investigate the opportunities and threats of consistent disclosures of social and environmental behaviors through digital media. It could establish its reputational effects in the long run.

State of the art Literature Analysis of Innovation Network Management Frameworks

Jan-Patrick Cap
Fraunhofer Institute for Production Systems and Design Technology (IPK), Berlin, Germany
jan-patrick.cap@ipk.fraunhofer.de

Abstract: Innovation is one of the main topics pushing economic activities today. The procedure to integrate innovation processes, which need a complex research and development (R & D) environment, is a challenge for enterprises to handle by themselves. As a result, innovation networks are one strategic solution for enterprises and other R & D related organizations and institutes, in order to successfully found and integrate innovation processes within their organization. Followed by further challenges regarding the management of innovation networks, the need of specific innovation network management knowledge and skills become a key competence. The following paper gives a state of the art overview of network management frameworks found in the relevant literature. The particular focus of this Paper lies on the management of innovation networks. The (Innovation) network management frameworks (INMF) of different authors were assembled in various literature research processes. Due to the small amount of INMFs discussed in pertinent literature, general network management frameworks that are applicable to examine innovation networks are identified as relevant as well. All frameworks were selected by their capability of presenting precise understanding about management of innovation networks. Further, the paper analyses all identified management frameworks in order to evaluate the competence of each framework implicating its specific characteristics. The analysis contains a description of all as relevant identified frameworks and elaborates their weaknesses and strengths while taking different innovation and enterprise environments into account. The evaluation process was developed for the specific needs of innovation network management and their individual partners. The conclusion of the paper provides a state of the art compilation and analysis of INMFs. The paper also points out the particular lack of research in this field and gives impulses to develop further ideas and specific INMFs.

Keywords: #Network Management #Innovation #Innovation Network #Literature research #Literature analysis #network management framework

1. Introduction

Even though innovation is one of the big buzzwords when talking about economic performance, the term's definitions are as numerous as its usage. Hauschildt et al. dedicate a whole chapter to the definition, containing a literature overview and the comprehensive approach form different perspectives (Hauschildt 2016, 3 ff.). The foundation of this paper is the definition of the Organization for Economic Co-Operation and Development (OECD).

"An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations." (OECD Publishing 2005, p. 46)

Müller-Prothmann and Dörr set up the often-quoted formula, that innovation is the idea plus the invention plus the diffusion (Müller-Prothmann, Dörr 2014, p. 7).

Especially enterprises with high investments in R & D face several risks when innovating. When innovations do not only turn into new products and services, but also require additional innovations of production, innovation processes claim time and resources. This way, innovations become unaffordable for newcomers and small and medium-sized enterprises (SME). In order to produce innovative, profitable products and reduce needed time for learning and economies of scale, new management approaches such as cooperation, coalitions and innovation networks are needed (Müller et al. 2014, 26 f.; Becker et al. 2011, p. 4).

To establish and sustain an efficiently productive network, special management skills outgrowing general management tasks are required. In addition, as management tasks become more complex, managers need to come up with solutions in a short amount of time. Therefore, pragmatic concepts to structure challenges and to get first solution ideas quickly are needed. That is where management tools (e. g. concepts, standardized processes and instruments) step in (Schawel, Billing 2018, p. 1). The following paper gives an overview on innovation network management research and literature, evaluating the provision of network management

tools, behaviors and their ability to incorporate innovation processes. The objective of the paper is to identify weaknesses and give directions for further research.

2. Evaluation Process

Following, the evaluation process is discussed. Networks became an advantage in competition not only for big players, but especially to SMEs in order to achieve company goals, ensure effective innovation processes, provide needed skills and resources and handle comprehensive projects. Networks require special management tasks in order to be successful and bring targeted advantages. Therefore, Agranoff and McGuire identified four key groups of network management behaviors, which support efficient and successful networks; activating, framing, mobilizing and synthesizing. In order to define these tasks, the authors gathered different tasks mentioned throughout literature and allocated them to the four groups of management behaviors (Agranoff, McGuire 2001, 298 ff.; Keast, Hampson 2007, 16 ff.). To each behavior group there are five different behaviors identified which are used to evaluate the INMFs in chapter 2.1 and 2.2.

2.1.1 Activating (A)

Activating is about (1) identifying the right participants for the network as well as stakeholders. Therefore, managers must know (2) about skills, knowledge and resources (potential) partners contribute to the network.

(3) Deactivating a partner who does not fit to the network anymore might also become as necessary as (4) integrating new participants and competences to the network. Activating also includes (5) forming network process and structure and implementing, arranging, stabilizing and cultivating both (Agranoff, McGuire 2001, 298 f.).

2.1.2 Framing (F)

Tasks of framing activities tend to seem less obvious then activating tasks but are as important. Main tasks are (1) establishing and influencing the operating rules of the network as well as prevailing values and norms.

Managers form the expectations of network participants, (2) influence (perception of) interaction, (3) create and share purpose and vision or (4) bring in alternative views. The aim is to (5) lay ground rules for decision-making in a way every participant is able to identify, work and decide according to the networks purpose (Agranoff, McGuire 2001, p. 299).

2.1.3 Mobilizing (M)

Managers (1) have to induce the commitment of participants and partners to the network and to obtain it constantly from them. (2) They sell new ideas to participants, which support the network and its purpose, (3) influence the development and achievement of common objectives and (4) embed the agreement on role and scope of network operations and the selection of stakeholders outside the network in order to form coalitions.

Mobilizing also means (5) to motivate and inspire stakeholders to keep their commitment and support the network's purpose (Agranoff, McGuire 2001, p. 300).

2.1.4 Synthesizing (S)

Managers (1) have to make sure environment and conditions of the network enable its participants to interact successfully with partners (2) in order to achieve the networks purpose. Different mind-sets and goals of various participants may become blockages to the cooperation. This risk must be minimized. Therefore, managers are urged (3) to establish relationships and interactions, which contribute to the networks purpose.

This can be achieved best by (4) reducing complexity, keep participants informed and (5) carefully choosing roles of participants (Agranoff, McGuire 2001, p. 300).

In this case, innovation networks are the object of investigation, contrary to Agranoff and McGuire. Therefore, innovation management behaviors also have to be considered while evaluating the frameworks. Hauschildt defines innovation management as the dispositive configuration of the innovation process or system in an enterprise. The dispositive configuration includes behaviors as setting and pursuing strategies and goals, decision-making, framing the flow of information, building relations and operating relations in order to put decisions into practice (Hauschildt, Salomo 2011, p. 29).

2.2 Overview innovation network management frameworks incl. strength and weaknesses

In order to get a comprehensive understanding of today's research concerning innovation network management not only network management research but also innovation management research was reviewed. Due to concision of this paper only frameworks regarding to (innovation) network management are analyzed and described further. Therefore, not only the behavior criteria of Agranoff and McGuire are taken into account in this chapter but also management view, concrete management tools and the innovation aspect of each framework are reviewed. For a better understanding, a short description of each framework is added. In chapter 2.2, a more analytical approach is presented. The evaluation aims to give readers insights about which INMFs explain the workflow of innovation network management best and offer strategic management tools.

2.2.1 Systematic framework for developing a network strategy – Juttner and Schlange (1996)

The framework follows three stages:

Stage 1, description, describes context (Network analysis) and actors (analysis of actors and relations).

Stage 2, evaluation, prepares an Interdependence Matrix (incl. dependence and relations) of the network.

Stage 3, interpretation, develops a portfolio of interdependences and interprets the strategic.

The different stages give a better understanding of complex decision processes in the network considering the actors' dependencies as a decisive factor of success.

Strength: The framework gives decision-makers a guideline in order to develop a strategy. It helps managers to analyze the role and impact of network partners and how relations work within the network. The framework enables managers to frame the network's strategy, and therefore vision and purpose. The framework examines the existing network and its participants but does not talk about choosing the right participants. It focuses on the relations, which is important in order to frame and synthesize the network. In terms of mobilization, the framework only covers the strategic development of objectives. Therefore, the framework is helpful in the ongoing process (Jüttner, Schlange 1996, 483 ff.).

Weaknesses: The frameworks lacks to give a guideline in order to establish the network and to mobilize partners. It is more about analyzing the existing network than to give concrete management guidelines.

2.2.2 A conceptual model of alliance network diversity and economic performance – Goerzen and Beamish (2005)

This model evaluates multinational enterprises (MNE) based on the impact of a variety of factors on the economic performance, regarding performance measurement and impact on the network. The diversity of the network has a special interest in this case.

Strength: Goerzen and Beamish look from a firm's perspective on the network of relationships surrounding it.

They aim is to characterize participants and the quality of relationships. Their thesis is that networks benefit from a certain level of heterogeneity. The strong diversity focus gives an excellent base to activate and synthesize the network. The authors point out the importance for managers to handle the risk of difficult interactions between the actors based on their diversity (Goerzen, Beamish 2005, p. 349).

Weakness: Because the focus lies on diversity, this framework does not provide insights on actual management tasks but outlines the risks, such as increasing management costs and diminishing returns.

2.2.3 Cybernetic model for innovation network management – Mirzadeh and Arasti (2012)

Based on the principles of cybernetics, such as the idea of focusing on strategic and feedback mechanisms, the framework examines the management of innovation networks. The framework identifies sophisticated modules; strategy/policy development, main process (primary process), supportive process and feedback process (process/product control). Further, the framework identifies soft supportive processes (culture, HR, R & D, PR etc.) and hard supportive processes (equipment, infrastructure, material).

Strength: By examining three aspects of network management, the model offers various insights of activating, framing, mobilizing and synthesizing the network. Network strategy contains different framing (creating vision and purpose), and mobilizing (whole strategic view on resources and partners) tasks. Network organizations provides insights of activating (introduce participants and processes to build up the network), framing (network governance), synthesizing (network behavior). Network information management offers insights of synthesizing by ensuring the information and communication flow (Mirzadeh et al. 2012, 578 ff.).

Weakness: The framework is highly comprehensive. It misses tasks like deactivating unfitting participants, bringing in alternative views, inducing commitment or choosing positions. The framework lacks constructive guidance as well.

2.2.4 Biplex network model – Vermeulen and Kok (2013)

The Biplex Network model focuses parallel on two different processes and networks: the innovation and the production network.

1. Stage: introduction into production, network actors organize themselves within the production (planning).
2. Stage: the earlier production network merges into the next generation of production, while former processes drain off.
3. Stage: a group of actors leaves the production network to evaluate product definition, market relevance and technical feasibility of the next generation.

Strength: The Biplex network model considers changing relationships during the product lifecycle, which gives insights on different terms of interaction. It also recognizes tasks of activating (choosing participants with the needed resources) and mobilizing (exploit existing resources and skills), but the framework lacks specification of behavior groups (Vermeulen, de Kok 2013, p. 11).

Weakness: The framework focuses on innovation and production processes and referring management tasks (e.g. handling conflicts between the two networks) but leaves out network management behaviors.

2.2.5 Framework for analyzing multi-level innovation networks – Ahrweiler and Keane (2013)

The framework displays the relationship between "cognitive and social aspects of scientific creativity and technological innovation" in three levels:

Concept level: Ideas are generated and clustered to unit-nodes.

Individual level: Unit-nodes (actors of the network) are connected by their similarities within their approaches to solve problems. They refine the developed ideas.

Social-organizational level: The unit-nodes (heterogeneous organizations) are connected by their level of relationship to each other. They work together in teams in order to develop and launch new products.

Strength: Ahrweiler and Keane argue that actors and their relationships are the main issues when establishing an innovation network (Ahrweiler, Keane 2013, p. 75). They recognize tasks of framing, mobilizing and synthesizing by establishing an appropriate social structure and environment in order to encourage creativity.

However, they refer to these behaviors more as network than as management tasks. In addition, they have a strong focus on creating an environment of relations and interactions in order to provide optimal conditions for a productive cooperation (Ahrweiler, Keane 2013, p. 78). Contrary to other frameworks, this framework is strong on creativity, bringing in different views and selling new ideas, which is important to be innovative as a network.

Weakness: The framework does not describe the importance of choosing participants and demand their commitment to the network and its purpose.

2.2.6 Management model for network-cooperation – Schubert (2008)

The author examines concrete management tasks within the network cooperation: Information system: Assembling information relevant for strategy, management, planning and network controlling.

Management: Processing strategic analysis, planning, execution and evaluation of the network. Quality management: Guaranteeing the compliance of the various appointed standards.

Strength: The SWOT-analysis focuses among others on potential participants. Followed by a network analysis during the initiating stage, both stages suggests several tasks of activating behavior. The network planning stage withholds tasks of activating (planning organization and product management), framing (setting goals) and mobilizing (setting goals and managing contracts). The realization stage focuses simultaneously on structural tasks (coordination, resource management, controlling and evaluation), while the network marketing stage is about framing (setting the vision), mobilizing (external communication) and synthesizing (internal communication) the network (Schubert 2008, 55 f.).

Weakness: Schubert's framework gives a wide few on different management tasks but leaves out difficulties networks face as a result of interaction of heterogenic participants. Schubert also shares the perspective of the network, not especially of the management. Therefore, tasks as deactivating participants, bringing in different views or selling new ideas are left out. The framework focuses on networks instead of innovation.

2.2.7 Network Management model – Riemer and Klein (2006)

Accounts the internal structures, strategies and processes of each network actor as well as external factors.
Four network management domains: designing governance structures, coordinating exchanges, fostering social integration, facilitating shared visions/ values.

Three perspective - levels: Network perspective: Management is represented in a PDCA cycle, planning (Plan), implementation (Do), controlling (Control) and reaction (Act). Actor perspective: Strategy, organization and technology of each actor are examined. Environmental perspective: Markets, regulations, laws and behavior of the industry are evaluated.

Strength: The four network management domains are similar to the behaviors of Agranoff and McGuire. Designing governance structures contains several tasks of mobilization and a few activating activities.

Coordinating exchanges and fostering social integration bear some framing and mobilizing tasks but mainly resemble synthesizing activities, while developing and articulating shared visions and values can be assigned to framing (Riemer, Klein 2006, 58 f.).

Weakness: The framework is comprehensive. It addresses network management directly and further encourages the idea of flexibility in order to be innovative even though it is more a general network management framework than specific on innovation. Activating activities seem to be discussed inadequately.

As most frameworks the importance of choosing the right participants or even excluding not fitting participants is not mentioned.

2.2.8 Three-Layer-Model (Drei-Schichten-Model) – Mack (2003)

This framework examines the management relations, transaction relations and the exchange of recourses within the network. The network is split up into three perspectives (Schichten): Management Perspective (Managementschicht): management units und relations and the out coming management process.

Activity perspective (Aktivitätenschicht): value adding elements and transaction relations of the production process.

Recourse/competence perspective: resources and competences and its entanglements as well as the following process of learning.

Strength: The resource and competence perspective sees the network as a constellation of resources and competences every network participant contributes to the network. The framework points out the importance

of the compilation and development of resources and competences (activating), but leaves out management tasks (Mack 2003, pp. 167–168). The activity perspective examines the output of the network in order to satisfy customers. This perspective underlines the importance of mobilizing each member in order to measure up to their commitments but again does not appoint any management tasks (Mack 2003, p. 182). Only the management perspective identifies different management tasks, but focuses on the position itself and its impact on the network.

Weakness: Mack's framework focuses more on production processes than on innovation processes.

2.2.9 Framework for the evaluation of innovation networks – Van der Valk (2011)

The framework examines different perspectives in order to discover concepts that influence the performance of innovation networks. Therefore, Valk et al. suggest a social network analysis to study the impact of knowledge diffusion on the innovation performance. Further, the framework adopts a resource-based view and addresses structure and composition of the network.

Strength: The framework has a strong focus on innovation and activating the right participants and resources. In addition, the commitment of participants is outlined (mobilizing). Therefore, the framework is helpful in order to establish and manage an innovation network on behalf of the named tasks.

Weakness: The framework leaves out general network management tasks and does not give constructive guidence (Valk et al. 2011, 26 ff.).

2.2.10 Orchestrating innovation networks – Dhanaraj and Parkhe (2006)

The framework examines the so-called network orchestration, which contains knowledge mobility – sharing and increasing knowledge within the network, innovation appropriability – exploding profit from innovation, and network stability – allowing a dynamic stability of the network while ensuring the network's profitable continuance. The authors also concentrate on a duality of a low-density/ high-centrality structure (Dhanaraj, Parkhe 2006, 660 ff.).

Strength: The framework focuses on the continuance of the network, while ensuring that its purpose (e.g. innovation) is reached. The authors examine innovation networks in particular. In order to reach its purpose the authors see tasks of activating (examining the contribution of participants, forming structure, buy-in the right competences), mobilizing (induce commitment, agree on objectives, motivate to keep commitments) and synchronizing (establish a profitable environment, ensure a purpose-driven network) as especially important to the network.

Weakness: On the other hand, the authors only look at loose interrelations within the network. Therefore, framing tasks to tighten relationships between members are not discussed. Matching this view, the framework does not take the perspective of the management but sees the hub firm as the responsible "orchestrator".

2.2.11 Integriertes Netzwerkmanagement-Konzept / integrated network management concept- Petry (2006)

This framework, based on Bleicher's St. Galler Management-Concept, sees a significant overlap of network-management- and Business-management-problems and therefore no need for a specific framework. Three levels of network management: Normative (Network contract, governance and culture), Strategic (Network organization and management system, Network strategy, problem solving and managing behavior) and Operative (operative processes and disposition systems, strategy-implementation and order fulfilment and performance and corporation behavior) (Petry 2006, 73 ff.).

Strength: The framework is comprehensive and applicable to different networks. It has a strong focus on framing the network, built up structure and induce commitment of the network participants. The author also points out the similarities between business management and network management.

Weakness: The framework has no view on innovation networks in particular. Further, it focuses on already established networks, and therefore does not consider activating the right participants or deactivating not fitting ones.

2.3 Evaluation of innovation network management frameworks

The following table shows an overview of the identified INMFs containing their operational area as well as the results of the evaluation. Every framework will be rated based on the criteria of Agranoff and McGuire (chapter 2):

- ○ The framework does not meet the sub criterion
- ◔ The framework rarely meets the sub criterion
- ◑ The framework partly meets the sub criterion
- ◕ The framework mostly meets the sub criterion
- ● The framework totally meets the sub criterion

Table 1: Evaluation Network Management frameworks

Model – Author	Area of application	Evaluation			
Network Management		A	F	M	S
Systematic framework for developing a network strategy – (Juttner, Schlange 1996, 483 ff.)	Formulating strategy and the strategic management process	◑	◑	◔	◑
A conceptual model of alliance network diversity and economic performance – (Goerzen, Beamish 2005, 336 ff.)	Measuring the impact of heterogenic relationships on performance	◑	◔	◔	●

2.4 Comparison of innovation network management frameworks

Four cluster options occurred while evaluating: relation- or process-oriented frameworks, comprehensive or specialized network view, innovation or network oriented management view, degree of management perspective.

Juttner and Schlange focus on the specialty of managing the network's relations but lack examining innovation processes. Contrary, the model merely scratches the surface of the evaluation criteria. The model of Ahrweiler is similarly facile considering the criteria, but has a strong focus on innovation and relations inside the network. The same holds for the model of Valk, which examines especially the establishment of an innovation network and activating partners. All three models take a network instead of the manager's perspective. To be mentioned is Valk's suggested social network analysis, which is one of the few approaches to recommend a management tool. Juttner and Schlange and Schubert are the only other authors mentioning analyzing tools.

Goerzen's model stands out because of its different focus on network diversity and therefore seems to not fit right into the other INMFs. On the contrary, it gives useful insights of synthesizing a network and analyzing the network's environment. Likewise, Petry misses the focus on innovations and fulfills the criteria on the same level as Goerzen but with a stronger focus on framing the network. The models of Vermeulen and Dhanaraj both have a strong focus on activating the network and on the innovation process. Vermeulen names different management tasks, but more with a business management perspective then a network management perspective in particular. Mirzadeh's model fulfills the criteria on a higher level. The model takes the management perspective and considers innovation without giving operational guidelines. Riemer and Klein on the other hand offer operational guidelines and also meet most of the criteria from the management perspective. Mack's and Schubert's models fulfill the criteria the best. While the model of Mack is very simple and easy to adjust, the model of Schubert is much more comprehensive. Still both models have a stronger focus on the network itself then on management guidelines and innovation processes.

Table 1 reveals that activating is the strongest behavior group in six out of eleven Frameworks (some frameworks have up to three strongest behavior groups). Framing counts five frameworks, synthesizing four and mobilizing two. This indicates that network frameworks focus on establishing a new network by activating the right partners and framing the ground rules. Even though, activating and framing are not only to be executed at the start of a network but constantly, mobilizing the partners and their commitment to support the networks purpose seems essential for an on-going effective and successful network. If analyzing not only the winning behavior for every framework, but counting the overall sum of the rating, framing is the least considered behavior. Agranoff and McGuire also mention that framing is the less obvious behavior in network management, but just as important as the others. (Agranoff, McGuire 2001, p. 299)

3. Conclusion

This paper aims a comprehensive literature overview on INMFs as well as an evaluation based on the abilities of each framework to manage a network while ensuring innovative outcomes and covering activating, framing, mobilizing and synthesizing tasks. This "management behaviors groups" were identified by Agranoff and McGuire and are common evaluation criteria throughout English network management literature (Keast, Hampson 2007, p. 366).

As the evaluation shows, state of the art research on INMFs lacks a framework that offers concrete and comprehensive management guidelines referring to the identified behavior groups of Agranoff and McGuire in combination with a focus on innovation networks. Even though Mack's and Schubert's model cover the four behavior groups almost completely, they still show weaknesses in combining all behaviors to full extent, while giving operational guidelines on managing the network and the innovation process. The results show that research activities conspicuously often take the perspective of the network itself instead of the perspective of the manager in particular. Therefore, the focus lies on the required accomplishment of the network instead of craving out the right management tools to achieve the networks purpose.

Due to the conciseness of this paper, innovation management frameworks were not part of the evaluation, but should be considered in further research activities.

Further research activities require a framework that combines all four behavior groups with a management perspective and operational guidelines in order to manage the network and the innovation process. The framework should also be useful to establish, maintain and reconstruct the innovation network. In order to establish a successful innovation network, that enables newcomers and small enterprise to handle innovation processes and established companies to involve the innovative flexibility of smaller and younger enterprises into their innovation processes, further research activities need to meet the described requirements. Also framing needs to receive more attention in network management research in order to build stronger relations within the network by incorporating a structure of purpose and values that allows actors to identify themselves with the network. As shown in 2.3, mobilizing is another behavior lacking attention. Both could be supported by management tools such as the approaches of (social) network analysis suggested by Valk, Juttner and Schlange and Schubert. Therefore, network analysis as well as similar or consecutive ideas are an interesting research field in order to provide useful management tools and guidelines.

jan-patrick.cap@ipk.fraunhofer.de

Abstract: The superior question of this paper is how startups and spin-offs can be supported, and one major goal of this work is to give an overview of existing support mechanisms for new ventures. Through the research of affected stakeholders in the technology transfer process, the characteristics of incubation instruments and the development of the Venture Incubation Canvas, it provides an applied knowledge base for decision makers. The reader should get a picture about how different mechanisms help start-ups in various phases of their venture life cycle and have the necessary tools to create a robust and fruitful incubation business model from the beginning on. The abstract information, principles and the use of the model should be applicable in a general way for different projects and innovation (eco) systems. Since the paper aims at being used in projects in the area of R&D networks, it is important to provide knowledge about the process of transferring technologies into the economy and cast a light on the affected stakeholders. Moreover, a literature review about the different dimensions that are used to define start-up support programs is carried out and existing support mechanisms and best practice examples in the global market are examined. Finally, a practical model is introduced in order to simplify the set-up of an incubation mechanism.

Keywords: incubation mechanisms, venture incubation canvas, technology transfer

1. Introduction

Nowadays, the start-up culture is mostly shaped by digital business models and platform solutions with a focus on decentralization and dematerialization. Lower entry barriers, due to technological developments in the recent decades, make it easier for individuals and young companies to test their ideas, which was one reason for the emergence of a startup sub-culture grounded on a value-based and opportunity-driven entrepreneurial mindset. However, breakthrough innovations are still most often based on technical insights – new products, materials or technological principles. Therefore, intensive technological research still plays a major role, which makes universities and research institutes important partners due to their resources and scientific knowledge for long-term and uncertain technological research and product development. This is why countries around the world are increasingly perceiving science and the transfer of technologies and innovations as important drivers of economic and social transformation processes towards an innovation- and knowledge-based economy (Salomao Martins & Plonski, 2015). One important factor for the successful development and implementation of innovative technologies and products is the support of startup. This paper examines different types of support mechanisms that help start-ups in various phases of their venture life cycle. When starting a business, founders must develop the aspiration, a concept and define their business model as the *pre-startup phase.* At the *start-up phase,* business owners develop, test and validate their product or service with potential customers. Dee et al. (2015) describe the next stages as *early-stage venture*, where financing is provided for further growth due to commercial manufacturing and sales, and *late-stage venture*, where companies have reached a stable growth rate. (Dee et al., 2015).

The principles of technology transfer, as well as various involved stakeholders, their values and the potential conflicts that can arise out of this interaction are outlined in chapter 2. Chapter 3 focuses on the support of new ventures and comprises a literature review about different support programs along with an analysis of best practices and success factors of incubation mechanisms and startups in general. Chapter 4 defines the Venture Incubation Canvas, a practical model, which allows decision makers to create a support mechanism based on their endogenous needs and resources. Chapter 4 also comprises an example of the model by Fraunhofer Venture's instruments, illustrating varied mechanisms and its individual key players, activities, incubatees and incubation goals.

2. Technology Transfer – Make Research Useful

Technology transfer is a specification of knowledge transfer. It is important to understand the present possibilities of transferring technologies and the values and objectives of different stakeholders through a new venture is only one possibility of transferring technology. The techno-economic network (TEN) describes three “poles” in the technology transfer process – the scientific, technical and market pole.

S*cientific pole:* includes various institutions of scientific research, namely academic and non-academic research institutes.

Technical pole: models, prototypes and tests are conceived and developed. Patents, norms and technological rules build a framework, which is mostly found in specialized laboratories, research institutes or manufacturing. M*arket pole: "*refers to users or consumers explicitly generate, express or seek to satisfy demands or needs." (Callon, 1990, p. 134).

TEN helps to understand in which areas and stages technology transfer happens and who the affected stakeholders are. It is also used to interpret where obstacles and different values of stakeholders exist to estimate how these can impede the technology transfer. Technology transfer covers all poles of TEN and can be described as making technological knowledge and developments accessible for the economy and the society. The following forms of technology transfer can be identified (Spath and Walter, 2012; Kenney & Patton, 2009; Debackere and Veugelers, 2005):

- Collaborative research in form of R&D projects or joint ventures of enterprises and the science sector
- Development of formal and informal intellectual property (IP) by the science sector
- Technology-oriented start-ups, founded by researchers or students that gained their knowledge and experience within (non)-academic research institutions
- Technology-oriented spin-offs, founded by researchers or students from (non)-academic research institutions, whereby the technology/knowledge is licensed from the institution to the spin-off
- Transfer of technology-ownership to inventors supported by various incubation mechanisms
- Non-exclusive licensing and public availability of knowledge through open source strategy
- Publication of knowledge and technical insights
- Advanced training and consulting for startups, spin-offs or enterprises
- On-demand research staff for enterprise projects

The final decision on how to transfer technologies is context-based and influenced by the feasibility, the available resources, the expected outcome and the overall mission and vision of the science institution. The possibility to transfer technologies through a new venture seems to be getting more attractive. Siegel and Wright (2015) observe an increase in university startup creation, licensing and patenting in different countries.

Moreover, Festel (2011) states that the gap between innovations from academic and scientific research and the commercialization of industrial applications can be closed more efficiently through new ventures. The process of transforming research results into marketable technologies or products is the most challenging stage in the TEN. Hence, Laredo and Mustar (1996) provide a helpful scheme:

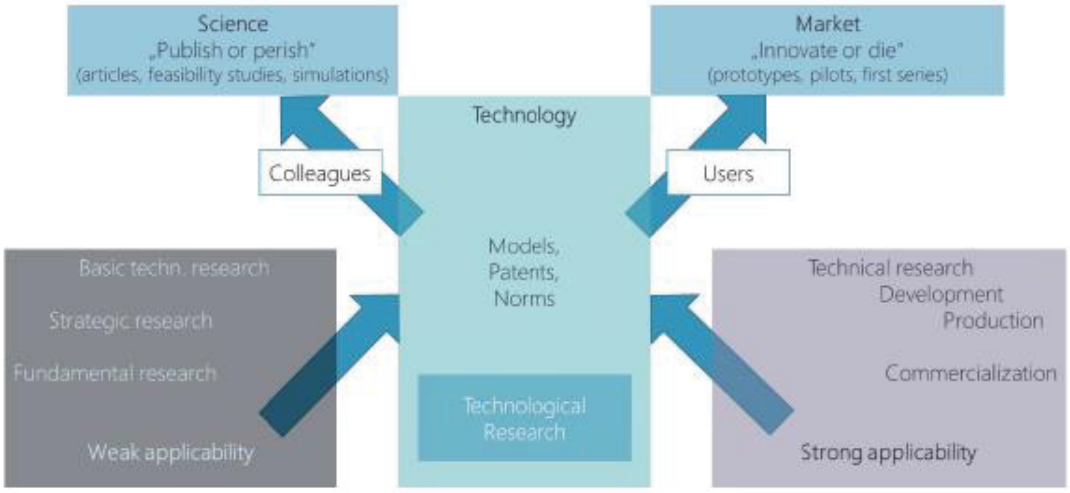

Figure 1: Techno-Economic Network referring to Laredo and Mustar 1996

Huszár et al. (2016) distinguish between the *entrepreneurial scientist*, who plans to commercialize his research results as a new venture and the *traditional scientist* who shows no interest in commercialization. The

entrepreneurial scientist is more likely to have "an important role in spin-off performance through being able to identify and exploit suitable opportunities" (Grimaldi et al., 2011, p. 31). Institutional decision makers have to search for risk-takers and committed staff with the need to return the obtained investment for his knowledge to the society if their aim is a successful commercialization of technologies. However, Spath and Walter (2012) describe both the loss of good and capable researchers and employees and the sacrifice of long-developed research results as problems for science institutes during the technology transfer process.

Expectations and goals might differ between the technical pole and the market pole, especially considering timeframe and financing. Nazaryeva (2015) writes, "while researchers may need funding and industry support when the technology is still in the process of development, the companies expect a final product ready to launch" (p. 63).

3. Incubation – Supporters and their Offers

This chapter looks at the different dimensions of start-up support programs found in the literature. I*ncubation* is the process of growing something under controlled circumstances. *Business incubation* fosters entrepreneurship culture and management activities by providing finance support, coaching, networking and similar services to incubatees (entrepreneurs). The general goal of incubation is to increase business survival rates and foster young firms to grow. The literature on support distinguishes between non-profit and for-profit business models. *Non-profit* incubation programs are mostly run by public entities or academic and science institutions and financed through public grants, membership fees and donations as well as revenues from services, products or events. *For-profit* incubators belong to independent providers, venture capital companies and corporations and realize their funding usually by private investors like Business Angels, Venture Capitalists (VC), corporate VCs or sometimes-public subsidies. Another differentiation made are top-down or bottom-up programs. *Top-down* programs are usually initiated by governments or institutions and backed by law and innovation policies, while *bottom-up* programs are built upon the future client's needs and the discoverable circumstances observed in the environment.

3.1 Incubation Mechanisms

The best-known incubation mechanisms are business accelerators (BAs) and business incubators (BIs).

However, different instruments can also be used to support start-ups as Table 1 shows by giving an overview of the subsequently presented incubation instruments and programs:

Table 1: Typology of Incubation Mechanisms

Incubation Mechanisms	Stage of Intervention	Funding	Time Restriction / Duration
Events and Workshops	pre-startup, startup	hybrid	no
Courses and Consultation	pre-startup, startup	public	no
Competitions and Pitches	all stages	hybrid	no
Co-Working	all stages	hybrid	no
FabLab	all stages	hybrid	no
Technology Transfer Offices	pre-startup, startup	public	yes / short-term
Business Incubators			
With walls	startup, early-stage venture	public	yes / 1-5 years
Virtual Incubators	pre-startup, startup	hybrid	no
Corporate Incubators	startup, early-stage venture	private	yes / 1-5 years
International Incubators	startup, early-stage venture	public	yes / 1-5 years
Business Accelerators			
Accelerator - Investor-led	early-stage venture	hybrid	yes / 3-6 months
Accelerator - Matchmaker	early-stage venture	private	yes / 3-6 months
Accelerator - Ecosystem Builder	startup, early-stage venture	public	yes / 3-18 months
Active Investors			
Founding Angels	pre-startup, startup	private	yes / long-term
Business Angels	startup, early-stage venture	private	yes / middle-term
Venture Capitalists	late-stage venture	private	yes / short-term
Science and Technology Parks	all stages	public	no

Events and Workshops can either support researchers to solve or to develop entrepreneurial scientists, leading to more high-quality spin-offs or start-ups. Additionally, researchers can network with people from different backgrounds and find fitting founding partners.
Courses and Consultation clarify first administrative questions, to learn how to become an entrepreneur and to help founding teams with specific problems they face.

Competitions and Pitches are excellent opportunities for entrepreneurs to "go out" with their idea or product. These competitions can range from a submitted business plan to a pitch in front of an audience or potential investors.

Spaces of Collaborative Innovation, such as *Co-Working, FabLabs & Co.*, allow close and frequent interactions between individuals and create and transmit knowledge (Capdevila, 2013, p. 4).

Technology Transfer Offices (TTO) are independent entities or departments inside a science institution that accompanies scientists and engineers who are willing to found a business. TTOs often intervene in the idea and pre-start-up phase

A *Business Incubator* (BI) is a legal entity that manages a combination of incubation mechanisms, namely legal and business consulting, management and technical support, access to capital and networks, infrastructure and human resources. Four different types of incubators can be identified:

Business incubators (with walls): offer traditional forms of incubation mechanisms with a variety of incubatees inside the provided infrastructure.

Virtual incubators (VI): digitize processes and information and provide services online.

Corporate incubators (CIs): often operating as a unit inside an existing corporation (for-profit).

International incubators: their goal is to offer foreign companies or start-ups a "soft landing", i.e. helping with administrative, legal and taxation questions, as well as the relocation of their families, translation services or language and cultural training (Lewis et al., 2011).

While BIs focus on radical innovations and the survival of new ventures, *Business Accelerators* (BA) focus on scaling a business to foster incremental innovation (Haines, 2014, p. 283) which does not leaves the required room for radical innovation. Lewis et al. (2011) define a BA as a "late-stage incubation program, assisting entrepreneurial firms that are more mature and ready for external financing or a facility that houses a modified business incubation program designed for incubator graduates as they ease into the market." Miller and Bound (2011) describe five main features of the offerings and business models of BAs:

- Open to all, yet highly competitive, application process
- Provision of pre-seed investment (10k€ – 50k€), usually in exchange for equity (5% - 10%)
- Focus on (small) teams not individual founders
- Time-limited support programs ('boot camp') attended by events, intensive mentoring, education, and access to networks (3-6 months)
- 'Cohorts', 'batches' or 'classes' of start-ups rather than individual companies

The rapid validation process for investment and customer acceptance through network development and access to influencers stand out among the advantages of the BA. That results in admission to sophisticated funding opportunities. Among BAs, Clarysse et al. (2015) identified three archetypes:

Investor-led: bridging the gap between the early venture stage and follow-up financing by private investors like venture capitalists, business angels or corporations.

Matchmaker: often implemented in corporations, aim to (1) provide their customers new or improved services and products or to (2) make use of the company's technologies.

Ecosystem builder: are government-backed accelerators that foster innovations, solve societal problems or promote an entrepreneurial culture in strategic areas or industries.

An *active investor* who is supports the new venture beyond transferring and recalling money is an important incubation mechanism. Four types of active investors can be identified:

Founding angels (FAs): identify unmet needs and investigate potentials in their partner's intellectual property portfolios in order to form, fund and manage a new company (Festel, 2011).

Business angels (BAns): are mostly private individuals who invest alone or in syndicates during an early stage in new and growing unquoted businesses who have problems to find investment (see figure 2)

Venture capitalists (VCs) with a typical investment size of ~10k €, <100k € and >500k €: mostly invest in later stages of the venture life cycle and want to see infrastructure, track record and liabilities instead of a big idea.

Public-private venture capital funds (PPVC): e.g. the German High-Tech Gründerfonds (HTGF). Besides an initial 600k € investment for R&D projects, prototyping and market entry, HTGF provides support with recruiting and financial questions and access to a network of entrepreneurs, managers, experts, service providers and investors plus investment managers for exits and IPOs.

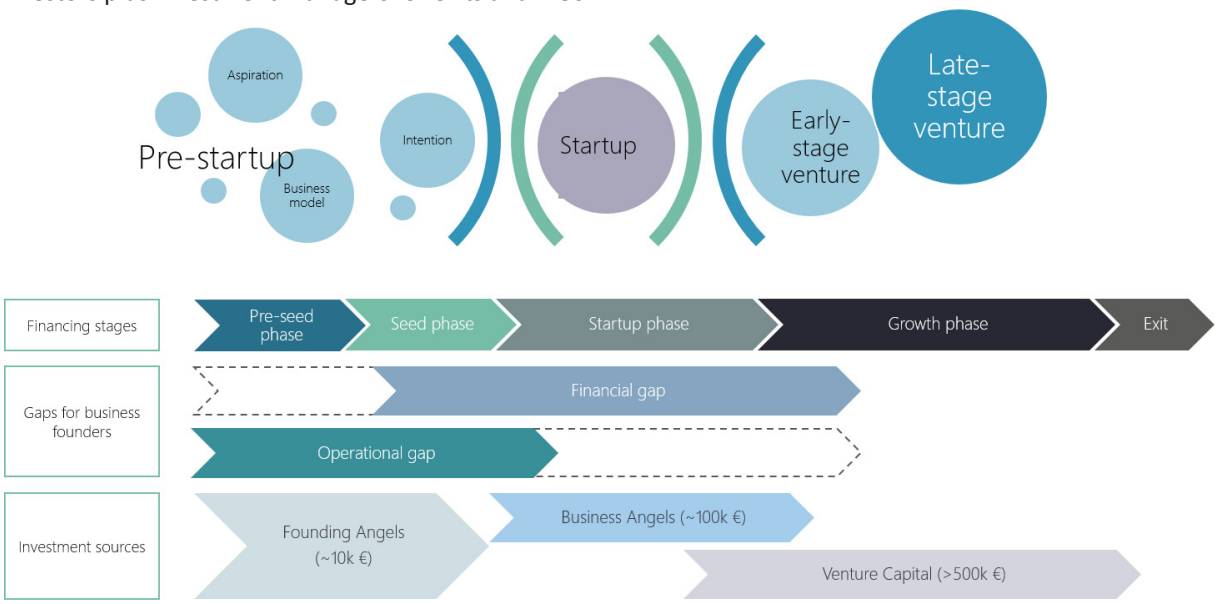

Figure 2: Different investment sources in the venture creation process

Science and Technology Parks are a vibrant mix of policies, programs, spaces and facilities with high standards as well as high-quality value-adding services, (IASP). The infrastructure for incubation combines several of the above-described elements and goals, with a focus on technology transfer and the incubation of innovations and new ventures.

3.2 The Role of Incubation

The literature contains several suggestions on necessary indicators for the success of start-ups or entrepreneurs. Therefore, this paper looks at some general aspects, but always keeps an eye on incubated scientific and technology-based start-ups. Gartner (1985) describes four areas of success: the (1) individual entrepreneur, who brings an entrepreneur background and personality, the (2) process of how the entrepreneur identifies opportunities, develops products and builds an organization, the (3) environment, in form of access to resources and infrastructure, and the (4) organization with all aspects regarding the internal and external business activities and connections.

Research shows that the management and the composition of incubation program's advisory boards serve as excellent success predictor. There are three main sources of success for the incubator: selection process and criteria, business support services, and networks (Yusubova & Clarysse, 2016). Especially the selection process has a determinant impact on the overall success (Ratinho, 2011). In addition, to be successful in transferring

technologies, the management must have a proactive behavior in networking and business support. They need to attract R&D projects and produce useful knowledge, contribute to knowledge transfer and its dissemination and develop activities to promote technical and social events (Amaral, 2015). Moreover, the offered services and its provision, is a determinant of a successful incubation practice and matters more than a host region's innovation capacity or program age or size (Lewis et al., 2011). Relan (2012) argues that financial support without mentoring is insufficient. Another crucial factor to help new ventures to leave the incubation program successfully is business development. It is important to prioritize the activities, get the first clients and support founders in contracting questions, create the business organization and find the next financiers. Incubators should maintain connections to legal and intellectual property specialists. One frequently discussed issue is the venture's length of stay inside an incubation program. For university spin-offs, Rothaermel and Thursby (2005) found evidence that a close connection to a sponsoring institution reduces "the probability of new venture failure and, at the same time, retards timely graduation." Incubation programs create a protective environment as well, which can make the step into the real market more difficult.

However, the regional capacities matter to a successful venture development after an incubation program.

Lewis (2005) states that with the venture's "transition to adulthood," regional capacity (e.g., urbanization, workforce skills, capital access and availability of higher educated employees) matters more for the venture's growth than the incubation program's quality.

Another observable force of incubation programs is their educational path. Even if incubation programs and the incubated companies fail, other cultural characteristics and personality traits have been evoked, namely "taking risks, accepting failure, valuing openness, collaboration and a flat hierarchy, being honest and resourceful and having a sense of equity and a pay-it-forward mentality" (Haines, 2014, p. 280). Almost all researchers agree to the point that specialization is a key for incubation programs' success because of higher levels of economies of scale (Bruneel et al. 2012), a bigger share of tenants with a complete service portfolio and a faster company growth as a result of more intensive service delivery (Ratinho 2011).

Figure 3 gives an overview where instruments are preferably applicable depending on the stage, the relative necessity of resources, the barriers for the ventures acceptance and the supporter's risk in the case of the supported venture's failure.

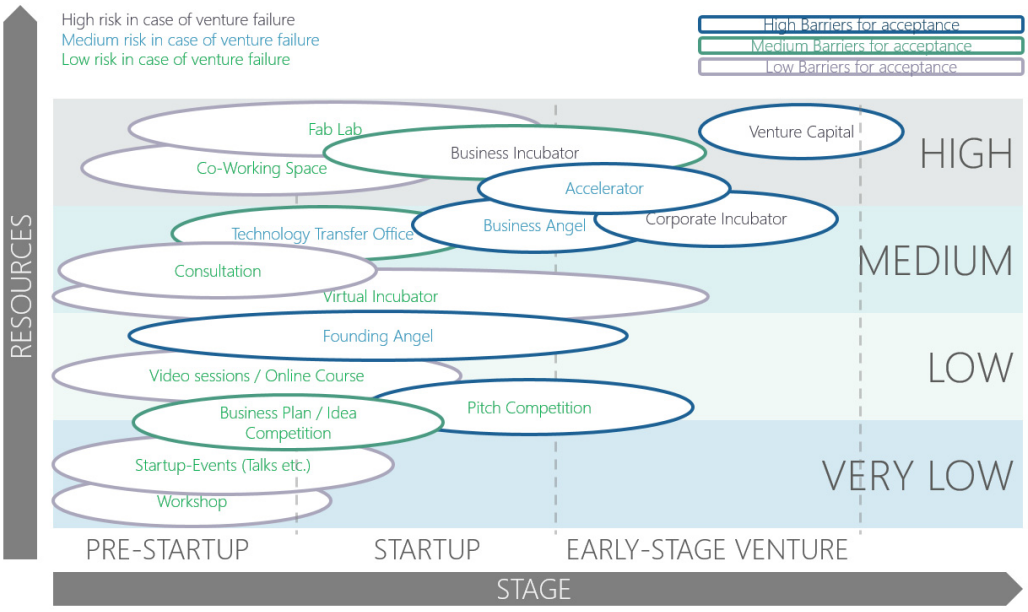

Figure 3: Application of incubation mechanisms depending on the venture stage

4. The Venture Incubation Canvas

Founder of new incubation mechanism occupy the same challenge as founders of new ventures like a financial strategy, a sustainable business model and an offering that delivers and creates value for customers, clients and other stakeholders. Therefore, this chapter extracts single elements of existing incubation business models

and classifies them in a model called Venture Incubation Canvas (VIC). This model enables a simplified, flexible and individual creation of an incubation program for support program managers.

4.1 Elements of Incubation Business Models

Following possible elements of an incubation business model are linked to the VIC's building blocks. In addition to the traditional Business Model Canvas (BMC), the VIC is expanded by the building blocks *financing* and *incubation goals,* due to the strong influence on all other components.

4.1.1 Financing

The funding strategy lays the foundation for all offerings and activities, which can support new ventures or create value in any other kind. At the beginning of the incubation business model generation, decision makers must clarify whether their program is non-profit or for-profit. The motivations for their work are societal, scientific or cultural goals. Anyhow, non-profit incubation program have to build a financially independent business model as well.

4.1.2 Key Players

Program managers have to figure out who their key partners and players are and what they can supply. Key players do not always have to play an active role in the incubation program, but are an important part of the network or play a promotional role. For example, program managers can only introduce investors, experts or mentors to clients if they are able to provide mental or financial support to them. Programs should focus on the creation of alumni networks since they could return value in various forms into the program.

4.1.3 Program Offerings

The incubation literature often classifies the offerings in three main sectors: business support, access to networks and infrastructure. Infrastructure itself is also covered in a separate VIC building block. The combination and characteristic of the provided services let decision makers define their key activities and eventually help describe their incubation value proposition.

4.1.4 Infrastructure and Resources

Incubation programs need infrastructure and resources to work and provide offerings to clients: *Human resources* are partly contained in the building block of key players and influence the activities an incubation program can provide (e.g. high-qualified consultants or experienced mentors). *Intellectual resources* are, for instance, specific knowledge, intellectual property, copyrights, databases and trademarks or brand names. *Physical resources* contain facilities, technological equipment or machinery. *Financial resources* are determined by the building block of funding and the acquisition of key partners. *Cultural resources* describes the culture of the incubator itself which works as an arbiters of cultural capital within new venture by shaping certain values, norms and beliefs (Haines 2014).

4.1.5 Incubation goals

The goals of an incubator are self-defined, can be unique and, in the VIC, influence all other parts of the incubation business model. The purpose of the incubation goals is to highlight the importance of predefined goals.

4.1.6 Incubatees

Incubatees are not just customers who pay for services, but carry resources as ideas, skills, knowledge, experience and diversity. Through fitting selection criteria, the incubation management gathers the right incubatees. The number and the compound of incubatees can become a cultural resource for the incubation business model itself (figure 4). Incubation programs "sell" this resource to investors, government entities or corporations, i.e. all stakeholders that find interest in the created community and ecosystem.

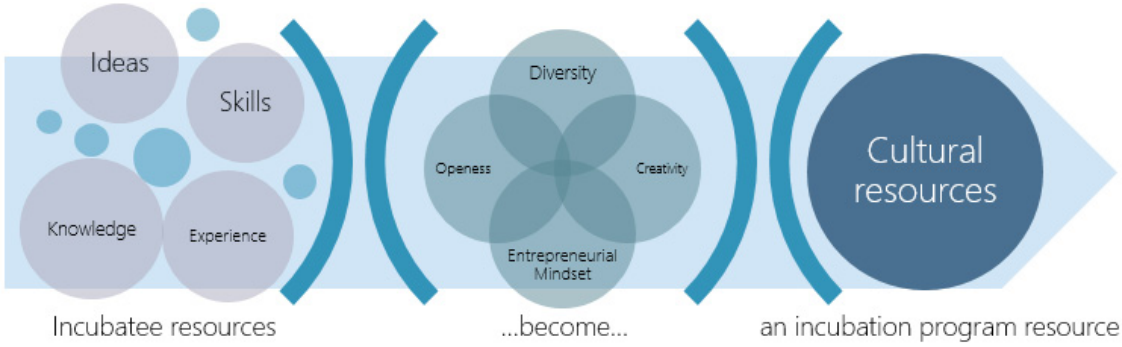

Figure 4: Incubatees as a resource

4.1.7 Selection Criteria and Process

The incubators must build a strategy for their selection process to find the incubatees who fit into the program's culture and help to achieve the defined goals. The selection process reaches from screening a business plan to a multi-stage screening process, where applicants are interviewed and presented to stakeholders.

4.1.8 Touchpoints

Touchpoints represent interfaces between an organisation and their users, customers or other stakeholders, in this case incubators and its clients. Key players need to be reached, e.g. through start-up community platforms, where investors, start-ups and incubators can connect with other entrepreneurs, employees or start-ups, alumni networks or proactive scouting like visiting start-up events, pitch competition or talks.

4.1.9 Revenue Model

If at all, incubation models only receive income from their customers through indirect channels. However, they can look for other sources three different ways of generating income from incubates: growth-driven, fee-driven and independent (figure 5) Dee et al. (2015).

Figure 5: Incubation program's revenue streams

4.1.10 Cost Structure

The cost structure summarizes all the costs that accrue inside the incubation program. Osterwalder and Pigneur (2013) show two forms of cost structures for traditional business models: cost-oriented and value-oriented. Intuitively, incubation models should be value-oriented with excellent services to support young ventures. In the end, incubators have to provide the best possible and tailored services to clients at the lowest costs.

4.1.11 Incubation Value Proposition

The incubation value proposition (IVP) describes the product that an incubator sells through the combination of activities, infrastructure, resources and key players. These offerings impact whether or not founders join the

program. The IVP for an incubation program must provide answers to the questions of who is addressed, what activities are offered and which key player can be included in the programme.

4.2 The Venture Incubation Canvas exemplified by Fraunhofer Venture

Fraunhofer Venture (FV) is a part of the Fraunhofer Society, which focuses on the support and transfer of technologies or products that appeared inside the Fraunhofer Institutes (Fraunhofer-Society, 2016). Figure 6 shows the stage-gate incubation process by FV that accompanies Fraunhofer researchers from the idea over the venture creation to VC investment readiness. Following the different program-steps are described.

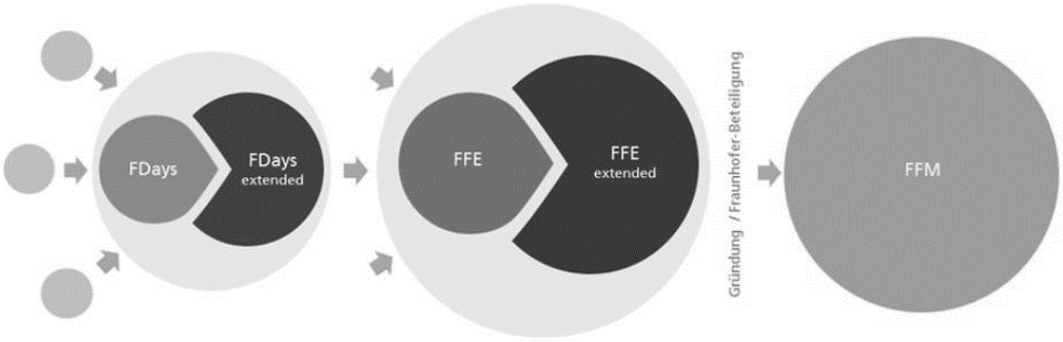

Figure 6: Fraunhofer Venture Support Programs (Fraunhofer-Society, 2016)

1. Idea stage: Fraunhofer researchers are invited to "Business Ideation"- workshops where they can evaluate their idea and detect customer usage, market potential, management team or market entry strategy.
2. FV's FDays: 12-week program with a 15k € project volume where the teams participate "micro-accelerator" in six training days ending in a business model pitch at Demo Day.
3. FDays extended: This additional six-weeks program offers a 20k € partly1 financed project volume for further idea development.
4. FFE ("Fraunhofer fördert Entrepreneure"/"Fraunhofer promotes entrepreneurs"): Successful applications receive a 12-week program with 50k € partly financed project volume in order to create a business plan ready to initialize the venture's spin-off; Resources, infrastructure, legal form and shareholder structure are defined. Researchers reduce foundation-incorporated risks and understand the challenges behind the creation of a new venture.
5. FFE extended: offers follow-up support for further development of technologies and products with up to 100k € project budgets, so the spin-off prepares for VC capability and Fraunhofer Society's participation. At the end of FFE extended, the Fraunhofer participation department decides about a potential interest in the spin-off and participation in the "Fraunhofer fördert Management"/"Fraunhofer promotes management" (FFM).
6. FFM: The program provides a 100k € premium budget for coaching and external expertise and management to support the new venture in order to increase the company valuation for future financing rounds.

5. Conclusion

It was the aim of this paper to develop a methodology to support new ventures in applied R&D networks. This work provided an overview of the technology transfer process through the techno-economic network (TEN) (Callon 1990) framework in order to identify the obstacles and stakeholders involved in the process, understand in which areas and at which stages technology transfer happens and identify who the affected stakeholders are. Next, we looked at the different dimensions of startup support programs, where the popular archetypes of business incubation were described with the use of existing literature and best practice examples. Lack of capital, poor management skills, personal and professional underdevelopment and insufficient understanding of the business environment, plus the specific challenges of their product, are common problems and the reason why many young companies fail (Dee et al., 2015; Etzkowitz, Mello, & Almeida, 2005). This is where business incubation comes in, where governments, academia, science, private

[1] FV assumes 50%, while the respective Fraunhofer institute finances the remainder.

organizations, corporations and investors intervene to support and stimulate the emergence or the growth of businesses and startup ecosystems through investment, business support and facilities (e.g. Clarysse, Wright, & van Hove, 2015). However, while doing the research for this paper, it became apparent that existing mechanisms are not clear to define since they are interpreted differently because of changing market conditions and the need for diversification, but also to match with the existing circumstances inside the ecosystem where incubation programs are applied. For this reason, in chapter four, single elements of the above-described incubation mechanisms are extracted and classified in a model called Venture Incubation Canvas (VIC). Based on that approach, incubation programs' business models should be easier to build, adjust, decouple or extend. Moreover, eventually, it can be stated that "THE methodology" cannot be developed from the outside and a final methodology needs to be developed and implemented by the ecosystem's stakeholders. The key building blocks of an incubation business model are the financing and the incubation goals. Decision makers and stakeholders need to fill the building blocks and create their individual incubation program on this foundation.

Abstract: The Portuguese business structure is essentially composed of small and medium-sized enterprises (SMEs), which, despite their size, generate employment and contribute to the increase of national income. In many of these companies, some of them having less than ten employees, management and operational functions are often carried out by the entrepreneur. In addition, the entrepreneur does not always have technical knowledge in management, nor do they have the available time (since they have various responsibilities within the company) to develop and implement a management strategy that allows the enterprise to remain in the market while adopting a more conscious, consistent and sustained orientation. Within the scope of the Operational Program for Competitiveness and Internationalization - Portugal 2020, the Balanced ScoreCard (BSC) strategic management instrument was developed and implemented in several companies and sectors of the Portuguese economy. This instrument was crucial in initiating a process of strategic thinking which, quite possibly, would not have happened in such a short time horizon. This research work analyses through an essentially qualitative research the way the BSC instrument was developed and implemented. Another objective is to understand the main advantages of its use and its main application constraints. The data was gathered through a semi-structured interview developed for the owners of four Portuguese SMEs in the northern region Portugal, targeted under the abovementioned programme framework. The results demonstrate the instrument was essential for the development of a structured strategic thinking, as well as for a better performance and, consequently, to the improvement of the competitiveness of the targeted companies. The results also show the instrument had to be adapted and simplified and its implementation has to involve all the employees of the enterprises.

Keywords: Balanced ScoreCard, SMEs, strategic thinking, performance, competitiveness, Portugal

1. Introduction

The Portuguese business structure is composed, from north to south of the country, mainly by micro and small and medium enterprises (SMEs) (Instituto Nacional de Estatística, 2018, Pordata, 2018). In fact, if we look at the Portuguese business structure, micro, small and medium-sized companies hold a majority compared to large companies. Notwithstanding their small size, and since their number is large, they contribute significantly to the Portuguese Gross Domestic Product (GDP) and to employment creation. Thus, according to data published in Pordata (2018), in the year 2016 there were 1,213,107 SMEs in Portugal, corresponding to 99.9% of the total number of companies in the country. In this group, 1,167,993 (96.2%) were micro-sized, 38,866 (3.2%) were of small size and 6,248 (0.5%) were of medium size, according to the data collected from INE (2018). Still, and according to the metadata information of Instituto Nacional de Estatística (2018), a company is considered micro if it has less than 10 employees and a total turnover and/or balance sheet which does not exceed 2 million euros; a company is considered small if it has between 10 and 49 employees and an annual turnover and/or total balance between 2 and 10 million euros; and a company is considered medium if it employs between 50 and 249 people and has an annual turnover between 10 and 50 million euros, or an annual balance between 10 and 43 million euros.

In Portuguese micro enterprises and in SMEs, when the entrepreneur has an average education level and the human resources department does not employ any personnel with qualification in management, the strategic planning of the company is not always considered from a medium to long-term perspective. However, in an increasingly competitive market, it is essential that companies make use of all their skills, both material and technological, as well as their human resources, which are essential to increasing their productivity and competitiveness. Effectively, without these competencies, organizations will not be able to interact in a more

competitive market and thus position themselves sustainably in order to achieve consistent growth and organizational excellence (Requeijo et al., 2018).

With the aim of stimulating smart, sustainable and inclusive growth, the Partnership Agreement between Portugal and the European Commission, called Portugal 2020 is being implemented through 16 Operational Programs to be developed between 2014 and 2020. Among these 16 Operational Programs, the ones that stand out Compete 2020 - Competitiveness and Internationalization Operational Program and the North Region Operational Program 2014-2020.

In order to achieve a more equitable distribution of funds, the Portuguese territory was divided into three distinct zones, taking into account the level of GDP per capita, accordingly: i) regions which are considered to be less developed, showing a GDP per capita of less than 75% of the EU average, which include the North, Centre, Alentejo and Autonomous Region of the Azores; (ii) regions in transition, which show a GDP per capita between 75% and 90% of the EU average, including the Algarve region; and (iii) more developed regions, which show a GDP per capita above 90% and include the Lisbon region and the Autonomous Region of Madeira. The companies targeted in this research are located in the northern part of the country and have been involved in the Compete 2020 Program. As part of the operationalization of this program, the Balanced ScoreCard strategic management tool was developed and implemented in a set of companies, while adapted to the reality of each company.

Therefore, the objective of this research is to identify and understand the benefits from the participation of a group of companies in the operational program Compete 2020 - Competitiveness and Internationalization Operational Program and the North Region Operational Program 2014-2020, during which it was developed and operationalized the Balanced ScoreCard strategic management tool.

Consequently, and to pursuit on the proposed objective, in section two a theoretical introduction to the Balanced Scorecard methodology and its use as a tool for strategic management in micro and SMEs is made according to the relevant existing literature; in the section three the procedures for the development and implementation of BSC in the group of companies involved are explained and in the section four the main conclusions of this intervention and the advantages and gains for the participating companies are described.

2. Balanced ScoreCard as a strategic management instrument

The economic and financial situation is the result of certain decisions that encompass other areas of the company, such as customers, internal processes, and innovation and learning, namely all those involved in the operational process. Hence, it is extremely important to define non-financial indicators that allow the measurement of organizational performance, and to complement the economic vision that only some entrepreneurs adopt in companies (Brandão et al., 2008, Ravi et al., 2005, Davis and Albright, 2004, Norreklit, 2000).

The consideration of non-financial indicators defined alongside with financial indicators allows organizations to align their mission, vision, values, objectives and behaviors, as well as to develop a continuity of improvement of processes, which translates into enhanced products or services and, consequently, in better results and quantifiable successes and failures (Rompho, 2011). This process should be continuous, and organizations should, at the end of each cycle, diagnose, coordinate, monitor and evaluate the results obtained for each defined indicator in order to measure organizational performance. Thus, performance measurement and evaluation provide the necessary feedback, the indispensable understanding, and the motivation required to initiate strategic thinking, structural change, and organizational learning processes.

It is this organizational learning (Brandão et al., 2008), the organization's ability to learn, to change and to adapt itself to new market demands, which makes it assume a more dynamic perspective and which will allow the necessary and essential adaptation to happen in a competitive and sustained way, in a market that is increasingly competitive.

The fundamental issue of the analysis lies in strategic thinking (Valdez et al., 2017), structural change and organizational learning (Brandão et al., 2008), the definition and determination of performance measures

being an essential process for all stakeholders involved to understand, adapt and undertake necessary efforts for the company to achieve the main goal, which is generation of profit.

The success of contemporary organizations depends more and more on the quality of the products and services they offer. However, most of the time this is not in itself a sufficient condition for a company to remain in the market. Considering the reality of the micro and small Portuguese companies, one of the big players in the entire business process is the entrepreneur, often a one-man show and the only person in the company who happens to hold several business functions, ranging from operability to strategy; in many of these cases, strategic thinking, a key factor in the medium and long-term permanence of the company in the market, is being relegated to the background. This characteristic was likewise mentioned by Andersen et al. (2001) and Valdez et al. (2017).

The development and implementation of this tool of strategic management, BSC, enables companies involved, and more specifically the entrepreneur, to stop worrying about the strategy and planning of their business. Moreover, this methodology was developed by Kaplan and Norton in 1992 and was widely used in and by several organizations (from micro to large size), since its main objective was to capture the tool's complexity in a holistic way (Prieto et al., 2006, Rosemann and Wiese, 1999, Andersen et al., 2001, Rompho, 2011, Johanson et al., 2006, Rodrigues, 2018).

Some of the advantages of using this instrument as a strategic management system is that it allows: a reflection and definition of a set of performance indicators and their link to the company strategy (Bhagwat and Sharma, 2007); understanding the relation of operational control to mission, vision and strategy (Fernandes et al., 2006); the correct definition and clarification of cause and effect relationships; attention of entrepreneurs to stay on the most critical aspects associated with their business; and, finally, the fact that its implementation fosters a holistic, broad and integrated vision of organizational performance (Kaplan and Norton, 1995, Rosemann and Wiese, 1999, Johanson et al., 2006, Prieto et al., 2006). In fact, this process allows to understand the important relationship between the different goals and objectives of all the diverse stakeholders in the company, such as managers, customers and employees (Akkermans and Van Oorschot, 2018).

Also, according to Andersen et al. (2001), Valdez et al. (2017) and Fernandes et al. (2006), the BSC implementation both in micro, SMEs and large companies allows to determine the direction the company should follow, a deep acquaintance of the organization, the ability to focus and to prioritize and the agility to change whenever necessary.

Likewise, the BSC seems to be extremely important not only in defining indicators for the four different perspectives already mentioned, but also in the identification of skill gaps at an organizational level, given their complete nature, in accordance with Brandão et al. (2008), Prieto et al. (2006) and Rosemann and Wiese (1999).

3. The implementation processes

The development and implementation of a BSC is a time-consuming process and must follow appropriate procedures. Kaplan and Norton (1995) consider the following steps for their development: preparation, interviews with senior management, executive workshop (first round), interviews (second round), executive workshop (second and third rounds), implementation, and subsequently, periodic reviews. Since in the cases mentioned the process occurred in micro enterprises, companies in which the entrepreneur and manager were one and the same person, the process tended to be simplified (Andersen et al., 2001), having elapsed as described below.

Therefore, the BSC's development and implementation process advanced as follows: an initial meeting was held with the entrepreneur, manager or selected team to follow up the project, during which the entire procedure was explained and the implementation schedule was defined. After that, a timetable was issued, which was signed by all those involved in the process, and a weekly schedule for follow-up and progress meetings was also defined. This procedure occurred according to the aforementioned (Kaplan and Norton, 1995).

The following week a diagnosis of the company was elaborated, which was the starting point for all the work developed. In order to elaborate and to prepare this diagnosis, it was necessary to research, collect and gather all the information related to the company's strategy, which was later used as input in the first phase of BSC development: i) internal to the company: financial plan (if existent), marketing (if existent), balance sheets and income statements for the last 3 years, Simplified Business Information [Informação Empresarial Simplificada] for the last 3 years, quality improvement programs (if existent), customer analysis (sales evolution, margins, payment deadlines, economic and financial situation , etc.) and interviews with senior management; ii) external to the company: competitive analysis, trend analysis, technological evolution analysis, market share evolution, comparison with Banco de Portugal data and sector data (INE and Pordata); and iii) analysis of data of the largest competitors—their characteristics, positioning and analysis by market. After the diagnosis of the company was completed, a working session was held with the remaining employees of each of the companies, with the purpose of integrating them throughout the process, since it held great importance in the development of this instrument and, consequently, in the strategy of the company (Andersen et al., 2001).

Actually, one of the reasons that is pointed out for the failure to implement this instrument in SMEs is lack of involvement of the organization's employees (Rompho, 2011).

The following session had the objective of defining the strategic themes and should validate the following assumptions: there should be no more than 5 strategic themes; strategic themes are realistic and achievable by the organization; themes support and are related to strategic objectives; themes have a positive influence on the organization; themes give direction and impact to what is important; each theme is different; themes have a strategic scope, that is, they are valid for the duration of the context in which they are defined; the themes are consistent with the mission and the vision; the themes have an impact on the financial objectives of the organization.

The subsequent work sessions were aimed at building the mission and operational vision of the business strategy and, later on, at the development of the dashboard, which contains: i) the four distinct perspectives of BSC (Rompho, 2011, Davis and Albright, 2004, Johanson et al., 2006): financial, customers, internal processes, and innovation and learning; ii) the indicators, with their source and metric, for each of the perspectives; iii) the strategic objectives and the respective goals, defined annually and for a time horizon of 3 years; iv) the programs or activities to be developed, for each indicator and/or group of indicators; and finally, v) budgeting. The development of the dashboard took an average of 7 work sessions, of 4 hours each, in each of the companies under contract.

The following table shows some of the indicators defined by the companies, for each of the perspectives, for the construction of the strategic objectives.

Table 1: Indicators defined by companies

Financial perspective	**Customer perspective**
Annual turnover	Overall customer satisfaction
Liquidity	Percentage of customers who would recommend the company
Gross margin	Percentage of customers viewing the company as a partner
Solvency	Return rate of major customers
EBITDA - Earnings before interests, taxes, depreciations and amortisations	Service award rate
	Number of new customers based on annual turnover
Operating result	Increase in the number of new subscribers / year
Net income	Advertising turnover volume increase
Financial autonomy	Frequency of publication
Return on equity	Number of new customers
Return on assets	Number of visiting customers
Results by business area	
Profitability by business area	
Internal processes perspective	**Innovation and perspective**
Number of orders to suppliers	Number of hours of training per year
Value of orders to suppliers	Employee satisfaction
Number of trips made for purchase	Employee stress
Inventory rotation	Evaluation rate of training effectiveness
Days of stock	

Internal processes perspective	Innovation and perspective
Implementation of Safety and Hygiene at Work Internal communication Timely conclusion/delivery of technical pedagogical dossiers National Authority for Civil Protection accreditation Definition of process phases Definition of the procedure in each phase Implementation of defined procedures Definition of the monitoring and control system System implementation Preparation of basic report (with indicators) to present to the bank	

Source: Self elaboration based on information collected from the companies

All the processes were completed by August 2017, and the results were evaluated in March 2018, while the goals of the indicators were updated whenever it was necessary. In an interview with the businessmen, it was concluded that the implementation of this strategic management tool allowed each of the companies involved to define a set of activities that reinforced their presence in a more systematized and sustained manner in a competitive market, while allowing them to rethink their activity, in view of the endogenous and exogenous component of the organization itself. These perspectives were aligned with several researchers like Andersen et al. (2001) and Ravi et al. (2005).

Thus, the companies, after implementing the defined activities, rethought the internal processes inherent to the development of their activity, improved their results, increased the number of clients—in short, improved and reinforced their position in the market in which they operate or have strengthened their performance as well as their competitiveness.

Among other things, the BSC supports organizations to define, implement, maintain and improve proactive strategies to identify and solve internal problems, including financial, customer, and internal processes, as well as learning and development (Ravi et al., 2005, Johanson et al., 2006).

4. Discussion

This paper highlights the importance of the need for adequate strategic management in SMEs, as well as the scarcity of resources, usually human resources, of micro and small enterprises, which convey in the lack of adequate management procedures that would allow these companies not only to stay in the market sustainably but also to develop a growth strategy that would allow them to grow and thrive in competitive markets. In fact, authors like Singh et al. (2018) consider the performance evaluation crucial to competitiveness and to companies' sustainability.

Accordingly, through the participation of micro, small and medium companies in funded programmes, this gap is minimised, and entrepreneurs have access to knowledge transfer, provided by the consultants who intervene in the company, initiating a strategic framework and management thinking process, which otherwise would hardly happen, at least in the short term.

5. Conclusions

In general terms, the following results were achieved within the group of intervention companies: generation of higher value for entrepreneurs, increase in financial and investment capacity, growth in turnover, increase in customer numbers and customer loyalty, achievement of new customers and/or new markets, increase of market share, increase in profitability, increase of productivity, innovations in the production process (internal process), anticipation of the needs of target markets, increase of the number of training hours for human resources, and increased employee satisfaction.

The implementation of the project made it possible for companies to adopt practices that allow them to better adapt to the current competitive requirements, with the definition of new indicators, new goals and new activities that will allow them to consolidate their positions in the market. This idea was also shared by (Requeijo et al., 2018, Valdez et al., 2017, Bhagwat and Sharma, 2007, Rodrigues, 2018).

The improvement of the internal processes is also expected to be reflected in the increase in the number of clients, in a higher percentage of budgets awarded and, consequently, in an increase in the rate of growth of turnover, as well as in the increase of the number of clients. On the other hand, the planned training actions should enable human resources to achieve better satisfaction and motivation and, certainly, better performance and higher productivity.

Therefore, it is concluded that the development and implementation of the Balanced ScoreCard strategic management tool is a great asset for a more systematized and sustained development commitment, which will have repercussions in the future and will bring improvements not only in the short but medium time horizon, since the development of skills resulting from this cooperation has ensured a greater performance of companies and demonstrated that a growing increase in the respective organizational processes is possible, with clear advantages in terms of their performance in the market.

Small and Medium Enterprises and New Ventures in Entrepreneurial Ecosystems: The Case of Industrial Districts and Innovative Startups in Italy

Angelo Cavallo, Antonio Ghezzi and Cristina Rossi-Lamastra
Politecnico di Milano School of Management, Milan, Italy
angelo.cavallo@polimi.it
antonio1.ghezzi@polimi.it
cristina1.rossi@polimi.it

Abstract: To date, contributions in the field of EEs have mainly focused on EEs' definitions, actors, key attributes, and consequences on new ventures' creation and growth. To the best of our knowledge, the few studies that explicitly examine the relations among EEs' actors under-remark the linkages between Small Medium Enterprises (SMEs) and new ventures. We deem that this relation is important, especially for EEs located in countries characterized by an underdeveloped Venture Capital (VC) market, a limited number of large corporations and a massive presence of SMEs, often operating in traditional industries, which are the main engine of local and regional development. This study sets the stage for advancing our understanding of this under-explored relation to stimulate novel directions for academic research and practice-oriented conversations on EEs and, more generally, on regional development. To this end, first, we systematize the (limited) extant knowledge on the relation between SMEs and new ventures in EEs. Then, for the shake of relevance, we provide descriptive evidence of this relation in the context of Italian Industrial Districts (IIDs), a peculiar case of EEs, where Italian SMEs tend to agglomerate. Specifically, by using GIS techniques, we found evidence that Innovative Startups tend to locate within IIDs. Interestingly enough, no evidence supports the view that Innovative Startups operate in the same industry of specialization of the IID. Finally, the study presents a possible research agenda on the topic, which we hope can be of interest for both academics and policymakers.

Keywords: Entrepreneurial Ecosystem, Industrial Districts, Entrepreneurship, Geo-Proximity, Industry Relatedness

1. Introduction & Background

Scholars define entrepreneurial ecosystems (hereafter: EEs) as "sets of interdependent actors and factors coordinated in such a way that they enable productive entrepreneurship within a particular territory" (Stam, 2015, p. 5). The concept roots in the regional development and strategy literature (Yun et al., 2017; Erina et al., 2017) and emphasizes that entrepreneurship happens in a community of individuals, organizations, and regulatory bodies located and interacting in specific geographical area (Isenberg, 2010; Acs et al., 2017; Kuratko et al., 2017). Several scholars conceive EEs as complex and "evolving" dynamic systems (Acs et al., 2014; Feld, 2012; Isenberg, 2010; Spigel, 2017). Consequently, Neumeyer et al. (2017) examine EEs as complex social organizations by means of social network data analysis; other researchers introduce system dynamics and simulation methodologies in EE research (Yearworth, 2010; Yun et al., 2017). Despite we do not want to deny the value of these efforts, we recognize that most of the literature has seriously questioned the feasibility of modelling a complex and dynamic system as a whole (Pruyt 2013; Harrison et al., 2007). As suggested by Forrester (2007) - the father of complex modelling - to gain understanding of complex systems we should first focus their smaller parts and key and context-specific relationships (Sterman, 2000; Ghaffarzadegan, 2011).

Expanding on this argument, we contend that we can foster our understanding on *why and how* new ventures are created and growth in EEs by going deeper into the most important relations linking their actors (see e.g., Spigel, 2017 for a similar argument). The growing strand of the research on EEs, which addresses this topic, has, to date, focused on the relationships linking new ventures to incubators, venture capitalists (VCs), local universities, and large corporations. Many contributions recognize the paramount importance of incubators for fostering local entrepreneurship (see for instance Campbell and Allen, 1987); likewise, there is wide consensus on the key role of universities in EEs. Specifically, universities viewed as sources of entrepreneurial opportunities and technical solutions, which stimulate the creation and growth of new ventures. VCs are regarded as key actors in EEs alike. This holds especially true when referring to innovative entrepreneurship as these specialized investors can fill the financial and knowledge gaps that innovative startups experience in their early development stages. Finally, several contributions point to the leading role of large corporations in supporting new ventures in EEs (e.g. Bhawe and Zahra, 2017).

Conversely, the relations linking new ventures, in general, and innovative startups in particular, to SMEs has to date gone largely under-remarked. We consider this an important gap in the literature on EEs. Indeed, evidence exists that many EEs, where the VC market is under-developed and there are few large corporations, are rich in SMEs (often operating in traditional industries), which are deeply embedded in the territory. It is reasonable to imagine that, in these contexts, SMEs can play a leading role in stimulating the creation and growth of new ventures - even of the innovative ones - and can create important synergies with incubators and universities. Indeed, as we explain in the following, despite suffering from liability of smallness, SMEs can be focal resource-providers and privileged partners for new ventures and innovative startups, with which they can establish win-win relations. This study is a first attempt to fill this gap.

To this end, first, we discuss why the relations between SMEs and new ventures can be key in EEs, also systematizing the (limited) available knowledge on the topic. Then, we provide descriptive evidence pointing to this relation in the relevant context of the Italian Industrial Districts (IIDs), a peculiar case of EEs, where Italian SMEs, operating in the same industry, tend to agglomerate (Becattini, 1989).

The remainder of the study consists in four sections. Following the introduction section, Section 2 illustrates the Research Design. Section 3 illustrates the results. Finally, Section 4 discuss the results and conclude the study, focusing on its academic contribution and relative policy implications.

2. Research Design

2.1 The Empirical Setting

The academic relevance of the Italian case is threefold. First, VC market in Italy is underdeveloped and there is also a limited range of large corporations: these characteristics provide fertile ground for the interaction between innovative new ventures' and SMEs - typically populating an Italian Industrial District (IID) - a crucial element for the growth of a local EE. Second, IIDs represented a successful story of entrepreneurship, extensively debated in literature (e.g. Becattini, 1989; Camagni & Capello, 1988; Pyke et al. 1990), that led Italy to be the 6th economy (by GDP) in the World. The Italian Industrial Districts experienced several crises and transformation phases to date, but still represent an important engine for the Italian economy. Third, we are currently witnessing a new big wave of innovative and growth-oriented entrepreneurship. As a result, more than 8,000 innovative start-ups had registered and claimed to be innovative, according to the Italian Chamber of Commerce Firms Register. For a more detailed description of the new Italian legislation on 'innovative start-up', see Colombelli (2016), and Calcagnini et al. (2016).

2.2 The Database

Data on innovative new ventures and Industrial Districts (IIDs) in Italy informed our analysis. Specifically, data on innovative new ventures was collected from the Italian Chamber of Commerce Firms Register - Special section (Register). As a result, the data set includes 8406[1] firms established in Italy between 2009 and 2017, distributed across 110 NUTS3[2] (provinces) and classified by industry through ATECO[3] 2007 codes. Data on 141 Industrial Districts, also distributed across 110 NUTS3, were collected from ISTAT (The Italian Institute of Statistics).

2.3 Measuring Geographical Proximity and Industry Relatedness

We express distance in kilometers and travel time in hours. Distance is as a continuous measurement of geographical proximity (Ellwanger and Boschma, 2015) and it has been calculated by means of the great distance formula (Pearson, 2011). Latitude and Longitude geographical coordinates were collected for each innovative startup and industrial district. As a further measure of geographical proximity, we also calculated the shortest travelling time by car (Fritsch and Schilder, 2006) using Google.maps, an on-line route planning tool.

[1] Updated to 29/12/2017.

[2] NUTS stands for Nomenclature of Units for Territorial Statistics, geographical nomenclature subdividing the economic territory of the European Union (EU) into regions at three different levels: NUTS 1, 2 and 3 respectively, moving from larger to smaller territorial units. (Source EUROSTAT).

[3] Italian version of the European nomenclature, NACE Rev. 2, published in the Official Journal of 20 December 2006 (Regulation (EC) no 1893/2006 of the European Parliament and of the Council of 20 December 2006).

After measuring spatial distance, we were able to identify the closest IIDs for each innovative new venture. In accordance with our research interest, we then measured whether there is industry relatedness between innovative new ventures and their closest IID. Industry relatedness is commonly measured by indicating whether two activity codes belong to the same level within the hierarchy of an industrial classification system (e.g. Frenken et al., 2007). Some scholars also use other specific measures for relatedness, such as product-relatedness (see for instance Neffke et al., 2011) or technological-relatedness (e.g. Ahuja and Katila, 2001). Since, the latter is more appropriate for large firms rather than small ones (Aghasi et al., 2017) (as in our sample) and no data is available on products, we measure industry relatedness based on ATECO codes. Despite its weaknesses (e.g. Markides and Williamson, 1996), ATECO classification is the only consistently available information for our sample. ATECO codes discriminate the core business activities of a firm to the division (2-digit), group (3-digit), class (4-digit), category (5-digit) and subcategory (6-digit) level. Since many firms in our sample do not present data in terms of group, class, category and subcategory, we focused on divisions. Thus, we operationalized industry relatedness with mutually exclusive binary variables, as a widely accepted and used measure in literature (e.g. Ellwanger and Boschma; 2015). Specifically, we measure industry relatedness between the new ventures and the closest IID based on the following variable: INTRA_Division, equal to 1 if the innovative new venture shares identical first two digits of its ATECO code (division) with at least one of the IID's codes, zero otherwise.

3. Empirical Evidences

In accordance with the main interests of the present study, we closely look at the geographical proximity and industry relatedness. Table 2 and Table 3 illustrate the distribution of the spatial distance between Industrial Districts (IIDs) and innovative new ventures in kilometers, as well as in terms of travel time (hours). According to ISTAT, the average geographical area occupied by IID in Italy is 400 km^2. As, methodologically, we localize each IID with the geographical coordinates of the center of the geographical area that it covers, it is reasonable to assume that - within 10 km distance from an IID - the new venture is located in an IID's geographical area. Results in Table 2 illustrates that this is the case for 18% of the total sample of new ventures. Furthermore, we find that the 73% of the total sample of innovative new ventures is located within 40 km from the closest IID. Thus, we may consider reasonable that - within 40 km distance - two entities can be accounted as being in geographical proximity. Similarly, while considering travel time.

Table 2: Distance between Industrial Districts and Innovative new ventures*

	<10 Km	*10-40 Km*	*40-100 Km*	*100+ Km*
Number of innovative start-ups	1465	4615	1535	712
Percentage	18%	55%	18%	9%
Cumulated	18%	73%	91%	100%

*Number of Observations: 8327

Table 3: Travel time between Industrial Districts and Innovative new ventures*

	<30 mins	*30-60 mins*	*60-120 mins*	*120+ mins*
Number of innovative start-ups	4296	3118	308	605
Percentage	52%	37%	4%	7%
Cumulated	52%	89%	93%	100%

*Number of Observations: 8327

Once identified the closest IID for each new venture, we measured their distance in terms of industry. As shown in Table 4, results clearly indicate a certain distance in terms of industry between new ventures and their closest IID.

Table 4: Industry Relatedness between Industrial Districts and Innovative new ventures

	Intra-Division
Number of innovative start-ups	447
Percentage	5,37%
Cumulated	5,37%

*Number of Observations**:** 8327

4. Discussion and Conclusion

The Entrepreneurial Ecosystem Research, though being an emerging field, can count on numerous and precious contributions within the field of entrepreneurship. For instance, the body of knowledge dealing with entrepreneurial dynamics such as new venture creation is extensive. To foster our understanding on *why and how* new ventures are created and grow in EEs, scholars should focus on the most important relations linking their actors (Spigel, 2017). The growing strand of the research on EEs, which addresses this topic, has, to date, focused on the relationships linking new ventures to incubators (Campbell and Allen, 1987), venture capitalists, local universities, and large corporations (Bhawe and Zahra, 2017). In accordance with Acs et al. (2017), Anselin et al. (1997), and Florida et al. (2017), EE are territory and context specific. Thus, the key relations in EE should consider local and contextual dimension - as a dominant logic in entrepreneurship. In the light of these arguments, we contend that scholars investigating EEs characterized by an underdeveloped Venture Capital market and a low number of large corporations should focus on the key relation between SMEs and innovative new ventures. In this study, we aim at opening a debate and provide further research direction to explore such key relation in EE. By introducing the theoretical setting (in Section 1), we provide initial argumentations on the main features and differences characterizing SMEs and innovative new ventures, and thus, why partnerships and collaboration among those key players in EE may work and should be encouraged by specific policy measures. To further this debate, we need both qualitative and quantitative studies. For instance, exploring cases of partnerships between SMEs and innovative new ventures may enhance our understanding of the mutual benefits they may exploit. Beside successful case history, also worst cases and failure cases should be investigated. As regard, several studies are needed focusing on specific context and industry of reference in order to further our understanding on good, best and bad practices while SMEs and innovative new venture are partnering.

Along debated in literature, the “serivatization process” involves many SMEs operating in manufacturing (e.g. Vandermerwe and Rada, 1988; Baines, et al., 2009) and may also represent a promising avenue to further EE’s research. SMEs typically are more product than service oriented. However, today customers require additional services that may complete the product, expand its uses and scope. In some cases, products are replaced by services. In other words, companies are selling the usage of a product rather than selling it. The *serivatization process* may represent a specific type of collaboration project leading to mutual benefits for SMEs and innovative new ventures. Many companies, in order to face new trends and threats and be sustainable, are required to build additional services around a focal product (Coreynen, Matthyssens, and Van Bockhaven, 2017). This process is not easy for “giant” companies and similarly for SMEs. Future research may investigate whether innovative new ventures may support IIDs’ SMEs through their servitization process. Moreover, scholars that are demonstrating a major attention on digital entrepreneurial ecosystem may find of a great interest to investigate the role of “digital servitization process” (Opresnik and Taisch, 2015) as factor enabling SMEs and innovative new ventures collaboration and ultimately fostering digital entrepreneurial ecosystem.

Recently emerged another hot topic that deserves great attention while dealing with EEs: how entrepreneurial dynamics can be governed (see e.g. Colombo et al., 2017) and what are the key actor that may have a major role here: nobody - “invisible hand”? (Isenberg, 2010), policy makers? (Stam, 2015), universities? large corporations? (Bhawe and Zahra, 2017), investors? (Colombo and Murtinu, 2017), joint ventures (Audretsch and Link, 2017); and in which phase of the EE evolutionary process? (Colombelli et al., 2017). In this study, we highlight that also SMEs may play a major role in EE. Future research should focus, not only on how SMEs may favor the birth and growth of innovative new ventures, but also, their supportive role to other EEs’ key players

such as incubators, angels, VCs etc. In addition, we argue that a promising research direction will investigate whether SMEs may replace some of the key players aforementioned and compensate to the absence of an active venture capital market. Here, qualitative and especially quantitative studies are required to foster our current knowledge on the topic.

In this study, we also started to search for "signal" of connection between SMEs and innovative new ventures. Specifically, we provide descriptive evidences on the geographical and industry proximity between SMEs and innovative new ventures. Our descriptive evidence suggest that innovative new ventures tend to agglomerate within or close by IIDs - typically populated by SMEs operating in the manufacturing sector. A large body of literature argue that effective collaboration may be favored by geographical proximity (e.g. Rallet and Torre, 1999; Knoben and Oerlemans, 2006). However, several other forms of proximity exist (Boschma, 2005) that need further investigations such as industry proximity. As regard, we find no evidence on industry relatedness between innovative new ventures and IIDs. Scholars, while adopting different theoretical lens, have along debated around industry relatedness as factor fostering rather than depressing the potential advantages of collaborations between organizations. For instance, organizational learning theorists suggests that interactions among industry related companies may favor the exploitation of synergies leading to better innovative and economic performance (Cohen and Levinthal, 1990). Conversely, some scholars argue that being too industry-related may reduce the learning opportunities and affect innovation performance (Sapienza et al., 2004; Cloodt et al., 2006). Similarly, scholars following a Resource-Based-View perspective argue that resource relatedness may enhance collaborations among companies. Conversely, the economic theory of complementarities informs about the benefits of resource complementarity in alliances and acquisitions (Harrison et al., 1991; Tanriverdi and Venkatraman, 2005). We recognize that the first evidence we find deserves a deeper investigation that may confirm or not our result.

Peripheries in Peripheries – Within-Region Differences in Financial Constraints

Jesper Lindgaard Christensen and Daniel S. Hain
Aalborg University, Denmark
jlc@business.aau.dk
dsh@business.aau.dk

Abstract: Earlier literature has analysed regional finance gaps by comparing metropolitan areas with peripheral areas on a relatively high level of aggregation and most often in a U.S. or U.K. venture capital context. Financial capital has been found to be concentrated in metropolitan areas and access to capital easier because entrepreneurs leverage on proximity to capital providers. However, regardless of whether it is metropoles, when there is an urban centre of a certain size or relative dominance in a region, it can be hypothesized that financial capital is likely to be attracted to this urban centre even within a peripheral region. The literature has been silent regarding financial 'centres' within peripheral areas. Survey responses from managers in 834 firms are used in the empirical analyses. We find that even within the periphery there is a periphery-core difference. We also find indications of differences in whether firms are financially constrained depending on the levels and types of geographical aggregation that are used in the models. Intra-regional differences accentuate the need for considering the appropriate regional level of policy making and the policy instruments. The paper contributes specifically to the analysis of geographical scale in regional financial constraints. The issue of scale is in the core of economic geography yet often disregarded both in research and in the process of designing regional policies.

Keywords: regional development, financial constraints, entrepreneurship innovation, periphery, economic geography, public policy

1. Introduction

The literature on financial constraints has primarily focused on characteristics and behaviour of firms pertaining to their liabilities of smallness and newness, or to their risk profile stemming from their industry, market, or innovativeness. However, additional characteristic of financially constrained firms concerns their location. Regional innovation policies at super-national, national, and regional levels of aggregation have therefore introduced an array of regional innovation financing instruments and –institutions such as regional venture capital funds, Regional Development Agencies, regional loan funds, ERD funding etc.

Despite the policy interest, we know relatively little on this aspect of financial constraints, and the studies we do have suffer from fundamental limitations. Generally, the approach adopted in the literature consists of analysing regional disparities with respect to financial capital between prosperous and peripheral regions. For example, Zhao and Jones-Evans (2017) study differences in access to finance in Nuts1 regions in the UK. The present paper adopts a novel approach by exploring whether there are intra-regional differences in the financial gaps between firms in urban areas and firms in peripheral areas even *within* a peripheral region. Hence, when Zhao and Jones-Evans find that access to finance is difficult in Wales compared to other regions in the UK it would perhaps be more interesting to know if there are e.g. differences between Cardiff in Wales and the rest of Wales, or if the patterns found for e.g. Scotland hide within-Scotland differences.

Therefore, the core research question and hypothesis tested in this paper is that in the context of an urban centre of a certain size or relative dominance, financial capital is likely to be attracted to such an urban centre despite the general tendency for the capital in a country to be clustered in the major city. If so, then the use of only averages to compare regions defined at a high level of aggregation, and possible by political-administrative boundaries may be misleading or may render incomplete results and lead to inexpedient policy conclusions. Earlier studies have called such research (Lee and Drever, 2014, Zhao and Jones-Evans, 2017), however, most data sources do not allow a sufficient geographical break down.

Our study has several contributions. A large share of the earlier studies of access to finance in a geographical perspective focus on venture capital finance, fx Boston and Silicon Valley in the U.S. or Cambridge and the Southeast region in the U.K. These are places in which industrial evolution and finance functions well, and they are not representative for the vast majority of regions. Even if specialised forms of finance like venture capital may be important to industrial evolutionin these areas the broad majority of firms do not access venture capital rather relies on bank finance. By incorporating all types of finance for investment purposes, we obtain

more complete information on the access to finance landscape. We focus on cities in Denmark that in an international context are relatively small, which in itself is novel in this literature. Finally, our data allows a geographical break down that entail small areas. The analysis is based on data from surveys of 834 private firms in North Jutland covering different aspects of access to capital. Our case region is well suited for answering the question of a potential 'second-order' periphery, as it is a peripheral area in Denmark but has a clear urban centre. Denmark is said to have relatively small regional differences, which makes it an expedient context to study these problems in because potential problems, if identified in this context, are likely to be stronger in other countries.

2. Earlier literature on the geography of financial constraints

The economic geography literature on financial constraints has generally been relatively scarce (Pollard, 2003). Likewise, the entrepreneurial finance literature has not sufficiently examined the geographical aspects of finance (Mason, 2010). Studies of the geography of venture capital shows that a disproportionate share of financial capital is managed and invested in metropolitan areas (Martin et al., 2003; Mason and Harrison, 2002), and the location of venture capital firms has typically been in metropoles. Not only quantitative, also qualitative differences persist; the venture capital funds in more peripheral areas involve public funds to a greater extent, and (related) the differences in amounts invested persist to a larger extent than the number of investments (Mason and Pierrakis, 2013). The informal venture capital market is generally regarded as more evenly dispersed (Harrison et al., 2010), but there is also a concentration of this type of finance, again in the UK in the London and Southeast regions (Jones-Evans and Thomson, 2009). The concentration of financial capital in prosperous, urban areas is found in virtually all countries but to a varying degree. Comparing concentrations of financial capital in the U.K. and Germany, Martin et al. (2003) found that German financial capital is less concentrated and involves a greater number of financial centres. This finding may relate to differences in political-administrative structures and to different city structures, as there are relatively many larger cities dispersed throughout Germany.

Several studies of the geography of entrepreneurial finance have found that investors prefer investing in firms that are not excessively distant from their own locations. Preference for proximity to investee firms stem from the fact that transaction costs and search costs are reduced with close spatial proximity. Investors monitor their portfolio firms by providing guidance and act as a sounding board to the management of a firm. Some of the information in this interaction, such as budgets, progress reports and similar codified information can be transferred across distance by mail. However, to build a business relationship with a portfolio firm, investors engage in personal interactions with the portfolio firm to facilitate the transfer of tacit knowledge. Because tacit knowledge is dependent on the building of common means of understanding, communication and, above all, personal trust, tacit knowledge is often spatially grounded (Gertler et al., 2000; Zook, 2002, 2004). Such personal interactions require a certain frequency of face-to-face interaction, which adds to transaction costs.

Transaction costs related to post-investment monitoring may be reduced by spatial proximity, geographical proximity is also important prior to the investment process. Because investors use referrals and their networks to both generate a deal flow and assist the due diligence process, local informants reduce search costs. Information on the potential of investment opportunities is not publicly available and is often spatially bounded (Zook, 2004, Kolympiris et al., 2017) and interpreted by actors in the same socio-economic context (Allessandrini et al., 2010, Wray, 2012). Moreover, interactions between parties (i.e., a financier and a firm in this case) are also affected by social, institutional, organisational and cognitive proximity (Boschma, 2005), not only spatial.

Depending on the extensiveness of networks of financial community, intermediaries and firms, the pure awareness of sources of capital may also differ (Mason and Harrison, 1998, Mason, 2007). Demand for finance may differ between localities, as business activities are often unevenly distributed (Mason 2007, Lee and Drever, 2014, Lee and Brown, 2017). Earlier literature (Lee and Brown, 2017) has found that both actual and the non-articulated demand for external finance differ between peripheries and urban centres, both types of demand being less in peripheries.

In sum, we hypothesize that

1. Within peripheries concentration of capital and resulting distances between investor and investee leads to relatively higher financial constraints outside urban areas

2. The possible effect in Hyp.A is enhanced by firms' innovativeness, smallness, newness, actual short-term economic performance, projected short-term economic performance.
3. Demand for external finance is lower for firms in peripheries of the periphery

3. The data and case region

The *data* are based on surveys of private firms with at least five employees in North Jutland, Denmark. The respondents were asked about their views of the past and future development of a number of variables including innovation and access to financial capital. In turbulent periods of time as in financial crisis especially issues of access to finance are affected, which means that responses from a single year may not be representative. As our primary interest is not on the level of financially constrained firms per se but rather the relative proportions (periphery – center) the effects from financial crisis is reduced as it affects firms in both sub-samples. Only to the extent that the crisis has different effects on urban and rural areas the analyses should account for the effect of the crisis. We reduce this possible effect by using data from surveys in several years. In order to maximize the number of observations and to eliminate possible effects from variations over time we cluster the responses from four consecutive years, 2010-13 and obtain a total of 834 responses. Data collection methodology and questions were constant over all year. Firms were phoned to ask for participation in the survey, then emailed a questionnaire. The core question re dependent variable was: 'Did your firm during the past year experience problems in obtaining external finance for development activities?' Yes/No/Did not apply/DKNA.

Response rates are incomparable to other surveys that rely on random sampling. In our case response rates may be interpreted and measured during the process of phoning firms to ask for participation, or they could be interpreted as the share of respondents who accepted to participate in the survey, but nevertheless did not fill in the on-line questionnaire. The firms included in the gross sample represent approximately 30% of the employment in the region.

Our *case region* is located in the north of Denmark and has traditionally been characterised as a peripheral area within Denmark, evidenced by economic indicators of regional development. Aalborg is the metropolitan centre of the region. By January 2017, the city had 139,000 inhabitants. The cities of Frederikshavn, Hjørring and Hobro may thus be classified as urban areas, although they only have 23,500, 25,700 and 12,000 inhabitants, respectively. In many contexts such cities would be classified as villages. In this small region (in a small country with only one large city, Copenhagen), these cities are relatively large and contain several well-known and relatively large firms.

4. Empirical analyses

We split the sample of firms in different geographical areas (as explained below) and estimate a model that takes into account multivariate and interaction effects and control for possible effects from differences in firm characteristics. In robustness checks, different geographical aggregations are tried out.

4.1 Geographical scale

The test of the overall hypothesis regarding the relevant geographical scale of financial constraints is based on two geographical aggregations stemming from three geographical areas. The first area is Aalborg as the urban centre. The second area is the three above-mentioned areas that are smaller but perhaps still urban. The third area contains the residual peripheral areas within North Jutland. Our sample is split in 31% of firms in the Aalborg city, 17% in the semi-sized towns, 52% in the remainder of the region.

4.2 Variables

The answers to survey questions are self-reported and subjective; however, there is no reason to believe that a potential bias from this should be either particularly severe or systematically distributed in the geographical areas we compare. Table 1 provides an overview of variables used in the analysis. The dependent variable is a dichotomic variable based on the respondents' statement on whether the firm has in the latest year experienced financial constraints on their development activities. Firms were also asked about how dependent their development activities were on external finance. In our analyses we use this variable for filtering out firms who do not feel constrained, however, we perform analyses on the full sample as well.

Table 1: Measurement of variables

Variables	*Indicator*
Independent	
Geographical areas	Aalborg, Aalborg+Semi-urban, Peripheral. Based on post codes
Size of firm 'firm size'	Log of number of empl. in full time equivalents
Innovation intensity 'e_inno'	No of innovations per employee
Age of firm 'firm_age'	Log of years since establishment
Short term economic performance 'r_result_n'	experienced improved/unchanged/worsened development in economic results in the quarter prior to the survey
Short term economic prospects 'r_result_p'	foresee improved/unchanged/worsened development in economic results in the next quarter following the survey
Industry 'firm indu_ 1,2'	NACE2 sectors
Organisational form	Subsidiary etc
Incremental innovation 'innoinc_ln'	Has incremental product, service-, process innovation within the past year
Radical Innovation 'innorad_ln'	Has radical product, service-, process innovation within the past year
Dependent	
Constrained access to capital	Perception of the constraint – Yes/No/do not know.
Filter	
Need for finance	External finance valued highly in development processes

4.3 Empirical approach

The literature has discussed potential endogeneity problems in analyses of financial constraints (Mina et al., 2013, Lee and Drever, 2014, Lee and Brown, 2017, Zhao and Jones-Evans, 2017), that is, firms who do not demand external financial capital will not feel constraints on their financing and should therefore be accounted for in the empirical analyses. One could assume that potential endogeneity problems are similar across sub-regions but in recent literature (Lee and Brown, 2017) we do have indications of different patterns in the demand for finance among firms in the peripheral and urban regions, and therefore choose both to do a two-stage estimation to account for potential differences in demand for finance, and to use a filtering variable for the same purpose.

4.4 Correlations and frequencies

Table 2 and 3 shows correlations between our main variables. The survey includes a selection question regarding whether firms express demand for finance and we proposed that this may work as a selection devise for disregarding firms who were not in demand for finance. In the second correlation table this selection is applied, reducing the focused sample to 399 firms.

Table 2: Correlation Coefficients (full sample)

Lower-triangular cells report Pearson's correlation coefficients, upper-triangular cells are Spearman's rank correlation

*** p<0.01, ** p<0.05, * p<0.1

We note from table 2 and 3 that correlation coefficients are all below the 0.5 threshold indicating no multicolinarity issues. In table 2 firm characteristics like size and age and economic results correlate with constraints. The table also provides the first indications of regional differences in financial constraints: the Aalborg city region is significantly and negatively correlated with constraints, whereas the peripheral parts of the region is positively and significantly correlated. The results regarding the need for finance variable are also interesting. Age does not seem to matter for demand, but unsurprisingly economic results do. Correlations with regions are highly significant indicating demand variations among regions. In the reduced sample (table 3) firm size is still correlated with constraints. Although the expected signs are at the regional correlations with constriants the statistical significance is no longer there.

Lower-triangular cells report Pearson's correlation coefficients, upper-triangular cells are Spearman's rank correlation

*** p<0.01, ** p<0.05, * p<0.1

In table 4 we list results from comparing constraints and demand in different regional aggregations. In the top part of the table we compare Aalborg and the rest of the region, and in the lower part of the table Aalborg is merged with the semi-sized towns. Both demand and constraints are shown for the full and reduced sample. T-tests indicate that there is a difference in demand between periphery and urban areas the demand being less in peripheries. Constraints also display a difference, however, in the reduced sample the statistical significance disappears. This is partly caused by the fact that the number of observations is less than half of the full sample, but it also indicates differences between firms in these two types of regions.

Table 4: Frequency analysis

	Rest of NJ	Aalborg	Difference	(p-value)
Firm in need for external finance	0.51	0.40	0.11	0.00
Firms experienced finance constraints (no selection)	0.20	0.13	0.08	0.01
Firms experienced finance constraints (selection)	0.39	0.31	0.08	0.14

	Rest of NJ	Aalborg + semi	Difference	(p-value)
Firm in need for external finance	0.53	0.43	0.10	0.00
Firms experienced finance constraints (no selection)	0.20	0.13	0.08	0.01
Firms experienced finance constraints (selection)	0.40	0.33	0.07	0.18

4.5 Regression results

Finally, Table 5 and 6 provides the results of the estimations of a random effect logit model. Again, we estimate both the full sample models and the reduced model.

Table 5 shows that firm size is still highly significant and in accordance with extant literature smaller firms are more constrained. Both economic results and innovation intensity are also significant. The same pattern applies regarding regional differences. Coefficient for Aalborg city ('region1') has negative sign, for periphery positive, indicating a significant difference between regions in how financially constrained they are; in the periphery more firms are constrained. In this model we also try out a different geographical aggregation where the basic is municipalities rather than postcodes. This aggregation is expected to be less precise compared to the city-oriented aggregation based on postcodes. The regi_3 variable covers areas south of Aalborg, which can be characterized as peripheral in North Jutland. There is a positive and significant coefficient for this region, however, not for the area north of Aalborg.

Table 6 shows results for the reduced sample. Generally the significance and size of coefficients drop indicating that the heterogeneity in demand has a substantial impact on results, in line with findings in other literature (Lee and Brown, 2017). Our frequency analyses did, though, indicate that in our case demand in the periphery seem to be higher than in the urban centres, contrasting findings in Lee and Brown (2017). Overall results still hold. Firms in Aalborg city are less constrained, in periphery more constrained. In the semi-sized towns there is no significant coefficient. Firm size remains highly significant. Increased innovation intensity is, as in the full sample model, associated with more financial constraints. Incremental and radical innovation variables have the expected sign – radical innovation rendering more constraints – but none of these two variables are statistically significant. Overall, the results reveal parameter estimations on our variables of primary interest in

line with the proposed hypothesis. Specifically, the variable representing the urban area defined as Aalborg in addition to the semi-sized towns is negative and significant indicating that firms in the urban area is less constrained than in the periphery. However, the geographical aggregation where Aalborg is defined as the only urban area has stronger significance and larger coefficient.

5. Conclusions, discussion, and policy implications

We found in the empirical analysis of the 'periphery of the periphery' of financing' hypothesis, evidence that the perceptions of the extent of a possible financial constraint in the North Jutland region differed between firms that are located in urban centres and peripheral areas, especially if urban areas are considered to be the primary centre, Aalborg. Thus, intra-regional financial constraints do appear to differ between these two geographical areas. Apparently, Aalborg is considered the primary growth pole as firms in the semi-sized towns also reported significantly higher financial constraints. It was clear that some of the differences were driven by differences among regions in how much firms demand external finance. The size and level of significance of coefficients decreased when firms with less dependence upon external finance were filtered out. Using different forms of geographical aggregation changed results.

Generally the results show that geography is important; the level and type of geographical aggregation is vital to a meaningful discussion of the financial constraints that firms face. This message may be simple but is important and should not be overlooked because the results have implications for the assessment of the need and rationale for policies. Usually averages are used in access to finance analyses and in the policy process, however, this study points to a potential second-order problem: the averages comparing the major metropolitan area in a country and peripheries may find disparities between their respective accesses to capital. However, if intra-regional differences exist, then the need for policy may be enhanced or should be re-oriented. The typical method of comparing means across regions may obfuscate the real problems, as firms within regions in peripheries may differ in terms of financial constraints depending on whether they are located in a central urban area or not, rather than if they are located in the peripheral region as such.

Generally, our findings suggest the substantial need for a research agenda on the extent of intra-regional disparities. Related, the findings spurred interest in testing even more types of geographical aggregation such as including individual firm level indices for location in dense business environments.

A number of limitations apply to this study. Because we used a case from Denmark in this paper, one may question the generalisability of the results. However, replicating this study in other geographical contexts with larger disparities is likely to render even stronger results.

Abstract: With many industries facing disruption of existing business models, emerging technologies (ET) becomes a critical choice. This paper is presenting and discussing a risk management framework for ET based on Failure Mode Effect Analysis (FMEA) and ISO 31000:2018. This paper is based on (1) a literature review on FMEA and ISO 31000 particularly related to technologies in early stages of conceiving, design and appropriation, (2) a case study of ET and risk in heavy mechanical manufacturing, (3) a set of micro-cases from the industry. Two models are proposed. First, an overall model framework is defined connecting early stages of technology screening, scouting, foresighting to the ISO 31000 framework extending this with continuous improvement of the model and the handling of the ET elements. Second, FMEA is suggested extended with an uncertainty factor to be multiplied onto the risk priority number (RPN). The uncertainty factor is closely linked to the ISO 31000 framework in parameters like e.g. novelty of the ET, growth predictions, duration of the ET study, industrial impact, ambiguity of definitions. ET is inherently associated with risk but often not a managed risk, extending ET risk focus into FMEA and ISO 31000 is providing a clearer and more uniform RM throughout the innovation life cycle. The presented framework can support better decision making and adherence to standardized risk management in later stages of development and implementation of the ET. FMEA can connect ET to other risk management, risk mitigation and continuous improvement approaches such as design, project or production FMEA. Introducing a common language in early stages of innovation can "lower the barrier" for SME's and organisations in emerging economies to access ET rightfully.

Keywords: Risk Management**,** Emerging Technologies, ISO31000, FMEA, Management of Technology

1. Introduction

Risks are an ever-pressing concern in every implementation process and can ultimately end up threaten the entire investment of a project, but as all projects worth pursuing involves risk, Risk Management (RM) have become a closer and closer integrated part of Project Management (PMI, 2017; Bentley, 2010). A multitude of different tools and approaches has been developed for handling RM over the years. However, academic research involving RM approaches specifically for Emerging Technologies (ET) seems fairly lacking. This creates even larger barriers between high uncertainty ET and successful implementation of these in an organization, partly because of a lacking way of structuring the RM approach, and partly because traditional tools for planning, assessing, handling and monitoring risks simply are not adapted for the uncertainty following ET.

Implementing ET means commercializing it, which means that even though the technology itself is not rapidly changing, the contextualized utilization might differ significantly. Bonnin Roca et. al. (2017) describes this as: "Commercializing an emerging technology that employs an immature production process can be challenging particularly when there are many different sources of uncertainty". This implicates that the uncertainty characteristics of ET necessitate a new approach to RM specifically tailored to these types of risk profiles. The purpose and outcome of this article is to examine and investigate, if the RM approach is different, when dealing with emerging technologies, and conclusively create a risk management framework for emerging technologies (Stilgoe et al., 2013), thus leading to the research question: What is the relationship between risk management and emerging technologies, and how to accommodate for high uncertainty?

Most academic research on RM focuses on, what is defined as "traditional occupational risks" (TR) (Brocal et al., 2017), which in its nature is foreseeable with the right historical information; in other ways the estimates for future events relies heavily on historical events. When dealing with TR this may be quite logical but "new and emerging risks" (NER) are rarely a substantial foundation of historical experience. Here traditional RM approaches seems to lack the predictive power, when the technology is rapidly changing.

There do exist standards for RM, including the ISO 31000 standard (ISO, 2018), but also this is criticized for being too rigid and unable to evolve with the ever changing environment and best practice (Olechowski et al., 2016). This article will therefore seek to investigate, which value the ISO 31000 can bring to RM of ET, and where the standard will prove itself inadequate.

2. Literature review

2.1 Emerging Technologies

Emerging Technologies has been in the centre of innovation studies for decades however precise definitions lack (Green et al., 2005). Despite numerous suggested definitions, a broad consensus about what ET really is, are still to be drawn within academic communities. Rotolo et al. (2015) suggest to define ET in a context independent setting, through an extensive literature review with definition below. This shows the variety of understandings, as to how different authors have interpreted ET. Based on this analysis the definitions of ET have then been compiled and redefined with regards to five attributes, namely: (i) Radical novelty, (ii) Relatively fast growth, (iii) Coherence (iv) Prominent impact, (v) Uncertainty and ambiguity. The conclusion is a synthesized and general applicable definition of ET stating: *"...a relatively fast growing and radically novel technology characterised by a certain degree of coherence persisting over time and with the potential to exert a considerable impact on the socio-economic domain (s) which is observed in terms of the composition of actors, institutions and the patterns of interactions among those, along with the associated knowledge production processes. Its most prominent impact, however, lies in the future and* so in the emergence phase is still somewhat uncertain and ambiguous" (Rotolo et al., 2015). Cozzens et al. (2010) defines ET as "a technology that shows high potential but hasn't demonstrated its value or settled down into any kind of consensus". ET is characterised by are uncertainty, network effect, unseen social and ethical concerns, cost, limitation to particular countries, and a lack of investigation and research (Halaweh, 2013). ET is typically associated with scientific innovation with potential to create new industries or transform existing ones (Day and Schoemaker, 2000). Dedehayir and Steinert (2016) define ET by consumers 'must have' aptitude in line with Gartners Hype-Cycle.

In order to understand ET as a definition in the light of RM, the term needs to be re-contextualized to the company setting. This means, creating a tool allowing technology to be easily categorized as either emerging or mature. Becker (2010) have stressed the importance and the potential of failure, if employees are not adequately attuned for change. According to (Dietrich and Cudney, 2011) need for new production technology can originate from one or more of four needs: (1) Lower priced parts. (2) Reduction in lead-time. (3) Quality performance increase. (4) Increase in production flexibility.

To meet a specific need as well as justifying ET in a supply chain, it is argued ET should be evaluated on a variety of levels in order to ensure that the ET is implemented in a timely manner with acceptable affordability and supportability. According to (Ratcliff, 2009) the levels in which one would evaluate the previously mentioned parameters are manufacturing and the technology readiness level. The most obvious risk therefore arise when there is an unequal equilibrium between the technology readiness level and the manufacturing readiness level.

In the context of implementation, ETs is not about formulating a clear definition, but rather how to make it accessible in a Project Management perspective, to distinguish between emerging and mature technologies.

2.2 Risk Management

Risk Management (RM) is a widely understood term, from a highly strategized way of controlling a project from early start to post-project events, RM have become an embedded part of many projects (Themsen and Skærbæk, 2018; Villa et al., 2016). Risk is an inherent part of any project; implementations that does not contain any risk are generally considered non-value adding for an organization (Ward and Chapman, 2003; Szymanski, 2017). The more risky a project is, the more value it can add to the organization. RM is a way to increase the likelihood of success of the tasks during the whole process of project execution (Olechowski *et al.*, 2016). Uncertainty assessment have become a more central focus in Project Management (Ward and Chapman, 2003). Amongst researchers, RM as a term has not reached a broad consensus, which is why it is important to clarify what the characteristics of RM are (Ahmed, 2017).

RM is defined by (ISO, 2018) as *"coordinated activities to direct and control an organization with regard to risk"*. To understand the definition, some underlying terminology has to be presented. RM is a proactive

process of looking forward to reduce or eliminate threats before they occur. A risk has been defined as either *"an uncertain event or condition that, if it occurs, has a positive or negative effect on a project objective"* (PMI, 2017) or as *"an uncertain event or set of circumstances that, should it occur, will have an effect on the achievement of the project's objectives"* (Hillson, 2012). Academics differentiate between uncertainty and risk (Szymanski, 2017), depending on whether or not it is measurable.

Studies show that usage of RM is not widely applied by Project Managers (Raz et al., 2002; Brookes and Clark, 2009). Nevertheless it can be assumed that when dealing with ET in a well-thought and structured way some aspects of RM should present itself. Risk identification is one of the fundamental parts of RM. It is divided into two distinct phases:

1. Initial risk identification, occurs when organization haven't ever assess the risks in a structured way.
2. Continuous risk identification, namely, recognition of new risks which arise after initial risk identification and changes to them (HM Treasury, 2004).

RM presumes the general assumptions in the project, and creating the outlines and objectives. After targeting the risks, these decisions can be made: (1) Acceptance: major consequences are taken into consideration, at the same time there is no action taken. (2) Transfer of risk: shift the risk to another entity able to neutralize the risk. Insurance, can be an example of this approach. (3) Reduction: this action aims to lower the probability of threat or eliminate it. Expanding the resource repository could be an example of this approach. (4) Avoiding: prevention or elimination of the risk in the entire process (Szymanski, 2017).

The ISO 31000:2018 standard provides users with a state of art approach regarding RM. In general terms RM refers to the architecture, which consist of RM principles, a RM framework and RM processes. The model of this ISO standard is illustrated in Figure 1. For RM to be effective, an organization should at all levels comply with principles mentioned in figure 1 (de Oliveira et al., 2017). The framework assists in assessing and managing risks effectively through the RM process at varying levels. The RM process should be comprised of different activities to assure that it is an inherent part of management, culture and is reflecting the Business Processes of the organization (ISO, 2018).

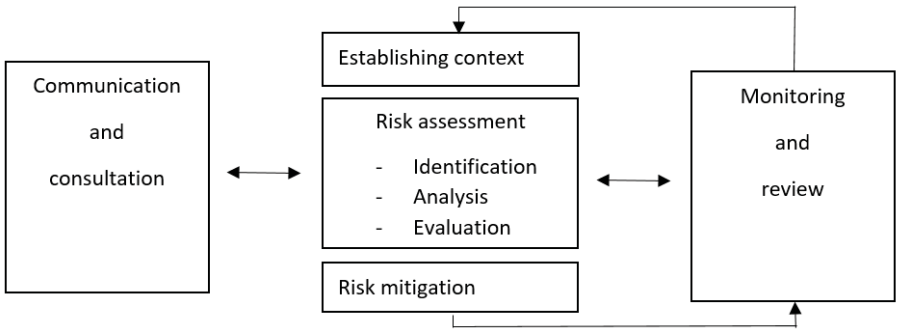

Figure 1: The ISO 31000 risk management framework

FMEA is a systematic and analytical tool, of a proactive nature, which is utilized as an evaluation of potential process or product failure modes (Card et al, 2012). FMEA stands for and facilitates the process of: (1) Targeting the threats. (2) Identifying actions that reduce or eliminate the chance of failure. (3). Documentation of the process (Reid, 2005). Through quantitative assessment, FMEA allows identification of risk. Listing the Failure Modes that are understood by the circumstances that potentially can cause a more severe failure. Failure Effect define the consequences of failure modes to occur. Risk Group presents who in the organization is affected by the failure mode and Risk Causes reflect the factors which caused the failure.

The Risk Priority Number (RPN) is calculated by placing three subjective ratings: severity (S), occurrence (O) and detection (D) on scale from 1 to 10. It is suggested that the ratings should be based on 10 point scale to increase the accuracy of the results. By multiplying the estimated numbers, result from 0 to 1000 of risk severity reveals (Reid, 2005). In Table 1 a simplified FMEA model is illustrated. A critique of the FMEA can be made, due to the fact that it does not take uncertainty into consideration, in situations where estimations are based on risky assumptions. Consequently, the FMEA might therefore not be a good fit for ET.

Table 1: FMEA framework

FAILURE MODE	FAILURE EFFECT	S	RISK GROUP	RISK CAUSES	O	CONTROL	D	RPN

3. Method

The study has dealt with the methodological challenge of seeing little scholarly references on the link between RM and ET. Use of analogues, empirical approaches and inductive elements have been found useful along application of validation and triangulation principles of multi-method approaches (Saunders and Lewis, 2009).

The empirical data consists of two parts. (1) A case study developed from interviews and action research in a large engineering and manufacturing company. (2) A micro-case summary.

The questions concerning RM are constructed using the themes in figure 1 combined with questions regarding ET. The interviews should help gain an understanding of the practical implications of using RM when implementing ET, and whether the companies have a combined approach. The interviews have four overall themes; Risk Design, Risk Assessment, Risk Implementation and Risk Monitoring. Within each of the four themes, questions are formulated regarding ET e.g. in Risk Design: *"How would you describe the maturity of the technology at the start of implementation?"* and in the case of Risk Monitoring *"Do you keep an eye on the risk profile on technologies, you have previously worked with?".*

To summarize, the paper represents the outcome of a broad qualitative, case-based, socially inspired study in a range of Danish companies

4. Case study

4.1 Case: AR in MechCorp

MechCorp is a global leader in renewable energy, but is in many ways organized as a mechanical manufacturing organization. MechCorp has decided to start using Augmented Reality (AR) as an Emerging Technology. AR will entail a rethinking of the relationship between product engineering, production planning, engineering-to-product knowledge transfer and work instructions, and workforce skill management.

Engineering processes must onwards not only produce mechanical artefacts, but also work instructions according to quality standards and a digital transformation to the AR context of the manufacturing.

The AR system works like this: The engineering design processes using PTC Creo (CAD/PLM/PDM) follow usual processes but will always work in 3D. The 3D drawings are converted into a semi-animated format in PTC Vuforia. This is converted into an animated format using Unity or PTC ThingWorx. Work instructions are connected to the 3D objects. Workers wearing AR goggles will be presented for relevant work instructions when looking at designated objects through camera object recognition. In the actual case, work instruction for electrical connections are in focus. Thousand are connections are to be made on each product, the AR system will guide workers for each assembly process and replace hundreds of pages of manuals.

The AR system represent an ET for MechCorp as the company is striving for reduced tact time of complex assembly processes that are too costly to automate. Benefits of the ET will be faster and more precise work instructions to workers by avoiding workers need to retrieve information for each assembly. Also, workers tend to internalize work instructions and work from experience only. This is problematic as the number of identical products is very low. Risk of selecting AR as ET is e.g. (1) failure to reduce tact time leading to loss of competitive edge, (2) negative economy of needing to produce ever more complex work instructions, (3) MechCorp follow a strategy is "everything digital" – no room is left to fail the strategy, (4) defects related to workers not using correct work instructions. As MechCorp is in a highly competitive market, AR is seen very critical to sustained success, and risks of implementation AR will have serious consequences.

4.2 Micro-case studies

The MechCorp case is supplemented by a range of primary "micro-case" studies stated in table 2 from companies in Denmark. The cases were collected by the authoring team but not elaborated further due to space constraints.

Table 2: Selected micro-cases involving ET and RM

Company	Emerging technology	Risk assessment	Risk management
Software consultancy	Virtual reality	Lack of business cases Lack of technical skills	Budget control Skill build-up with universities
Industrial cutting tool manufacturer	3D printing	Lack of precision Too costly	Post-processing Assurance to alternative technologies
Agricultural feeding machinery producer	Internet-of-things	Lack of dynamic capabilities	Organisational improvement and training
Heat exchanger producer	Robots	Too complex	Validations using 3D scanners
Bank	Pay-by-car	Cheating Malfunction	Compliance reviews Testing

5. Risk management framework development

In developing a framework for RM in ET it is necessary to deal with the multitude of uncertainty, bias and "inflated expectations". A framework for RM must be relevant and meaningful and be based on measureable and objectively identifiable decision parameters. The suggested framework consists of five phases, subdivided into respectively the pre-project, project and post project, see Figure 2; these five phases are directly constructed from the ISO 31000 with an embedded iteration from "Continuously improve the Framework" to both the "Design"- and "Mandate & Commitment"-phase. Between the pre-project and project, we see a decision gate, where the technology emergence is evaluated, with the purpose of deciding whether or not this framework is right for the project.

It should be seen as an overlay on an existing Project Management process, and can be applied for both rigid state gate models and agile Project Management approaches; whether used on individual iterations or the project in its entirety, the *framework* aims to be a guideline choosing the RM approach, building on common standards.

5.1 Mandate and Commitments

As technologies have a broad range of characteristics, it is important to gain insight of the technology's capabilities, as it can affect the company's ongoing effectiveness and further commitment. As a part of the pre-project, the company should therefore answer questions related to the chosen technology. To help assess these characteristics the Gartner's Hype Cycle might be useful. The following questions should be answered:

- What is the radical novelty (newness) of this technology?
- What are the predictions of future growth of the chosen technology?
- Has the technology been used and explored throughout a long period of time?
- Have or will the technology cause a big impact on the industry you are working in?
- How is the technology connected with uncertainty and ambiguity?

5.2 Project emergence evaluation

The purpose of the project emergence evaluation gate is to evaluate intended technology for implementation is an ET or not, Table 4a and 4b. The framework is therefore based on an evaluation along the attributes of the y-axis in regard to risk (Low, medium & high), multiplied by the potential impact on the organization. The sum conclusively tells whether it is an ET or not. Table 3 is a representation of how the sum can be interpreted in regards using the *Risk Management Framework for implementing Emerging Technologies* or not.

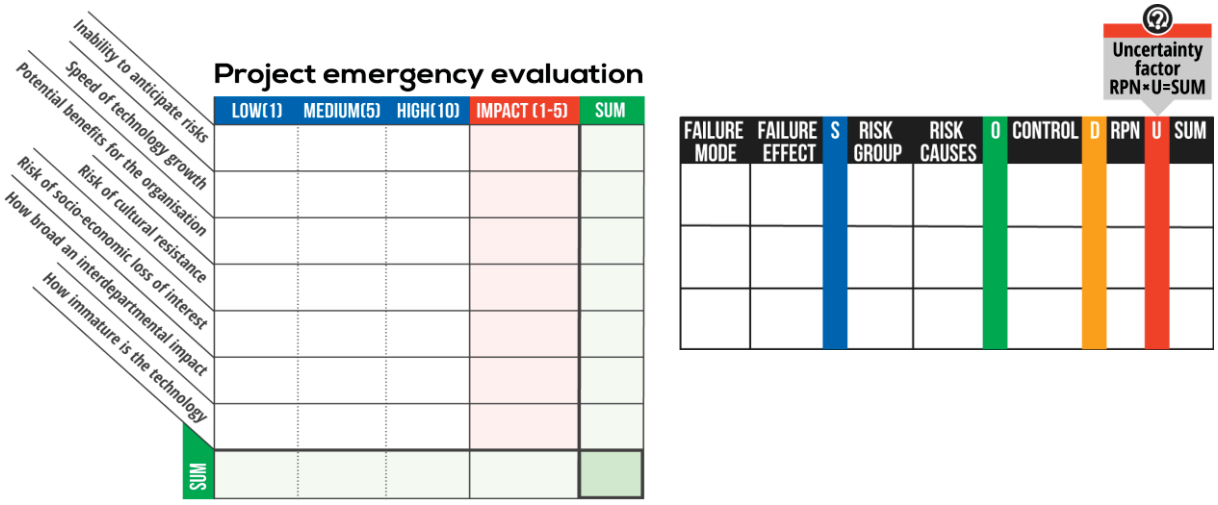
Table 3: The project emergence decision table

Use the RM framework	SUM > 175
Uncertain	100 ≤ SUM ≤ 175
Don't use the RM framework	SUM > 100

The project emergence evaluation gate is built on the foundation of the technology readiness assessment matrix, but in a more simplified company specific context (Cox, 2008). The attributes on the horizontal axis are derived from the literature review in which a clarification of ET in the light of RM is evaluated, that is, the risks that ET can impose within an organization.

It is important to note that the impact is a property based on the company's individual impact evaluation. The evaluation of the same technology can vary between companies. The tool is therefore suggested powerful in cases where the company is uncertain whether the technology is an ET or not.

Tables 4a and 4b: Project emergency evaluation tool and modified FMEA table



5.3 Designing the approach

The purpose of this phase is to design the RM framework for ET. To do so, the company needs to "[...] understand both the external and internal context of the organization" (ISO, 2018). In order to understand the organization's external and internal factors a SWOT analysis (Carpenter and Sanders, 2001) could be the structural base of this design, which will give the company the possibility to easily construct their own approach towards accommodating potential risks when implementing ET. This is illustrated in Figure 2.

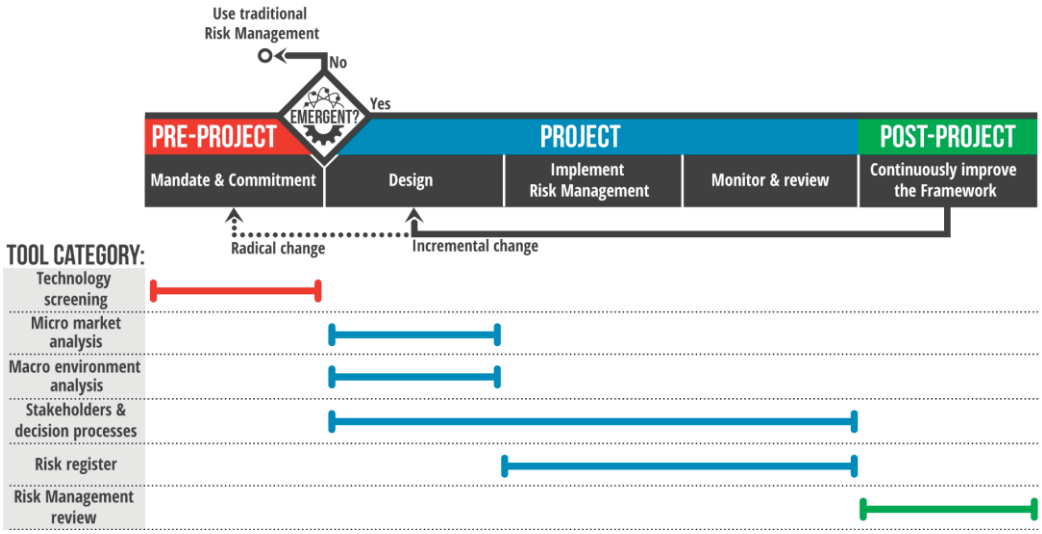


Figure 2: Risk Management Framework for implementing Emerging Technologies

To evaluate the organizations internal factors; resources, capabilities, core competencies and policies should be investigated. To do so tools such as stakeholder- or value chain analysis could be used (Carpenter and Sanders, 2001).

To evaluate the organizations external factors, the environment and competitors should be investigated. Tools such as the PESTEL analysis and Porter's Five Forces could be used (Carpenter and Sanders, 2001). Various tools are to be appropriately selected for each phase as illustrated in Table 5.

Table 5: Risk review methodologies

Tool category	Utilized tools	Influenced phases
Technology screening	Technology roadmap Comparison matrix Gartner Hype Cycle *(Dedehayir & Steinert, 2016)* technology maturity assessment	1
Macro environment analysis	PESTEL	2
Micro market analysis	SWOT Porters 5 forces	2
Stakeholders and decision processes	Power/interest matrix *(Treasury, 2015 / orange book)* Action process map and decision gates Disaster recovery plan Supply- and valuechain impact	2,3,4
Risk register	FMEA *(Daimlerchrysler, 2005) (Card. et al, 2005)* PRINCE2 Risk Register (*PRINCE2: A Practical Handbook, Colin Bentley)* Risk Matrix (severity/likelihood) *(Talbot, 2012)*	3,4
Risk management review	Risk register evaluation → Estimations vs occurrence Risk Management KPI's	5

5.4 Implementing Risk Management

According to the ISO 31000 standard, implementing Risk Management consists of six parts (ISO, 2018): (1) Planning: The appropriate timing? (2) Mapping processes and policies (3) Compliance with requirements (4) Ensure roles and decision making (5) Information and training sessions (6) Accordance with stakeholders.

When dealing with ET, process mapping becomes a particular valuable tool, for defining patterns of action for scenarios of different failure modes. The following tools are therefore recommended; A continuation of the stakeholder analysis, FMEA (Reid, 2005) and Risk identification process map (Merna and Al-thani, p. 50, 2008).

As earlier stated in the RM literature review, the FMEA has certain shortcomings. Therefore, when dealing with ET, an extra factor needs to be added, which is the uncertainty factor "U". The uncertainty factor should be multiplied with the RPN result, in order to account for the overall uncertainty of the technology. For example, if a failure mode with a relatively low RPN still have a high uncertainty, this will be leveled to be more realistic.

5.5 Monitor and review

The company should measure, monitor and review their activities throughout the whole process. Following actions should continuously be taken in order to ensure effectiveness of RM and support high performance:

- Defining RM Key Performance Indicators(KPI's)
- Progress measurements and deviations monitoring
- Review compliance with RM policy and report progress
- Assess the effectiveness of RM (ISO, 2018).

To monitor and review the framework the tools; Risk Response Process Map (Carpenter and Sanders, 2001) and FMEA should be considered.

5.6 Continuous improvement

After assessments made during the Monitoring and review phase, further improvements and changes can be conducted. In case of necessity of serious changes, as presented in the framework, incremental or radical changes can be implemented. When this occurs, the process should be of an iterative nature upon building the framework, where the process either start again at step 5.1 or 5.3, dependent on the changes. To evaluate and improve the framework the following questions should be answered:

- What was the framework missing and how can these be addressed based on these shortcomings?
- Which improvements could be applied to each phase of the framework?
- Did the project encounter unforeseen risks and how well were these risks managed?
- Did the description of the project change compared to the finished project?
- Did the framework lack any tools?

6. Discussion and conclusion

Risk Management Framework for implementing ET is derived empirically. Scarce explicit knowledge was shared with regards to RM during the interviews. More interviews and studies of motivational and behavioural factors should be conducted in order to establish a bigger empirical foundation, as to how RM is applied in practice. Consequently, the chosen tools in the framework may therefore be subject to further adjustments in future research.

Overall it is paradoxical to impose an RM framework to ET that by nature is uncertain. However, as many organisations increasingly rely in ET, professionalization of ET is expected to include the ability to do RM. Application of the framework needs to be tested in practical environments, to secure its usability and improve upon it.

The research indicates that in order to effectively manage risks in projects concerning ET, a framework needs to be highly applicable in a practical environment. This means detecting projects dealing with ET. From various definitions and varying company perceptions of what categorizes an ET, to what sort of implications in regards to RM companies should be aware of, the definitions have been synthesized into seven definitions to help ease the assessment:

- Inability to anticipate risks
- Speed of technology growth
- Potential benefits for the organisation
- Risk of cultural resistance
- Risk of socio-economic loss of interest
- How broad an interdepartmental impact?
- How immature is the technology?

Traditional RM approaches lacks a way of dealing with the increased uncertainty derived from projects with ET, due to the absence of historical foundation; in other words, the approach have to change, to accommodate for the relational gap between RM and ET. The paper proposes a strategized way of structuring the RM approach, when dealing with high degrees of uncertainty and ambiguity, derived from a systematic literature review and qualitative case studies. This is addressed with a *Risk Management Framework for implementing Emerging Technologies* based on the ISO 31000:2018, Failure Modes and Effect Analysis (FMEA). The framework consists of the following five phases: (1) Mandate and Commitment, (2) Design, (3) Implementing Risk Management, (4) Monitor and review and (5) Continuously improve the framework.

Abstract: The paper addresses the role played by research-based spin-off firms (RBSOs) as knowledge dissemination mechanisms, through their position in knowledge networks. Previous research found that, despite the continued relevance of links with research organisations, these firms frequently play an intermediary role between academia and industry, and started characterising the forms assumed by that role (Conceição, Sousa and Fontes, 2017; 2018). This paper extends this approach by proposing that the composition and structure of the knowledge networks and the position occupied by RBSOs are not homogeneous, but vary between industries, being associated with the nature of the knowledge prevalent in that industry. For this purpose, the paper draws on the notion that innovation process in firms and industries are strongly shaped by their specific "modes of knowledge creation" or "knowledge bases", which have been categorised as analytical, synthetic or symbolic (Asheim and Coenen, 2005). According to the literature these modes of knowledge creation influence the nature of interactions that take place (Moodysson et al, 2008; Plum and Hassink, 2011; Salavisa et al, 2012) and, therefore, they are expected to introduce some differentiation in the knowledge networking behaviour of the RBSOs. The empirical research is based on the data on the publicly funded collaborative research and technology development projects established by the population of RBSO created in Portugal until 2007, encompassing both domestic projects, funded by national programmes (237 projects) and international projects, funded by European Framework Programmes (216 projects) and covering a broad spectrum of industries. The industries were classified according to their knowledge bases. The knowledge networks, associated with the participation of RBSO in those projects, were (re)constructed and analysed using a set of measures from social network analysis, with a view to uncover and assess their composition and structure. The results show that, despite RBSOs common academic origin, there some differences in the structure of the knowledge networks of firms in different industries, in particular between those characterised by an analytical knowledge base (of which biotechnology emerges as the most paradigmatic case) and a synthetic knowledge base. These differences have implications for position and role of RBSOs in the networks.

Keywords: Analytical vs. synthetic knowledge bases; Knowledge network, Research-based spin-offs; Social network analysis

1. Introduction

This research addresses the roles played by firms whose activities are based on knowledge generated in research organisations. The literature offers different definitions and labels for this category of organisations.

In this paper we define them as firms whose creation was based on the formal and/or informal transfer of knowledge or technology generated in public research organisations (Djokovic and Souitaris, 2008; Mustar et al, 2006; Pirnay et al 2003) and label them research based spin-offs (RBSOs).

There is now a significant body of research on this group of firms, which have addressed their genesis, advantages or disadvantages and roles played (for reviews see, for instance Grimaldi et al, 2011; Miranda et al, 2017; Mustar et al, 2008; Rasmussen, 2018; Wright, 2014). The literature generally agrees that these firms can offer relevant contributions to innovation and technological development, although there is some debate on the extent and conditions in which these are achieved. Given RBSOs particular strengths and weaknesses, some authors have argued that one key role of these firms is to act as conveyors of knowledge across organisations, by accessing, transforming and translating knowledge between different knowledge, organisational and cultural contexts (Autio, 1997; Fontes, 2005; Harrison and Leitch, 2010; Perez and Sanchez, 2003; Walter et al, 2006). Accordingly, it has been argued that RBSOs impact is more clearly expressed through the value they create in knowledge and innovation networks (Conceição, Sousa and Fontes, 2017; 2018; Hayter, 2016; Rasmussen, 2018). But while there has been some recent research in the networking behaviour of RBSOs (Hagedoorn et al, 2018; Aaboen et al, 2016; Fontes and Sousa, 2016; Benghozi and Salvador, 2014), it only rarely addresses RBSOs knowledge networks.

Previous research addressing this issue found that RBSOs frequently play an intermediary role between academia and industry and started characterising the forms assumed by that role (Conceição, Sousa and Fontes, 2017; 2018). This paper extends this approach by proposing that the composition and structure of the knowledge networks and the position occupied by RBSOs are not homogeneous, but vary between industries, being associated with the nature of the knowledge prevailing in that industry. For this purpose the paper draws on the notion that innovation process in firms and industries are strongly shaped by their specific "modes of knowledge creation" or "knowledge bases", which have been categorised as analytical, synthetic or symbolic (Asheim and Coenen, 2005). According to the literature, these modes of knowledge creation influence the nature of interactions that take place (Moodysson et al, 2008; Plum and Hassink, 2011; Salavisa et al, 2012) and, therefore, they are expected to introduce some differentiation in the knowledge networking behaviour of the RBSOs.

The empirical research is based on data on the publicly funded collaborative research and technology development (RTD) projects established by the population of RBSO created in Portugal until 2007. The analysis encompasses both domestic projects, funded by national programmes (237 projects) and international projects, funded by European Framework Programmes (216 projects). The knowledge networks, associated with the participation of RBSO in those projects, were (re)constructed and analysed using a set of measures from social network analysis, namely for studying their composition and structure. The RBSO selected operate in a broad spectrum of industries, which were classified according to their knowledge bases.

The final goal is to understand whether different knowledge base affect the networks established by RBSOs, with impact on the roles played by these firms.

2. Conceptual Framework

2.1 RBSO intermediate role

Research-based spin-offs (RBSO) have been found to play an important role as knowledge transfer mechanisms (Bathelt et al, 2010; Helm and Mauroner, 2007). In fact, RBSOs are set-up to commercially exploit the results of academic research, transforming it in technologies, products or services and making them accessible to the society. Moreover, if successful in their endeavour, RBSOs are likely to continue acting as sources and disseminators of new knowledge over time. The effectiveness of RBSO as a "bridge" between academia and the industry depends on entrepreneurial actions, such as opportunity identification, risk taking, resource mobilisation that can be more effectively achieved through networks (Grandi and Grimaldi, 2003; Walter et al, 2006).

Previous studies (Conceição, Sousa and Fontes, 2017; 2018) indicate that the parent research organisation is an important actor in most firms' national knowledge networks. Moreover, half of these spin-offs only establish formal technological relationships with research organisations, reproducing a frequently depicted pattern among RBSOs. However, the other half was found to also establish relationships with non-academic organisations. Among these, a still substantial number emerge as a central element in tripartite technological relationships, including the RBSO, research organisations and firms or other organisations located downstream. This result points to a bridging role of RBSOs in entrepreneurial ecosystems, connecting academic and downstream organisations. Furthermore, when considering the network formed by the RBSO and its partners, several spin-offs are found to occupy a position as brokers between the other network actors, potentially facilitating the circulation of knowledge across them (Conceição et al, 2018).

Concerning the broader knowledge networks established by Portuguese RBSOs in the context of collaborative RTD projects at National and European levels, the authors concluded that these RBSOs have the conditions to play an intermediary role relatively to other Portuguese organisations, which can assume different forms in diverse contexts (Conceição, Sousa and Fontes, 2017). In the networks formed in the context of national projects they are frequently in a position to bridge between research organisations and firms. In the international networks formed in the context of European Union projects, where RBSOs will tend to assume a less relevant position, their most important role is as connectors and/or conveyors of advanced knowledge produced these international contexts and the Portuguese organisations with whom they collaborate, either in the EU projects or in other Portuguese projects (Conceição, Sousa and Fontes, 2017).

In order to better understanding the intermediate role played by RBSOs, it is crucial to assess whether are these roles are uniformly performed across the whole population of RBSOs, or differ between industries. The argument of this paper is that it is likely to be the latter case. The rationale is that the composition (i.e. the type of organisations involved) and structure of knowledge networks is associated with the nature of knowledge, which is likely to vary between industries. This will influence the type of partnerships established and the conditions in which RBSOs interact with their environment, thus affecting the roles these firms play towards other organisations. This argument is supported by the knowledge bases literature, according to which the contents of knowledge relationships are determined by firms and industries specific knowledge bases (Asheim and Coenen, 2005; Plum and Hassink, 2011). Thus, industries with different knowledge bases are expected to differ with regard to the structural dimension of knowledge networks (Martin, 2013).

2.2 Knowledge bases Literature

The principal contribution of the knowledge bases literature was to advance the idea that innovation process of firms and industries are strongly shaped by their specific knowledge bases (Asheim and Coenen, 2005; Asheim and Gertler, 2005). The knowledge base approach was presented as an alternative to conceptualizations of knowledge such as high- tech, medium- tech and low- tech (OECD, 1996) and tacit versus codified knowledge (Boschma, 2018; Moodysson et al, 2008), which these authors considered insufficient to fully explain the nature of the processes at work.

This literature distinguishes three kinds of knowledge base: analytical (science based); synthetic (engineering based); and symbolic (creativity based). An *analytical knowledge base* is depicted as having the following features: innovation relies on the creation of new knowledge; scientific knowledge is very important; collaboration between firms and research organisations is relevant; knowledge creation is based on deductive processes and formal models and appeals to abstract "know-why"; codified knowledge is dominant due to the existence of extensive patenting and publication activities (even if tacit knowledge is also present); and the outcome is more frequently radical innovation. A *synthetic knowledge base* is described by the following aspects: innovation is mostly based on existing knowledge, either through application or novel combinations; knowledge creation arises from specific problem solving, through inductive processes of testing and experimentation; interactive learning with clients and suppliers is more relevant; tacit knowledge is dominant; and the outcome is mainly incremental innovation (Asheim and Gertler, 2005; Moodysson et al, 2008). Finally, the concept of *symbolic knowledge base*, which was introduced later, is related with processes that deal with the creation and communication of cultural meanings, symbols, ethics and aesthetics. In this sense, symbolic knowledge is mainly (but not exclusively) tacit, closely linked to specific socio-cultural contexts and difficult to transfer directly across the geographical space (Manniche, 2012).

2.3 Knowledge bases & knowledge networks

The distinct modes of knowledge creation associated with the different knowledge bases impact on the way firms develop their knowledge networks (Moodysson et al, 2008; Plum and Hassink, 2011; Martin, 2013). Thus, knowledge interactions with universities and other research-oriented organisations are more frequent in the analytical mode, acting as complementary sources to internal R&D activities. Relations with research organisations are also present in the case of the synthetic mode, but interacting with clients and suppliers for problem solving, often through face-to-face exchanges and/or informal bartering, is more relevant. The more formalised and codified nature of the knowledge being produced in the analytical mode makes personal interactions less important than in the synthetic mode, and also invites (or even recommends) a greater formalisation of the knowledge exchanges.

Plum and Hassink (2011), drawing on data on two groups of German firms (biotechnology and automotive), predict and empirically corroborate the existence of sharp differences between knowledge networks associated with each knowledge base - analytical and synthetic. Knowledge networks differ across fundamental dimensions: composition, link content, average importance of the relations and geography.

Comparing the two networks, they found that: the share of universities is much higher in biotechnology networks, while ties with suppliers and customers predominate in automotive networks; the average importance attributed to each kind of partner for the firms' innovative performance is also distinct across the two groups, although not so strikingly; the content of the ties differs, with a much higher share of 'scientific oriented' ties on total ties in biotechnology networks, and a much higher share of 'practical oriented' ties in automotive networks; finally, regarding the geographical reach, a clear difference occurs, with a much higher

share of international connections, and particularly of extra-European connections, in biotechnology firms, versus the overwhelming dominance of regional and domestic connections in automotive networks.

Similarly, Martin (2013) argues that industries with different knowledge bases diverge, not only with regard to the type of knowledge involved in innovation activities, but also with regard to the nature of innovation networks, namely their structural, relational and geographical dimensions. This author defends that, in the case of an analytical knowledge base, the innovation networks involve a relatively small number of actors and an intensive collaboration between those actors, based on formal collaboration between organizations, or, less formalized, within communities of scientists knowledgeable in a particular issue-area. As analytical industries deal with scientific knowledge that is not dependent on a particular geographical or social-cultural context, cooperation and knowledge exchange can take place between scientists and research units that are widely dispersed across great distances (Martin, 2013). Regarding the synthetic knowledge base, Martin (2013) defends that networks are predominantly national or regional. Synthetic industries are constantly engaged in solving engineering problems, which require know-how and practical skills. In this sense, the importance of tacit knowledge and interactive ways of learning implies that spatial proximity plays an important role for collaboration and knowledge exchange. Companies are more likely to engage in intensive cooperation with suppliers and customers, which are located within the regional or national milieu, where a common institutional framework facilitates interactive learning and knowledge exchange (Martin, 2013). Concerning the third type of knowledge base, the author argues that innovation in symbolic industries is dominated by creativity and artistic skills, while the dominant mode of innovation is flexible and based on temporary and project-based cooperation. The importance of cultural knowledge and sign values suggest that cooperation and knowledge exchange takes place first and foremost within the regional milieu, while national or international collaboration is less frequent (Martin, 2013).

This literature supports our argument that RBSOs in different industries are likely to have different knowledge bases and establish different networks. In fact, although RBSOs are companies created to explore knowledge and technologies developed in research organisations, and thus are often analysed as a group, the literature has shown that they not necessarily homogenous organisations (Conceição et al, 2012). In particular, they can use different types of knowledge in their innovation activities and thus establish different types of knowledge relationships (Lubik et al, 2013; Conceição et al, 2012; Bathelt et al, 2010). With respect to evidence on network differences at the industrial level, research that specifically compares the RBSOs networks in different industries is scarce. However, a comparison between innovation networks of biotechnology and software found differences between them, in particular in networks concerned with formal exchange of technological knowledge (Salavisa et al, 2012).

Thus, this paper draws on the knowledge base concept to uncover eventual differences between the knowledge networks formed by Portuguese RBSO in different industries, as a basis to understand whether the intermediary roles previously identified are dissimilarly distributed across industries. For this purpose, two industries are considered: biotechnology with an analytival knowledge base and environment and energy with a synthetic knowlwdge base.

While biotechnology was considered as representative of an analytical knowledge base in research on the knowledge networks of technology-intensive companies (Salavisa et al, 2012), the case of the energy and environment industries has not been previously addressed (to the best of our knowledge). However, some evidence on the characteristics of the knowedge developed/applied and the innovation activities conducted in these industries suggests they are more likely to fall within the synthetic knowledge based category. In fact, energy and environement industries are highly multidisciplinary, but predominantly encompass engineering activities, supported on disciplines - e.g. electrical, electronics and information engineering, mechanical engineering, materials engineering, environmental engineering - that are classified as under the “Engineering and technology” label in the OECD Fields of Science classification (OECD, 2007). This is the case even for some of the renewable energy technologies that have registered the greatest development in Portugal – wind and wave energy – therefore providing opportunites for the emergence of RBSOs (Fontes and Sousa, 2017). The knowledge base underlying wind energy technology was described as mostly encompassing disciplines such as mechanical and electrical engineering mixed with software and aerodynamics (Bergek and Jacobsson, 2003). Wave energy technologies are also reliant, to a great extent, on similar disciplines. This is supported in Portugal by the fact that the disciplinary bases of the main research centres where technologies were developed are mechanical engineering or naval engineering. Moreover, as the renewable energy technologies

mature and utilities and other large firms occupy dominant positions, a significant part of the opportunities open to RBSOs in this field rest on developing advanced solutions for more specific problems associated with the operation of the technologies (efficiency, costs, reliability) or with grid integration, due to the renewable energies distributed and intermittent nature (Fontes and Sousa, 2017).

Another growing area of opportunity for new firms is the broad field generically identified under the "energy efficiency" designation, which has equally application-oriented and combinatorial characteristics. The activities conducted by RBSOs operating under the "environmental" label are also mostly concerned with solving complex problems in the areas of waste and water treatment or air quality in buildings, and will equally entail, to a large extent, applying existing knowledge and specialised competences to develop new solutions. Thus, in both cases, the activities are likely to involve combining, in new ways, knowledge originating from a variety of disciplines; interaction with users will be relevant given the problem solving perspective; and the knowledge produced will tend to be more context-specific and tacit, even if they may occasionally need to resort to scientific research to solve more complex problems.

A comparison between the composition and structure of the knowledge networks in these industries will enable us to assess eventual similarities and differences in terms of the type of organisations with whom RBSOs establish relationships (composition) and in terms of the structure of the networks, which give indications of the type of connections they may help to establish.

3. Methodology

3.1 Data sample: the Portuguese RBSOs

For this study RBSOs were defined as firms created by entrepreneurs who have some stable connection with a university or other research institution - such as faculty members, researchers and graduate students - and who are applying knowledge obtained or technology developed as part of their research activity; and firms created by external entrepreneurs based on the transfer of technology developed by a research organisation (Conceição, Faria and Fontes, 2017).

The empirical analysis is based on the set of RBSOs created in Portugal between 1979 and 2007 and surviving to this date, which corresponds to the known population created during this period. It should nevertheless be noted that although the first firm identified was established 1979, spin-offs creation only took-off in the 1990s, the majority of the firms included having been established already in the 2000s (Conceição, Faria and Fontes, 2017).

These RBSOs firms are active in a wide variety of industries. In what concerns industry distribution, information & communication technologies (ICT) represent 40.67% of the population with 133 RBSOs, followed by the Biotechnology with 64 firms (19.57%). The smaller proportion corresponds to Engineering with 19 RBSOs (5.81%) (Conceição, Faria and Fontes, 2017).

3.2 Collaborative RTD Projects: data and analysis

To identify the formal networks established by the RBSOs, the paper draws on data on collaborative projects established by Portuguese RBSOs, at national and European level, in the context of all public programmes.

Given RBSOs reliance on public funding for research and development activities (Wright et al, 2007), this data is expected to offer a good coverage of the formal technological relationships by established these firms in this domain.

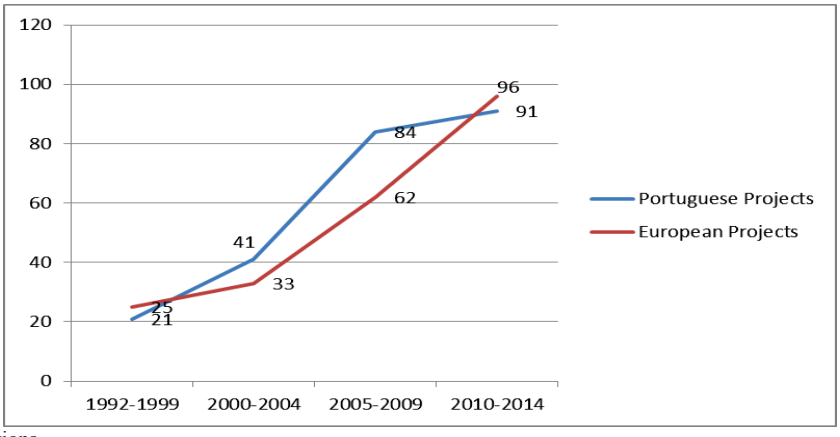
The Portuguese data, regarding the collaborative RTD projects funded by national support programmes, was obtained from the National Innovation Agency (AdI later ANI) database and covers the period 1992-2014. The European data, regarding the joint RTD projects conducted in the context European Framework Programmes, was obtained from the European Commission Community Research and Development Information Service (CORDIS) database and covers the same period. All National and European projects with Portuguese spin-off involvement were identified (table 1), totalling 453 projects (237 Portuguese projects and 216 European projects). Since not all RBSOs were involved in at least one type of project, the analysis ended-up including 112 RBSO, which totalled 510 project participations: 281 participations in Portuguese projects and 229

participations in European projects. Figure 1 presents the distribution of Portuguese and European projects over time.

Table 1: Descriptive of Portuguese and European projects.

	Number of projects	Number of RBSOs involved	Number of project participations of RBSOs
Portuguese funded projects	237	92	281
European funded projects	216	64	229
Total PT & EU	453	112*	510

Source: Own calculations.
* 44 spin-offs participated in both types of project



Source: Own calculations.

Figure 1: Distribution of Portuguese and European projects by start year (1992 – 2014)

Data was collected (in May 2016) on the characteristics of each project and on the partners. Then, both RBSOs and partner organisations were characterised by type and location. The RBSOs were also classified according to the industry where they conducted their principal activity: biotechnology, energy & environment, electronics, engineering and ICT. The "parent" research organisations of the RBSOs were identified and their presence in the same project of their spin-offs was signalled (table 2). As mentioned above, in this research only two industries are considered: biotechnology representing an analytichal knowledge base and energy & environment representing a systhetic knowedge base.

Table 2: Descriptive of Portuguese and European projects by Industry

Industry	Portuguese funded projects		European funded projects	
Biotechnology	47	20%	52	24%
Energy & Environment	14	6%	17	8%
Electronics	47	20%	56	26%
Engineering	9	4%	9	4%
ICT	109	46%	73	34%
Services	9	4%	9	4%
Total number of projects	237		216	

Source: Own calculations.

Collaborative projects constitute two-mode networks that link organisations to an event - the projects. From these we have extracted a one-mode network, considering inter-organisational networks, where a tie joins two organisations, if they collaborate in the same project. We have built symmetric adjacency matrices, valued by the number of common projects and conducted Social Network Analysis (SNA), using UCINET software. The diagrams were obtained with NetDraw software.

SNA provides information on the realtions and structure, as well as on the position of the actors in the network (Wasserman and Faust, 1994). From the vast set of SNA measure we will focus our attention on: i) the size of the network, in terms of number of actors and ties; ii) the network composition, in terms of the share of each type of partner, both considering a tipology of actors (spin-offs, other companies, reseach organizations, other

type of organizations; and their location); iii) the positioning of actors, assessing their centrality; iv) the structure of the networks, considering the measures of density, distance, centralization and cohesiveness.

4. RBSOs knowledge networks: Analytical KB (biotech) vs Synthetic (Energy & Environment)

The RBSOs knowledge networks are represented in Figures 2 and 3, where the colour of the nodes represents the type of actor (spin-offs in blue, other companies in red, research organizations in yellow and other type of actors, including public and non-profit organizations, in green), the shape represents the nationality of the organization (Portuguese in squares and foreign in clircles) and the size is proportional to degree centrality.

Figure 2: Knowledge network of Biotechnology RBSOs

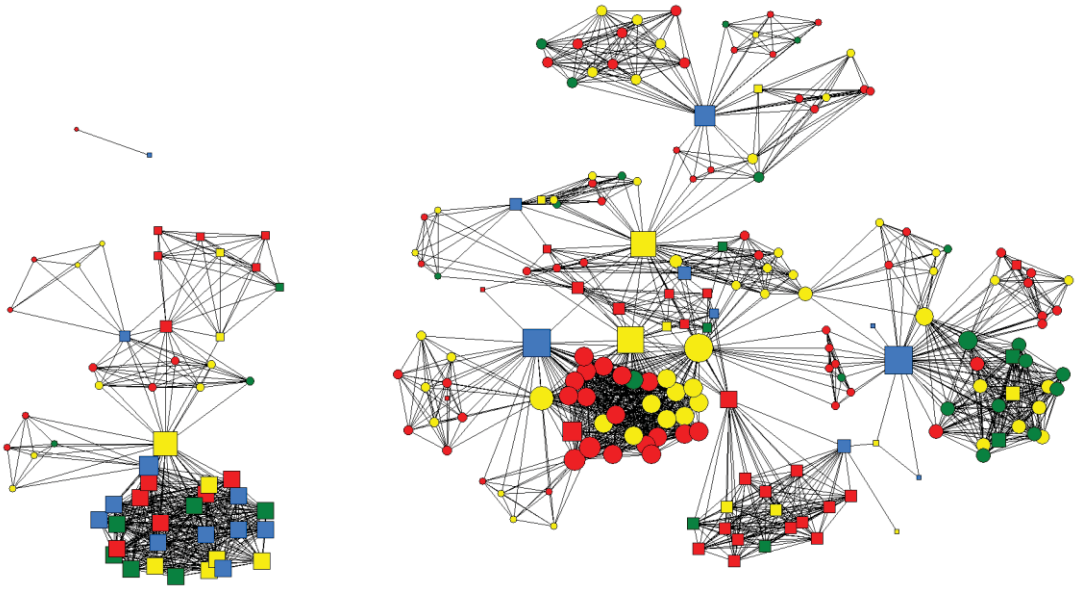


Figure 3: Kowledge network of Energy and Enviroment RBSOs

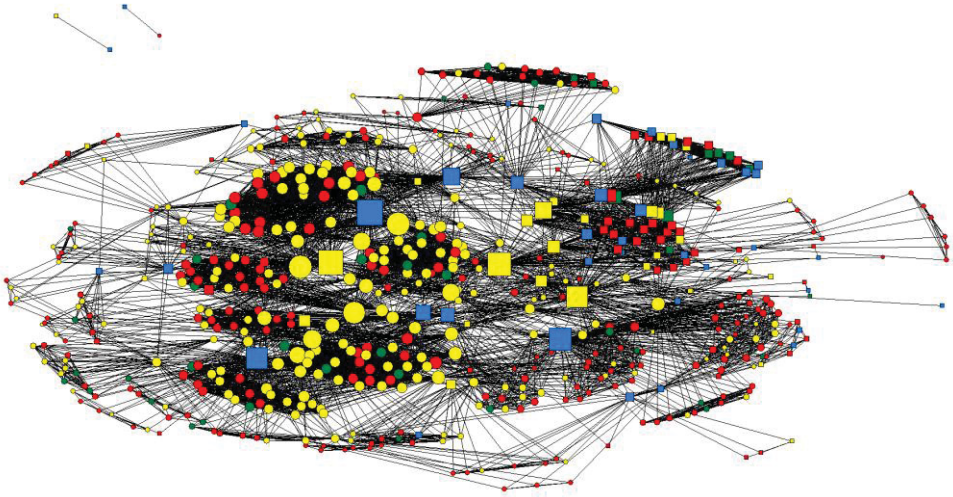

Table 3 presents the size and composition of the RBSOs knowledge networks in the two industries. It shows that the knowledge network of biotechnology is larger, notably in respect to the number of ties, stressing the importance of research collaborations in the industry. It also shows, that the frequency of interaction with research organizations is higher in biotechnology and that the frequency of interaction with other companies is higher in energy & environment, which in line with previous research, being consistent with the presence of an analytical knowledge base in the former and a synthetic knowledge base in the latter. Similarly, it also shows that national partners are more frequent in the industry with a synthetic knowledge base - energy & environment - while international partners are more frequent in the industry with an analytical knowledge base - biotechnology.

Table 3: Network size and composition

		Biotechnology	Energy & Environment
Size	Number of actors	612	240
	Number of ties	6785	1970
Composition	Spin-offs	6.2%	8.3%
	Other companies	43.9%	45.0%
	Research organizations	42.6%	31.7%
	Other organizations	7.2%	15.0%
	National organizations	19.9%	35.8%

Source: Own calculations.

Table 4 presents two centrality measures for the whole network and for the particular types of actors. Centrality measures enable to detect more favourable network positions, enabling access to new business opportunities access to the most relevant knowledge sources and access to better information about what is happening in the network, leading to a increase in innovative performance (Gilsing et al, 2008; Van Der Valk and Gijbers, 2010). In this paper two different centrality measures are used: degree centrality, enabling to capture those actors that are more active in the network and betweenness centrality, enabling to capture those actors that lie between the various other organisations, acting as knowledge brokers.

Table 4: Degree and Betweenness Centrality

		Biotechnology	Energy & Environment
Average Degree Centrality	Overall network	22.7	16.6
	Spin-offs	30.4	23.1
	Other companies	17.7	15.0
	Research organizations	26.9	7.2
	Other organizations	21.7	16.8
	Centralization Index	2.4%	7.7%
Average Normalised Betweenness centrality	Overall network	0.302	0.519
	Spin-offs	1.44	2
	Other companies	0.03	0.12
	Research organizations	0.46	0.89
	Other organizations	0.02	0.04
	Centralization Index	14.9%	26.1%

Source: Own calculations.

It is possible to observe differences across the two industries. Firstly, the biotechnology network exhibits a higher activity, refelected by the higher average degree centrality – each actor has in average 23 partners. Secondly, the distribution of the degree centrality across actor type shows that research organizations are the most relevant knowledge provider in biotechnology, while other organzations (followed closely by other companies) perform this role in the energy & environment network. Thirdly, in the energy & environment network, it is possible to observe a higher ability to broker between groups, expressed by a greater betweeness centrality. Fourthly, the energy & environment network shows a higher centralization index (both for degree and betweeness), indicating a higher variation in the centrality scores among the organizations and, therefore, reflecting a larger separation between the core and the periphery of the network. Since, more skewed distributions can give more benefits to central actors relatively to more peripherical ones, the most central actors in the energy & environment network can see their power reinforced by this structure. Table 4 also shows that, in both industries, research organzations are performing the role of brokers.

Table 5 presents a set of measures to characterize the structure of the networks. Knowledge circultes more easily when networks are connected and dense and have shot paths between the actors (Van Der Valk and Gijbers, 2010). In this case, althoug the networks have the same number of components - there is a path conecting all the organizations - in biotechnology the largest component includes a higher proportion of the total number of actors, and this is reflefted in a higher connectedness (proportion of the organizations that can be reached in the network. In the energy & environment industry we found a denser network, reflecting that the proportion of the relations that are possible, taking in to account organizations present in the network, were established by the RBSOs. Previous research has found that networks with a higher density favour the sharing and transfer of knowledge since they promote trust (Tortoriello et al, 2012), and provide better oportunites to asses the reliability of parters (Gilsing et al, 2008), to establish a share language (Obstfled, 2005) and to build absorptive capacity (Gilsing and Nooteboom, 2005), being very important to exploitation processes. On the other hand, less dense networks – case of biotechnology – facilitate the acquisition of

valuable non-redundant information contributiong to bring new ideas and to identify new opportunities (Burt, 2004; Zaheer and Bell, 2005; Zheng, 2010), being very important for exploration processes.

Table 5: Network structure measures

	Biotechnology	Energy and Environment
Number of components	3	3
Share of the largest component	99.3%	77.1%
Density	3.6%	6.9%
Connectedness	98.7%	64.2%
Average distance	2.9	2.9
Diameter	5	5
Clustering coefficient	0.496	0.974
Small-world index	21.6	9.6

Source: Own calculations.

No differences were found across the industries rearding the diameter and the average distance: in both cases the longest geodesic distance is 5 and the average geodesic distance is 3, meaning that to reach any other organization in the same component it will take 3 steps.

Efficiency in knowledge transfer is also related to the small-world characteristics of a network (Watts and Strogatz, 1998; Cowan and Jonard, 2004), i.e., the combination of many local ties and few more distant ties. Small-world networks tend to be formed by sub-groups, exhibiting a higher clustering coefficient (the density in the neighberhood of an actor) that is reflected in a fast diffusion of knowledge in the sub-group, and by the fact that most pairs of nodes will be connected by at least one short path, indicating that the knowledge can reach the whole network. This has important consequences for the easiness of information and knowledge flows and therefore for the innovation processes. Table 5 shows that the biotechnology industry exhibits a higher small-world index due to it more connected nature. This reflects a more descentralized search process (Easley and Kleinberg, 2010) that can be explained by the distributed nature of knowledge production in this industry (Whittington et al, 2009).

5. Conclusions

This paper proposed that, despite RBSOs common research-based origin, the composition and structure of their knowledge networks might vary between industries, being associated with the nature of the knowledge bases prevailing in the industry. This proposition was explored on the basis of a comparative analysis of the formal knowledge networks (national and international) formed by RBSOs in two industries - biotechnology and energy & environment - which exhibit characteristics that suggest the predominance of substantially different knowledge bases: analytical for biotechnology and synthetic for energy & environment.

The results show that there are indeed relevant differences in the composition and structure of the networks formed by RBSOs in these industries, which denote substantially different networking behaviours. In particular, the findings concerning the size (higher number of ties and greater component size) and the composition (greater weight of international partners) of the biotechnology network, as compared with the energy & environment, are in line with previous research on the characteristics of the networks in industries with the two types of knowledge bases (Martin, 2013). Similarly, concerning the structure, the finding that the biotechnology network exhibits a higher activity, reflected in the higher average degree centrality, is equally in line with previous reseach, which indicate that companies in analytical industries interact with a higher number of partners than those in synthetic industries (Martin, 2013).

The consistency of our results with features identified by previous research, involving a broader range of companies, supports our association of RBSOs active in these industries to the two generic knowledge bases, in particular our tentative association of the energy & environment industry to the synthetic knowledge base. More importantly, it suggests that despite RBSOs distinctive characteristics, their networking behaviour is strongly influenced by the dominant knowledge base in the industries where they operate. In addition, our research identified other differentiating features that reinforce the industry-specificity of the RBSOs knowledge networks studied. This variety is relevant since it has implications for the position and role of RBSOs in these networks. Thus, subsequent research will explore in greater detail the influence of these diverse network features in the RBSOs potential bridging role.

Abstract: Existing literature has shown that research-based spin-offs firms usually exhibit lower death risks than other start-ups. However, few studies have focused on the survival determinants of these particular firms. From a matched employer-employee data set this paper fills this gap by providing evidence using a sample of RBSOs created in Portugal from 1979 until to 2007 and observed until 2012. Specifically, we investigate if firm characteristics and location characteristics play a role on their survival. Our results show a positive impact on the probability of survival of these firms (such factors as firm size and age) as well as the location of spin-offs in municipalities with high entry rates and low exit rates.

Keywords: academic spin-offs; firm survival; duration analysis.

1. Introduction

The entry of new firms in the market bringing in new knowledge, technologies or products is seen as an important driver of economic growth (e.g. Shane 2004; Vincett 2010). Spin-off firms are a particular case of new firm entry. Academic or research-based spin-off (RBSO) relates to a firm whose creation is based on the formal and informal transfer of technology or knowledge generated by public research organizations (Mustar et al. 2006; Djokovic and Souitaris 2008). The study of RBSO has assumed a growing importance in the literature reflecting the importance of these firms as a mechanism of exploitation and transfer of scientific knowledge produced in research institutions, serving also as measure of success of the parent organization (Wright et al. 2007).

An empirical regularity emerging from recent evidence is that these firms exhibit lower death risks than other entrants in the same industry (Mustar 1997; Callan 2001; Di Gregorio and Shane, 2003;Smith and Ho 2006; De Cleyn et al. 2015). Whereas, on average, 40% to 50% of the firms in a given market survive beyond the seventh year (Eurostat/OECD 2007), in the case of research-based spin-offs the survival rate can be as high as 90% (Smith and Ho 2006). A possible explanation could be that RBSOs benefit from numerous advantages, either in the set up phase or throughout the life of the firm such as the high number of employees with PhD degrees, greater experience in research, privileged access to financial funds and networks with the academic system (Lockett and Wright 2005; Walter et al. 2006; Jong 2006). However, these firms usually have on average less experience in industry, which could act as a disadvantage and offset those potential advantages (Colombo and Piva 2012).

Empirical evidence on the survival of RBSOs is still very limited. Whereas some studies have explored the topic using cross-section data or case studies, only Nerkar and Shane (2003) have so far investigated the topic using duration analysis. Their data included 128 spin-offs from the Massachusetts Institute of Technology (MIT) founded between 1980 and 1996. They found that having a radical technology and broad scope patents in a fragmented industry reduces the RBSO´s failure.

Using a unique dataset, this paper analyzes the survival of Portuguese RBSOs from 1986 to 2012. The study goes beyond prior research in using a larger and more comprehensive database than previous studies that corresponds to the population of Portuguese academic spin-offs. Moreover, this study provides an integrative view by simultaneously investigating the role that founding conditions, parent and location characteristics play on RBSOs´ survival.

2. Theoretical framework and hypotheses

2.1 Spin-off Firm´s characteristics

Regarding firm level attributes, the literature has pointed out firm age as a key variable in determining the firms´ survival. Audretsch and Mahmood (1994) considered that the likelihood of firms to survive tends to increase along with the age of the firm The positive relationship between firm age and survival probability is sustained in several studies (e.g. Dunne et al. 1989; Agarwal and Audretsch 2001; Agarwal and Gort 2002).

Regarding the impact of firm's conditions on firm's survival Geroski (1995) argues that the likelihood of survival is greater for larger firms than for small firms. Several studies have confirmed Geroski´s proposition in that the firm´s survival is positively related to firm size (e.g. Dunne et al. 1989; Geroski et al. 2010; Mata et al. 1995; Agarwal 1997; Agarwal and Audretsch 2001; Agarwal and Gort 2002).

Several empirical studies show that firm's human capital, in particular the level of qualifications of its founders, positively influences its survivability (Storey and Wynarczyk 1996; Gimmon and Levie 2010). Saridakis et al. (2008), using a sample of 622 UK small firms, concluded that firms whose founders had a higher level of qualifications (founder's education degree) have a higher probability of being competitive and thereby survive.

Comparing the RBSOs with other high-tech start-ups, Colombo and Piva (2012) consider that the main difference between them are the peculiar genetic characteristics of spin-off firms, in particular the high number of PhD degrees, the strong ties with academia and a greater experience in research but, on average, less experience in industry. Based on a sample of 64 Italian RBSOs and a matched control sample of non-academic high-tech start-ups the authors conclude that the initial competences of the entrepreneurial team are potentially a key source of competitive advantage and leave an enduring imprint on the firm's development.

2.2 Spin-off´s region characteristics

The geographical location of the firms seems to exert a positive effect on business rate of growth, where some regions that are characterized by high resources and wide market opportunities are more conducive to firm growth. As such, metropolitan areas hold strong attractions for small firms with high technological ability.

Indeed the spatial concentration of higher education institutions, technological research facilities, centers of knowledge, science parks and incubators in metropolitan areas increases information accessibility and has a positive influence on firms' innovative capacity (Frenkel 2001; Holl 2004; Salvador (2011); Smith and Bagchi-Sen 2006; Schwartz 2013).

Agglomeration externalities are frequently pointed out as an important determinant of firms´ geographical concentration. Audretsch et al. (2005) argue that knowledge spillovers represent a significant form of agglomeration externalities and that the location decision of new firms should be influenced significantly by access to the sources of such spillovers. The propensity to cluster geographically should be higher in industries where knowledge and innovation activities plays a more important role, namely for high technology and knowledge-based industries and services (Baptista and Mendonça 2010; Magrini and Galliano 2012). According to Woodward et al. (2006) the high-technology plant births are highly concentrated around some regions.

From an empirical study of high-technology location decisions in U.S. counties, the authors found evidence that agglomeration effects, the availability of qualified labor and natural amenities, as well as, university R&D expenditures exert a positive influence on the decision to locate high-technology firms in a county.

Regarding start-ups, the literature postulates a positive link between entrepreneurship and innovation performance (Baptista et al. 2008) where high start-up rates are associated with higher levels of technological innovation in the developed countries (Anokhin and Wincent 2012). Regarding the specific case of knowledge-based start-ups, the entry rate across regions measures the capacity of region on catching up start-up firms.

The regions with high entry rates are more attractive for knowledge-based firms (Baptista and Mendonça 2010).

3. Data and Methodology

3.1 Data collection

Our starting point for this study was the population of Portuguese RBSOs created since 1979 until 2007. In order to identify the population of Portuguese spin-off firms, a comprehensive list was made of spinout firms from Portuguese public research organizations. In this regard we started by collecting information from universities and other public research organizations in order to identify their spin-off firms.

We were able to identify 327 RBSOs created up until 2007. Based on these firms' fiscal number, which we have collected, we asked the Portuguese Ministry of Employment and Social Security for information regarding the identification codes of these RBSOs on Quadros de Pessoal, without the possibility of any matching, in order to preserve data confidentiality.

From the population of 327 RBSOs, the response from the Ministry of Employment and Social Security allowed us to get a sample of 234 firms on Quadros de Pessoal (public RBSOs, for instance, would not figure in Quadros de Pessoal due to the nature of the inquiry). After cleaning the dataset from some inconsistencies we ended up with data for 215 firms, the study sample.

We use data for the Portuguese economy from twenty-five waves of Quadros de Pessoal, a matched worker-firm longitudinal data set. Annually, the Portuguese Ministry of Labour and Social Solidarity gathers information on all firms, from the private sector, with wage-earners. Data collection is based on a mandatory response survey to firms.

Quadros de Pessoal includes information on two hundred thousand firms a year, on average, and their workers (over two million a year). Each firm and worker is uniquely identified in the data set and this allows researchers to follow them over time.

Firm level information includes the date of creation, number of establishments, number of workers, sales, industry, and region, among other. Workers' files present data such as age, gender, date of admission into the firm, date of latest promotion, education, hierarchical level, occupation and wages.

3.2 Method and empirical variables

In this paper the event is the failure of a research-based spin-off founded in Portugal from 1979 until 2007; the failure is define as a firm that ceases operations. For those firms that have not exited at the end of our period of analysis (2012), we do not have information on how long they survive (our empirical approach deals with this right censoring Table 1).

Table 1: Descriptive statistics of events

Spells	Frequency	Percent	Survival time		
			25%	50%	75%
Completed	59	3.17	4	6	11
Right-censored	1,800	96.83			
Total	1,859	100			

Source: Computations from the authors based on Quadros de Pessoal, 1986-2012.
Note: Survival time is measured in months.

Of the 215 spin-offs analyzed, only 59 firms closed their activity in the observed period (1986-2012). This reduced death risk is in accordance with previous empirical studies that mention the high levels of survival of the RBSOs vis-à-vis other start-up firms (Zhang 2009). Considering the survival levels by age of the spin-off firms, we observe that most of the failures occur in the early stages of the start-ups' life. About 8% of these firms fail in the second year of activity but failures increase substantially in the subsequent years, to a cumulative total of 34% by the fourth year and of 42% by the fifth year which is in line with the stylized fact that most of the unsuccessful start-ups fail in the early stages of their life. The probability of failure for the start-ups that survive the first years of activity declines steadily with the firm's age. This is consistent with evidence that older firms are more diversified and less risky than younger firms (Agarwal and Audretsch 2001).

Table 2 presents the descriptive statistics of the dependent variable and covariates and Table 3 the correlation matrix.

Table 2: Definition and summary statistics of variables

Variables	Definition	Mean (standard deviation)	Percent
Time to event (in years)	Survival time to death, in years	7.29 (4.19)	--
Died	=1 if firm died	--	3.17
Firm Characteristics			
Firm age	Age of the firm, in years	8.78 (6.05)	--
Firm size (log of number of employees)	Size of the firm, as the logarithm of the number of employees	2.00 (1.11)	--
Founder PhD	=1 if founder has a PhD	--	3.60
Region Characteristics			
Higher Education Institutions	Number of higher education institutions in the municipality	10.87 (13.70)	--
Entry rate	Ratio of the number of new firms entry to the total number of firms in the municipality	0.038 (0.03)	--
Exit rate	Ratio of the number of firms exits to the total number of firms in the municipality	0.11 (0.05)	--
Hight tech	Ratio of the number of firms on high technology industries to the total number of firms in the municipality	0.002 (0.001)	--

4. Results

The non-parametric estimation of the survivor function plotted in Figure 1 shows a survival rate of 99.72% after the second year, 97.91% after six years and 93.29% after seventeen years. Our results reveal that Portuguese RBSOs survival rate is superior to other Portuguese start-ups (Mata el al. 1995; Nunes and Sarmento 2011).

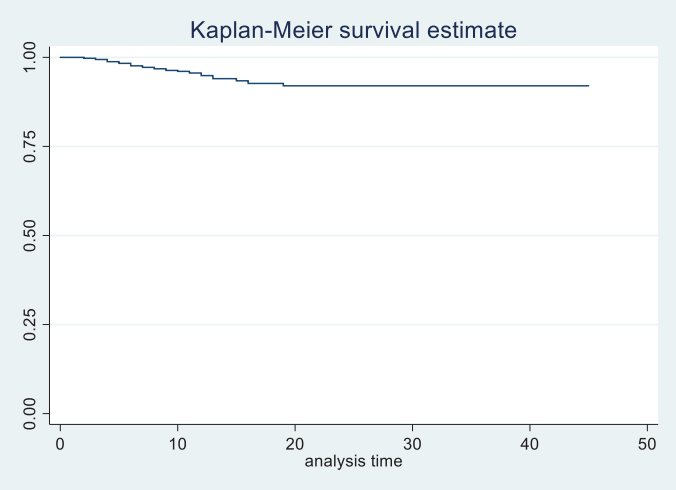

Figure 1: Kaplan- Meier Survival Function of Portuguese RBSOs

In order to analyze the determinants of RBSOs' survival and test our hypotheses, we estimated the parametric proportional hazards models (Exponential, Weibull, Gompertz) (Table 4). These models produce results that are directly comparable to those produced by Cox regression. In fact, in all PH models (semi-parametric or parametric), the exponential of estimated coefficient indicates the ratio of the hazard for a 1-unit change in the corresponding covariate, i.e., a positive coefficient reflects a higher hazard and a negative coefficient represents a smaller hazard.

Table 4: Proportional hazard models' coefficients

Variables	Exponential	Weibull

Notes: * p<0.05, ** p<0.01, *** p<0.001. Gompertz model is not concave. Number of observations: 1,859 observations. Number of failures: 59 failures

In order to select the parametric model that fits better our data we also estimated the Accelerate Failure-Time Parametric Models (Table 5). In AFT models the effect of covariates is multiplicative with respect to survival time, whereas for PH models the assumption is that the effect of covariates is multiplicative with respect to the hazard. In the case of AFT models, the parameters measure the effect of the correspondent covariate on the mean survival time. In assessing model fit, the Akaike Information Criterion (AIC) combines two criteria: parsimony and the log-likelihood. The smaller the AIC score, the more appropriate the model. [1]

[1] We have performed different model specifications which additionally included variables such as firm sales and/or the existence of science parks in the region or being in a metropolitan area. Nonetheless, due to the existence of high correlation levels between some of

Table 5: Accelerate Failure Time models' estimates

Notes: * p<0.05, ** p<0.01, *** p<0.001. Generalized gamma model is not concave. Number of observations: 1,859 observations. Number of failures: 59 failures

Comparing all parametric models, we conclude that Weibull model fitted data better than other distributions in multivariate analysis. In fact this distribution presents the smallest AIC value and also the largest log-likelihood (see Table 3 and Table 4). Thus, we will comment on the Weibull estimates.

Regarding the firms characteristics, our results shows that *Firm Size* does seem to be key in explaining spin-off survival since results show that a one-employee increase on firm´s size decreases the hazard by 49.14%. This result is in line with previous evidence (e.g. Mata et al. 1995). Likewise, if we consider the firm´s age, the results are in agreement with previous empirical studies, where older firms have higher probability of survival (Agarwal and Audretsch 2001; Agarwal and Gort 2002). One-year increase on *Firm Age* decreases the hazard by 68.02%. Together, these results suggest that the key firm-level characteristics in determining RBSO spin-off survival are not different from those that are relevant to any other start-up.

Regarding region characteristics, results show that the being located in a metropolitan area, with spatial concentration of higher education institutions, science parks and incubators, is not important in determining RBSOs survival. However, when the firm is located in a municipality with higher capacity to capture start-up (Baptista and Mendonça 2010) the firms have higher probability of survival. Estimates show that a unit increase of the variable *Entry Rate* decreases the hazard by 100%. Complementarily estimates show that a unit increase of the variable *Exit Rate* increases the hazard by 3147124.3%. This result supports for the positive influence of agglomeration economies on innovation (Magrini and Galliano 2012).

5. Conclusions and policy implications

Previous studies have shown high levels of survival of RBSOs as soon as these exceed the so-called period of "infant mortality". Yet, few studies have focused on the determinants of these high survival rates. Using a matched employer-employee data set this paper fills this gap by providing evidence using a sample of RBSOs created in Portugal from 1979 until to 2007 and observed until 2012. Specifically, we investigate the role of two types of effects that have been put forward in literature as being relevant to understand the survival of

the variables, we did not include those variables in the final specification. Regarding firms characteristics the correlation analysis indicates high levels of correlations between Firm Size and Firm Sales (0.79). Regarding region characteristics variables the correlation analysis indicates high levels of correlations between Higher education institutions and Science Parks/Incubator (0.54) also between Higher education institutions and Metropolitan Area (0.47).

these particular firms, namely spin-offs characteristics and region characteristics where the spin-off firm is located.

Our results suggest that firm size and age is the spin-offs characteristics that matters most to determine RBSOs´ survival, where the larger size the lower the probability of exit by the firm and where older the spin-off is the lower the likelihood of exiting the market. The possession of a PhD degree by the team founders do not seem to be relevant in discriminating survival rates among spin-off firms. In this regard our results indicate that certain inherent characteristics common to RBSOs are less important to explain differences among survival rates than the well-known size and age effect that has been found in firm survival studies and is common across different types of firms.

Regarding the region characteristics, results show that being located in municipalities with high entry rates and low exit rates seems to be important factors influencing the survival of spin-offs corroborating the largely accepted view of the importance of local spillovers and agglomeration externalities in determining firms´ survival. As such, there seems to be no difference between RBSOs and other start-ups regarding the region´s role on their survival.

Our results provide several implications from a policy point of view. First, public policy and parent organizations should support RBSO firms by helping them to have more employees since their set-up. Second, local governments should implement policies that help the start-up of firms and contribute to the ease of doing business, so that they can attract new firms into the region, as agglomeration economies and spillovers effects are very important to spin-offs survival.

A limitation of our data is that it does not allow us to properly identify the industry in which the firm operates according to the economic classification. We are only able to identify the technology area. Thus, two important lines for further research would be to explore the role played by market characteristics, namely competition, and by individual characteristics of the founding team members.

Abstract: This paper presents the case of two initiatives, AgorIP (IP Commercialisation) and Accelerate (Life Science & Health Innovation platform), devised to support the commercialisation of research in Life Sciences & Health. This activity is set in the region of south west Wales, UK, where comparatively low levels of Business Expenditure on R&D make the research output of Swansea University and local Health Boards particularly important to support knowledge-based enterprise. The research aim of the paper is to examine as to whether the initiatives' novel 'Open Access Open Innovation' philosophy represents a practical implementation of the non-linear Technology Transfer model proposed by Bradley et al. (2013). In this regard, the case explores novel components of the initiative including their 'zero-waste' approach whereby all opportunities are progressed along a pathway identified as most appropriate, using a proportionate investment of resources. Data drawn from the Pilot/Initiation period of the initiatives suggests that these principles are in action, with early insight having potential implication for further development, practice and wider policy. This includes recognition of the inherent complexities of such activity, and the need for further data to emerge in order to fully determine the impact of the approach.

Keywords: Technology Transfer, Regional Innovation Systems, Smart Specialisation, University-Industry Interaction; Life Sciences & Health

1. Introduction

This paper explores the commercialisation dynamics of opportunities progressing through two Technology Transfer initiatives, AgorIP/Accelerate, which use an 'Open Access Open Innovation' approach, as part of a wider effort to realise knowledge-based economic development in south west Wales. It examines the AgorIP Intellectual Property Commercialisation initiative which is currently being expanded through the Accelerate Technology and Health Innovation initiative, with the common aim of supporting wider Life Sciences & Health innovation. This paper builds upon the broader regional case and context described at the ECIE 2017 conference in Paris by Davies et al. (2017). Progressing the Open Access Open Innovation framework beyond the AgorIP *commercial* focus, into development of *technology*, *clinical* and *user* innovation perspectives through the Accelerate partner initiative aims to draw upon wider ecosystem resources to support innovation. (Gibson S, 2007)

AgorIP and Accelerate are embedded within the Swansea Bay City Region as a core component of its Internet Coast City Deal (SU, 2017) initiative for knowledge-based regional economic development. This initiative aims to further develop infrastructure (capital funding) to support innovation, though recognises the need to address the requirement for activity and dealflow in order to deliver benefits. This includes alignment with revenue activities including AgorIP and Accelerate (SU, 2016) which aim to deliver increased activity by creating greater quality and volume of commercialisation opportunities from publicly-funded research within the region.

Drawing upon theory from Regional Innovation Systems (Cooke 2004, Abbey et al. 2008), Technology Transfer (Tornatzky and Association, 2000) and wider University-Industry Interaction, the case study explores the interactions of these initiatives with the wider regional Life Sciences & Health ecosystem. This is alongside efforts to maximise their engagement with the 'Innovation Corridor' running through the Swansea Bay City Region, as part of the broader support environment.

2. Life Sciences & Health Innovation in South west Wales

South west Wales has a proud economic history at the centre of the industrial revolution (Mathias, 2013) though has since been struggling in its transition to a knowledge-led economy for reasons including

persistently low levels of Business Expenditure on Research & Development (Mom et al.) (Edmonds, 2000), along with weak endogenous entrepreneurship and business growth (Cooke and Clifton, 2005). A subsequent focus upon high Gross Value Add sectors, including the grand challenge areas of Life Sciences & Health became Welsh Government policy as it aimed to restructure the regional economy (WG, 2013).

In the broader context, the global life sciences and health sector is a major driver of UK productivity and export activity (Bell, 2017), and is characterised by the challenge and opportunity of disruptive forces including demographic change and pressures upon public health systems. In parallel, while the value of sales of pharmaceuticals and medical technology are projected to grow strongly the market structure is evolving with reduced role for blockbuster drugs, and new technological frontiers being crossed such as IoT and AI (Deloitte, 2018). In this respect the Internet of Health & Wellbeing is enlarging the region's capture of this growing global opportunity rather than competing within a zero-sum game. As effectively described by NESTA (Hutton and Schneider, 2008), the nature of innovation brings inherent uncertainty and with that imperfect allocation of resources into the unknown. This makes for challenging market conditions where information paucity and asymmetry and subsequent risk aversion leads to market failure as investment remains within sectors (or mature segments thereof) and regions providing historic returns.

UK Government identified a 'nascent' life sciences cluster of biotechnology companies in Cardiff and Swansea in 2001 (DTI, 2001) described by Cooke (2001) as 'mini-agglomerations'. These had a focus on medical devices, as subsequently presented in Davies et al. (2018a). This cluster sits within a broader Welsh life sciences sector employing roughly 10,000 people and contributing ~£2bn GVA to the economy. It is notable though that health service activity in south west Wales alone of Abertawe Bro Morgannwg (ABMUHB) and Hywel Dda University Health Boards (as part of the ARCH A Regional Collaboration for Health initiative) is itself greater in scale. Collectively, these two Boards present 30,000 employees across a range of roles (ARCH, 2017), contributing in part to a general regional imbalance towards public-sector employment. However, the nature of the activity and sectors involved does present specific innovation potential within the Regional Innovation System (RIS) as described by Cooke (2004a), (2004b), and Davies et al. (2015).

The major RIS actor of NHS Wales is an integrated health system which differs to the fragmented nature of the US system described by Herzlinger (2006) (or even by comparison NHS England). In terms of innovation and absorptive capacity it does though still involve barriers of; substantial regulation; a rigid business model (dominated by NHS) (Hwang and Christensen, 2008); public procurement constraints (Uyarra et al., 2014); and stringent regulation of patient information.

In this regard, the public health system certainly poses some tougher questions with regard to market orientation than those relating to other public services (Hodgkinson et al., 2012). The resultant reduced absorptive capacity and 'porousness' of open innovation walls is however noted, and policymakers are aiming to address these issues (WG, 2015), with initiatives such as AgorIP and Accelerate as part of the response.

3. Theoretical Context

Previous sections have presented the broad context and ambitions which surround the AgorIP and Accelerate initiatives, which relate to multiple theoretical contexts of RIS, Smart Specialisation, Open Innovation and University-Industry Interaction, though at its core is theory relating to Technology Transfer.

Technology transfer from academia, itself exists in the broader context of University-Industry Interaction as described by D'Este and Patel (2007), who also suggest that its associated mechanisms of patenting and venture spin-out may attract disproportionate levels of attention. However, it is also presented that there are linkages between mechanisms such as shown by Dechenaux et al. (2011), where one type of engagement relates to another. Technology transfer was historically considered as unidirectional and linear (D'Este and Patel, 2007), as presented in the model originally described by Siegel et al. (2004), in Figure 1 below.

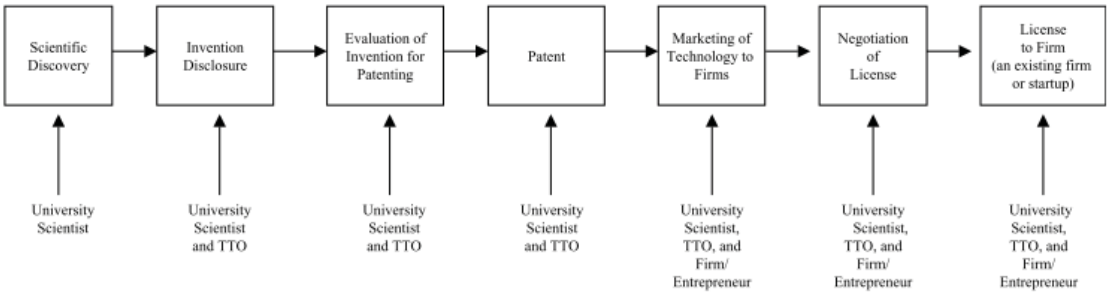

Figure 1: Linear Technology Transfer Process (Siegel et al., 2004)

However, greater complexity including multiple potential transfer pathways, including outside of formal channels are a limitation of the linear model. Observers such as Perkmann and Walsh (2007) suggested that University-Industry relationships were distinct from Technology Transfer, while others such as Dechenaux et al. (2011) emphasise their interconnection. However, both perspectives embrace Open Innovation (Chesbrough, 2003) recognising how organisations source opportunities through relationships. This has subsequently been reflected in Bradley's discussion of a proposed Alternative Technology Transfer Model (2013), within the construct of the 'entrepreneurial university' (Gibb and Hannon, 2006).

In this context, the role of the Technology Transfer Office is central to the process, with recognition of TTO experience being an important success factor (Hülsbeck et al., 2013). In this regard, a lack of TTO skills in the UK has long been noted as a key challenge (Siegel et al., 2003) (Decter et al., 2007), including specifically within Wales (WAG, 2004). Other factors relating to TTO operation have also received examination, including proximity and critical mass of activity. This has included the perspective offered by Macho-Stadler et al. (2007) of TTOs developing a reputation through scale of innovative activity, though conversely Siegel et al. (2003) suggest potential decreasing returns with increased scale. Further facets, including delivering efficiency in TTOs has been examined by Anderson et al. (2007), observing significant variation in performance, and suggesting a number of factors for consideration, including scale, variation in policies and incentive structures.

This broader debate sits alongside a view of a lack of viable TTO activity within Wales, as noted by WAG (2004) with suggestion for integrated or shared services to overcome the lack of sustainable scale within any one Welsh university.

In terms of TTO output, it is licensing or investment into spin-out ventures which are considered as principle results of the process, whether it is linear (Siegel et al., 2004) or otherwise (Bradley et al., 2013). Selection of paths, is in itself an area of ongoing discussion, including by Wright et al. (2006) having described the preference of venture capital to invest in university spin-outs once they have been developed (Ferguson and Olofsson, 2004), which is arguably picking winners when the race is already well underway and is consistent with Di Gregorio and Shane (2003) suggesting an importance of funding availability at spin-out early stages. It also echoes Ambos et al. (2008) describing the tensions of industry preferring later less risky endeavours than the earlier academic stages of discovery, with tighter control of intellectual assets that pulls against academics' eagerness to openly disseminate findings. Therefore, maximising the commercial readiness of opportunities represents an important factor in commercial attraction, investor readiness and successful innovation.

4. Approach

In the above context this study examines the emerging AgorIP project portfolio and proposed Accelerate activity for development of life sciences and health innovation along with its integration within its regional innovation system. Its central aim is to examine the pathways of the technology transfer process from source to output, and therein its claimed 'Open Access Open Innovation' philosophy.

Using the approach presented below (Fig.2), adapted from Stake (1995), and applied by Huxtable-Thomas et al. (2015) to examine an ESF-supported project the study provides an initial view of the initiatives and their contexts. This will support ongoing development of the study, including wider research of the region's *Internet Coast* City Deal initiative (SU, 2017). The study is undertaken through a bibliographic review examining how the initiatives compare to the theoretical technology transfer processes of (Siegel et al., 2004) and (Bradley et al., 2013), in the context of the sectors and their RIS.

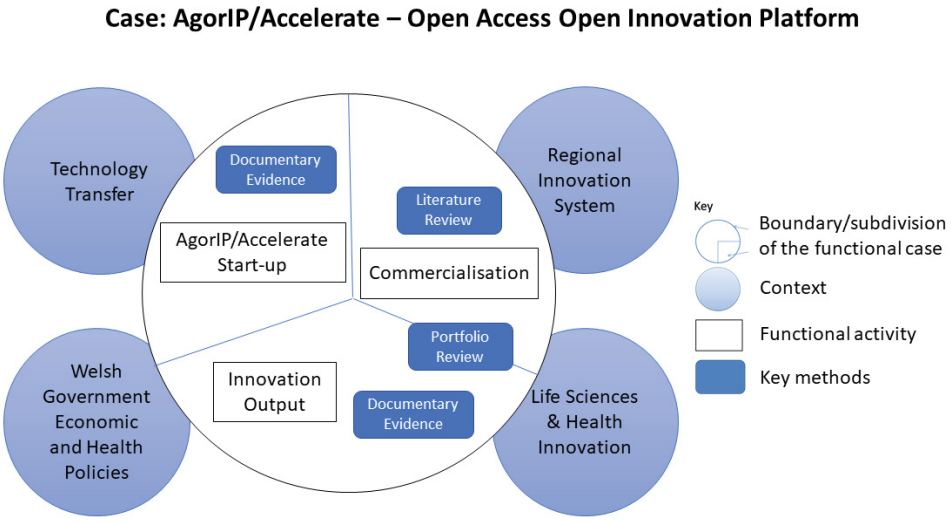

Figure 2: AgorIP/Accelerate Model and Review

The study examines the initiatives in the relevant contexts of Technology Transfer, Life Sciences & Health innovation, Regional Innovation Systems and Welsh Government Economic and Health Policies, applying mixed methods (Creswell and Clark, 2007) involving;

- Review of the original AgorIP and Accelerate project proposals/model in the context of Technology Transfer processes; and
- Review of current and emerging AgorIP project portfolio data and Accelerate partnership

The above framework also supports integration of further data and methods to build upon the study, including longitudinally, as well as providing a basis for planned examination of the cases of individual innovations emerging from the initiatives.

As European Regional Development Fund (ERDF)-supported projects (WEFO, 2013), AgorIP and Accelerate are required to maintain detailed project records, along with ongoing independent evaluation of their activities.

These records, together with the original project business cases and supporting documentation provide the basis of this study. Data made available and reviewed within the study relate to the origin, maturity (technology readiness level), sector, and output of opportunities progressing through the technology transfer process. Due to the early stage of the activity there were insufficient data for statistical analysis, though sufficient to identify commercialisation pathways involved in the process.

4.1 AgorIP and Accelerate

AgorIP (with Agor being Welsh language for 'Open') has been developed in partnership between Welsh Government, academia and industry to commercialise technology from universities and clinical research. In parallel, the forthcoming *Accelerate* initiative extends this philosophy to *technical*, *clinical* and *product* perspectives of innovation opportunities as presented in Figure 3 below.

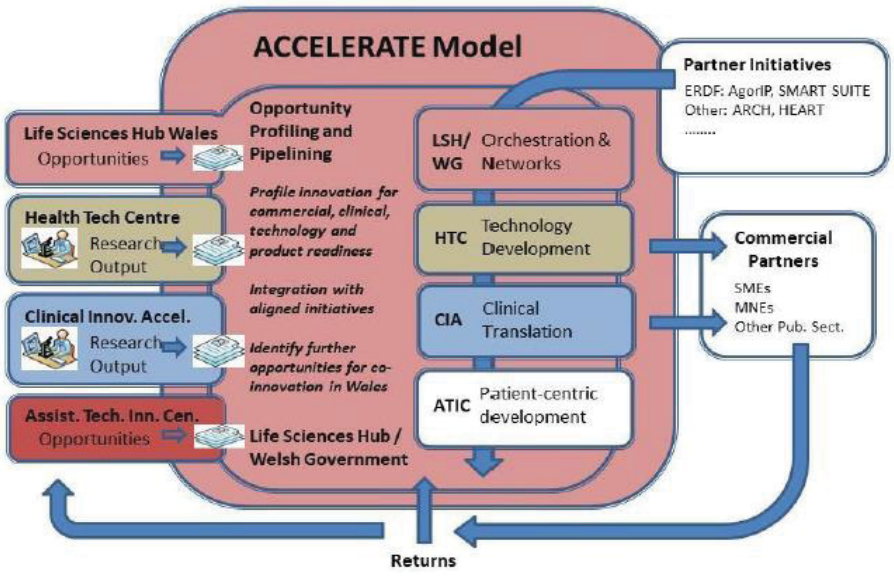

Figure 3: Accelerate Model

Both AgorIP and Accelerate present the same '*Open Access Open Innovation*' and '*zero-waste*' approaches (SU, 2016), with the former focused on achieving investment readiness and the latter focused on *unmet clinical need*, *technology*, *ecosystem engagement* and *user-centric* perspectives of opportunities. Each initiative draws opportunities from diverse sources including universities, health boards and industry (SU, 2016).

The initiatives aim to capture and develop intellectual property emerging from universities and health boards and wider sources which is subsequently developed with co-investment from the partners. This is planned to involve in-kind staff effort by specialists from the universities, and investment for services such as market research, regulatory advice and other services, as required to support commercialisation of an opportunity to a point of 'investor-readiness' (SU, 2016).

The *Open Access* element aims to disincentivise or at least accept the 'bypassing', or simply the non-use of the system by academic and clinicians who wish to otherwise develop their opportunities. This also relates to a claim of allowing the initiatives to focus efforts on those who wish to engage and avoid the role of 'policing' commercialisation activities.

The stated aim of the *zero-waste* principle involves progressing each opportunity onto the most appropriate pathway, with success defined by the relevant partners but underpinned by the broader regional economic development mission. This allows all disclosures to be supported, though with proportionate and appropriate use of resource, along the most advantageous pathway (e.g. licence or spin-out).

Over the planned 3 years of delivery the combined initiatives aim to develop 400 opportunities, register for over 100 patents and support creation of ~200 jobs (SU, 2016). This would represent a significant contribution to the sector, which for reference would represent adding to previous growth from initiatives such as the Institute of Life Sciences which created ~800 jobs in the period 2007-15 (Davies et al., 2018a).

5. Analysis

The AgorIP project, as of March 2018 had been underway for 27 months, including its initial 'mobilisation', while the Accelerate project was still approaching funding approval. At this point AgorIP had developed a portfolio of 261 opportunities across sectors including Life Sciences & Health, Information and Communications Technology and Renewable Energy generation and management.

Clearly, as opportunities take time to develop, this portfolio predominantly relates to the input rather than innovation success. At this stage, 27 opportunities had already progressed to become spin-out companies (with IP invested into the venture) attracting external investment, with a further 12 resulting in licensing arrangements. This mix of outputs demonstrates a diversity of transfer mechanisms and not a favouring either

of spin-out or licence as a form of output. From this portfolio, 107 opportunities (41%) related to Health & Life Sciences, compared to the 50% target for the sectors included in the project plan (SU, 2016). This mix of sectors also implies potential for Open Innovation (Chesbrough, 2003) with diverse sources, disciplines and potential destinations for technology transfer.

While the above is based on a relatively early and limited number of opportunities it gives an indication of overall input and output, and the nature of the pathways involved. The above figures present an emerging pipeline of individual projects including some contemporary forms of innovation (Davies et al., 2018b). Furthermore, the AgorIP project activity to date also involves some structural and operational changes to commercialisation activity amongst the partners including;

- Harmonisation of IP policies between Swansea University and University Health Boards of Abertawe Bro Morgannwg and Hywel Dda. This presents an alignment of organisations with common terms of engagement for industry and other partners. This suggests response to one of the more UK-specific challenges identified by Decter et al. (2007) where variation between organisations presents a challenge to industry engagement.
- Integration with delivery of knowledge transfer mechanisms such as consultancy arrangements (through Swansea Innovations), which aims to protect against potential overemphasis on patenting and spin-out described by (D'Este and Patel, 2007) avoiding internal competition to separately pursue knowledge transfer and commercialisation pathways.
- The use of intensive mentoring to the point of directing spin-outs, including surrogate entrepreneurs supported by strong networks across sector fora, as suggested by Wright et al. (2006) to negate weak entrepreneurial focus and skills amongst researchers.

In parallel, the emergence of the Accelerate initiative has moved emphasis from a purely commercial perspective for opportunities to also incorporate *technology*, *clinical* and *user* innovation perspectives. This has involved partnership with specialist facilities/expertise in the regional innovation centres of the Institute of Life Science; Welsh Wound Innovation Centre; Institute of Sustainable Design; Cardiff Medicentre; and the Life Sciences Hub Wales.

Accelerate also develops greater scale through wider geographical engagement, and broader partnership including the second mini-agglomeration (Cooke, 2001) around Cardiff. This responds to the 'Critical Mass' issue noted in the Smart Specialisation Self-Assessment from Welsh Government (WG, 2014), along with observations of key commentators (Gibson S, 2007) describing a need to focus on developing greater scale of commercialisation activity.

6. Conclusion

AgorIP is still at its early stages, particularly considering commercialisation timescales involved in Life Sciences & Health innovation, while Accelerate remains to become operational. Therefore, data emerging from the initiatives are limited. Realisation of the initiatives in themselves do however represent recognition of the need to create dealflow, described by commentators such as Gibson S (2007) in order to achieve the knowledge-based economic development presented in regional policy (WG, 2014, SU, 2017). The mixture of university and health board opportunity sources reflects the proposed 'Open Access' while the zero waste philosophy together with broader cluster engagement also acknowledges the important issue of recognising that awareness of TTO is a key determinant in levels of 'bypassing' them to pursue opportunities (Huyghe et al., 2016). Furthermore, the involvement of multiple organisations as both sources and destinations of opportunities suggests the more complex dynamics with multiple pathways of the model proposed by Bradley et al. (2013) presenting an advancement in practice compared to the earlier linear model from (Siegel et al., 2004).

The AgorIP and Accelerate approach presents a practical implementation of the non-linear Technology Transfer model proposed by Bradley et al. (2013), including importantly the Open Innovation paradigm. A key element of the case has been not decoupling the initiatives from their context or relevant timescales. In this respect, the regional history of prior initiatives and forthcoming endeavours such as the Internet Coast City Deal presents opportunity for further research into this technology transfer approach. This includes regard to

the specific context of Open Innovation across public and private sector partners, with potential relevance to other post-industrial regions.

Is Portuguese Higher Education Developing Students Capacities for Innovation? The Truth behind Learning Outcomes

Diana Dias and Diana Soares
Universidade Europeia, Lisboa, Portugal
diana.dias@universidadeeuropeia.pt

Abstract: The political and social discourse about innovation becomes dominant in our economy and society, which impacts also on educational and labour market systems. Particularly for Higher Education, boosting knowledge and innovation appears as a strategic mission, calling for innovative research, innovative pedagogies, and innovative organizational structures. Similarly, fostering students' abilities to innovate appears as a vector of this strategic mission. Based on this framework, this study intends to explore if, effectively, innovation (or the capacity to innovate) appears as an expected learning outcome to the achieved by students at the end of their qualification. Using a qualitative approach, the contend of learning outcomes proposed in all programs submitted to quality accreditation in Portugal (since 2009) was analyzed. In general, results indicate that innovation is fairly mentioned (about 35,8% of the programs mentioned it at least once). From a total of 39742 segments coded, innovation is mentioned 1704 times, which correspond to 4,3%. A cross comparison between academic degrees revealed that innovation is particularly relevant for PhD degrees and integrated masters. Significant differences are found according to disciplinary areas. Environmental sciences, art and design programs, engineering and computer sciences clearly emphasize innovation as an expected skill to be achieved by their students. Some implications to practice need to be debated, confronting these results with literature insights.

Keywords: higher education, innovation, competences, learning outcomes.

1. Introduction

Fostering and cultivating innovation, or the ability to innovate and to create, appears as a central vector in Higher Education mission. This skill is particularly required on job market, desirable not only for technological development but also as a problem-solving facilitator. As future workers, university students are a main source to contribute for future innovations in their organizational settings. Thus, an education that promotes innovation and entrepreneurship is essential on the development of students' innovation spirit, entrepreneurial consciousness and innovation ability (Jing, Li, Zhang, & Li, 2016), supporting their transition from education to labor market.

In the literature, the ability to innovate appears closely connect to entrepreneurship skills regarded, also, as a personality trait. The willingness to change (Mueller & Thomas., 2010) or the tendency to think creatively (Martín, Potočnik, & Fras, 2017) are some personal facilitators of the ability to innovate. A set of skills is critical to an innovative performance. These skills for innovation may include technical skills (to know-what and to know-how), cognitive skills (critical thinking, imagination or creativity) and behavioural and social skills (persistence, conscientiousness, self-esteem, communication, collaboration), working as building blocks of students ability to innovate (Avvisati, Jacotin, & Vincent-Lancrin, 2013).

It is in the context of Higher education that students start to develop and achieve these skills for innovation. However, the acquisition of these outcomes and competences varies depending on university experiences, academic degrees and or the study program/disciplinary area students chose.

The differentiation of competences and expected outcomes across qualification degrees is well documented in the literature. According to the National and the European Qualification Framework (Bergan, 2007), each academic degree should be characterized by a set of LOs, ranging from discipline-specific knowledge to a set of wider generic skills and competences. Different qualifications are expected to have different LO and a variety of competency profiles. From a Bachelor to a PhD degree, LO becoming progressively more demanding, as the complexity of skills and competences rises (Werquin, 2012). Some guidelines – Dublin Descriptors - could be used to distinguish academic qualifications or degrees (Joint Quality Initiative informal group, 2004). For instance, communication skills become more demanding as the qualification level increases. In a bachelor degree, students are expected to have the ability to interpret relevant data to inform personal judgments. In turn, students who completed a master degree are expected to have the ability to integrate knowledge and reflecting on social and ethical responsibilities linked to the application of their knowledge and judgments.

Finally, in a PhD degree, learners are expected to be able to promote contexts, technological, social or cultural advancement in a knowledge-based society. Another important vector of differentiation between degrees is related to the learning skills domain. While a bachelor student is expected to have achieved the skills needed to study further with a high level of autonomy, a master student is already expected to be able to study in a self-directed and autonomous manner. A PhD student is expected to be able to promote technological, social or cultural advancement, using innovation as a tool to gather those achievements (Joint Quality Initiative informal group, 2004).

Disciplinary differences in teaching and learning leads also to an interdisciplinary variation in students competency-profiles (Sin & Soares, 2018). For instance, students from arts and design programs tend to have a higher score in critical thinking and interpersonal relationship skills, while engineering students scored highly in problem solving (Jessop & Maleckar, 2014). Using the classification developed by Biglan (1973) and reviewed by Neumann and colleagues (Neumann, 2001; Neumann, Parry, & Becher, 2002), disciplinary areas could be categorized as "hard pure," "soft pure," "hard applied," and "soft applied." Hard pure disciplines (e.g., physics) to be typified as having a cumulative, atomistic structure, concerned with universals, simplification and a quantitative emphasis. Soft pure disciplines (e.g., history) to be "reiterative, holistic, concerned with particulars and having a qualitative bias" (Neumann et al., 2002, p. 406). Hard applied disciplines (e.g., engineering) are characterized as "concerned with mastery of the physical environment and geared towards products and techniques," while soft applied disciplines e.g., education) care about "the enhancement of professional practice and aiming to yield protocols and procedures" (Neumann et al., 2002, p. 406). Focusing on innovation skills, results from Avvisati, Jacotin, & Vincent-Lancrin (2013) indicated that these skills are particularly required in some disciplinary areas. For instance, in manufacturing industries, over 50% of tertiary-educated employees involved in innovation have an engineering (42.9%) and a science degree (7.8%), suggesting the relevance of those skills in these specific study programs.

Based on this theoretical framework, this study intends to explore if and how Portuguese Higher Education Institutions transfer innovation into LO, defining this skill ("the ability to innovate") as an expected outcome to be achieved by their students. A comparison between academic degrees and disciplinary areas will be also analysed.

2. Methodology

2.1 Procedure

A content analysis of the LO identified in the proposals of new study programs submitted to accreditation by the Portuguese Agency for Higher Education Accreditation (A3ES) was carried out using the MAXQDA software (version 12). Six steps were taken to identify patterns (themes) within the data. This analysis followed a conceptual framework, in which 24 technical and generic skills were included, such as specific knowledge, critical thinking, ability to innovate, problem solving, autonomous work, team work, or This procedure uses a theoretical thematic analysis approach, instead of a data-driven option (Braun & Clarke, 2006).

2.2 Measures

At an initial stage of the accreditation process, HEI submit an accreditation proposal to A3ES: "Request for Accreditation of a Study Cycle". In the description of each study cycle that is submitted, institutions must describe what are the "intended learning outcomes" they expected students will achieve at the end of a specific period of learning. Data analysis focused on information included in this question, and which is limited to 1000 characters LOs included in all proposal of study programs submitted to accreditation in A3ES, from 2009 to 2014, were examined (n = 2890).

From those documents, 50,8% correspond to 2nd study cycle (master degree) proposals, while 34,8% refer to 1st study cycle (bachelor degree), and 14,4% to 3rd study cycle (PhD degree).

3. Results

From the content analysis of the LO emerged different outputs. Firstly, the frequency of each category coded informs about the relevance of "ability to innovate" in all 24 skills assessed. Secondly, a comparison across academic degrees and disciplinary areas is also performed, informing about what specific areas and qualifications emphasized more this skill.

Accordingly, as presented in Table 1, "critical thinking" and "discipline-specific knowledge" are the most mentioned skills in all documents analysed. In turn, "cultural awareness" and "communication in a foreign language" seems to be less relevant competences. Focusing in "ability to innovate" skill, results show that this skill is fairly mentioned. From a total of 39742 segments coded, innovation is mentioned 1704 times, which correspond to 4,3%.

Table 1: Percentages of each skill in all coded segments

Skills	**%**
Critical thinking	11,82
Discipline-specific/technical skills	9,71
a) Applied knowledge	8,98
b) Theoretical knowledge	4,89
Information management	6,97
Generic knowledge	4,49
Ability to innovate	*4,29*
Organizing and planning	4,13
Problem solving	3,88
Written communication	3,76
Information and communications technology	3,51
Oral communication	3,48
Team work	3,16
Autonomous work	2,76
Leadership	2,74
Creativity	2,68
Social, economic and environmental sustainability	2,65
Lifelong learning	2,51
Adaptability to new contexts	2,25
Personal and social responsibility	2,11
Ethical and professional regulation	1,98
Strive for excellence	1,45
Decision making	1,43
Entrepreneurship	1,42
Interpersonal relationship	0,93
Cultural awareness	0,42
Communication in a foreign language	0,32
Total	**100,00** (total of 39742 segments coded)

A cross comparison between academic degrees revealed that innovation is particularly relevant for PhD and integrated masters. As table 2 reveals, almost 8% of PhD programs and 6% of integrated master programs mentioned this skill.

Some differences are also found according to each disciplinary area. Results show that 10% of manufacturing industries programs emphasize innovation as an expected skill to be achieved by their students. Programs such as art and design, environmental sciences, agriculture, forestry and fisheries, engineering and computer sciences programs also stressed this skill. On the other hand, management sciences and transport services programs do not give any prominence to this skill.

Table 2: Percentages of "ability to innovate" skill in each academic degree and each disciplinary area

		Ability to innovate (%)
Academic degrees	Bachelor	2,84
	master	4,26
	Integrated master	*6,11*
	PhD	*7,76*
Disciplinary areas	Educational Sciences	2,95
	Arts and design	*8,96*
	Humanities	4,63
	Social sciences	3,47
	Information and journalism	4,66
	Management sciences	0,00
	Law	2,46
	Life sciences	2,82
	Physics	5,11
	Mathematics	4,84
	Computer sciences	*6,34*
	Engineering	*6,59*
	manufacturing industries	*10,42*
	Architecture and construction	5,17
	agriculture, forestry and fisheries	*7,47*
	Veterinary sciences	2,06
	Health sciences	1,47
	social services,	1,61
	Personal services	4,02
	transport services	0,00
	Environmental sciences	*8,51*
	Security services	3,91

4. Discussion

This study aims to explore the relevance of graduates "ability to innovate" on the context of Portuguese Higher Education. The content analysis of learning outcomes provides a comparison between specific and generic competences, as well as comparison across disciplinary areas and academic qualifications.

In general, results showed a clear trend towards the inclusion of innovation as an expected learning outcome, being one of the most quoted generic skill (after critical thinking and information management). Portuguese Higher Education Institution seems to be committed to the promotion of an education for innovation, in which the ability to innovate, critical thinking skills, specific and general knowledge appears as crucial dimension in graduates' competency-profiles. The combination of those skills is already discussed by Avvisati and colleagues (2013). Skill for innovation includes not only technical skills (represented in our study by specific and general knowledge), but also cognitive skills (such as critical thinking or information management). Accordingly, an interesting question need to be asked: could innovation be considered a single skill or a combination of skills?

The comparison across qualification degrees suggest that innovation is particularly relevant for PhD and Integrated Master programs. According to the Dublin descriptors, skills and competences required in each domain become more complex as the level of qualification increases (Joint Quality Initiative informal group, 2004). A PhD program, as the last stage of qualifications, is highly demanding for students, due to the innovation and for the expected quality required on a research and on an elaboration of a thesis). If a bachelor student is expected to be able to elaborate a portfolio, a PhD student is already expected to develop an innovative research in a high competitive field.

When contrasting disciplinary areas, a similar result from Avvisati et al. (2013) also is revealed. Innovation is clearly emphasized on programs related to manufacturing industries, closely connected to engineering and computer science areas. Art and design programs stress, also, innovation as an important learning outcome.

Here, virtual environment and these new design techniques and methodologies could be working as a reinforcement of innovative skills.

To conclude, some implications from our result should be discussed. Firstly, even though with different weights, the truth is that Portuguese Higher Education understand innovation as a core LO to be achieved by their students. Innovation seems to be particularly relevant for some specific programs (such as manufacturing, engineering, art and design) and for some academic degrees (PhD). Being the "ability to innovate" a required skill for labor market, institutions should try to foster these skills for innovation, regardless of the discipline or the academic degree. Several pedagogic practices, some of them already implemented worldwide, such as problem or project -based learning, design thinking, case studies, competitions or simulation seems to have a great impact on the development of students' skills for innovation.

The Role of Vocational Education in the Formation of Career Trajectories in Russia

Aleksei Egorov
Higher school of Economics, Moscow, Russia
aegorov@hse.ru

Abstract: The paper analyses the role of vocational education in formation of professional trajectories of Russian employed population during the period 2005-2015. Based on longitudinal data we explore the differences between career paths of workers that had the experience of vocational training and workers without such experience. We contribute the debate regarding vocational training and its role in innovation and economic development utilizing methodology of sequence analysis and Markov chains with long memory (mixture transition distribution models (MTD)). MTD models suggest the analysis of categorical data sequences instead of quantitative data that is standard for this kind of research. Such methodological approach allows not only estimating casual effects of participation in vocational education programs on the wage level, but exploring how vocational training influences the whole career path. Our findings suggest that those workers who participate in vocational training have lower probability of different negative events in their careers including job loss. Moreover, mixture transitions distribution models suggest that for such workers the current career status determined by longer history of previous career events than for those employees that had not any experience of participation in vocational education programs. These results give the evidence that vocational education is important factor of success on the labour market, providing greater flexibility of career paths that is crucial in innovation development of the labour market and economy as a whole. Findings of the study also have important policy implications. Importance of vocational training on individual level suggests that investment in vocational education on societal level will bring positive returns. This kind of education provides the flexibility of individuals on the labour market, through vocational training workers obtain new skills and knowledge that allows them utilizing new technologies and innovations. Development of vocational education may be considered as policy-making instrument that can generate positive economic outcomes.

Keywords: Labor market, career trajectories, vocational education, sequence analysis, MTD models

1. Introduction

Increasing rates of technological and innovation development determine the increase in requirements for the competence of employees. The structure of demand on the labor market is changing: workers that can be flexible and adapt to constantly changing technologies become more and more in demand. Increasing demand for such workers, undoubtedly, leads to the increase in their wages that makes investment in human capital profitable (Becker, 1964).

Human capital generally defined as the accumulated stock of knowledge, skills, competence. It is usually approximated by the level of education or average years of schooling without splitting it into levels. However, in conditions of innovative economy vocational education becomes one of the most important types. Surely, higher education, for instance, provides a set of fundamental knowledge that is crucial for the success on the labor market. Today the most important characteristics of the workers are flexibility, adaptability, ability to learn quickly, acquire new skills and change the career trajectories. Vocational training provides the conditions for the development of these mentioned characteristics. Particularly, vocational education increase mobility on the labor market through short courses that allow people obtaining new qualifications needed for profession change.

Most existing studies in this field look at the problem of vocational training from two general perspectives. The first one is exploring the relationship between participation in vocational education programs and wage level. The second one is probability estimation of vocational programs existence in some particular industries. The first type of research is on individual level, the second one is on institutional level. This study opens new vision of vocational training since it looks for influences of vocational education participation on the whole career paths using methodology for life course analysis.

2. Related literature

The theoretical framework of this study is human capital theory that was developed in (Becker, 1964); (Schultz, 1960). This theory suggests that education is an investment in human capital that bring positive returns in the future. There are a lot of empirical studies giving the evidence that development of education leads to positive

economic outcomes both on individual (Mincer, 1974);(Psacharopoulos, Partinos, 2002) and macro (Barro, 1996); (Mankiw et al., 1992); (Barro, Lee, 2010) levels.

Human capital is rather wide concept that includes not only formal education, but also a vocational one. After 1960's the separate flow of research regarding vocational training was formed. The general directions of the research in this field are the analysis of the vocational training on the labor markets with imperfect competition (Acemoglu, 1997); (Acemoglu, Pischke, 1998); (Acemoglu, Pischke, 1999); relationship between vocational training and labor productivity (Ballot et al., 2006); government support of vocational training programs (Berger, Walden, 2002). One of the most important empirical works in the field of vocational training is (Bassanini et al., 2005) where authors provide comprehensive analysis of the vocational workplace training in European countries.

There are much less empirical studies on vocational training for Russian labor market. There are two main kinds of research in this field for Russia. The first type is the research of relationship between participation in vocational training and the level of wage (so-called return to vocational education). For example, in (Berger et al., 2001) it is suggested to separate vocational training that leads to obtaining of new qualification and the vocational training the leads to the development of the existing competence. Without such separation authors failed to find statistically significant influence of vocational training on the wage level. After separation the results change and the influence of the vocational training leading to new qualification on wage level is observed. Another type of research in this field for Russian labor market analyses the probability of the presence of vocational education programs in different industries (Roshchin, Travkin, 2017).

In general there is a gap in the literature devoted to the Russian labor market that provides the analysis of vocational training participation on the professional trajectories. This study aims to fill this gap and provide an empirical evidence that vocational training helps to form such career paths that are needed for innovative development of the labor market and the economy as a whole.

3. Methodology and data selection

This study is based on the Russian longitudinal survey- Higher school of economics (RLMS-HSE)[1]. This survey started in 1994 and contains different questions regarding employment, education, health, income. For this study the period from 2005 to 2015 was chosen. This choice is determined by the tradeoff between number of years and number of individuals in the sample. During the time some individuals fall out of the sample, so when we take longer period, the number of individuals for which we have data available for each year in the period decreases. Ten years period covers significant part of the career paths and at the same time allows keeping in the sample number of individuals that is enough for estimation of the models. In total, our sample contains 2017 individuals, 536 out of 2017 individuals had an experience of vocational training within 10 years interval.

The idea behind methodology implemented in this study is to form two groups of workers and then compare them in terms of career paths. This first group includes people who had experience of participation in vocational training programs. The second one includes respondents without such experience. To compare these two groups directly would be incorrect since the different characteristics of individuals in two groups may differ significantly. For instance, we can expect that the share of respondents who are working in the fields of education, science, healthcare and culture in the sample containing people with vocational education experience will be higher since for such professions training is a crucial thing. In order to overcome this problem we have formed control group artificially using propensity score matching technique.

The idea behind propensity score matching methods (Rosenbaum, Rubin, 1983) is that we estimate logistic regression where dependent variable reflects the treatment (experience of participation in vocational training in our case). In other words, propensity score as defined as conditional probability of being treated given the set of covariates X (1).

$$(1)\ P(x) = Pr[T = 1|X = x]$$

[1] Russia Longitudinal Monitoring survey, RLMS-HSE», conducted by National Research University "Higher School of Economics" and OOO "Demoscope" together with Carolina Population Center, University of North Carolina at Chapel Hill and the IInstitute of Sociology of the Federal Center of Theoretical and Applied Sociology of the Russian Academy of Sciences. (RLMS-HSE web sites: http://www.cpc.unc.edu/projects/rlms-hse, http://www.hse.ru/org/hse/rlms)

Different characteristics of individuals are used as explanatory variables in this regression that are believed to important determinants of participation in vocational training. After propensity scores estimation, control group was formed based on nearest neighbor technique suggesting that for each individual from the treatment group (with experience of vocational education) we select one individual from those who had no such experience and who is most similar in terms of propensity scores. In other words, control group contains individuals who had probability of participation in vocational training very close to probabilities for the individuals from the treatment group at the begging of the period. Such technique allows balancing covariates in both groups and makes comparisons between groups appropriate.

Descriptive statistics (mean values) for some characteristics used for propensity score matching procedure are presented in the table 1. Mean values show that covariates in two groups are rather unbalanced. Particularly, individuals in the sample 2 are more educated, shares of respondents working in the fields of education, science, culture and healthcare are two times higher in this sample. It can be noted also that people that have experience of participation in vocational education programs usually live in a larger cities and work in a larger companies, the share of females is higher among them, have higher tenure.

Table 1: Mean values of the samples used

	Sample 1 – workers without experience of vocational training	**Sample 2 – workers with experience of vocational training**
Population of the city of residence, people	618010	854816
Marital status (share of married respondents), %	77,2	72,3
Gender (share of females), %	48,8	64,4
Age, years	35,2	32,8
Share of respondents with secondary education, %	41,6	28,7
Share of respondents with professional secondary education, %	27,2	27,8
Share of respondents with higher education, %	18,2	37,7
Share of respondents working in the fields of education, science, culture, %	10,9	20,9
Share of respondents working in healthcare, %	5,0	12,8
Company size (# of employees), people	649,2	682,9
Tenure, years	5,5	6,0
Experience, years	14,7	12,8
Average salary, roubles	6297,2	7799,4
Share of respondents working in hazardous industries, %	16,1	25,4
Share of respondents working in the state-owned companies, %	52,9	63,5
Share of respondents working in the foreign companies, %	3,3	5,1

After formation of the treatment and control groups it is necessary to compare the changes that happens to individuals from different groups in time. The usual approach to model such evolutions is a Markov chain model formulated as follows. We consider discrete random variable X_t that takes values on the finite set {1,…,m}. The aim of the modelling is to predict the value of X_t knowing the values of this random variable in the previous period. The simplest model of this type is a Markov chain that suggests that current value of X_t depends only on the value of this variable in the previous period (2).

$$(2)\ P(X_t = i_o | X_0 = i_t, \dots, X_{t-1} = i_1) =$$
$$= P(X_t = i_o | X_{t-1} = i_1) =$$
$$= q_{i_1 i_0}(t)$$

If we consider all possible combinations of i_0 and i_1 we will obtain the matrix that contains probabilities of moving from one state of the chain to another one. Markovian property suggesting that the present depends only on the previous period is not suitable for the socio-economic research. Particularly, in the context of this

study we can not assume that the present career position of the individual depends only on the position the she had in previous period. In order to relax this assumption we use modification of the Markov chain that is called mixture transitions distribution model (Raftery,1985). This model adds the so-called long memory to the standard Markov model meaning that presence depends not only on the one previous period, but depends on several previous period (3).

$$(3)\ P(X_t = i_o | X_0 = i_t, \dots, X_{t-1} = i_1) =$$
$$= P(X_t = i_o | X_{t-l} = i_{t-l}, \dots, X_{t-1} = i_1) =$$
$$= q_{i_l,\dots,i_0}(t)$$

In this case the matrix of transition probabilities becomes much more complicated and model becomes computationally difficult. In order to simplify calculations Raftery (1985) proposed to split MTD models into several Markovian models with different lags and than consider a linear combination of these simpler models (4).

$$(4)\ P(X_t = i_0 | X_{t-l} = i_l, \dots, X_{t-1} = i_1) = \sum_{i=1}^{l} \lambda_g\, q_{igi_0}$$

Where q_{igi_0} is a transition probabilities with dimension mxm (like in standard Markovian model), $\lambda_g$the weighting coefficient of the model g in the linear combination (mixture). Obviously, in such setting the model requires much less parameters to estimate.

Like standard Markov chains MTD models are estimated using maximum likelihood. Usually several models are estimated with different amounts of lags and then compared based on some information criterion. In this study Baysian information criterion is used in order to compare the models.

In the dataset for MTD models construction we have formulated 9 possible states that are “no changes”, “promotion”, “demotion”, “job loss”, “real wage increase”, “real wage decrease”, “workplace change”, “profession change”, “horizontal mobility inside the company”. Different combinations of these events are also possible, so in total out sample contains 23 different states.

4. Results and discussion

Results of the logistic regression estimation that is used for propensity scores calculation are presented in the table 2. Regression shows that the statistically significant determinants of the likelihood of experience in vocational training are the level of education. gender, employment in the fields of education and healthcare, company size, average salary, work in the hazardous industry. Particularly, more educated workers, workers with relatively high salary, people who work in a large companies and in the education and healthcare sectors tend to participate in vocational education programs more often. Experienced professional and individuals working in hazardous industries tend to participate in such education programs rarely.

Table 2: Results of the propensity score matching

Variables	**Estimated coefficients (logit)**
Marital status	-0.101
	(0.190)
Secondary education	0.861 *
	(0.410)
Secondary professional education	1.232 *
	(0.411)

	(0.193)
Employment in the field of education	0.926 ***
	(0.248)

Variables	Estimated coefficients (logit)
Employment in the field of science and culture	-0.136
	0.373
Employment in the field of healthcare	0.927 **
	(0.292)
Tenure	0.007
	(0.444)
Tenure squared	0.001
	(0.194)
Company size (# of employees)	0.031 *
	(0.030)
Average salary	0.075 ***
	(0.017)
Hazardous industry	-0.729 ***
	(0.201)
State-owned company	0.280
	(0.193)
Foreign company	0.528
	(0.376)
Job change in previous period	0.071
	(0.107)
Experience	-0.029**
	(0.011)
Pseudo R2	0.150
Prob>chi2	0,000

In order to from control group based on the propensity score 1:1 nearest neighbor technique was used. Total amount of respondents in each group is equal to 536. Differences in covariates distribution before and after matching are presented on the figure 1. This figure shows that the matching technique was implemented successfully and the differences in covariates do not exceed 20% of the standard deviation. In order to obtain additional evidence that the control group was formed correctly we conducted t-tests in order to compare mean valued in treatment and control groups. All tests showed that differences in means are nor statistically significant that makes our comparisons correct.

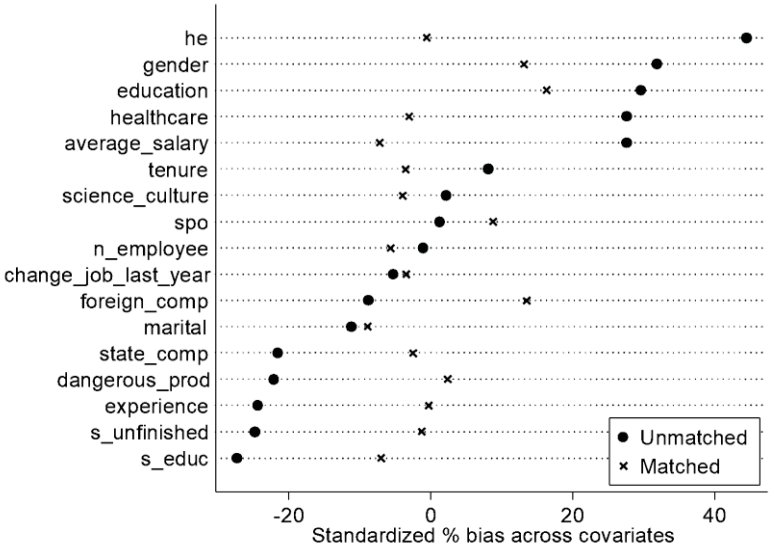

Figure 1: balance of covariates in treatment group and control group obtained using propensity score matching

Source: author's elaboration

For control and treatment samples, we have estimated MTD models separately. As was mentioned earlier, our dataset contains 23 different states. However, such amount of states make our model very complicated and computationally difficult. At this stage, it was decided to restrict the sample by 5 possible states by aggregating

initial ones. After such aggregation, we obtained 5 possible states that are “No changes”, “Positive changes”, “Negative changes”, “Unemployment”, “Neutral changes”.

The results of MTD models estimation presented in the table 3. We have considered 11 different models that are model of independence (assumes that presence does not depend on past), Markov chain and MTD models with number of lags from 2 to 10. In order to compare these models and to choose the best one Baysian information criterion values were calculated (the best model corresponds to the lowest BIC).

Table 3: Results of mixture transitions distribution models estimation

#	Model type	Sample 1 – workers with experience of vocational training (BIC)	Sample 2 – workers without experience of vocational training (BIC)
1	Model of independence	12943	14324
2	Markov chain (1 lag)	9343	12343
3	2 lags	7345	10322
4	3 lags	6356	8433
5	4 lags	6187	4323
6	5 lags	5639	3234
7	6 lags	5236	1498
8	7 lags	4865	**1843**
9	8 lags	3456	2439
10	9 lags	2734	4393
11	10 lags	**2130**	6434

Results resented in the table 3 shows that for the treatment group (with experience of vocational training) the best models is MTD with 10 lags. The best model for control group is MTD with 7 lags. In other words, current labor market status of the individual from the treatment group depends on the career paths in the previous 10 years or even more, since the sample period does not allow estimation models with higher amount of lags. For the individuals form the treatment group the length of the previous career paths that determine current position is equal to 7 years.

For the best models (according to BIC) we have calculated transition matrixes that are presented in the tables 4 and 5.

Table 4: Transition matrix for the sample of people with experience of vocational training

Without vocational training	No changes	Positive changes	Unemployment	Negative changes	Neutral changes
No changes	0.02	0.81	0.07	0.08	0.01
Positive changes	0.008	0.50	0.06	0.40	0.01
Unemployment	0.0005	0.24	0.73	0.025	0.0005
Negative changes	0.01	0.53	0.06	0.39	0.007
Neutral changes	0.02	0.45	0.05	0.39	0.09

Table 5: Transition matrix for the sample of people without experience of vocational training

With vocational training	No changes	Positive changes	Unemployment	Negative changes	Neutral changes
No changes	0.03	0.78	0.02	0.15	0.05
Positive changes	0.01	0.48	0.03	0.44	0.03
Unemployment	0.00	0.35	0.59	0.06	0.003
Negative changes	0.01	0.52	0.041	0.41	0.02
Neutral changes	0.04	0.59	0.01	0.27	0.09

Analysis of the transition matrixes shows that in general, probabilities of different negative career events are lower for the individuals from the treatment group. Particularly, if currently individuals are in the state “no changes”, for the treatment group probability of positive changes in the next period is 0.03 points higher, probability of unemployment is more than 3 times lower, probability of negative changes is almost 3 times higher. Moreover, respondents from the first group can leave the “unemployment” state with significantly higher probability.

5. Conclusion

This study is an attempt to analyze the impact of vocational training not only on separate characteristics such as level of wage or probability of unemployment but on the whole career paths. MTD models estimation results show that knowledge, skills and competence of workers that did not have any experience of vocational training obsolete at a faster rate. Current career position of this people depends only on their past from 7 years ago up to now. All career events that took place earlier do not have any influence on what is happening in period t. What is more important, individuals from the control group tend to have higher probability of different negative career events, including unemployment.

In overall, conducted analysis allows making four important conclusions. First of all workers that do not participate in vocational education programs have higher propensity to lose the job and to be unemployed. Secondly, career trajectories of individuals from the treatment group are more diverse, vertical as well as horizontal labor mobility occurs relatively more often. Thirdly, professional trajectories of the treatment group are more predictable. Finally, knowledge and skills are tend to obsolete at a higher rates in the sample that contains people without experience of vocational training.

Abstract: The paper presents a case study related to the production of medicinal and aromatic plants in rural territories within a conceptual and methodological framework focused on social innovation and networks. The case study presents specificities that allow the debate on methodologies and approaches aiming the promotion of rural development of territories with structural problems such as desertification. The concepts operationalized in order to understand these realities and problems offer interesting potentialities in the discussion of the challenges and design of solutions to overcome the main problems of rural territories.

Keywords: social innovation, networks, rural territories, ADCMoura, Baixo Alentejo

1. Introduction

The linkage between social innovation and territorial development has been established in the literature (Estensoro, 2015; 2016; Bellemare & Klein, 2010; MacCallum et al, 2009). But extant research focus mainly on urban territories and, therefore, there is a gap in the analysis of social innovation in rural territories, their specific problems and challenges (Ferreiro & Sousa, 2017).

This research applies the concept of social innovation and the methodology of social network analysis to the case study of EPAM project (Entrepreneurship in the value chain of medicinal and aromatic plants in Portugal), which started in 2011 and aimed the promotion of development of the medicinal and aromatic herbs sector.

The EPAM project is led by ADCMoura, a Portuguese Association of Local Development located in a very low-density region - Baixo Alentejo. EPAM is presented as a social innovation envisaging economic and rural development across several European countries. Networking, research, dissemination, and training, constitute the tasks of a 'collaborative methodology' and a 'strategic and innovative platform'. The project establishes a network of collaboration between different sectors and actors (public, private and non-profit) in the value-chain of aromatic and medicinal herbs. These networks convey and promote social capital.

The paper uses the case to critically discuss: i) the role of social innovation in the development of rural territories; ii) the network arising from the project and its importance to rural development.

2. Social innovation and rural development

Rural development corresponds to one central issue in political and scientific agendas within European Union. The importance of agriculture in the European project is expressed by the institutional and political centrality of Common Agriculture Policy (CAP), namely in budgetary terms. The sectorial bias has been gradually transformed in a more territorial view; the *rural* is no more synonymous of agriculture. Nevertheless, farmers continue to be key actors in rural territories in terms of control of natural resources (e.g. land) and other material and immaterial assets such as knowledge involved in food production, a strategic and central economic activity regarding food safety and sustainability. According to Dax & Fischer, "While many experts ask for sustainable urban development as priority action in the adaptation strategies, the contribution of rural regions to sustainable approaches should not to be underestimated. Rural regions have particular features in terms of innovation and have specific potential to kick off the discussion on the feasibility of post-growth trajectories" (Dax & Fischer, 2018, p.219).

The paradigm shift towards a territorial perspective in rural development research and public policy involves the consideration of local resources and skills and, therefore, the reflection on the way to take into account

local specificities and skills envisaging sustainable paths of territories. As point out by Dax & Fischer, "The concepts for rural development have, therefore, turned increasingly towards making use of the specific local assets and presenting diversity of regions as a valuable feature and not an obstacle that future regional activity should seek to overcome" (Dax & Fischer, 2018, p.219). The concept and the practices of social innovation, in its dimensions of mobilization of local resources and the empowerment of communities, constitute a fundamental tool within this political and analytical framework.

Research on social innovation can be considered as a tool of transformation of spatial relations (MacCallum et al, 2009, p.12) in the context of territorial development In fact, and territorially speaking, social innovation takes place also with the transformation of place-based social relations improving governance and decision-making forums, but also "the reproduction of place-bound and spatially exchanged identities and culture. […].

Social innovation is quite often either locally or regionally specific, or/and spatially negotiated between agents and institutions that have a strong territorial affiliation" (Idem, ibidem).

According to Bellemare & Klein (2010) the role of territory in the dynamics of innovation, as well as in regulation and governance of societies, remained unknown until recently. However, and according to the same authors, "after some years, we discover the territory, and this happens not only within the privileged scientific areas of, and for example, geography, spacial economics or urbanism […] but also in other areas such as sociology and economics […]" (Bellemare & Klein, 2010, p.2); and "the territory emerges as an important analytical dimension, in such a way that Pecqueur (2006) mention a territorial shift within a world economy" (Bellemare & Klein, 2010, p.2).

The evolution of the 'role of the territory in the analysis of societies' was developed within the planning and scientific realms and knows important milestones with the utopian socialists of the XIX century (e.g. Fourier, Owen and Kropotkine) as well as Marshall and 'industrial districts'. Thus, the territorial dimension was central in the proposals envisaging communitarian and solidarity values as well as in the analysis of socioeconomic dynamics and developments started with the industrial revolution (industrialization and urbanization). The funcionalist and territorialist paradigms represent completely different views on territory and its development.

The 1970', with the economic crisis, give rise to the valorization of local/endogenous resources and the respect for local and communitarian identities. Important steps toke place by the concept of social innovation in the approaches to these realities and new models of development, namely public policies and the 'new role' of the State. Therefore, current debates on social innovation represent new developments of a previous debate started in Europe some decades ago in the XX century.

The debate on social innovation within official institutions (OECD and EU) involve the presentation of definitions: there is social innovation "whenever new mechanisms and norms consolidate and improve the well-being of individuals, communities and territories in terms of social inclusion, creation of employment, and improved quality of life. Social innovation aims to respond to new needs that are not addressed by the market, and which may encompass conceptual and organisational aspects, and changes in the relationships between communities and respective territories." (OECD, 2010); 'social innovations' are social in both their ends and their means: "Specifically, we define social innovations as new ideas (products, services and models) that simultaneously meet social needs (more effectively than alternatives) and create new social relationships or collaborations. In other words they are innovations that are not only good for society but also enhance society's capacity to act" (European Commission, 2010, p.33).

Within academy we find different and several definitions for social innovation. According to Chambon, David and Devevey (1982), a milestone in this debate, "social innovation signifies satisfaction of specific needs thanks to collective initiative, which is not synonymous with state intervention" (in Moulaert, 2009, p.13), and "can occur in different communities and at various spatial scales, but is conditional on processes of consciousness raising, mobilization and learning" (Idem, ibidem, p.13).

Networks are vital to social innovation. Firstly, social innovation is often produced in collaboration processes with people and organisations from the civil society who are engaged in finding an answer to a social problem (Hulgård, 2010). Social innovation involves the interaction multiple stakeholders (Spear & Hulgård, 2007).

Moreover, networks provide resources for the social innovation process. Both organisations from the local community and from other geographies provide important tangible (e.g. financial resources) and intangible resources (e.g. trust and legitimacy), namely in rural areas (Muller & Korsgaard, 2018; Richter, 2018; Vestrum, 2014; Steinerowksi & Woolvin, 2012; Evans & Syrett, 2007). Networks with non-local actors can be very useful to gain and diffuse knowledge, to attract resources that are not available within the locality and to scale-up social innovations. Therefore, networks related to social innovation tend to gather different actors from different geographical scales.

The case under analysis (section 3) provides a good example of the potentialities and role of networks in the mobilization of local and non-local resources in order to develop entrepreneurial activities in a particular sector (medicinal and aromatic plants).

The revision of literature presented in this section allows the identification of the following analytical dimensions envisaging the case study related with networks of aromatic and medicinal herbs developed in different rural territories and presented as a social innovation initiative: 1. the importance of local resources in territorial development projects; 2. the role of networks in the promotion of social innovation; 3. the promotion of new relationships between communities and territories through social innovation.

3. Social innovation and networks in rural territories: the case of EPAM

ADCMoura is a non-governmental and non-profit organization founded in 1993, inspired by the principles of local development, social and solidarity economy and equal opportunities. Its main goals are: to contribute to the economic competitiveness and innovation in rural and vulnerable territories; to preserve and value natural and cultural assets; to raise environmental awareness through education; to defend the equal access of all citizens to social, educational, health and cultural services; to push for social cohesion and citizen's participation. It is settled in the county of Moura, in the Portuguese southern region of Baixo-Alentejo, very low-density region.

Over the 25 years of its existence, ADCMoura has acquired experience and competences in areas as diverse as community animation, intervention with disadvantaged social groups and ethnic minorities, environmental education, support to companies and entrepreneurship, training, network facilitation, among others. ADCMoura is a member of several national and international organisations and networks in social, entrepreneurial and rural development thematic areas, being the most relevant related to the economic value chain of Medicinal and Aromatic Plants (MAP).

EPAM - Entrepreneurship in the value chain of medicinal and aromatic plants in Portugal (https://epam.pt) - is the name of a project led by ADCMoura started in 2011 and supported by the National (Portuguese) Rural Network Program. The initiative continued after the project´s end in 2013, and was developed further through new partnerships and activities. It has enabled the development of a consolidated methodology and a set of tools to support the development of the MAP sector, acting at the levels of network animation, research and provision of information, training, promotion (both at national and international levels) and representation. It has been contributing to a strategic and innovative networking ecosystem, at the service of the stakeholders in the sector. Therefore, the EPAM case study, considered in this research, includes a permanent, strategic and widely-participated work for the sustainable development of the MAP sector in Portugal started, denominated by "EPAM process" (https://epam.pt/o-projecto-o-processo/) where several funded projects have been implemented, involving organisations from different countries:

- MEDISS - MEDiterranée Innovation Senteurs Saveurs (MED) | 2009-2012 (FR, IT, PT)
- ADLA - Actions for the Development of the Great Lake Alqueva, in which ADCMoura is a partner, with a cross border intervention linked to the promotion of the "Scents & Flavors" network of the Lands of the Great Lake Alqueva (POCTEP) | 2012-2015 (PT, SP)
- Training for the Production of Aromatic and Medicinal Plants (PRRN) | 2014-2015 (PT)
- Several funded (ESF) vocational training courses and courses for entrepreneurs (in partnership with MAP farmers) | since 2009
- Herbartis - Adult training on handicraft production of medicinal and aromatic plants (Erasmus +) | 2015-2017 (SP, PT, IT, FR)
- Inov@sfileiras (PDR2020) | 2017-2019 (PT)

More than a hundred activities on topics related to MAP were organized in the framework of these projects and other occasional opportunities, including Local and National Meetings of MAP Producers, Workshops, Seminars, Technical Visits, Shows, Working Groups, Promotion Activities in Portugal, France, Italy, Spain, England, Germany and Belgium, totalising more than 3 thousand participations of stakeholders of the sector.

Due to the success of these initiatives ADCMoura / EPAM was invited to join the Mediterranean network CEDDEM - Center d'Etude et de Développement Durable Euroméditerranéen (www.ceddem.org), the European association EUROPAM - European Herbs Growers Association (www.europam.net/) and the Portuguese network CCPAM – Centro de Competências das Plantas Aromáticas, Medicinais e Condimentares (Competence Centre on Aromatic, Medicinal and Condiment Plants), to which ADCMoura presides at the moment. Recently, in November 2017, the EPAM's animation methodology and tools integrated the list of good rural development practices presented in AGRI INNOVATION SUMMIT Lisbon.

Considering the above-mentioned projects, the EPAM's network was reconstructed (Figure 1). For each project the partners were identified and characterised according to two dimensions: the type of organisation (reflected in the colours of the modes) and the geographical scale (reflected in the shapes of the nodes). For the type of organisation, eight categories were considered: MAP producers belonging to the EPAM network (in pink); other MAP producers (in purple); other enterprises (in blue); organisations from the education, science and technology sectors (in yellow); public entities including local authorities (in red); associations for local development (dark green); and non-profit organisations (light green). For the geographical scale, three levels were considered: Portuguese organisations (circles); European organisations (squares), non-European organisations (triangles). The size of the node is proportional to the number of participation in EPAM projects.

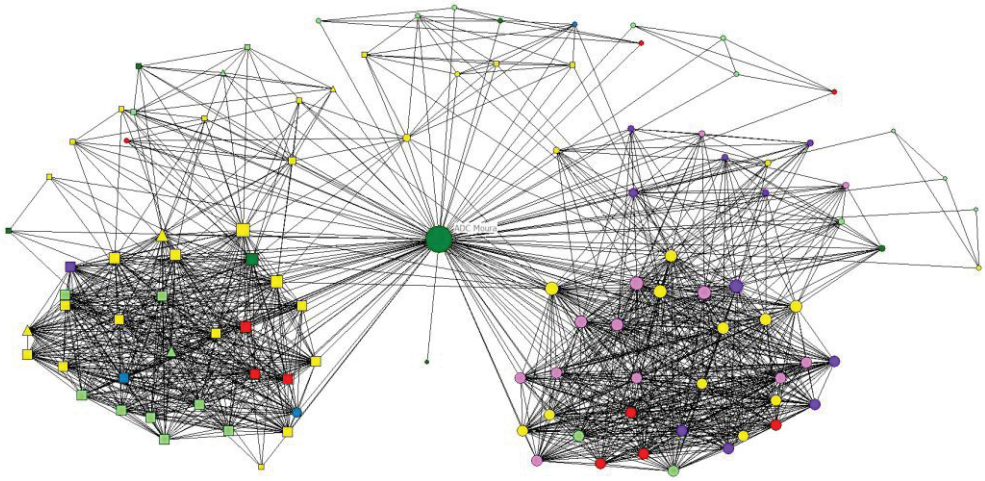

Figure 1: EPAM network

Figure 1 reveals the multi-actor, multi-scale nature of the network that supports this social innovation. MAP producers are embedded in an ecosystem that includes all sorts of stockholders, public and private, commercial and non-commercial, local and foreign. The network also reveals a certain divide between national and foreign organisations, due to the fact that, beyond ADCMoura, which is present in all projects, most projects only mobilise national or international organisations. This fact, gives ADCMoura, which is a local development association, the opportunity to transfer knowledge and best practices from and to different geographical scales, enabling to replicate and scale-up the EPAM's social innovation.

Other and important results are expressed by network analysis and complemented by other sources of information (e.g., site of ADCmoura). First, ADC Moura appears as the centre of the network establishing a clear division between national and international entities/partners. However, some national entities interact also with international players, namely in education, scientific and technology sector. In fact, these entities constitute an important player in this network, expressing the importance of interactions with universities and other scientific and technological actors within the development of the sector. European entities are central at this realm; secondly, EPAM is a network-based project, enabling the constitution of other networks through

the different, and diverse, activities developed through time (e.g., training, workshops, field visits); this aspect is visible in the networks established by different players in national and international context; it also worth to mention the fact that this network was promoted by other, national and public, network (Rede Rural Nacional, National Rural Network, an initiative of the Portuguese Government (Ministry of Agriculture).

Thus, network design corresponds to a central methodology in EPAM case from its start (Government initiative) and main steps of evolution, namely the recognition of EPAM as a best practice envisaging the promotion and development of other local products and their value-chain. The photos illustrate different dimensions and dynamics of the project EPAM (training, field trips, conferences/dissemination, exhibitions of the products of the value chain).

Source: https://epam.pt/o-projecto-o-processo/

4. Conclusions

The presentation of EPAM as a network-based approach to the development of local products corresponds to one of the dimensions that explain its reference as a social innovation project. Other important aspects involve the participation of diverse stakeholders (players of the sector, such as enterprises, universities and other education and scientific entities) and the development of different activities that contribute to the development of the sector. This case corresponds to an interesting case within the literature of rural development considering the mobilization of local resources, knowledge as well as different players through the value-chain. The integration of these diverse activities and players is made through a tissue of connections in national and international contexts. However, the bridging between national and international levels is not

clear. The network was designed with the collaboration of a governmental department of the Ministry of Agriculture and is polarized in ADCMoura, the most important actor and the main driver of the network. The case of EPAM offers interesting insights to the debate and reflection of rural development dynamics, namely the importance of central public players and funding and the role of local development associations in the promotion of innovation and exploration of local resources and knowledge (scientific and non-scientific-tacit) and practices. The constitution of EPAM as a best practices case is also pertinent and deserving further research.

DIVE-IN: Problem First Team Formation in Entrepreneurship Education

Paul Flynn
National University of Ireland, Galway, Ireland
paul.flynn@nuigalway.ie

Abstract: Many startups teams are formed around ideas. This is most evident at the outset of entrepreneurship education programmes, at startup weekends, hackathons and founder formation events where people enthusiastically pitch ideas for others to gather around. Texts such as Business Model Generation, Crossing the Chasm amongst others often inform the completion of a Business Model Canvas ahead of pitching for investment. Recent developments have aimed to provide a step-by-step process that can test the commercial potential of an innovation, including the formidable Discipled Entrepreneurship. However, all of these texts and processes have a starting point of technology first or very well formed idea first. In contrast, this study explores the experience of 33 participants aiming to return to work after a period of unemployment that do not have a technology or a well-formed idea as they engage in a one year postgraduate diploma in technology innovation for entrepreneurship development. Inspired by social constructivist thinking, this study aims to establish the effectiveness of a designed problem pitching and collaborative validation process on team formation for sustainable innovation driven entrepreneurship. DIVE-IN (Define, Investigate, Verify, Empathise - Ideate & Narrate) asked programme participants to collaboratively negotiate their interpretation of a validated problem within a highly scaffolded learning environment. Qualitative data gathered suggests that while participants initially struggled to gather around a problem statement without a clear vision of a solution, the process of structured collaborative negotiation solidified their formation as a team and ensured that any solution to their identified problem had, at a high level a commercial viability. Participants viewed this process as a key informant of whether or not to proceed to solution ideation and as a critically important learning outcome for the development of a sustainable career as a serial entrepreneur. This paper will outline the conceptual framework supporting this process, detail the method of execution and present an analysis of the impact of the process on the participants. A model is presented for others to adopt and/or adapt in cognate settings.

Keywords: Entrepreneurship Education, Collaboration, Innovation, Higher Education

1. Introduction

The popular vision of an entrepreneur is one of a charismatic leader who has a clear vision, determination, the capacity for effective autonomous action, innovativeness, passion and flexibility (Rauch and Frese, 2007).

Indeed, for many years the characterisation of successful entrepreneurship focused on individuals and the identification of traits that might be recognised in similar individuals (McCelland,1961; Birley, 1985). Recent research has shifted focus to recognise that understanding the dynamic functions of founding teams is now of vital importance (Cooney, 2005; Vyakarnam and Handleberg, 2005; Kamm, et al., 1990). Much of this work has been carried out with high performance heterogeneous teams within established organisations or within heterogeneous founding teams who have demonstrated enhanced performance as consequence of their heterogenous composition (Bunderson and Sutcliffe, 2002). Recent thinking in the development startups has identified that individuals who seek co-founders should also seek heterogeneous candidates. Such individuals are often found at startup events where team formation centres around the pitching of an idea and the attraction of other individuals who may be able to make significant contributions to the development a fledgling venture. Venues such as hackathons and startup events are typical for such activity. A dearth of work exists that may serve to inform the formation of teams at shorter events particular here there is an absence of an advanced technology or well-formed idea to start from.

This study explores the experience of 33 participants aiming to return to work after a period of unemployment that do not have a technology or a well-formed idea as they engage in a one year postgraduate diploma in technology innovation for entrepreneurship development. Presented here is an overview of an innovative approach to team formation which explores the impact a problem first approach to team formation rather than the traditional idea first approach. A design research approach (Barab, 2004) was taken to the development of the programme which allowed the development of a conceptual framework to act as a lens in order to analyse the effectiveness of the designing methodology. This methodology, DIVE-IN (Define, Investigate, Verify, Empathise - Ideate & Narrate), reflective of a design-thinking (Brown and Wyatt, 2010; Scheer, Noweski, and Meinel, 2012.) paradigm facilitated:

1.

- The generation of a problem pool to DIVE-IN to.
- The refinement and definition of clear problem statements
- Problem selection through investigation
- Initial team formation based on negotiated verification
- Understanding with the validated problem though a scaffolded collaboration activity
- High-level response ideation
- Collaborative narration of the problem and the high-level response

This paper will outline the conceptual framework supporting this process, detail the method of execution and present an analysis of the impact of the designed process on the participating students and their associated teams. A model is presented for others to adopt and/or adapt in cognate settings.

2. Framework

Many start-ups teams are formed around ideas. This is most evident at the outset of entrepreneurship education programmes, at start-up weekends, hackathons and founder formation events where people enthusiastically pitch ideas for others to gather around. Texts such as Business Model Generation (Osterwalder and Pigneur, 2010), Crossing the Chasm (Moore, 2002) amongst others often inform the completion of a Business Model Canvas ahead of pitching for investment. Recent developments have aimed to provide a step-by-step process that can test the commercial potential of an innovation, including the formidable Discipled Entrepreneurship (Aulet, 2013). However, all of these texts and processes have a starting point of technology first or very well formed idea first. For those who wish to start a venture and do not have a technology or well-formed idea the prospect can be quite daunting. Increasingly the term innovation is being included in module descriptors within higher education institutions as they attempt to respond to the demands of industry (Finkle and Deeds, 2001). In the context of this study the term '*innovation*' is removed from the team formation process and replaced with the term '*problem identification*'. In order to facilitate this the study draws on a suite of design informants that are anchored in 6-step process of team formation - Define, Investigate, Verify, Empathise - Ideate & Narrate (DIVE-IN) - forming a conceptual framework.

For those who wish to create a new venture the journey to forming an idea that responds to a market need or pull can be long and frustrating. Often this this described as a spiralling process where iterative refinement reveals the appropriate path to take (Aulet, 2013; Petersen, 2015). This study posits that picking a problem or suite of problems to investigate the commercial viability of any potential solution may prove more advantageous for those who do not have a technology or well-formed idea from the outset. The initial step in this process is problem pool generation based on the use of Maslow's Hierarchy of Needs and in particular addressing the basic needs of security, safety, food, water, warmth and rest (Maslow, 1943). In the context of this study the hierarchy is used to help identify possible problems within chosen domains such as, but not limited to, agriculture, construction and health. Initially, this process asks participants to engage as individuals in the problem identification phase. Asking participants to work on their own to identify problems facilitates the expression of personal interest that may support the development of common frames of reference when presented with a challenge to overcome within a shared domain, thus helping to support the development of a collaborative response (Miyake, 1986; Rochelle, 1992; Barron, 2000). As noted by Barron (2000), "*for such forms of convergence to occur, students must organise themselves to engage in coordinated activity. Coordination is fundamental for the establishment of what has been called mutual knowledge or common ground.*" (p.404). It is intended that ultimately, the refinement and definition of multiple, clear problem statements with a view to confirming the commercial viability of any potential solution.

The formation of teams for problem solving is far from a new concept however, in contrast to Cox (1996) who advocates that the role of entrepreneurial education programmes is to develop the self-efficacy of the entrepreneur the purpose of this study was the formation of a heterogeneous team committed to solving a problem that all team members understand (Drayton, 2011). Team work is complex and requires pedagogical design particularly to support collaborative engagement (Stahl, 2002; Author, 2016). Scaffolding is required if all participants are to learn not only from each other and the lecturer (Vygotsky, 1978) but also within the designed learning environment (Goodyear, 2005). In the case of this study scaffolding or support for student engagement with content and each other is vital to support the development of Barron's (2002) concept of mutual undertaking and common ground within educational scenarios. The development of this shared understanding is considered fundamental to the solidification of the teams within this study particularly if they

are to have any chance of surviving beyond the educational programme within which they are enrolled. Consequently, in order to inform the methodological consideration of this study the following questions were formed:

- How can the use of Maslow's Hierarchy of Needs support the development of a problem first approach to entrepreneurial team formation?
- What are the supports that students require in order to define and select problems to solve?
- How does the development of common ground through structured investigation support the development of team formation?

3. Methodology

The participants in this study were a collection of individual that were aiming to return to work after a period of unemployment and were engaged in a one year, part-time postgraduate diploma in technology innovation for entrepreneurship development. The initial enrolment number for the programme was 38 however this reduced to 33 largely due to reasons of a personal nature. It is interesting to note, hover, that one of the participants who exited the programme did so due to the team working aspect of the programme and explicitly stated a need for individual engagement in entrepreneurial activity. Participants attended lectures on Thursday morning and engaged in workshops on Friday mornings as well as being supported by various course materials delivered online and through live feeds. For many participants it had been a considerable amount of time since their last engagement with formal education and for 31 of the participants it was their first time to engage with a postgraduate programme although all had completed an undergraduate degree programme at some stage in their educational history. The context of this study was a twelve week module focused on problem identification for entrepreneurial venture creation. Students had been given a 12 week module that had the MIT Disciplined Entrepreneurship (Aulet, 2013) as a core text. For this study a qualitative interpretive approach was employed and triangulated data was collected using the following techniques: ethnographic observation, students reflective submissions, face-2-face focus groups, digital questionnaire, student submitted artefacts and the observation of critical colleagues.

4. DIVE-IN

Generation of a problem pool to DIVE-IN to: Each week students received a lecture on a Thursday and a workshop on a Friday. The first step in this process was conducted within the first face-2-face workshop session of the 12 week module. The lecture the previous day had introduced Maslow's Hierarchy of Needs to the students and they were tasked with identifying at least two domains that they might be interested in, to list at least two problems that related to Maslow's basic needs and which they thought might be worth exploring related to personal interest. For many students this is a daunting task. Maslow's Heirachy allows them to make a personal connection, it acts as a touchstone for the students. Students were asked to post their domains on a board with post-its and the lecturer grouped the domains under common headings. It is important to note that no names were allowed to be placed on the domain titles. The domain groupings were then placed at intervals around the room. The problems identified by the students were collected by the lecturer on uniform coloured post-it notes and placed under each domain grouping. Again no names were permitted to be visible with the uniform colour minimising identification of the posting participant. Two teaching assistants condensed the problem lists by removing similar challenges. Subsequently participants were asked to place their name above a domain label and not beside a problem statement.

Refinement and definition of clear problem statements: The room had been pre-arranged so that to could facilitate groups of four working together. Each list of names beside each domain was split into four and assigned a table to work at. The entire problem list for that domain was provided to each group within the relevant domain. Participants were given exemplars of poorly and well defined problem statements as well as templates to support their refinement and definition of the information they were dealing with. When each group had formed a list of problem statements these were placed back on the wall and participants were given time to decide where they wanted to dedicate their efforts. Students were also permitted to change domain and encouraged to walk around the room and view the problem statements generated by other groups and to place their name under one domain topic.

Problem selection through investigation: Having selected their preferred domain each student was tasked with investigating the list of problems that had been refined and defined under each domain topic.The

participants were instructed to use steps 1-6 of the Disciplined Entrepreneurship (DE) process (Aulet, 2013) to investigate the early state commercial viability of a high-level solution and to rank the list by indicating which problem they considered emerged from the DE process most likely to succeed. This process was completed during a single week interval between workshops.

Initial team formation based on negotiated verification: During the next scheduled Friday workshop each domain grouping was asked to create a table outlining the problem statement list and their names. Students had been asked to rank the problems during the week and the scores were entered into the table by the students. At each domain grouping students were instructed to take the three highest scoring problem statements and to write them on post-it notes. The ranking served to validate the commercial potential or realistic nature of the problem however students were asked now decide on which problem they would like to address based on personal interest. Where a problem statement generated enough participants to form two teams this was facilitated and in turn where less than two participants has placed their name beside a problem, this problem statement was removed and the student was asked to join a team that was focused on their next highest ranking problem statement.

Understanding with the validated problem though a scaffolded collaboration activity: All of the students who selected a problem statement would have carried out the same DE process analysis. Using a generic template the students were tasked with completing a team charter in order to communicate their individual understanding of the problem statement and to come to a shared or mutual understanding, not only of the problem statement, but also of their raison d'être. An important component of this stage is the articulation of intent by each member, specifically in relation to whether they consider their participation in the programme as purely an academic exercise or if they have ambitions to continue the project beyond the programme should the opportunity present.

High-level response ideation: In order to test the mutual understanding of the problem being addressed by each team the individuals in the team were tasked with, over the course of the following weeks, ideating some high-level solutions to the problem they were attempting to address. During the next scheduled workshop students presented their favoured idea and invited questions from their fellow team members. The individual contributions reveal misunderstandings and/or disconnection from the problem being addressed by the group.

Post individual contributions the group votes on the high-level idea that they wish to progress through the remainder of the DE process for the remainder of the semester and possibly beyond.

Collaborative narration of the problem and the high-level response: Finally, in the next scheduled workshop the team are asked to present, to the rest of the cohort, their agreed problem statement, the rationale for picking it and their next steps. The construction of this collaborative narrative further serves to cement the shared understanding of the problem being solved and the team's agreed response going forward.

The DIVE-IN process takes three weeks to complete within a part-time programme. It is dependent on students having face-2-face engagement and having been provided with a structured process of market/customer discovery and validation such as the Disciplined Entrepreneurship process, specifically steps 1-6.

5. Findings

RQ1: How can the use of Maslow's Hierarchy of Needs support the development of a problem first approach to entrepreneurial team formation?

Findings show that participants found that this approach to problem identification had a positive impact on the formation of their entrepreneurial teams. In general the cohort viewed this as a refreshing approach to team formation and was a significant change from their previous experiences at events such as hackathons. As one participant noted:

> *"For some reason, after events or courses that I have attended in the past when I leave I don't really have anything to fall back on. It was great to see some sort of process, or way, to find a problem to*

solve. While [Maslow's Hierarchy] doesn't get you to a specific question or statement it made the challenge less daunting - repeatable even."

The development of Maslow's Hierarch of Needs as a framework within which to approach large, 'umbrella style' problems was well received by the majority (94%) of the participants. However, two participants felt that it was still too vague and did not paint a clear enough picture of challenges that could be a addressed. In terms of the value of the process to the development of teams focused around a problem, 100% of the participants indicated that they chose a problem to address based purely on a personal interest that was explicitly linked to Maslow's list of basic needs:

"It's like this; you can use each of the basic needs as a window to look through, at your domain. Straight away you can start listing problems and who those problems might affect. Boom, you are straight into [DE] steps 1-6"

The triangulated findings associated with this research question indicate that the use of Maslow's Hierarchy of Needs did support the development of a problem first approach to entrepreneurial team formation. In addition, the process was viewed as something that participants felt they could repeat beyond the programme.

RQ2: What are the supports that students require in order to define and select problems to solve?

Within previously delivered programmes students were observed as becoming frustrated when they did not have any guidance on where to look for a problem. In this programme exemplars of high-level problems were provided by the lecturer in order to scaffold their engagement. However, it would be useful to provide a start-to-finish example of the problem selection process with a strong narrative on how decisions were made along the way. As one student commented:

"The supports are great. We have worksheets, we have some worked examples. Everything runs pretty smoothly but I want to know what makes a person decide to look at something in a certain way. Is there a way to capture that way of thinking because it would give me some confidence around my own thoughts."

This was an interesting insight into the difficulty that students face when making decisions and their entrepreneurial self-efficacy. While the detail in this comment is revealing it was not replicated by others within the data set. However, the wider literature does indicate that novice entrepreneurs often exhibit low levels of entrepreneurial self-efficacy and in particular in relation to gender within cohorts (Markman, Balkin, and Baron, 2002; Wilson, Kickul, and Marlino, 2007). It is reasonable to conclude that a narrated process of problem selection for students to refer to, may prove to be valuable.

RQ3: How does the development of common ground through structured investigation support the development of team formation?

The participants (85%0 placed a high value on the development of common ground during the team formation process. In particular, students felt that they began to get to know each other. This was something that felt was lacking in other team formation situations where they indicated it took longer for this to happen. Two members of the same team commented:

"I had no idea that [x] thought about this problem in the same way as I did and it wasn't just that we agreed on the day. The work that we did during the week lined up. It could have been a photocopy. It made it much easier to talk about the problem and make decisions together after that"

"The work that we carried out was done on our own. I thought that this was a little strange given that we were in the process of forming teams but, when we came back, it seemed to make it easier to talk to

each other. Our research had given us a language that we both knew about - even if we didn't fully understand it yet."

While it is clear from this exemplar of the wider data set that the structured process of investigation allowed students to develop common ground for discussion it also encouraged the participants to engage with each other in a way that felt unstructured and informal:

"When we started talking about the problems we had investigated it didn't feel like we were reporting. It felt like we were chatting because we all knew at least something about the problem we were discussing. It made it easier to see the person we might be on a team with rather than just the problem."

Another participant commented:

"Even when we started to disagree about which problem to choose you knew it was because people cared about what they were disagreeing about. That's okay in my book. I can be on a team with somebody who cares but I don't always agree with."

6. Challenges

The most significant challenge face by the participant teams and the facilitating lecturer was the issue of academic engagement versus intention to create an entrepreneurial venture. While every attempt to mitigate this was made (as noted within the team charter formation description) this issue became problematic for two of the teams engaged with the programme. Despite the instruction to reveal intent from the outset it appears that this requires additional consideration for future iterations of the DIVE-IN process. As one participant commented:

"For me this was an academic exercise. I want to learn and I have no intention of going into business for myself or as part of a new company after this programme. For me this was a way becoming more attractive to a potential employer. It was fun for a while but it got way too serious and they became frustrated with me."

However, for another participant in a different team the revelation by a team member that their commitment to the team was purely academic was seen in a different light:

"[X] said that he had no intention of staying with the team beyond the programme but would do everything he could to work with us on the project - and he did - and more! It was a pleasure! Now we are in a funding pipeline and he has moved on to other things. [The] Team Charter sorted all that stuff out at the beginning - we all knew where we stood from the get-go."

7. Discussion and Conclusions

This study aimed to evaluated the effectiveness of a designed problem pitching and collaborative validation process, DIVE-IN, on team formation for sustainable innovation driven entrepreneurship. DIVE-IN (Define, Investigate, Verify, Empathise - Ideate & Narrate) asked team members to collaboratively negotiate their response to a validated problem within a highly scaffolded learning environment. The triangulated findings, within this purposive sample, imply that a structured process of problem first team formation did support the development of teams.

It is important to note that there are some limitations associated with this study. The study was carried out in a mandated academic setting over a 12 week semester. A condensed and accelerated design of the process for execution at a two-day or three-day event would reveal the adaptability of the process for startup events and/or hackathons.

The data collected and analysed in this study indicates that the use of Maslow's Hierarchy of Needs did support the development of a problem first approach to entrepreneurial team formation and was viewed as a

process that could be replicated by participants bond engagement with the programme. The DIVE-IN process also revealed a need for deeper understanding of the micro-decision making associated with entrepreneurial pathways. It can also be concluded that the development of common ground through structured investigation did support the development of team formation by breaking down interpersonal barriers and accommodating a collaborative negotiation of the team formation.

Possible directions for future research include the development of a deeper understanding of how entrepreneurial self-efficacy is developed within entrepreneurial education programme and specifically in relation to entrepreneurial micro-decision making.

Abstract: The paper examines micro-entrepreneurs' resilience to significant changes in a company. The focus of this research is on uncovering the kinds of changes and crises entrepreneurs met and on how to classify these changes and crises? The unexpected changes that entrepreneurs may face can have a significant impact on both their current and future activities and can be directed either at the individual or the business level. In micro-entrepreneurship, entrepreneurs typically have to address changes and crises alone. To a micro-entrepreneur, a sudden change can be challenging because he/she does not necessarily have a support network to provide useful or sufficient help (Alonso et al., 2015). Managing such situations requires resilience and flexibility from entrepreneurs and companies alike. This empirical research was qualitative by nature and the research method was a retrospective multiple case study. The data collection method was based on semi-structured thematic interviews with 12 entrepreneurs and managers from the social and health care sector in Northern Finland. All interviews were audio-recorded and transcribed. The transcriptions were analysed by content analysis with an interpretative approach, each on a case-by-case basis. The data were processed using qualitative data analysis software. Preliminary results suggested that the challenges that micro-entrepreneurs considered the most serious related to internal and external interventions, such as problems with staff, management, management models, authorities, institutions and bureaucracy. In addition, emotional interventions like one's own wellbeing and a lack of guidance and support related to real crises is a reality of a micro-entrepreneur's life.

Keywords: micro-entrepreneur, entrepreneurship, resilience, change, case study, Finland

1. Introduction

According to the European Union (EU) definition, a micro-enterprise is as an enterprise which employs fewer than 10 persons and has annual turnover and/or an annual balance sheet total that does not exceed 2 million euros (European Commission, 2003). Micro-enterprises represent more than 95% of European enterprises (Muller et al., 2016) and are considered a driver of the EU economy. There is a lack of academic research on micro-enterprises (Kelliher and Reinl, 2009), and thus a considerable gap in the literature regarding the reality of running a micro-business (Samujh, 2011).

In Finland, nearly 95% of companies are micro-enterprises (Statistics Finland, 2018). It is widely acknowledged that micro-enterprises experience resource scarcity, which forces them to operate under financial and expertise constraints (Kelliher and Reinl, 2009). Micro-enterprises are largely influenced by their owner-managers (Burns, 2010), who play a pivotal role in an organisation's focus and success (Kelliher and Reinl, 2009; Burns, 2010), which often makes micro-enterprise culture an extension of the owner's personality. In general, when a micro-entrepreneur faces unexpected changes or crises, he/she has to resolve them alone.

Even though it plays a significant role in entrepreneurship, this phenomenon is little-studied. Studies by Bruderl et al. (1992), which take as a theoretical framework the fields of organizational ecology and human capital theory, suggest that human capital may be a company's most important resource, because it affects both performance and development. Further, Ayala and Manzano (2010) argue that an entrepreneur's resilience—the tool they use survive crises—is one of the key factors to entrepreneurial success. Thus, resilience—the human system's ability to cope with significant change and survive—can be considered a meta-competence (Cheetham and Chivers, 1998). A resilient system is able to adapt to changing conditions and to develop new ways to succeed.

In psychology, resilience is defined as an individual's ability to tolerate difficult conditions and stressors without experiencing psychological distress. Severe conditions cause emotional reactions; but a resilient individual has a kind of mental elasticity and the capability to transform situations, which allows him or her to successfully negotiate stress. Bernard and Barbosa (2016, p. 89) have stated that "entrepreneurial resilience is as a form of emotional and cognitive ability that is useful for the entrepreneur, particularly when bouncing

back after failures connected to their entrepreneurial initiative." At an individual level, resilience is seen as a function of personal ability in the face of crisis and as an ability to adapt to new situations (Sawalha, 2015).

Thus, resilience is individual's invisible meta-competence, which is a driver for behaviour and entrepreneurial intention and an underlying factor in various situations. According to Coutu (2002), the characteristics of the resilient individual are an ability to accept reality, a belief in there being a meaning to existence and improvisation skills. Therefore, the identification and development of resilience is necessary for an entrepreneur to maintain their business and keep it within their control, and to ensure its independence and ability to cope with crises. All of these definitions are consistent with the studies that find micro-enterprises to be flexible, agile and adaptable actors. This study seeks to find out whether an entrepreneur's resilience is related to these characteristics attributed to micro-enterprises. In order to study micro-entrepreneurs' experiences and resilience related to significant company changes or crises, this research posed two primary questions: What kind of unexpected event, change or crisis occurred in our case companies? (RQ1); and how can these unexpected events, changes or crises be categorised? (RQ2).

The empirical case study was qualitative by nature and was conducted in social and health care micro-companies in Northern Finland. The data collection method was based on semi-structured thematic interviews with 12 entrepreneurs and managers. All interviews were audio-recorded and transcribed. The transcriptions were analysed using an interpretative approach and the analysis method was a content analysis. The transcriptions were analysed case by case. The data were processed using NVivo 11 data analysis software.

This research provides perspectives on what kind of situations or enterprise crises micro-entrepreneurs may have to experience and how the possible phenomena can be categorized? The results of the qualitative case study include the micro-entrepreneurs' descriptions of unexpected events related to their business, as well as the ways in which these events or crises might be categorized by using the framework of Conner (1993) and Hoopes & Mark (2004).

The paper first presents a theoretical discussion of the concept of resilience in general and how it relates to entrepreneurs' businesses. It then presents the empirical approach of this study, including how the study was structured and the reference framework for methods and findings. Finally, it includes a discussion related to the study's findings and implications.

2. Theoretical framework

Over the past 10 years, resilience has become a fashionable concept in business, used to explain adaptability in the face of sudden changes or crises. As a theoretical concept, resilience can be located in two quite different scientific traditions: psychology and ecological systems theory. In psychology, resilience can be defined based on an individual's ability to cope with trauma and as well as on factors affecting traumatic survival (Bonanno, 2004; Bonanno and Mancini, 2008). Resilience in ecological systems theory refers to the nonlinear recovery and adaptive dynamics of ecosystems. In ecology, resilience is generally defined as the capacity of a system to absorb disturbances and to reorganize in the midst of changes, allowing the system to maintain its function, structure and identity (Folke, 2006; Zolli and Healy, 2012).

Resilience is often talked about in conjunction with flexibility, agility and elasticity in work context. Because of the nestedness of systems, the resilience of an entire ecosystem depends on the agility and adaptability of its smaller parts. Mutually dependent and free systems are the most flexible and most capable of transformation, provided they are local and multifaceted. This reflects the central role that biodiversity plays in creating resilience and self-adaptability (Folke, 2006; Zolli and Healy, 2011). In psychology, resilience is usually defined as "a dynamic process that generates positive adaptation in a situation where significant adversity is experienced" (Luthar et al., 2000; Bonanno, 2004). An individual indicates resilience, when he/she maintains his/her ability to take action in and adapt to a crisis situation despite being vulnerable during that situation.

Resilience, however, cannot be considered in isolation from an individual's socioeconomic background. The psychological concept of resilience differs from the ecological one in that it is more sensitive to understanding intentionality. The relationship between resilience and personal, demographic or socioeconomic factors is a central question. Empirical studies indicate, for example, that work situations and wider social resources are resilience-enhancing factors. In addition, studies related to cognitive resources also correlate with individual-

level resilience (Luthar et al., 2000). However, the comparatively significant psychological resilience of certain individuals does not mean that those individuals would experience crisis situations as positive events. Rather, it is about recovery and maintaining functional capacity. In addition, the same factors affecting resilience depend on context and may lead to very different reactions. Resilience that expresses itself as mental stamina is a recognized phenomenon, for example, but psychological research focuses on the factors that influence its evaluation (Bonanno and Mancini, 2008).

For a couple of decades, the organization's research has looked for features related to resilience that are suitable for changing working life and which resilient individuals and organizations use for coping with change. Conner (1993) and Hoopes and Mark (2004) have noticed the following counterparts, which affect from the surprising changes to a stabilization of the situation (Table 1).

Table 1: The counterparts modified from Conner (1993) and Hoopes and Mark (2004)

Counterparts	Definitions
Optimism - pessimism	**Optimism:** The ability to look at a situation realistically and in a positive light and to see opportunities rather than threats. **Pessimism**: Will not take any action, because they know that it will not work. Believes that the failures of the past will be repeated in the future, but even worse.
Strong self-esteem - a weak sense of self-efficacy	**Strong self-esteem:** Has a strong sense of basic trust in themselves and their environment. There is also a strong belief in their own ability to influence a situation. **A weak sense of self-efficacy**: Underestimates their own talents, cannot recognize their own achievements or development.
Strong focusing - poor orientation of consciousness	**Strong focusing:** Always aware of priorities and how to proceed. This can also be called impulse control. The ability to focus on a specific issue and close the mind from irrelevant and disturbances. **Poor orientation of consciousness:** Loss of focus in critical situations.
Flexible thinking – inflexible thinking	**Flexible thinking:** The ability to consider alternatives, understand cause-and-effect relationships and examine situations from multiple perspectives. **In-flexible thinking:** Drawing conclusions too quickly and not reconsidering these conclusions even if they prove incorrect. Always consider themselves right.
Social flexibility - coping alone	**Social flexibility:** Understanding how to utilize others' competencies and having the courage to ask for and accept help. **Coping alone:** Showing mistrust towards others, dealing with problems in isolation
Systematic - unsystematic	**Systematic:** Taking systematic, structured, and disciplined action, and sharing plans with others so that they can participate. **Unsystematic:** Offering a one-point solution to problems that, from the outside, seems like an improvisation.
Risk-taking ability - safety-conscious	**Risk-taking ability:** Dares to take action to try one direction, correcting direction later if necessary. **Safety-conscious:** Is risk-averse and waits for clarification in all situations. Proceeds only in safe situations and environments, seems uncertain or procrastinates.

3. Methodology

The qualitative approach of this empirical study aims to provide an understanding and analysis of micro-entrepreneurial resilience. Qualitative research (Bryman, 1988; Merriam, 2009) explores the ways in which people understand and interpret the significance of their reflections and experiences, in other words, their social reality. The case study strategy used in this study is often selected for research focusing on a particular real-life phenomenon (Ghauri and Grønhaug, 2005). This retrospective multiple case study uses a well-founded research methodology which allows the study to describe actual phenomena in their own context, answering the question "how" without the use of investigators who are the subject of their own research (Yin, 1994).

Compared to single case studies, multiple case studies yield more reliable results (Miles and Huberman, 1994; Baxter and Jack, 2008) and allow for the examination of an issue from multiple perspectives. Multiple case studies are considered more robust and helpful in terms of both generating and testing explanations (Herriot and Firestone, 1983) and they provide a stronger basis for theory building than single case studies (Yin, 1994).

The objectives of this study and the evidence presented are based on interviews with 12 social and health care micro-entrepreneurs in Northern Finland. In these interviews, the subjects reflected on and assessed situations in which they encountered difficulties or crises related to their business. In-depth interviews are usually conducted with a limited number of participants, allowing them to provide much deeper insight than the standardized and structured interview format (Legard, Keegan and Ward, 2003). This method is particularly

effective for small-scale research studies or studies where a lot of research is required before general patterns can start to be observed (Johnson, 2002).

The analysis of the interview data used open coding to identify the main topics of discussion (Strauss and Corbin, 1990). The analysis process started with repeated readings of the transcribed text in order to gain an in-depth knowledge of the research subject. Then, open coding was introduced in order to create links and comparisons between topics. This analytical review was associated with continuous comparison of the codes, which helped to explain overlays and contrast in data, which in turn facilitated building new sub-themes. These sub-themes were evaluated, limited, and categorised with each other by interrogating them further on the codes. By combining relevant sub-themes into separate groups at a higher level, the abstraction level offered emerging thematic groups that secured the theoretical saturation. Table 2 lists the codes, sub-themes, and thematic categories produced by a complete data analysis.

4. Findings

This section provides analysis of the unexpected events, changes or crises occurring in micro-entrepreneurs' case companies and how to categorise those events. The findings are presented in four subsections, each focusing on one of four key thematic categories that emerged from the data: 1) internal intervention, 2) external intervention, 3) wellbeing intervention and 4) tangible intervention (see table 2). These four terms categorise the resilience of micro-enterprises and increase the knowledge related to micro-entrepreneurship.

Table 2: Codes, sub-themes, and thematic categories describing entrepreneurs' resilience

OPEN CODES	SUB-THEMES	THEMATIC CATEGORIES
Change of owners, departure, change of focus in business, core business, change in all, lack of control, change of stakeholder groups, threat, interruption, fear, misjudgement, wrong target group, wrong recruitment, correct management, all knowledge only in one person, too fast growth, uncontrollability, dismissal of a worker	The firm's internal affairs; the functional identity of entrepreneurship and ownership; factors related to the business' concept and pressure to change; competence and knowledge about the workforce and its resources; lack of organizational expertise	**Internal intervention**
Political decision-making, feminine industry, maternity leave, problems of cooperation, bureaucracy, competitive bidding, limitations, increased control, authorities, regulatory requirements	Challenges of securing independence in the face of bureaucracy; the specificities of the various sectors and, in particular, the feminine sectors; cooperation and the development of competencies with the various authorities; institutional control over the business	**External intervention**
Uncertainty, justification of existence, vulnerability, identity, inadequacy, lack of fluency, frustration, lack of competence, relocation, loneliness, heavy time	The entrepreneur's physical and mental wellbeing; the entrepreneur's wellbeing at work; need for peer support for entrepreneurs and the possibility of discussion and disengagement	**Wellbeing intervention**
Fire, having to move unwillingly, indoor air problems, ventilation, monetary crisis, foreign currency loans, debt	Expert assistance, counselling and guidance in difficult situations and crises	**Crisis intervention**

Internal intervention includes changes to the company's internal dynamics. These can include changes in ownership, management models or personnel. In this study, changes in ownership elicited strong reactions from both stakeholders and staff and required a great deal of time and a lot of mental resources. Such changes may also come from outside the company, for example, a blurring of the core business idea due to a dwindling number of customers or ineffective market behaviour. However, the root causes of these problems are within the company.

> *[…] we had to start [to] quickly clarify and reflect on what the purpose of this company is … why this company exists. (Firm 1, owner)*

> *[…] the workers felt sorrow and disappointment and such a feeling of being betrayed [because] they did not know and they were not told that the other owner would leave and replace the new owner. The*

company was a very close, small work community, and for the first time I realised that this is also a company. (Firm 3, owner)

External intervention comes from outside the company. It is often a macro level change related to legislation or regulations. Although information and guidance about such changes is often available for business owners, it may be difficult for entrepreneurs to understand how to apply this information to their specific working environment. The slow pace of legislative changes may come as a surprise and there may be uncertainty or additional work involved due to authorities' varied interpretations of new legislation. The social and health sector is currently turbulent, and entrepreneurs feel that they have been part of the so-called "game blocks." Forecasting and planning for a company's future development has become more difficult.

[…] social decision-makers woke up to the need for effectiveness and cost-effectiveness, and then began to drive down such activities as this company produces. We have not succeeded enough to bring enough evidence that we are genuinely an alternative to the forms of service provided by the authorities and decision-makers […] (Firm 5, owner)

[…] in proportion to the number of staff in recent years has been the most maternity leave in this company's history. In four years, we have had 13 maternity leave, if I'm not terribly lying. It's a huge amount ... the kids are wonderful, of course, and maternity leave is wonderful, yeah, but if you're thinking of euros and the subordinate arrangements we have to be a substitute and the cost, they are really huge […] (Firm 2, owner)

Wellbeing intervention is related to the entrepreneur's own experiences and feelings. Entrepreneurs did not talk about wellbeing at work, but instead about how they coped with difficulties, maintained motivation, or, sometimes, felt inadequate. A lack of delegation or the unwillingness to delegate added to entrepreneurs' sense of inadequacy, as did the feeling that their competence in some areas was insufficient. A sense of loneliness at work was the result of frustration or underestimating their own competence. These issues meant that even a little adversity could temporarily seem more significant. The lack of peer support increased feelings of frustration and inadequacy.

[…] our organizational structure is too vulnerable, because I'm … the only one who knows these things […] (Firm 4, owner)

[…] now there are a lot of balls in the air and there is such inadequate feeling that everything should be done and the employees are out of focus ... Part of my feelings is that the staff feel that the owner does not appear and does not belong and maybe she not even have interest what we are doing here. Do they think that I'm lazy and they just make money for me and the company? (Firm 11, owner)

Crisis intervention refers to a sudden crisis, independent of all the previous categories, which could not be resolved, for example, a fire or an abrupt change in office space due to an existing office being sold. The lack of expert advisers increased resilience, because the entrepreneur felt he would often stay alone.

[…] we can probably set up some moving company, we have been moved so many times during these years. … There was the situation that in those premises where we were, there was a problem with ventilation. They had rental facilities. (Firm 7, owner)

[…] that was such a very foggy time for me, there were really heavy years. ... We had a foreign currency loan and I called my colleague, another owner, for the loans to be terminated because I had the feeling that something was happening. The prime minister had argued that Finland did not devalue, and therefore the partner said it was not worth terminating because he trusted the prime minister. In the morning when I woke I heard that at night there was a mark floating or devalued. I called again to a partner if it is time to terminate now? It is no longer worth it, he said […]. (Firm 9, owner)

5. Discussion

This study aimed to research events, crisis and events faced by micro-entrepreneurs and determine how to classify them. Although there is research on resilience in business, this topic has not been studied at all in the

context of micro-entrepreneurship, which is now a socially significant phenomenon. There is thus a natural connection between the existing literature and this study.

The analysis produced four distinct categories of intervention. This categorization can show signs of both ecological and psychological resilience (Bonanno, 2004; Bonanno and Mancini, 2008; Folke, 2006; Zolli and Healy, 2011). Internal and wellbeing interventions are the result of a company's internal affairs or the entrepreneurs themselves. External and crisis interventions originate outside the company and are, in some cases, difficult to foresee. This indicates that resilience is not only a matter of personal psychology and behaviour, since environmental factors can play a major role.

When under pressure, performance is emphasized and the ability to adapt to high pressure situations can be a virtue. Fatigue is avoided because it is easily linked to the idea of inferiority. This study also showed that a sense of underachievement can also be linked to negative experiences in one's personal life or a lack of physical fitness and the idea that "I'm not getting better, so I have to do more" can form a dangerous circle.

Curiosity, the desire to learn from experience, and determination were engines of change and action. If a person is motivated to persevere in spite of difficulties but they were not determined enough, then nothing happened. In addition, a sense of proportionality is important, that is, the ability to recognise the importance of things in a larger context (Hoopes and Mark, 2004).

Both anticipated and unexpected changes can disrupt a business. But a strong sense of resilience allows individuals and groups to cope with these changes appropriately. As Cheetham and Chivers (1998) argue, self-reflection and resilience are meta competences that are related to learning. Resilience is indispensable and enables better self-assessment. It also augments practical business skillsets.

Entrepreneurs did not interpret their interactions with unexpected or difficult situations as resilience, but rather as the ability to adapt or change—adopting a positive attitude, for example, could create enough confidence to survive a crisis. Several of the entrepreneurs' stories included a very realistic and structured analysis of events. As Coutu (2002) has argued, a realistic approach to handling business problems may lead to such an accurate description of those problems. Compared to Conner's (1993) and Hoopes and Mark's (2004), this is an optimistic viewpoint: entrepreneurs who can analyse a situation realistically and in a positive light see opportunities rather than threats.

6. Implications

6.1 Practical implications

According to Alonso, et al. (2015), micro-entrepreneurs often have to address changes and resolve crises alone. To a micro-entrepreneur, a sudden change can be challenging because he/she does not necessarily have a support network to provide useful or sufficient help. This analysis of the kinds of resilience entrepreneur's show in their careers and how we might categorise these types of resilience creates a greater understanding of the bigger phenomenon of micro-entrepreneurship and how micro-entrepreneurs describe the kinds of resilience they showed. The main finding of this study is that the nature and source of resilience differs on a case-by-case basis and is affected by a larger framework, whether that is the company's internal functions or its macro environment. This study also provides important information for facilitators, business advisers, and institutions working with micro-entrepreneurs.

6.2 Research implications

In general, there is too little research on micro-entrepreneurs, even though they play a significant role in Finnish business. This study offers a new approach to both entrepreneurship and resilience research and provides a starting-point for further research in this area.

7. Conclusions

This study was the first step in researching the resilience of micro-enterprises. The research identified and categorised the factors that contribute to micro-enterprise resilience. The next step is to examine micro-entrepreneurs' experiences of difficult situations or crises, how these situations affected their actions and decisions, and how they resolved these situations. In addition, the relationship between resilience and a firm's growth and success warrants further study.

The Entrepreneurial Dream: Happiness, Depression and Freedom

Michael Fowle
Edinburgh Business School, Heriot-Watt University, UK
michael.fowle@ebs.hw.ac.uk

Abstract: Entrepreneurs have very high rates of depression. Some academic research suggests that adverse circumstances force people into entrepreneurship through lack of opportunity: entrepreneurship is less a choice than a symptom of lack of choice. While some entrepreneurs are indeed forced by circumstance, more react to opportunity. Several studies confirm that most Western entrepreneurs are attracted by the promise of freedom and autonomy, but many discover that, in reality, they have lost control of their personal, social and professional lives. 90% of startups will disappoint their founders and, in consequence, threaten their physical and mental health. Half of entrepreneurs say they have mental health issues and a third are depressed. The decision to become an entrepreneur increases these risks. Some researchers suggest that entrepreneurial personality types correlate with a higher incidence of general mental health issues, ADHD, depression and suicide. This paper uses research in entrepreneurship, psychology, philosophy and neuroscience to show that, contrary to current belief, entrepreneurs are not unusually prone to depression. They are in fact extraordinarily resilient, but their entrepreneurial projects often create high levels of risk, uncertainty, loss of control, fractured relationships and damaged identity. These, coupled with extreme lifestyles, lack of sleep and exercise and poor diet, combine to create exceptional physiological and psychological stress. These conditions, and not predisposition, lead to entrepreneurial depression. Entrepreneurial traits are a shield and protection, not a cause of distress. The conclusion suggests a range of mitigating philosophical, strategic and personal approaches to improve wellbeing and social and economic outcomes. In summary, entrepreneurs should keep themselves fit to lead, share the burden with a team and keep the project lean.

Keywords: Entrepreneuship, Happiness, Depression, Freedom

1. Why be an entrepreneur?

The Approved Index (2015) map of entrepreneurial countries identifies Uganda as the most entrepreneurial country in the world, with Sweden and Finland listed as among the ten least entrepreneurial. If this seems surprising it is worth noting their definition of entrepreneurship as "the percentage of an adult population who own (or co-own) a new business and has paid salaries or wages for at least 3 months". This measures not creative entrepreneurship but economic desperation. There is no developed country in the Approved Index top 25.

A more comprehensive and systematic view is taken by the GEM report (Global Entrepreneurship Monitor, 2018), which finds that most entrepreneurs are driven by opportunity rather than by necessity, and this is even more marked in developed nations. In North America 82.6% cited opportunity as their motivation. Segal et al. (2005) make explicit reference to Vroom's Expectancy Theory and conclude with an analogous suggestion that "self-employment intentions" are a function of self-efficacy, risk tolerance and perceived net desirability. This last factor contrasts the psychological benefits of self-employment with the more certain value or distress of regular employment: push and pull. While there is no doubt that some kind of inner calculus is involved in the moment of commitment to an entrepreneurial course of action, the generic motivations towards entrepreneurship are more likely to be found in Abraham Maslow's (1943) hierarchy of needs. The hierarchy shows physiological needs at the bottom and suggests that no higher needs can be addressed until these are satisfied. Maslow is much criticised for his research base, nevertheless, his model remains popular and is a simple, useful and memorable presentation of motivational factors. The adjusted version (Maslow, 1971) includes a sixth, "transcendent" tier, that of higher purpose beyond the individual.

Maslow's self-actualisation and self-transcendent levels are only open to the fortunate few who have satisfied and moved beyond the lower levels, "the awakened, the illuminated, the 'high plateau' People" (Maslow, 1979). The top two levels can never be fully satisfied but represent the unachievable drive towards betterment and the service of a higher purpose. This is explicitly spiritual or mystical, but while Maslow mentions religious calling he is careful not to limit himself to religion (Koltko-Rivera, 2006). His Transcendence is imbued with a Romantic sense of the sublime, and embraces humanistic, ecological, social or societal service: anything beyond the individual.

The entrepreneurial need to "make a difference" addresses the levels of self-actualisation and higher calling.

The constituents of the highest strata of the hierarchy predict the stated motivations of many entrepreneurs, for example the need for status and identity, progress and learning, challenge and achievement.

2. So Who Are the Entrepreneurs?

William Gartner (1988) warns against a trait-based definition of entrepreneurship, saying that we cannot identify the characteristics of dancers and use what they do to define the dance. While this is a compelling metaphor, we accept that there is a dance, and consequently we are justified in asking who is dancing, and why. As Carland et al. (1988) put it '"Who is an entrepreneur?" is a question worth asking'.

The answers come from a range of empirical research. Lüthje and Franke (2003) studied 512 engineering students at MIT and found that Entrepreneurial Intent is more influenced by personality factors (propensity for risk-taking, internal locus of control) than by environmental factors. A study of South African tertiary education students (Louw et al., 2003) identified "Competing against self-imposed standards", "Self-confidence" and "Dealing with Failure" as more apparent in students with entrepreneurial intent. Entrepreneurial Turkish students evidenced more of every entrepreneurial trait than their non-entrepreneurial peers, although their confidence is only marginally higher (Gürol and Atsan, 2006). If we accept Gürol and Atsan's list of traits, we have (i) locus of control, (ii) need for achievement and (iii) tolerance of ambiguity (Entrialgo et al., 2000); and (iv) risk taking propensity, and (v) innovativeness (Stewart Jr et al., 1999); along with (vi) self-confidence (Robinson et al., 1991).

There is an established link between low self-confidence and depression. Al-Asadi et al. (2014) confirm the correlation and suggest a causal spiral where low confidence leaves patients more prone to depression, and the increasing signs of depression undermine confidence. Entrepreneurs must be confident enough to commit to their risky ventures, and so should be less susceptible.

Locus of Control (LoC) was a concept introduced by Julian Rotter and his team in the 1950s and 60s to describe an individual's perceptions of his ability to influence his own life and specific outcomes. An external LoC suggests a belief that the circumstances and outcomes are driven by external factors. Krause and Stryker (1984) report that "*moderate externals are the most vulnerable to the effects of job and economic stress".* DuCette and Wolk (1972) find respondents with external LoC were characterised by "*a preference for extreme risks, low persistence, and atypical shifts in level of aspiration; they were more extreme in their estimation of success when responding to items related to academic, occupational, and cognitive activities".*

By contrast "e*xtremely internal types may be so overcome with a sense of personal responsibility for the occurrence of the stressful event that they may suffer from anxiety and depressive reactions"* (Krause and Stryker, 1984) and this evidences an inability to cope with life's ups and downs when they are genuinely beyond our control. Entrepreneurs, who characteristically have a marked but mild internal locus, should be more resilient to setbacks. Chen and Silverthorne (2008) report that "*Respondents who had an internal LOC perceived lower levels of job stress, and reported higher levels of job satisfaction and job performance"* while Krause and Stryker (1984) confirm that "*moderate internals are able to cope most effectively with stress".*

Entrepreneurs have a higher than average Need for Achievement or nAch (Begley and Boyd, 1987, Collins et al., 2004, Wu et al., 2007). This is associated with people who never switch off. In a study measuring a physiological hypothalamic–pituitary–adrenal (HPA) response and cortisol release, individuals with a high nAch were found to be more habitually stressed than their peers but coped better with challenging tasks and negative feedback (Yang et al., 2015). They fared particularly well where they had articulated both challenge and feedback as opportunities to learn and improve. Entrepreneurial activity involves very high levels of uncertainty. For many, particularly those with a need for control, this presents a problem and a source of stress. Entrepreneurs' tolerance of ambiguity serves as a buffer and allows them to continue even when the fundamentals of the nascent business are still open to question.

Uncertainty is risky, and entrepreneurs necessarily have a higher propensity for risk-taking. Risk-taking is a complex psychological trait. It includes elements of sensation and novelty seeking and impulsiveness. Zuckerman and Kuhlman (2000) confirm that these are personality traits rather than responses to opportunity, so all risks are more acceptable to the risk-taker. The gambler is more likely to take drugs, and the lothario

who takes sexual risks is more likely to crash a car. Nicholson et al. (2005) point out that typical risk-takers show high extraversion and low conscientiousness. This is the opposite of typical entrepreneurs, but lest this seems like a contradiction, they identify three different, but not exclusive, categories of risk-taker: the Sensation-Seeker, the Goal Achiever and the Risk Adapter. Of these, the Sensation-Seeker manifests a general predisposition towards risk and is unlikely to become a successful entrepreneur. The Goal Achiever accepts entrepreneurial risk as a condition of expected reward. The Risk Adaptor exercises increasing mastery of a skill or profession where risk is endemic (as is the case with many forms of finance or speculative trading).

Hvide and Panos (2014) observe "*More risk tolerant [stock market investors] are more inclined to start up a firm but of poorer expected quality than less risk tolerant individuals*". There has been some argument over the characteristic nature of entrepreneurial risk-taking since Brockhaus (1980). Astebro et al. (2014) suggest that entrepreneurs are not so much seeking risks as dazzled by opportunities. They habitually under-estimate the challenge and over-estimate their own abilities, with the consequence that they embrace risks that other would find unappealing.

Families, peer groups and role models all have a profound impact on intending entrepreneurs, and it seems that they also specifically affect risk-taking. Smith et al. (2014) identify the influence of peers on adolescent risk-taking while Kish-Gephart and Campbell (2015) noted the importance of social class for CEOs, where more affluent backgrounds led to the acceptance of greater risk, mitigated by the safety nets of social networks, family means and elite education.

Innovativeness is central to contemporary theories of Bricolage (Baker and Nelson, 2005) and Effectuation (Sarasvathy, 2009). Even Schumpeter's (1942) creative destruction calls for "the qualities of boldness, self-confidence, creativity and innovative ability" (Kirzner, 1999). Hmieleski and Corbett (2006) measure entrepreneurial activity and creativity, and find a clear link, supported by Rauch and Frese (2007). There have also been a large number of studies suggesting a link between creativity and mental health issues such as bipolar disorder and depression (Power et al., 2015). Silvia and Kimbrel (2010) acknowledge the potential link between mental illness and "divergent thinking, creative self-concepts, everyday creative behaviors, and creative accomplishments", support the correlation but find the impact is smaller than generally assumed.

We have examined the entrepreneurial personality and discovered that the characteristic traits are more likely to constitute a shield and a defence against the psychological risks of entrepreneurship. These traits not only characterise entrepreneurs, they are directly responsible for a secondary characteristic, resilience. Every worthwhile project has setbacks and we all fall down from time to time. Some projects fail because they could not have succeeded, some because they are badly managed and some because their sponsors are unable or unwilling to continue to the point of success. The resilient entrepreneur increases his likelihood of success in a project with potential, but also increases the cost of failure in hopeless projects, by carrying on. The essential commitment and faith in the project all too easily become delusion. Resilience is a buffer against short-term failures but an amplification of the cost of final failure.

3. The Call and Cost of Freedom

Entrepreneurship is hard to define, but "happiness" is even more problematic. Aristotle (c340 BCE) saw happiness as virtue, fulfilment, balance and engagement. Fulfilment requires excellence and the realisation of potential, which is judged in the context of purpose. The entrepreneur commits to a project with an investment of time, money, emotions and identity. Entrepreneurs become voluntarily blind to alternative courses and opportunity costs. They create their own purpose and commit to it wholeheartedly, taking them to the higher reaches of Maslow's hierarchy. Daniel Pink (2011) identifies three powerful human motivators: autonomy, mastery and purpose. These are also the key pillars of job satisfaction and overall happiness, and they lie at the heart of the entrepreneurial dream.

Entrepreneurs are drawn to "being independent and one's own boss" (Blanchflower and Oswald, 1998). Not only are they attracted by independence but "the self-employed report higher levels of job and life satisfaction than employees" (ibid), a finding echoed by Andersson (2008) and Hessels et al. (2018) . The freedom to make decisions, to develop specialist expertise and to pursue a worthwhile goal means that a commitment to an entrepreneurial project creates a sound basis for happiness: autonomy, mastery and purpose. Many entrepreneurs cannot imagine a life as an employee.

While the rewards are immediately psychological (and provisionally financial), there is a cost to embarking on a new venture. The lone wolf entrepreneur commits himself to isolation and a greater risk of failure, and this is possibly the reason that investors dislike single-founder ventures, although they may also be looking for the increased guarantee of continuity should the founder be unable to continue, as well as a range of core skills and experience. Nevertheless, singleton or team, new ventures rarely succeed. The Enterprise Research Centre (reported in Financial Times, 2017) finds that half of new businesses in the UK fail within three years, and Shikhar Ghosh's research at Harvard Business School (Blank, 2013) suggests 75% are investment failures while 95% disappoint their founders. Entrepreneurial freedom comes at a cost.

4. When the Dream becomes a Nightmare

For the majority of entrepreneurs, their current project will bring failure, not freedom. Failure leads to feelings of bereavement (Shepherd, 2003) which shares the symptoms of depression (although psychiatrists treat them differently). Michael Freeman who has researched the links extensively (Johnson et al., 2015, Freeman et al., 2015), tells us that entrepreneurs are by their nature more prone to depression, ADHD, substance abuse and suicide. It is true that there are links between creativity and bipolar disorder (Baas et al., 2016); goal-seeking and mania (Johnson, 2005); action-orientation and openness, and the same dopamine reward circuitry that leads to impulsivity, risk-taking and addiction. The links are, however, only apparent when the personality trait is extreme. We can all think of examples of the troubled genius, the manic inventor and the tragic business founder. These are memorable but heuristically biased (Kahneman, 2011) and not statistically representative. We can just as easily find stories of heavy smokers who live to 100, but this does not mean cigarettes hold the secret to longevity.

Many entrepreneurs succeed after a string of failures. This is of course the rationale behind the Martingale betting strategy where, after every loss at Head or Tails, the gambler doubles the stake. Eventually, so the dangerous reasoning goes, they must be lucky. Entrepreneurs often persevere when a more balanced individual might have accepted defeat. The iconic story of Rovio is testament to the single-mindedness of the founders. Three graduates of Helsinki's Aalto University started to develop games for mobile phones. They prevailed on friends and family and raised over €1m, but development took longer than anticipated, family members fell out and Mikael Hed, the CEO, left the company in 2005. Reality, of a sort, encouraged them to take on contract work in 2006 but that was insufficient and they started to cut their workforce. By 2009 they were down from 50 to just 12 staff, and close to bankruptcy (Cheshire, 2011). Realising that they had not taken themselves and their product sufficiently seriously they re-recruited Mikael Hed, raised more money and tried again. The founders had started saying "just one more try" after the third release. They were still saying it after fifty. What reasonable person would want to continue after fifty successive disappointments? Rovio, to the despair of their families and friends, were still insisting on "one more try" for their fifty-first title (which failed), and then for the fifty-second, which they called Angry Birds and which became the most downloaded iPhone game ever (Robertson, 2015). Somehow, the Rovio founding team had remained committed while their environment had become increasingly hostile and stressful. Many "normal" people would have succumbed to depression.

Not all entrepreneurs have such seemingly inexhaustible resilience. Eventually reality bites and this is apparent in the statistics. 49% of Freeman's (2015) research cohort of entrepreneurs reported depression and other mental health issues and there is a widely reported epidemic of founder suicides in Silicon Valley. Some authors ask what it is about entrepreneurs that makes them depressed. The better question is how so many entrepreneurs cope so well with failure when they are in a toxic environment that threatens nearly everything we accept as essential to happiness. Perhaps an entrepreneurial mindset helps us to happier, more meaningful lives. The Team Academy movement (Fowle and Jussila, 2016) uses entrepreneurial practice as a vehicle for developing self-efficacy, teamwork, resilience and business experience, and Tingey et al. (2016) report on entrepreneurship education as a means of encouraging attachment, confidence and mastery, self-control and optimism in American Indians. These traits are all significant in building defences against depression, but the circumstances of a fully commercial entrepreneurial project put them to the test.

Shneidman (1998) lists five psychological frustrations that lead to suicide, including (i) fractured control, (ii) assaulted self-image and (iii) ruptured key relationships. Founders pursue achievement and autonomy, but most find that a failing business, financial constraints and the demands of stakeholders lead to frustration and a loss of control. Entrepreneurship is attractive and founders build and promote an image of excitement,

competence and success to influence their backers, partners, staff and potential customers. For most, as disaster looms, the gulf between spin and reality becomes wider and increases the shame, humiliation and disgrace of failure and the collapse of self-image. The damage is particularly severe where the founder has relationships built on leadership and trust. Nobody loves a loser, and sometimes being honest about the challenges will be enough to destroy the company. As the position becomes more precarious, the dishonesty escalates. In order to save the company and those who depend on it, the founder betrays the trust of those same people and sets up an inevitable rift, akin to bereavement.

There is no doubt that commitment to an entrepreneurial venture triggers the probability of suffering all three of Shneidman's psychological assaults. Additionally there is the physiological impact of the entrepreneurial lifestyle. This becomes exaggerated in strongly entrepreneurial communities where there is a culture of extreme living. Silicon Valley is a unique and specific sub-culture but it influences attitudes to, and expectations of, all entrepreneurs. Douglas Coupland's Microserfs have eating, sleeping and psychological disorders. Wired (2007), Forbes (2014) and Entrepreneur.com (2014), offer entrepreneurs recipes based on ramen noodles, while Forbes (2011) and the Huffington Post (2014) claim that there is more to entrepreneurship than noodles, ironically reinforcing the association. The assumption is that diet, along with sleep, exercise and personal relationships have all been sacrificed to the greater cause. Doree Shafrir's "Startup" (2017) fictionalises the dysfunctional lives and lifestyles of startup entrepreneurs based on her journalistic observations. The ultimate expression of the entrepreneurial extreme is Belfort's drug-crazed and sex-addicted, semi-autobiographical Wolf of Wall Street (2013). The founder's self-image is a public relations pyramid scheme where the stakes (and the main characters) get higher, and the cost of failure escalates past the point of no return.

Social media has given us the blight of competitive happiness, and in entrepreneurial circles there is the analogous obligation to manifest success. Admissions of weakness are a personal failure and may well trigger business failure. Social pressure creates a spiral of adrenaline-based, high-energy activity. Failure is acknowledged, but only as a stepping stone to even greater success.

The outcome is that half of the entrepreneurs questioned by Michael Freeman report depression or other mental health issues. Depression rates are four times as high as they are amongst the general population. Freeman suggests that the entrepreneurial personality, and not the entrepreneurial decision, is the trigger.

However, we have shown that entrepreneurship is not a stage in the declining health of characteristically depressed people; it is a gamble with very high psychological stakes taken by naturally resilient people.

5. Guidance for Travellers

Why be an entrepreneur? The answer, as we have seen, is the building of identity, the autonomy, the excitement and the well-being that comes from wholehearted dedication to a purpose. Even unsuccessful entrepreneurs often speak nostalgically of their failed ventures and many look for another opportunity to start a business (Yamakawa et al., 2015, Hayward et al., 2010).

The appeal is seemingly irresistible, the rewards are high, but the penalty can be fatal. Is there a way that nascent entrepreneurs can navigate their paths without exposing themselves to psychological risk? Depression is a cycle fuelled by lack of sleep, lack of exercise and poor diet. Entrepreneurs should make a point of enforcing basic disciplines in each of these areas. It is plainly hopeless to expect to solve the problem simply by asking individual entrepreneurs to espouse a healthy work/life balance. However, as with risk-taking and the influence of role models, entrepreneurs are susceptible to the expectations of their cultural milieu. So many entrepreneurs now start in universities, accelerators or incubators that these organisations should consider themselves responsible in helping their alumni to healthier outcomes.

Where a self-imposed health regime may be an unlikely fantasy, competitive (or at least monitored) health is more likely to succeed. Fitbits and other health devices have a profound effect on some people's health (Mercer et al., 2016, Cadmus-Bertram et al., 2015, Lyons et al., 2014), and an even greater effect when their wearer is driven by performance metrics and goals (Michie et al., 2011). This gamification of health holds great hope for us all as we have the means and incentive to regulate our own lives. Even better is when we can create communities of health (Payne et al., 2015)ay. This explains the success of Weight Watchers (Ahern

et al., 2011) and the attempts of exercise apps like Runkeeper to move from self-monitoring to social, competitive and peer-regulated goals. The social environment helps, the smaller social group of fellow entrepreneurs allows the sharing of experience and the pooling of knowledge, and the founding team create a sense of camaraderie and shared purpose that strengthens resolve, mitigates the risks of loneliness and distributes the burden. New ventures founded by teams are more successful, at least in attracting funding, and failure is less painful.

Any venture, or any project will have challenges. Having a clear purpose, and specifically a purpose that is nobler or wider than simple profit helps founders to carry on when times are dark. When funds are running low, investor support is uncertain and progress seems interminably slow, then it is easier to carry on if the pain is matched by a belief that the venture is worthwhile: the new cancer drug will save lives; the educational product will transform the prospects for children; and the new building will allow thousands to enjoy healthy sports in all weathers. When Frankl was able to help others, even the horror of Auschwitz could not eradicate his satisfaction.

The final element is the enormous risk of the entrepreneurial venture. The sheer scale and potentially terminal consequences of failure still threaten the wellbeing of anyone supporting a new venture. But is the risk always unavoidable? In the last few years many venture creation courses have adopted the Lean Startup approach (Blank, 2012, Osterwalder and Pigneur, 2010, Ries, 2011). This encourages iteration and discourages a planned (and therefore prescriptive) route to a predefined but speculative objective or product. Instead there is a focus on experiment, engagement with customers, and learning. We have seen already that treating setbacks as learning experiences encourages resilience, but the Lean approach also reduces risk by embracing it early. Traditional planned business projects attempted to put the plan into action. Lean Startup tries to put the action into the heart of the plan. Risks are identified and tested as soon as possible in order to minimise commitment to untested courses of action. If product/market match is tested and proved or disproved then there is a rationale for continued investment. Founders have a sound basis for increasing the exposure of friends, family, other investors and staff and partners. Short-term failure becomes cheaper and more likely – as does long-term success. Both the scale and probability of failure dwindle, as does the personal and inter-personal liability of the founder.

Many entrepreneurs succeed on the second or subsequent attempts, but some are so damaged by an initial failure that they cannot carry on. The keys to psychological prosperity are (i) physical health and lifestyle, (ii) human relationships with family, friends, co-founders and other stakeholders, (iii) minimising risks through an accelerated lean approach, (iv) commitment to a greater purpose and (v) a sense of progress. Different industries have different cultures and attract different personalities, but the five keys are common to us all.

We can take positive steps to replace the culture of heroic all-nighters with competitive sleep monitoring, diet and exercise. We can use each other as regulatory mechanisms. We can reduce business risks by addressing them early and iterating with customer help. We can treat stakeholders as collaborators and recruit their expertise and networks. We can state and restate the purpose so that the team is inspired and aligned, and we can celebrate landmarks and turning points.

Driving, skiing and sky-diving all involve a level of risk, but it is the rewards and not the risks that attract us. In fact we train, prepare and adopt specific disciplines to minimise the risks of each. Similarly, entrepreneurs who can manage themselves as well as their ventures will reduce their exposure to physical, financial and psychological damage.

A Path to Leadership of Innovation for a Developing Country

Oleg Golichenko
Central Economics and Mathematics Institute of Russian Academy of Sciences, Moscow, Russia
golichenko@rambler.ru

Abstract: A path to leadership of innovation can be divided into two stages: the investment or catching up one and the stage driven by ingenious innovation. The development of national innovation system is providing the fundamental basis for a country to pass these stages and win a leadership on each of these stages. According the methodology of the study a national innovation system is represented as three interconnected macroblocks that interact with each other at the horizontal level: the business environment and the market; the environment generating new knowledge; and mechanisms for transferring knowledge. The content of the policy areas and actors' activity comply with the country's stages of development, including the resource stage, investment stage, and the stage grounded in the country's own innovations. NIS subprocesses are identified in this macrostructure as a result of decomposition of just mentioned blocks. In this study the block of mechanisms of knowledge transfer is disaggregated as three interacting channels of knowledge transfer. The block of business environment and market is decomposed to in accordance with the hierarchy of value-added chains. The paper is taking into account three such channels: open information channels, those of a transformation of open knowledge into pre-competitive and competitive one, and channels of commercial knowledge transfer. The study investigates in details the following tasks of public policy: how to shape and advance innovation modes on investment (catch-up) stage. The main futures of technology catch-up processes are considered. The crucial problems of successful entering the world market on the investment (catch-up) stage are associated hindrances on the external markets. Opportunities of integration in global value-added chains (GVC) are bearing in mind as a means of overcoming these hindrances. These opportunities are determined by the results of technology and organization revolutions of the last 15-20 years. The step to the next level of innovation leadership is transition from the investment stage to the one driven by ingenious innovation. However, the transition generates serious problems. Their solution requires particular post-catching up reforms.

Keywords: stages of development, innovation modes, competition, value-added chains, innovation shifts

1. Introduction

For a developing country, the paradigm of the actors' behaviour in its national innovation system, i.e. the widespread model or mode of this behaviour, plays a significant role in gaining the leadership of innovation. It includes a strategic choice at different levels of the hierarchy. The tasks of the strategy of top-level actors (including government) comprise the setting up framework conditions for shaping factors of technological competitiveness. At the level of enterprises and organisations, it is, first of all, a strategy of choosing models or modes of behaviour in carrying out their activities (Golichenko and Balycheva, 2016).

In the innovation system, building these strategies and construction of behaviour depends considerably on how and to what extent the following problems are solved.

How are the patterns or modes of actor's behaviour shaping and advancing at different stages of the country's development?

How can domestic enterprises succeed in the global market?

How to proceed with diffusion and incremental improvements of innovations to the creation of disruptive and ingenious innovations?

Below we are going to reply the questions raised. However, before answering these questions, let us turn to the methodology of the study.

2. Methodologies and literature review

As is known, in studies of innovation systems, it is assumed that the actors of these systems do not do optimal solutions to emerging problems and usually satisfy below optimal level of efficiency (Niosi, 2002). Under these conditions of bounded rationality, it is difficult to expect that a national innovation system (NIS) as a whole and its actors optimally perform their functions and missions. Consequently, it is necessary to focus not on the

optimal, but on the existing best practices. In the case that interests us, the use of best practices gives an opportunity to destroy dependence on the former path of development, unblock innovative activity, and introduce new rules (institutions) that offers a chance to move towards innovation leadership. In this study, these practices are sought among the newly industrialised countries of South East Asia.

A significant amount of literature has been devoted to the descriptions of the practices formed in this area over the past 20-30 years (see, for example, OECD, 2016, 2015, 2014, 2011). These descriptions can serve as an empirical basis for looking for the core rules that can enable to reach the innovation leadership.

The approaches of NIS are taken to achieve the stated goals. Unfortunately, these approaches are not sufficient to ensure a full-fledged method for studying a system (Golichenko, 2016). Such a method must be based on the transition from the micro to macro level (Lundvall, 2007, p. 102). The existing approaches are more focused on macro-level institutions and to a lesser extent on entrepreneurs operating at the micro level (Hekkert et al., 2007,p. 414). To addition, according to Edquist, when moving to a macro level, the innovation system is regarded as a single entity without breaking out the subprocesses and their actors (Edquist, 2006, p. 186).

In 2016, I proposed a methodology for studying the NIS that, on the one hand, takes into account the valuable results of the previous studies (Golichenko, 2016), and on the other, reduces the conceptual vagueness of the concept of the NIS and makes it possible to apply it to practical research on innovation systems. This methodology uses structural-objective and functional research methods. The first is used to solve the problem of the decomposition of NIS objects, and the second is applied to analyse the x-effectiveness of the NIS and its factors. It should be noted that the proposed methods develop the ideas of the structural and functional approach (Edquist, 2006; Hekkert et al., 2007; Johnson, 2001; Lundvall, 1992; Nelson, 1993).

Following the proposed methodology, the national innovation system is represented as three interconnected macroblocks that interact with each other at the horizontal level: the business environment and the market; the environment generating new knowledge; and mechanisms for transferring knowledge. NIS subprocesses must be identified in this macrostructure as a result of decomposition to reveal the main problems of the functioning of these macroblocks at the mesolevel. In this study, the block of mechanisms of knowledge transfer is disaggregated as three interacting channels of knowledge transfer. The block of the business environment and the market can be decomposed to meso units and meso populations (Dopfer, 2004) in accordance with the hierarchy of value-added chains. For this purpose, two types of the decomposition of hierarchical mesosystems are considered: vertically integrated and fragmented supply chains

The content of the policy areas and actors' activity must comply with the country’s stages of development, including the resource stage, investment stage, and the stage grounded in the country’s innovations (Porter, 1990). The stage-based approach to determining policy directions and measures for carrying out these policies allows the state to promote the process of the coevolution of the absorption capacities and increase the innovative capacity of enterprises in the national innovation system (Castellacci and Natera, 2013).

Let us now consider in more detail the methods of decomposition of these blocks and the main components of the stages of NIS development.

For a developing country, the paradigm of the actors' behaviour in its national innovation system, i.e. the widespread model or mode of this behaviour, plays a significant role in gaining the leadership of innovation. It includes a strategic choice at different levels of the hierarchy. The tasks of the strategy of top-level actors (including government) comprise the setting up framework conditions for shaping factors of technological competitiveness. At the level of enterprises and organisations, it is, first of all, a strategy of choosing models or modes of behaviour in carrying out their activities (Golichenko and Balycheva, 2016).

In the innovation system, building these strategies and construction of behaviour depends considerably on how and to what extent the following problems are solved.

How are the patterns or modes of actor's behaviour shaping and advancing at different stages of the country's development?

How can domestic enterprises succeed in the global market?

How to proceed with diffusion and incremental improvements of innovations to the creation of disruptive and ingenious innovations?

Below we are going to reply the questions raised. However, before answering these questions, let us turn to the methodology of the study.

2.1 Knowledge transfer channels

The mechanisms of knowledge transfer are primarily determined by nature of knowledge, namely, whether the knowledge is based on R&D or has one of the following alternative properties. It is public or private; codified or implicit; special or generic. In accordance with the listed properties of knowledge, three types of knowledge transfer can be presented (Golichenko, 2016):

- open information channels for pre-competitive knowledge transfer;
- channels for a transformation of open (public) knowledge into pre-competitive and competitive one;
- channels for commercial knowledge transfer, including embodied and disembodied technology diffusion.

It is worth noting that the system of interactive learning, embedded in NIS theory by Lundvall (1992), can be implemented in many respects through new knowledge transfer mechanisms.

The open channel as a mechanism of knowledge dissemination is exceptionally crucial when interaction is addressing to research and development (R&D) as well as the generic and pre-competitive phase of technology development. The critical characteristic of this channel is accessibility and opportunity that knowledge can be transferred without direct contact with a primary source of information. Such knowledge does not constitute a commercial secret since it is of public nature.

The second channel should be divided into two parts. The performance of the first is carried out by cooperation and partnership institutions. The usage of this part of the channel by enterprises through cooperation in the R&D area at the pre-competitive phase helps origination and evolution of some generic and pre-competitive knowledge, which, upon successful completion of the phase, may become private (as some intellectual property). The main components of the second part of the channel are institutions fostering new technology-based firms. They determine country’s ability to generate future radical technological changes.

The further transfer of knowledge obtained in the second channel can be carried out in frames of the third channel. The action of the channel includes adaptation and imitation known products and technologies, organisational and marketing innovations developed by other firms and companies. Diffusion of "external" foreign innovations can occur in the embodied and disembodied shapes in the channel.

The use of the channels depends heavily on the models of innovative activity firms. Below we are going to consider two basic models of actors' behaviour. The first type of the models corresponds to the investment stage of country’s development. The main driver of the stage is the technology catch-up. The second type is associated with the development driven by ingenious or radical innovations.

2.2 Global value chains

On the turn of the century, organisational innovations in value-added chains changed the concept of their actions and created new opportunities for developing countries' companies. Modern paradigms of interaction in global value chains are determined mainly by the degree of its fragmentation, more precisely, by the degree of rigidity of multifunctional relationships in production networks. Two extreme cases of global value-added chains (GACs) organisation could be distinguished. The first one relates to the organisation of the GACs functioning within the framework of traditionally rigid integrated production networks, and the second one is associated with flexible fragmented networks emerging in some knowledge-intensive economic activities.

Traditional paradigms of production organisation in the value chains. The vertical integration of traditional production networks introduces a hierarchy of subordination of production units (Gereffi et al., 2005). Consequently, there are no free market relations on the intermediate levels of the hierarchy. Two types of

such structures can be distinguished: vertical and quasi-vertical integrations. Both types of structures are related to closed product architecture; a hybrid combination is also possible.

Vertically-integrated structures are strictly hierarchical production systems in which the linkages are based on the bonds of ownership. The headquarters of a flagship firm takes full responsibility for governing the hierarchy. The dominant form of management is business governance directed from the top down. Quasi-vertical hierarchical structure arises if the firm's dominance in the value-added chain is not based on its ownership of business assets but rather on intellectual property including the brand, patents, technologies, and standards (Golichenko, 2011). The flagship firm checks suppliers and often assists them in creating and applying necessary rules.

The captive value-added chains look similar this kind of structure. Here, the hierarchy of subordination is built upon the technological complexity of the product (Gereffi et al., 2005). The complexity "tames" the participants of the production network by the performance of operations within the network of necessary functional components.

New paradigms of the production organization in production organization in value added chains. Last decades even powerful multinational companies were striving to connect their sub-divisions with external networks including firms, universities and institutes involved in the generation, storage, usage and absorption of knowledge (Castellani and Zanfei, 2007).

Standardisation causes the development of fragmentation processes and segmentation of many integrated companies. It is worth noting that fragmentation processes comprise the following vital phenomena:

- The unbundling of the product.
- The disappearance of "focal corporations" and expansion of factoryless producing firms (Bernard and Fort, 2015).
- The separation of different parts of production processes (Arndt and Kierzkowski, 2001).
- The acceleration of product and new technology development.

The non-linear innovation models in open networks replaced the linear models of in-house innovation (Chesbrough, 2003). The extension of open networks had caused technology modularity that means that some technological knowledge acquired the characteristics of standard commodity and production networks had been widely dispersed across firms and national borders. As a result, there was an integration of production, promotion of specialisation within open architecture structures, diminution of companies' core of competence, repudiation of the idea of vertical integration for some value-added chains (Amador and Gabral, 2016).

2.3 Stages of development

Policy areas in the NIS are usually formulated to solve the following tasks: increasing the innovation activity of businesses, expanding the processes of cooperation and knowledge diffusion and, and developing science. The stage-based approach to determining policy directions and measures for carrying out these policies allows the state to promote the process of the co-evolution of the absorption capacities and increase the innovative capacity of enterprises in the national innovation system (Castellacci and Natera, 2013).

At the investment stage, government policy promotes a shift from the mobilisation of primary factors at the preceding, resource stage to a technological leap forward due to a sharp increase in the use and updating of imported technologies as well as the incremental improvement of manufactured products. An essential part of this policy involves implementing economic incentives to improve the absorptive capacity of domestic enterprises by integrating them into the world economy and diffusing global knowledge. High-quality secondary and higher as well as vocational education makes it possible to launch the necessary technological absorption processes. A technological push policy should be generated, particularly, from the outside world.

There is a danger that the country, having coped successfully with the passage of many phases during the investment stage, will become “stuck” on it and will not be able to move to the stage of the country’s innovations. It is therefore essential to create the necessary institutional conditions and resource support during the investment stage for the transition to the next stage, it means that mixed public policy should be

designed and implemented during the investment stage that is aimed not only at completing the phases of the investment stage but also at creating institutions and resources that it can use to complete future stages.

The policy should be aimed at generating a post-imitation model of the NIS that is capable of creating radically new products and processes during the stage that is based on the country's innovations. At this stage, support for private and public investment in human resources in science and technology, as well as the development of a flexible labour market of highly qualified professionals, are the most critical objectives. At this stage, the policy of the technological push that is aimed at the creation of soft technologies and dual-use technologies is continued. The government should design a strategy to support market forces, including incentive schemes that are focused on the end of the innovation cycle. Significant efforts are required to strengthen the cooperative relations of the business and public sectors in R&D and the nonlinear interaction of these sectors, including the development of public-private partnership schemes.

Considerable public and private actions build conditions and provide incentives for joint orientation of government R&D sector and industry. At the stage, the lack of business motivation to search new knowledge sources can be a major obstacle to the cooperation of R&D and business organisation. The individual programs to accelerate technology diffusion in areas of nascent demand could assist in solving problems of increasing technological and organisational capabilities.

3. Main findings

In this part we are going to answer the questions that was put in the introduction

3.1 How to shape and advance innovation modes at investment (catching-up) stage

At the investment stage of development, catching-up countries mainly seek to increase performance and welfare as a result of absorption of technological imported knowledge. At this stage, the participation in the diffusion of innovations guides firms' behaviour. Assimilation and adaptation of these innovations require the actualisation of different types of organisations. The optimal organisation is vertically integrated enterprises for imported technologies diffusion and the introduction of incremental product innovations of foreign technology-based products (Golichenko, 2011).

Also, it must be borne in mind that success of this innovation model in many respects stems from the stable cycle of the interaction between external and domestic markets and incremental innovation improvements of imported technologies. The factors determining the effect of this cycle are the high elasticity of demand and fairly low production cost. They provide effective feedbacks, i.e. the growing demand gives producers incentives to strive for the further reduction of production costs and diminish prices, the latter, in turn, stimulates consumers to increase demand.

It is possible to reduce the production cost at the expense of involving the qualitative but relatively cheap labour. However, the opportunities of involving this domestic resource should be decreasing because of improving economic well-being. At the same time, employing cheaper labour abroad did not always give necessary effect. In these circumstances, the decrease of production costs could be only achieved thanks to the fast absorption and improvements of imported technologies.

The second component of the success is incremental product innovation based on upgrading imported technology. However, it is worth noting that since the domestic demand of developing countries cannot be enough to be the only driving force of the progress (Porter, 1990), the external demand has to make good the lack of this factor.

The product innovation provides an opportunity for a domestic company to sell products that could not be reproduced by its competitors for a while. The simplest way to do it is manufacturing the technologically sophisticated product whose novelty is provided using so-called closed product architecture (OECD, 2005). In this case, a large variety of the product can be provided by a complicated integration procedure based on firm's know-how. The careful technology process validation is necessary. It means that rigid relations (vertically integrated corporations) have to unite participants of the value-added chain. The outlined mechanism of gaining and maintaining competitive advantage was successful in Japan in 1980th (OECD, 2005).

The countries of South-East Asia imitated the Japanese strategy based on costs reduction and incremental product innovations driven by imported technologies. At the investment stage, actions need involving and supporting all available channels of knowledge diffusion to provide the fast growth of absorption capacity of enterprises. The open information channel and that of commercial knowledge transfer are of great importance (Golichenko, 2013). The performance of the third channel is much less significant at this stage of development.

For an adequate performance of the open information channel, it is extremely beneficial to develop the education of secondary and tertiary levels, vocational training, the processes of copying and inverse engineering. As the experience of China shows, the strict government bargaining power may assist to attract foreign investors in intra-firm training even outside of the application area of foreign direct investment (OECD, 2009).

If the diffusion of the knowledge of foreign origins takes place through the commercial knowledge channel, the substantial factors of this process are international trade, foreign direct investment (FDI) and intellectual property rights. FDI may be a key element of economic development on the stage (Guellec and van Pottelsberghe, 2001). However, FDI does not bring the advanced technologies in the absence of the balanced, proactive government policy, even if FDI volume is impressive (OECD, 2009).

South Korea gives us an example of the rational policy aimed at the arrangement of a relationship between domestic industrial modernisation and outside world. In this country, the companies' orientation to the external market was combined with the policy of import substitution. The policy was based on public financial support for the technology catch-up. Exemption from taxation for imported intermediate, long-term fiscal privileges, subsidies for prices of energy, transportation and equipment took place for selected types of economic activity. Besides, rights to intellectual property were strictly observed. Since from the very beginning Korea had refused to use FDI as a factor of technological development (Golub, 2003), it invested in human capital and R&D, that is, the focus was made on creating human resources in science and technology.

Although the technology catch-up processes occurred both in China in the 1960s and 1980s and Korea in the 1990s, nevertheless they had significant differences. China did not wait like Korea for final shaping its technology catch-up processes (OECD, 2008, 2016). The government was introducing the "Market for Technologies" model to build up technological opportunities. Special economic zones with a status close to free trade were created. Chinese firms were motivated to enter markets of developed countries. They were evolving successfully in processes of fragmentation of global value-added chains. However, by the middle of the second half of this century, the Chinese technology miracle became declining. Something similar had happened to Japan in the early 90s of the last century after the explosion of "economic bubbles."

3.2 How to enter world markets at investment (catch-up) stage

The fragmentation processes have become widespread in some industries. An example of such a phenomenon is computer production industry where, in the early 80's, vertically integrated structures were dominated. In the transition to personal computers, a computer from a product of closed architecture turned into a product of open knowledge. It was a result of standardisation of components of computer equipment, modules of computer systems and their interfaces.

The fragmentation created new opportunities for developing countries to take advantage of tapping into new technologies and catching up the latest technological achievements. These opportunities sometimes allow firms of these countries to pass through the multi-stage process of innovative development and reach an innovative maturity creating intra-link and inter-link innovations in global value-added chains. Standardization and modularisation of supplied components virtually weaken the requirements for control and monitoring understanding codified information embedded in the ingredients. As a result, a customer has considerable freedom to choose a supplier, and a company of global production network can participate in a variety of global value-added chains. Under these conditions, a firm of global production networks can choose one of the following types of innovative strategies.

- The support of the previous and the development of new competitive advantages in the link of the GVC.
- The creation of competitive advantages in some new links of former or new individual value chains.

- The development of competitive edges owing to functional innovations in a link or between links or several chains.

In the framework of the first strategy, companies try to reduce the cost of production to support already existing competitive advantages in the link. This purpose can also be achieved by introducing process innovations. The companies might also introduce product innovations to get new competitive advantages in the link on this occasion. The level of technological knowledge modularisation in the relationship guides a necessary degree of innovative novelty.

Following the second type of the strategy, the task is to reach competitive advantages in a new link of the GVC using freedom of interchain expansions. It also means that the company can "jump" to another chain if there is a way to apply its technology or product in a new chain. It is not difficult to do, for example, if the technology or outcome of the company is of generic nature and can be quick enough adapted to the new environment after minor changes.

The third type of the strategy provides competitive advantages due to fictional innovations. Functional innovations can take place in the same individual link or other links of either the former or new chains. The essence of functional innovations lies in substantial expansion, integration or changes of functions of enterprises.

All these three options can be mixed in some proportions depending on the stage of development of competitive edges.

3.3 How to shape and advance innovation modes at the stage based on ingenious or disruptive innovations

There are two trends of great importance in the world economy. The first is the transition of production from mass production to the individualised output of higher quality goods. The second is the shift from the integrated technologies towards technological modules which relationship can be quickly rebuilt to produce a variety of products meeting the individual demand of customers.

At this stage of development, there is the switch of public policy from supporting individual firms and organisations to the development of clusters of interconnected firms and research organisations, i.e. setting up system-integration and network models of continuous innovation. The regulation of cooperative processes takes two dimensions. The first addresses to move away from traditional supply-push policies towards a model based on joint development including public-private partnerships and networks of firms and actors both outside and inside national borders. The second dimension is associated with the market-pull or contractual relationship between public research and demand from the business sector (OECD 2011a).

Channels of commercial knowledge transfer become large-scale and more complicated. The open information channels and channels for the transformation of open knowledge into pre-competitive and competitive one are being intensively developed.

Also, it is worth noting that the essential feature of this stage is the diffusion of radical innovation. As it is known in the literature, problems with diffusion, as a rule, arise for radical or disruptive but not incremental innovations (Edquist, 2006). So that innovations could not be only commercially viable but also might be adopted quickly enough by consumers, public policy has to stimulate demand pull. In the framework of this demand policy, the government should influence innovation through reducing barriers to innovation activity. It ought to facilitate both the origin of new markets and the reconstruction of established markets (OECD, 2011b).

It should be noted that the public policy of technology push has to encourage the firms whose activities are related to high technologies to shaping and extending research knowledge bases. A firm innovating in high-tech fields is usually engaged in internal R&D activity. It forces the firm to form a particular knowledge base that is hard to imitate or replicate by its competitors (Grimpe and Kaiser, 2010).

The uniqueness of this research knowledge base is enhanced by the usage of tacit knowledge of firm's highly skilled personnel. Strengthening the knowledge base is facilitated by the organisational capability and routines of the firm, which allow efficiently managing this base. The specificity and uniqueness of the base and

regulatory capacity are assets of the firms that can shape the foundation of its isolationist barriers protecting from competitors. At the same time, a firm cannot ignore external sources of knowledge in innovation activity (Lavie, 2006).

Therefore, the critical issue of innovative development of the company at this stage is, on the one hand, the creation of conditions for its openness to external new knowledge sources, and, on the other hand, the isolationism and identity provided by its original research knowledge base.

3.4 How to move beyond incremental improvements to creation of highly innovative technologies

For a catching-up country, it is the quickest and easiest way to increase its technological capacity significantly by organising flows of technological knowledge from the outside world. However, as the country's technological capability is being developed, the country's innovation strategy must change. The span of time is needed to transform catch-up innovation modes into ones aiming at disruptive and ingenious innovations.

As a result, the "catch-up" (or almost "caught up") country faces the problem: how to create a post-imitation national innovation system that would give an opportunity for transition to the disruptive and radical innovation-driven stage. The need to address this problem is still relevant both for Japan and South Korea (OECD, 2014, 2015). The capacity of the development model based on the technology catch-up has been exhausted for the former, and it is close to exhaustion for the latter.

In South Korea, awareness of a need for the shift to the new paradigm of economic development mostly based on the creation and dissemination of disruptive and ingenious innovations came in the late 90s of the last century. As a result, the chaebols were seriously restructured and the leading role of the state was significantly reduced in the NIS. Besides, South Korea’s government, improving conditions for innovation, began to pursue pro-competitive policy, and continued to liberalise product market and labour markets. Reasonable efforts were made to develop venture and small business.

In the 1990s, Japan faced a problem: how to design post-catch up national innovation system that would give an opportunity for transition to the radical innovation-driven stage (Goto and Kazuyuki, 2009). At the end of the last century to address the challenge, Japan government decided now to "catch up" not high technology products as it was before but the elements of the U.S. institutional NIS mode. First, the process of "catching up" affected the institutional mechanisms for R&D development, technology transfer from universities to industry, and the cooperation of public research organisations, universities, and industrial enterprises.

How effective were these reforms? On the one hand, they led to tangible results: companies' annual expenditures on R&D increased. During the period of progressive reforms, the universities applications for domestic patents almost reached the level of U.S. universities. The number of academic spin-offs became compared with the U.S. universities' number (Shimoda, 2009). On the other hand, the revenues that Japanese universities had received from licensing were still meagre. Only a few academic start-up firms reached the stage of IPO (Initial Public Offering). In other words, it appeared uneasy to get out of the catching up the trap in which the country felt. It means that during the investment-driven stage, the policy has to facilitate building the resource and institutional foundation of transition to the next stage driven by ingenious and mainly radical innovations.

As for South Korea, it is worth noting that success in country's shift to a new model of development is noticeable. However, the development of a more advanced model of NIS requires an efficient organisation of new fundamental knowledge generation, enhancing processes of its transformation into pre-competitive and competitive one, creating the practical system of technology transfer of commercial knowledge.

Therefore, one needs to recognise that the simple catch up strategy leads eventually to a dead end position at the current level of the market and technology development (Golichenko, 2010). Apparently, during passing the investment (catching-up) stage, the institution and resource base for the transition to the next stage should be brought into being.

4. Conclusion

The economic success of NIS actors is determined mainly by their paradigm. Factors shaping this paradigm are:

- The stage of development through which the country has been moving.
- Channels for the dissemination of knowledge and technology and the effectiveness of their functioning.
- Behaviour models or mode of NIS actors providing success in passage through the stages of country's development.
- Efficient interaction of domestic companies with international markets.
- The ability of NIS actors (including government) to move to the emerging new paradigms corresponding to a higher level of innovation development in time.

While moving through the stage of catching up the known-to-the world market technologies, i.e. the investment stage, the NIS actors are actively using open information channels and channels for commercial knowledge transfer. The channels facilitate diffusion of technological knowledge and other innovative resources from the outside world to the country. At the stage driven by ingenious or disruptive innovations, the operation of knowledge dissemination channels is urgent, but chains for a transformation of open (public) knowledge into pre-competitive and competitive one begin to play a decisive role in the innovative activity.

The success of the NIS at the investment stage is, by and large, determined by the ability of domestic enterprises to establish a cycle of interaction between markets and processes of imitation (catch-up) of technologies. Factors contributing to functioning this mechanism are the high elasticity of demand and relatively low production costs.

The driver of development is external demand and domestic producers' supply to satisfy it. More precisely, the opportunity to offer domestic production in foreign markets gives the basis for competitiveness and economic growth of the country. These opportunities are realized if domestic enterprises can reap the fruits of modern technological and organisational revolution. Besides, the institutions that are traditionally attributed to this stage must be introduced at the investment stage before the beginning of the next step

At the stage based on ingenious and disruptive innovations, domestic companies, developing their absorbing capacity, not only apply and improve known-in the world market technologies but also create radical new ones. Two significant trends of production system dynamics are being used here. The first is the transition from mass products to higher-quality goods designed for an individual customer, and the second is progress in the modularity of technology and organisation.

Innovating in the Fashion Industry for a More Sustainable Production and Consumption

Abstract: The fashion industry is nowadays characterized by an accelerated rhythm of production and high materialism, which stimulates consumer needs, clearly creating excessive consumption. Textile products, or clothes, tend to have a very short life span, which leads to a lot of waste along different dimensions. For this reason, it is necessary to innovate and question the way we think about fashion. The main objective of this study was to understand how the fashion industry might be restructured so as to guarantee production and consumption patterns which would not have such a negative environmental impact. To this end, the current characteristics of the textile and clothing industry were analysed together with the content of the selected YouTube channels focused on the slow fashion concept. The proposed solutions seem relevant for the environment, promoting recycling and the reuse of items, as well as affecting transport and the education of the consumer. Factories to transform clothing for reutilization need to be built, more shops selling second-hand clothing need to be opened, and packaging needs to be more ecological. Consumers need to be geared towards using second-hand clothes and need more education and awareness in this direction. Slow fashion is a new concept, which we would like to see introduced as opposed to fast fashion proving that it is possible to innovate in our production and consumption patterns, while aiming for profit in a more balanced way and while respecting employees, society and the environment. Slow fashion emphasizes quality and not quantity, while also slowing down production and purchasing habits.

Keywords: Fashion, environment, scarce resources, responsible behaviour.

1. Introduction

According to the World Commission on Environment and Development (1987, p. 37), sustainable development "seeks to meet the needs and aspirations of the present without compromising the ability to meet those of the future". It represents a long-term approach which has as its objective to develop and achieve a healthy community through a joint effort concerning economic problems, as well as social and environmental issues.

The way we interpret development and how we act about it as a society has real consequences. This responsibility falls on everyone individually because the survival of humankind depends on choices we make and on the balance between individual needs and the needs of the surrounding environment. This is why our decisions and actions, as individuals, organizations and as communities are vital to make a difference we all need so much.

The current fashion industry is characterized by the fast pace of subcontracted production, by materialism and by the endless number of trends. This panorama, together with marketing communications, continuously stimulates consumer needs, creating a clearly excessive consumption.

Today, environmental and social concerns are increasingly perceptible. The question of sustainability has gained relevance within corporate cultures and the mind of the consumer and the current patterns of production and consumption are being increasingly questioned.

During the last decades, there has been a substantial growth in the number of successfully implemented instruments, agreements and treaties related to sustainability. New measures are related to climate change, biodiversity, agriculture, poverty, trade, investments, among others. The Objectives of Sustainable Development (OSD) are, precisely, one of such instruments and consist of a set of 17 objectives that imply a vast range of development problems that guide national policies in international cooperation activities.

The focus on the achievement of sustainable development objectives is clearly an opportunity for innovation and the creation of new markets. It is also a possible source of competitive advantage for companies that could benefit from partnerships or even a positioning marked by the use of OSD as an "anchor" of the brand and as a means of creating brand equity. For this reason, companies should not look at OSD as a barrier to their activity, but rather as a part of their identity and their relationship with the environment and the consumer.

2. Background of the study

Sustainable fashion, or slow fashion, is an alternative to today's clothing production and consumption patterns, proving that it is possible to implement a different system in which profit making is balanced with respect for workers, society and the environment.

Unlike fast fashion, which speeds up manufacturing process and shortens the lifespan of clothing items, this logic places an emphasis on quality rather than on quantity, calling for greater environmental and societal awareness and a reduced pace of production and purchase. Slow fashion is essentially the creation of clothing that promotes ecological integrity, social quality and an emotional connection through products, practices employed and relationships created (Fletcher, 2012a).

Sustainable fashion can therefore be seen as an ideology or a way of thinking about the world which, when applied through a designer, a choice of the consumer or a particular method of production, can have a very positive impact on the lives of employees, consumers, society and the environment.

3. Methodology

Mindful of the importance of a sustainable and conscious approach to clothing production and consumption as well as of a growing public awareness in this matter, we have opted to focus our research on the Objective of Sustainable Development no. 12, which consists in promoting the guarantee of sustainable production and consumption patterns.

The analysis of this OSD was made through the association with the textile and clothing industries, whose current patterns of production and consumption are largely incompatible with sustainable development. We combined this analysis with a review of consumer interests and perceptions in order to get a more comprehensive view. We searched the social network YouTube, which belongs to Google, with the keywords “slow fashion” and “sustainable fashion”. In the channels identified with the most subscribers, we reviewed the content. We limited the search to the users who used the topic of slow fashion as one of the main or recurring themes of the channel. For the remaining users, we analysed the content by randomly selecting seven videos from their channels.

4. Results

Some of the measures can be of special interest when dealing with the promotion of sustainability in the textile and clothing industries. They are presented below. These measures are organized according to the garment life cycle. In order to indicate concrete solutions, we have chosen to focus on a company that operates in the area of textile management and recycling, the organisation H Sarah Trading.

5. A proposal of measures to create sustainable production and consumption patterns in the fashion industry

At the global level, we risk exceeding the limit of resources that the Earth can provide us, as well as the limit of garbage and pollution that it can bear. Thus, one of our options for continued economic growth will be to shift our current production and consumption patterns, based on a linear system of extraction, production, consumption and waste, to a circular system that mimics the natural processes in which there is no waste but which can use the outputs in other processes. This model of sustainable development means that the resources we extract and produce are kept in circulation through reuse, recovery and recycling. In this way, economic growth is separated from the consumption of new resources, ensuring greater efficiency in the utilization of resources already existing in the production process.

At the level of the textile and clothing industries, this translates into the implementation of a circular life cycle of the product, which is constituted by six essential phases, as shown in Figure 1.

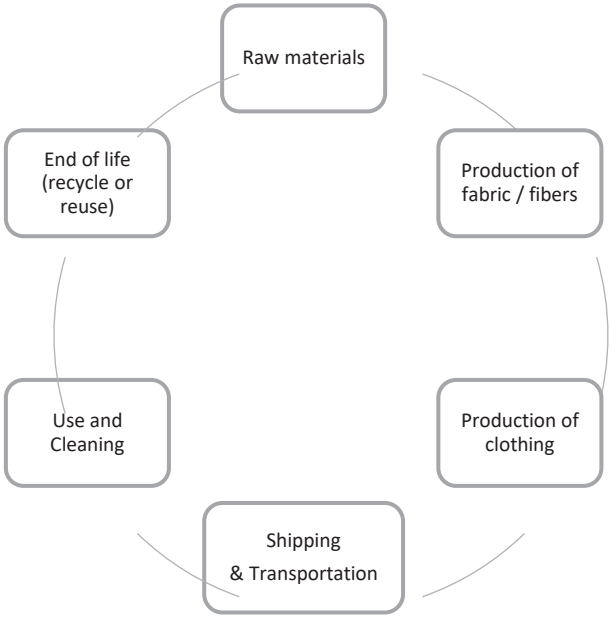

Figure 1: Circular product lifecycle (based on Wallender, 2011)

The understanding of these phases is important for the implementation of solutions since in order to cement sustainability in the fashion industry, all the activities involved in the design and use of a garment must be taken into account, from the manufacturing of the materials until the consumer discards them. In this way, solutions can be implemented at both the production and the consumer level.

6. Solutions at the production level

One might ask the following question: How can the business sector contribute to slow down the fashion industry?

- One possible alternative to implement in the fashion industry would be the training of designers in methods such as "zero waste". This method may consist of the elimination (during the cutting of the fabric) of the spaces between the various parts that make up the garment, in order to create a situation of patterns that "fit" together; or in the addition of scraps of fabric to the clothing in a creative way. All this in order to get the most out of the fabric used and to reduce the amount of material wasted.
  Design plays a very important role since it has an impact in all phases of the process: from the transformation of the raw material to the end of life of the garment. Therefore, the products must be designed in such a way that their recycling is possible. Thus, with a better use of materials, companies could not only reduce costs but also benefit the environment.
- Another alternative is the creation of more versatile garments, that is, pieces that can be used in different ways and that allow the hypothesis of updating and adaptation as new trends emerge. In turn, this update of clothing items involves the implementation of sewing workshops in stores (such as Mango, Zara, among others), so that customers can change, as they wish, the pieces of clothing purchased, by way of the good state of conservation of the these garments and the payment of a certain amount. The process of altering the clothes can be done by the customers themselves (who already know the art of sewing or who want to venture into it) or can be made by small factories with artisans (for those who prefer to see the process to be executed by other hands). This possibility of the customization of clothing would give customers the opportunity to closely monitor the entire customization process, generating a greater emotional attachment on their part, to their clothes. This will, consequently, stimulate greater care with the clothes that these individuals own.
- In order to ensure decent work processes, companies could highlight on the clothing labels all the countries through which the item went, giving more transparency to the production process. In addition, they could seek to associate themselves with Fairtrade certification and labeling organizations.

7. Solutions at the transportation level

Companies in the textile and fashion industry should take into account the ecological footprint that they leave, as regards the question of how the distribution of their products is achieved. Sustainable distribution should have the least possible impact on the ecological and social environments.

- To move products to their destinations with the least possible environmental impact and at the lowest cost, companies can use two solutions: (1) the optimization of the materials used in the production of transport packaging and (2) the way products are loaded onto the trucks.
  Eco-friendly and sustainable packaging is made from recycled materials, reducing the waste of resources during production. Given that millions of tons of packaging are used annually, the weight of packaging is a factor that can also make distribution and transportation more efficient (Richtel, 2016). Thus, reducing the weight of the individual packages by a few grams can easily add up to a large reduction in the total weight of packages used. On the other hand, the way the product is packed can also bring benefits: by using packaging of an adequate size for the product, it is possible to save space and costs in the shipping process. Right-sized packaging ensures that the product is packed safely, minimizing the need for fills (e.g., styrofoam). These distribution solutions reduce carbon emissions and the impact of waste on landfills.
- This eco-packaging policy can also be applied to delivery straight to the consumer. If the packaging in which the customer receives his or her order is duly identified and promoted as being environmentally friendly, the company can demonstrate its contribution to the preservation of the planet and of its natural resources. Firms will in this way convey an image of concern about sustainability and about social responsibility.
- The use of hangers made from recycled materials in stores is also a small step towards sustainability.

8. Solutions at the reuse and recycling level

In the circular cycle of clothing, recycling and reuse companies play a very important role. The entity we used in this research, H Sarah Trading, is engaged in textile transformation and in the re-routing of clothes (new or second hand), in order to avoid that its destination is the landfill. At H Sarah Trading, after clothes are collected, they undergo an exhaustive process of selection and packaging, followed by the routing to different destinations, depending on the state of conservation in which the materials are found. They can go to institutions/charity stores, if they are in good condition; they can be recycled and give rise to new products when they are no longer in a condition to be used again; they can also be exported, since in Portugal there are no companies specialized in the processing of used clothes (H Sarah Trading, 2017). As such, these must necessarily be routed to countries such as India and Pakistan, among others.

After the analysis, we would suggest:

- The construction, in this specific case, of a textile processing plant that would be used to complement this entire cycle of recycling and reuse, eliminating the need to export and allowing some materials such as cotton and linen to be recycled.
  In addition to reducing the amount of waste, a factory of this kind would also boost the local economy by creating jobs and increasing local empowerment.
  The plant could also attract potential partnerships with larger companies for waste management.
- The creation of partnerships is a way that could allow H Sarah Trading to collect goods that, from the perspective of the donor textile company, may be damaged or not in a condition to be sold, but are still good enough to be reused or recycled.
- Another measure that the company could apply could be to invest in collection campaigns in the community where it is located. In this way, it would promote social awareness and drive attention for the company's mission. This measure could be implemented by conducting campaigns at the local level in schools, universities, companies and even in public well-selected places, through the distribution of flyers, holding lectures and allocating specific containers for the collection of garments in strategic locations. The campaign could then be replicated in other cities and regions of the country, contributing to building sustainable fashion awareness. H Sarah Trading could also consider distributing their containers throughout the country.

- Finally, H Sarah Trading could also consider creating second-hand clothing stores. With the clothes collected through their campaigns and collection containers, the company could use the items in good condition for sale, at low cost, in second-hand stores. In addition, it could use articles from partnerships with the textile companies referred to above which are not in a condition to be sold from the perspective of those companies but which are nonetheless available for sale in these second-hand clothing stores.
  Selling second hand clothes gives them a new life and to people who buy them a good purchasing opportunity. People visiting second-hand stores are perceived by some as being in impoverished circumstances, but this is not necessarily the case. A part of second-hand customers seek good quality garments at a reasonable price or look for unusual pieces not replaceable by high-street stores.
  Second-hand activity discussed herein would be complementary, generating an extra profit. The success of Goodwill, the American company, could be used as an example and as an inspiration.
  Currently, the main focus of sustainable fashion is to reduce the impact of products by improving manufacturing processes and by increasing the recycling of fibers and textiles. However, the consumption of clothing by the customer is the essential part of the problem and both should be approached simultaneously.

9. Fashion consumers and slow fashion trends – A look at YouTube channels

As a result of the defined criteria, we reviewed 13 YouTube channels specifically interested in slow fashion, a concept which is gaining popularity. We randomly selected seven videos from each of the channels and analyzed their content. YouTube is an online platform on which content can be voted and on which authors may receive feedback about the interest their video has caused. This evaluation may possibly influence future decisions about the content of the channel. Viewers can also subscribe to the channel they like in order to not miss future videos. The initial screening and the selection of channels with a substantial number of subscribers makes us believe that the analysed content is a good representation of the interest of our research. We have classified the content in three categories:

- Fabric. Fabric composition, characteristics and care recommendations. Advantages and disadvantages of specific types of fabric. Quality of fabric. Quality versus price.
  We have found videos explaining the basic types of fabric and the differences between them. Natural and artificial fibres have different characteristics, which should be considered when choosing a garment. Natural fibres allow the skin to breathe. On the other hand, artificial fibres get dry quickly and are recommended for sports clothing.
  The obvious question is how much (more) a natural fibre is worth (and whether it is as discussed in some videos), and up to what extent we should be driven by quality. Users seem to enjoy the content where the YouTuber explains their reasoning when making a decision regarding the use of some fabrics (frequently dropping the use of artificial fibres). Videos showing how to recognize poor and good quality in clothes and how to dress well on a budget are also sought out.
- Garments and brands. Product reviews, product recommendations and product seeking. Brand reviews. Brand recommendations.
  Users enjoy watching product or brand reviews. Such reviews, especially when made by trusted (i.e., with ethical spirit, well-selected cooperation criteria and subscribed by several users) YouTubers, can be used as part of their successful business activity. It is important that the review goes in line with the channel idea and includes a personal (and honest) opinion. In this category, we have also found several videos with a list of essential pieces in the (small) wardrobe.
- Dealing with excess. Thoughts and considerations. Seeking opinions.
  There is a clear interest in videos suggesting how to style a different piece of garment in several ways ("how to re-wear…"; "x ways to style…") and on how to maximize the garments already in the closet (a "capsule wardrobe" concept). The art of combining a few pieces of clothing has quite recently turned into an interesting business opportunity. There has been a rise in the offering of online courses on how to build a functional wardrobe and on how to avoid excessive, compulsive purchases.
- Another group of videos focuses specifically on how to deal with the excess of clothing that we already have and that we do not use (but that we sometimes have difficulties in letting go of). We have also found videos on how to shop in the slow spirit, with packing and travelling tips.

There are also ethical reasons behind buying less. Users were interested in how to combine fashion trends and ethics, where to find ethical fashion brands, and which brands actually follow the ethical trade or the fairtrade movements.

10. Solutions at the consumer level

The consumer is constantly led to believe that he or she has to consume at a rapid pace. However, as concerns being responsible for the planet, we need to start feeling the power we posses as consumers. Consumer power is revealed when making decisions to buy (or not) from a certain brand, at a certain moment, or in a certain quantity. For this reason, to change the current system we can adopt behaviors as simple as questioning how the products we consume are made, what the impact of the production process is, how the way we eat is influenced by external factors or how material values influence our personal values and the relationships we maintain with what surrounds us. However, these seemingly simple behaviors are not obvious to most people, and many of them remain unfamiliar with the problems of the fashion industry. Thus, the first step to change is education.

- One way to educate the consumer about fast fashion practices and sustainable alternatives is storytelling, which is a marketing tool that combines audio-visual resources with words for compelling "storytelling". This tool is a powerful means through which companies can convey their personality in a memorable way, as well as other relevant information or even ideologies about the complex world in which we live.
  Narratives about the history of clothing can be communicated by introducing people and processes behind design, production or even recycling and reuse. Thus, through a holistic approach to the life cycle of clothing, the narrative contains greater transparency and greater communicative power. This, in turn, increases the capacity to educate the consumer and allows for the creation of a connection through the communication of the value of the product and the production processes involved in its creation.
  Being able to identify with company values encourages customer engagement with transmitted ideologies such as sustainable fashion. That is why storytelling is an effective way to encourage commitment in terms of conscious and responsible fashion consumption. Numerous studies over the years have proven that our brains are much more involved and attracted by stories than by facts. According to Gillett (2014), "when we read a story, not only are the parts of language lit up in our brain, but also any other part of the brain that we would use if we were to actually experience what we are reading".
- There are other ideas for stories such as using the voice and input of users/consumers or to communicate values such as resistance, diversity and quality in order to inspire people to connect with communities, with their personal identity or with nature.

11. Discussion

Nowadays, we live in a society of disposable clothing that remains less and less time in the closet. We buy more clothes than ever and use more synthetic fibres. Ready-to-wear collections are made quickly, in a standardized and economically feasible way, often using subcontracted production, so that consumers can constantly acquire the latest trends at a remarkably low price. This system has perpetrated irreparable damage to communities and to the ecosystem, undermining the foundations of life on Earth.

Some of the consequences include the exploitation of subcontracted workers, considerable environmental impact and the distortion of the consumers' perspective and their sense of value given to clothing.

Generally, getting new trends to the shops so quickly and at such a low price is only possible through subcontracting to countries with extremely cheap labor. Therefore, if a company is not satisfied with the pace of production, it can easily find a replacement who will do it faster instead of improving the relationship with the employee. In addition, many of these factories put production requirements above worker safety, resulting in disasters such as the collapse of the Rana Plaza building, in 2013, which resulted in the death of about 1,200 workers (Kasperkevic, 2016). That specific factory produced garments for brands such as H&M, Mango, Primark and GAP.

In terms of environmental impact, the problem lies not only in the production of clothing but also in the actions of the consumer and the waste generated. In manufacturing, a part needs to be spun, woven, cleaned, bleached, dyed, printed, cut and sewn. Thousands of litres of water, pollutant chemicals, and dozens of pesticides are used in the cultivation of materials such as cotton and a large amount of energy (such as transport), which results in the emission of CO2, is also used. Regarding consumption, data from the Portuguese Environment Agency indicates that 5% of 4,607 tons of urban solid waste is composed of garments or household linen that end up in a landfill or are incinerated (Tomás, 2016). Even the clothes that are donated often end up in the trash, due to the poor quality of the items, which cannot be reused. As if that were not enough, the fact that these parts are made of cheap materials and petroleum-based fibres, which do not decompose easily (such as polyester and nylon), means that it takes years for them to degrade, increasing pollution.

Part of the reason we throw so much clothing away is that we no longer bother with repairing the pieces. If clothing looks cheap and disposable, we treat it this way. According to Fletcher (2012b), the most problematic feature of fast fashion is, most probably, the consumerist mentality that it promotes. Based on a marketing communication mindset for the spreading of dominant forms of thinking about image, language and products, fast fashion limits our ideas about what fashion can be and normalizes low quality and the short durability of pieces. That is, it is a system that creates its very own conditions for survival.

For this multitude of complex problems there seems to be a multitude of solutions that seek to balance profit with other economic, social and environmental aspects of sustainability in companies. It is our individual choice to make a change in what are at times complex, societal structures we are a part of.

12. Conclusions

With this study we have aimed to understand how companies and consumers can contribute to the promotion of sustainable production and consumption standards in the textile industry and linked to fashion. We have suggested a number of solutions in the context of sustainable fashion with which it may be possible to achieve benefits, both at the community and at the environmental levels. The adoption of these measures is not only desirable but essential to determine the long-term success of sustainability policies.

Figure 2 summarizes our proposals – at the production level, at the reuse and recycling level, at the consumer education level, and at the transportation level. We propose a change of culture in the sector, acting on both production and consumption dimensions. Changing the culture in the entire industry is only possible if there is communication and the need for such a change is seen to exist. To this end, the government as well as relevant sectoral companies can make their contribution. Investing in responsible actions brings great benefits, including a better relationship with the consumer and greater resistance to international crises, which will far outweigh the costs involved. There will always be those who want to wear new clothes, so there is no risk to the sector in this respect. However, slow fashion promotes the reconsidering of purchasing habits and the slowing down of the pace of production. It emphasizes quality and not quantity, and a better use of resources along the value chain, and encourages a greater societal awareness. In the very near future the most successful companies will be those that have been able to adapt to new business models and pursue innovation while respecting societal well-being and the environment.

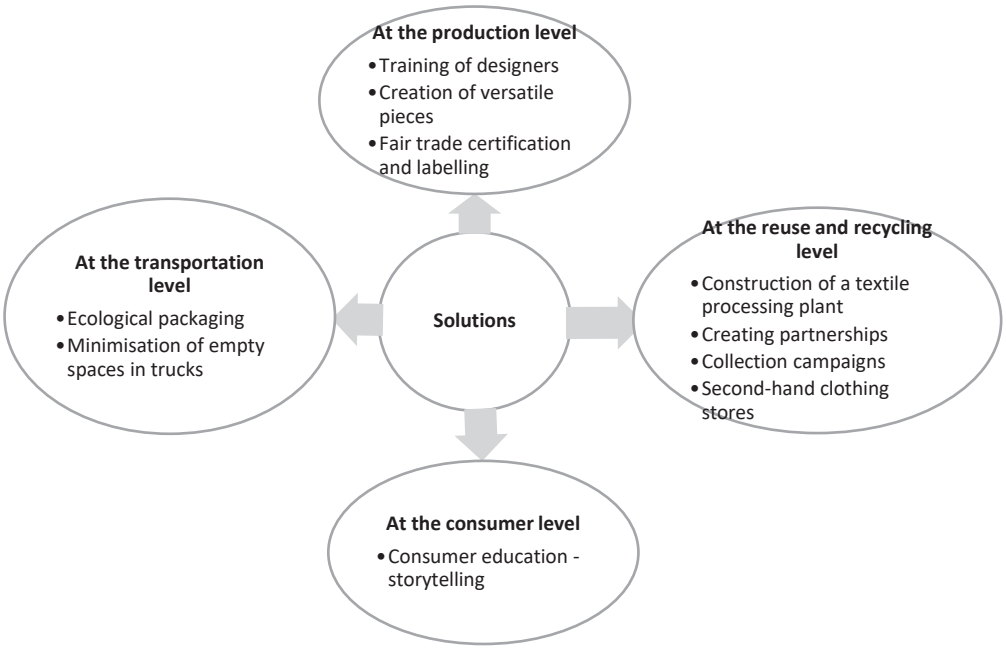

Figure 2: A summary of the proposals of the study

Teamwork and Innovation: The Moderating Role of Reward in the Fashion Industry

Theresia Gunawan and Sesilia Dyah Ayu Saraswati
Parahyangan Catholic University, Bandung, Indonesia
Theresia@unpar.ac.id
Sesiliadyh@gmail.com

Abstract: One of the industries that is quite vulnerable to the changes of consumer demand is fashion industry. In the fashion industry, the life cycle of a product is short, and differentiation advantages are built on brand image and product style, which can be imitated immediately. The importance of innovation for small and large firms in the developed and developing countries has provoked an immense interest of social scientists and practitioners to scrutinize this topic from many perspectives. In this study, we suggest that to propel innovation in the fashion industry, instead of individual work, teamwork is an ideal frame to foster the successful of new products development. Previous study stated that teamwork is essential to sustain the realization of the new product since it involves many areas of section. Thus, in this study, we try to explore to which extend teamwork may augment innovation in SMEs fashion industry in Indonesia. Moreover, even though a fashion industry is a business driven by art and passion, we also argue that reward is an essential factor for driving innovation. Hence, we also explore to which extend reward may strengthen the relationship between teamwork and innovation. According to the authors knowledge, despite a few of literature studies about teamwork and reward to innovation, but the teamwork and reward have been analyzed separately. Since all the team can get reward from the success of innovation, and it gives them more motivation to innovate, thus we proposed that reward could strengthen the impact of teamwork to innovation. Using ordinary least squares (OLS)- regression analyses, 50 designers from SMEs in distro- fashion district in Bandung - Indonesia were asked to complete the questionnaires. The result shows the impact of teamwork on innovation is moderated by reward, but in a negative way and the result has advanced the prior studies on innovation.

Keywords: innovation, teamwork, reward, SMEs and fashion industry

1. Introduction

Bandung is one of cities in West Java that the creativity of human resources is still recognized at national level.

In addition to title as a city with high creativity and innovation, Bandung is also famous of its fashion, art, culinary and beauty. The high population growth in Indonesia also implicates on the need of clothing products.

This condition opens an opportunity for the clothing manufacturers and fashion business to develop in Indonesia including Bandung, one of the cities in Indonesia that is potential for the profitable clothing industry.

The emergence of shopping places in Bandung has made this city increasingly potential as fashion shopping destination for tourists.

Due to the rapid growth of fashion industry in Bandung, many of the business actors are deliberately choosing business of Factory Outlet (FO), Clothing Company (CC) or Distro (Distribution Store) to earn monthly high profit. Along with the increasing number of distro established in Bandung, the competition has been raising among them. Companies should make strategy in marketing products to maintain its existence in fashion business. While implementing its strategy, a company as an organization will sometimes have to deal with changes. The dynamic of demands, trends and consumer's taste leads to a situation where a company should be adaptable, creative and innovative. The similar thing happens to distro, this fashion business is also demanded to provide products as attractive and unique as possible. Product innovation is required not merely to create new product, but also to discover new market opportunity, as well as creativity to connect existing business networks. However, further research is required to find out the driving factors of innovation (Menon, et al., 1999).

In the research, they suggest further exploration related to variables considered capable to support innovation such as the delivery of reward and teamwork. Teamwork is a collaboration of several people in a form of group work. Former studies highlighted the imperative role of teamwork to elevate the innovation of product.

Teamwork is required to support the success of the new product, and it involves many areas of department (Macchion, et al., 2017). Although there are many studies researching teamwork but only a few relate the teamwork with innovation (Naveh & Erez, 2004). Teamwork can affect an organization's achievement, and teamwork is believed to be one of variables that can influence innovation (Fay, et al., 2014). A team can be solid if the members are willing to share, provide constructive response, support and appreciate desire and success of each team members.

Rewards given to individuals or teamwork lead to satisfaction therefore will motivate a team to be more innovative in generating creative ideas. It will affect the productivity, and encourage each individual and team to be more responsible and innovative (Amabile & Pratt, 2016).

Despite the relevance of their contribution to innovation, but the possible links between the teamwork and reward have not been analyzed. In this study, we argue that if the team member could get reward from the successful of a new innovative product, and it will motivate them to be more innovative, thus we proposed that reward could strengthen the impact of teamwork to innovation. Referring to the explanation, arising an interest to conduct further research on the impact innovation; we want to figure out how reward can affect as moderation of relationship between teamwork and innovation. We hope this study may contribute to the existing of innovation studies.

2. Theoretical Background and Hypothesis

2.1 Innovation

Innovation has wider meaning than simply findings. Innovation is a process to transform creative ideas into products, services or operation methods. Innovation can also be interpreted as each brand new idea or concept that has never been exist or issued beforehand. An innovation usually consists of new breakthrough based on a particular research of the innovator (the person who creates an innovation). Innovation is commonly made on purpose by the innovator through various actions or planned research. It can be concluded that innovation is a creative process of new invention that is different to the existing ones. Being innovative for an entrepreneur is a process to transform an opportunity into concept and ideas that can be sold (Gunawan, Jacob and Duysters 2016). A change of view and behavior in society is generally an aspect that influences buying pattern and behavior. Therefore, innovation should always close to market, direct to market and be market-driven.

Innovation consists of three types according to (Kuratko & Richard M., 1995) namely 1. Discovery; 2. Development; 3. Duplication; and 4. Synthetic. The explanation is as following: 1) Discovery, creation of new product, service or process which has never been done beforehand, this concept tends to called revolutionary.

2) Development; is a development of existing product, service or process. This concept applied as idea to develop existing things. 3) Duplication, is imitating existing product, service or process. However, duplication is not only imitating but also adds creative touch to enhance previous concept therefore the new one has more capability to win the competition. 4) Synthetic, is the combination of existing concepts and factors to become a new formula. This process includes collecting a number of existing ideas or products to be molded into product that can be applied in new way.

According to Osajolo (2008) there are three types of innovation as follows: 1) Product innovation, which is often perceived as the most visible innovation to increase revenue. According to (Gunawan, et al., 2016) product innovation is defined as a product changes in material, fitur and design, but the changes is size and color is not considered as representation of innovation. 2) Process innovation is an innovation to provide facility to maintain and improve quality and to cut cost. 3) Market innovation is an innovation regarding to improvement of market target by serving mix target market. Innovation is essential for business actors to change market and existing "rule of the game". Business people can create new product types that are beneficial for market therefore consumers have a wide range of choice. Innovation is also important for companies to survive in dealing with technological development and dynamic consumer demands. If the company cannot keep up with the changes, the company sustainability will gradually weaken (Gunawan, et al., 2016).

2.2 Reward

Reward or recognition which is given to individual as well as team work can provide satisfaction to the individual or team work (Sarin & Mahajan, 2001). Such satisfaction can motivate them to be more innovative and to generate more creative ideas. It can also affect their productivity, spur each individual and team work to be more responsible and encourage themselves to take risks. According to (Hariandja, 2002), compensation is an overall remuneration accepted by employees as a result of work execution at an organization in form of money or others which can be in form of salaries, wages, bonuses, incentives, and other benefits such as medical benefit, holiday allowance, meal allowance, leave pay, etc.

When employees join a company or organization, indirectly appear various expectation that their needs can be fulfilled by the company. Usually, as reward of their contribution in achieving some corporate goals, the company will give material or immaterial rewards. In addition to remuneration, reward is also expected to encourage employees for higher achievement. Rewards can also be utilized as event to spread information; it can also draw personnel's attention and deliver information or remind them about the importance of something rewarded compared to others. As trainings that can motivate, rewards can also increase motivation among company personnels with performance measures, therefore it can help them in deciding how they allocate their time and efforts.

Rewards can be categorized into two categories, namely: intrinsic reward involves self-satisfaction received by someone whose work has successfully been completed and reached particular goals. In order to improve intrinsic reward, management can use various techniques such as augment responsibility, participation in decision making, and other efforts in order to enhance self-respect and encourage someone to be the best. While extrinsic reward consists of compensation given to personnel, either direct, indirect or non-monetary compensation. Direct compensation is a direct payment such as salaries or basic wages, over time or holiday honorarium, profit sharing, and other bonuses based on personnel's performance. Indirect reward is all payments for the personnel's welfare such as accident insurance, pension insurance, travel honorarium, medical benefit. Non-monetary reward can be an extra given by a company to its personnel such as working space with exceptional location and facilities, special parking space, and distinctive title. Forms of rewards or recognitions given to employees of a company are: Praise, Facility, Bonus, and Salary Increase (Mulyadi & Setiawan, 2001).

Creative behavior of an organization can be motivated by one of inputs in working environment that is reward (Amabile, 1997). Reward can be utilized as media to control, manage, and improve individual performance or team work. The policy in giving reward can support innovation in an organization. According to Bock and Young (2002) extrinsic reward that is believed capable to increase employee's motivation is reward in the form of money, career promotion, and educational opportunity. In their research, Sarin and Maharajan (2001) explain that reward is believed to have a positive impact towards new product developments. Base on previous illustration, a hypothesis drawn is:

H1 : Delivering rewards to employees has positive impact on innovation.

2.3 Teamwork

Mulyadi and Setiawan (2001) state that a teamwork is a group of people based on their complementary expertise, work together to achieve a common goal together. Teamwork creativity will affect the organization.

In their research, Woodman et al. (1993) state that composition of a team, characteristic, and processing factors in that team has a relationship on creative result in a teamwork. A teamwork can support innovation through distinct and background differences among the team members, shared openness to ideas, develop challenges of ideas, and share commitment to projects (Amabile, 1996). Teamwork performance can be measured by the existence of expertise diversity in the teamwork where each member can communicate well, open to new ideas from its members, develop challenges to each work, trust and help each other and have engagement in progress work. Former studies highlighted the essential role of teamwork to elevate the innovation of product. Teamwork is required to support the success of a new product, and it involves many areas of department (Macchion, et al., 2017).

According to Robbins (2013), there are three types of teamwork, namely: 1. Problem solving team; 2. Self-managed team; and 3. Cross functional team. The following is the explanation: (1) Problem-solving team is a

team that is formed to overcome various problems arisen in an effort to improve productivity. Basically, this team activity is identifying various problems, discuss how to solve the problem and take corrective action. (2) Self-managed team is a team intended to improve productivity by giving authority to a group to manage their work such as scheduling work, determining work method, supervising members, giving reward and punishment for its members and recruiting. The member of this group usually derived from one department of the same task. (3) Cross functional team is a team aimed at completing specific task, such as developing new product or planning. Members of this team derived from various departments that have different expertise and orientation who work together to achieve one goal.

Cooperation in a team is one of the characteristics of a high performance company. Teamwork is one of the backbones in an organization, because the team can move faster and be more innovative in overcoming problems faced by the company compared to what an individual can do. Based on the previous studies, a hypothesis purposed in this study is:

H2 : Teamwork in a company contributes positive impact on innovation

2.4 Reward and Teamwork in an effort to improve innovation

Rewards policy is believed to be able to motivate creative behavior in an organization (Amabile & Pratt, 2016). Dreher dan Daugherty (2001) in their book stated that reward is one way to encourage organization members to achieve more creative works. On the other side, teamwork allows a company to be more agile, flexible and responsive in dealing with challenges or problems and competition. In addition, many managers assume that team can cut off company bureaucratic line and develop new ideas more smoothly (Wei & Atuahene-Gima, 2009).

If a company recognizes the important of teamwork and give more reward to their efforts to innovative, they will be more innovative to create a new product. Therefore, we see that teamwork supported by reward can accelerate company innovation. In our point of view, reward will encourage teamwork to reach higher achievement and to take risks thus innovation will also improve. This explanation leads to the next hypothesis:

H3: Reward moderates the influence of teamwork on innovation.

3. Research method

Type of this research is quantitative method using OSL (Ordinary Least Square), to see the causal relationship of variables on research object. In this study, product innovation is the dependent variable; the independent variable is teamwork and reward as the moderating variable. Data were collected using questionnaire distributed to 50 employees at 20 distro outlets in Administrative Village Citarum Bandung Wetan. Samples were chosen using purposive sampling technique. All tests and analysis are processed using software IBM SPSS version 23.

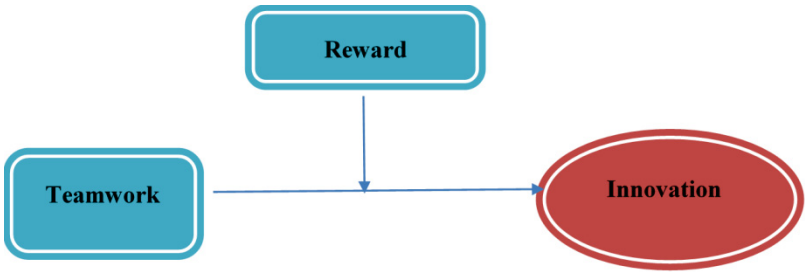

Figure 3.1: The Moderating Role of Reward

Reward is overall remuneration received by employees as result of performance in organization. Reward can take form of money such as salary, wage, bonus, incentive, benefits and other forms (Hariandja, 2002). Reward is measured using dimension: salary increases, bonuses, praises, promotion, facilities provision commensurate with the employee's hard work and loyalty. Teamwork exists through distinctions or background differences of team members, shared openness to ideas, build challenges to ideas, and sharing commitment to projects (Amabile, 1996). Teamwork is measured by sharing new ideas, teamwork makes less heavy job and teamwork leads to help and trust each other. Product innovation is change in a product: material, fitur and design,

however the size and color is not considered as representative of innovation (Gunawan, Jacob, & Duysters, 2016). Innovation is measured by how the company is known as innovative, number of new products annually and how the new product can be differed to its competitors. For the quantitative process, the responses are scored ordinally from highly agree, agree, less agree, not agree to highly not agree.

4. Result and Analysis

Data analysis technique used is Ordinary Least Square (OLS) linear regression. Before the regression, the data were firstly tested for their normality using Kolmogorov-Smirnov Test and value resulted is 0.20, higher than 0.05 therefore it can be concluded that the data were normally distributed.

Validity test method used in this research is Pearson Product Moment correlation analysis. A statement is considered valid if r-count value>r-table value. Invalid statement has to be excluded from the questionnaire or replaced with another question. The result show that all statements of variables innovation, reward and teamwork have r-count higher than r-table (0,2353) therefore all statements used in this research are valid.

Questionnaire's reliability is tested using Cronbach's Alpha where the instrument is considered reliable if the value is 0.600. The test shows that the value is higher than 0.60

The result shows that Reward and Teamwork has strong relationship to innovation. The following table illustrates correlation of teamwork on innovation is 0.376 while on reward is 0.096. Reward has correlation on innovation at 0.416. Therefore, it can be considered that the relationship of dependent and independent variables are fairly strong.

Table 4.1: Correlations of Innovation, Reward and Teamwork

Correlations

		Innovation	Reward	Teamwork
Innovation	Pearson Correlation	1	.416**	.376**
	Sig. (2-tailed)		.003	.007
	N	50	50	50
Reward	Pearson Correlation	.416**	1	.096
	Sig. (2-tailed)	.003		.509
	N	50	50	50
Teamwork	Pearson Correlation	.376**	.096	1
	Sig. (2-tailed)	.007	.509	
	N	50	50	50

**. Correlation is significant at the 0.01 level (2-tailed)

Precondition of regression model is the absence of multicolinearity. In multicolinearity, the decision is taken using two ways (Barrow, 2009): if tolerance value approaches 1 and Value of Inflation Factor (VIF) at regression model is lower than 3.00, the model is free from multicolinearity. The test shows that tolerance value is close to 1 and VIF is lower than 3.

Table 3.2 shows that teamwork has positive and significant effect on innovation (β=0.34, $p<0.01$). In addition, the coefficient table shows that reward has positive impact on innovation with significant value at (β=0.38, $p<0.01$)

Table 4.2: Regression Test of Teamwork and Reward on Inovasi

Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	4.329	1.920		2.255	.029
	Teamwork	.307	.112	.340	2.746	.009
	Reward	.175	.056	.384	3.104	.003

a. Dependent Variable: inovatif

Table 4.3: Regression Test of Reward on Inovasi

Hypotheses testing	**Model 1** Innovation	**Model 2** Innovation
Teamwork	0.34**	2.80*
Reward	0.38**	2.43*
Two- way interactions		
Teamwork*Reward	-	-2.13*
R2	0.29	0.35
Adjusted R2	0.257	0.310
F	9.491	8.310
N	50	50

*p<0.05
**p<0.01
***p<0.001

Based on the empirical study, it can be concluded that: Reward affects significantly on Innovation (β=2.81 p<0.05) since the statistic test results shows p-value lower than 0.05 therefore hypothesis 1: Delivering rewards to employees can affect company innovation thus increasing reward will increase company innovation. It is in accordance with previous research (Sarin & Mahajan, 2001) that reward contributes positive impact to organization due to satisfaction after receiving the reward which then motivate them to work better and generate innovative ideas.

Teamwork gives positive and significant impact on innovation. The analysis shows (β=2.43, p<0.05) thus hypothesis 2: Teamwork in a company contributes positive impact on innovation is accepted. Teamwork can increase innovation in a company since creative ideas are generated from both formal and informal communication and discussion of the teamwork. Therefore, increasing togetherness in teamwork can spur innovation.

In this research, reward significantly strengthens causal relationship of teamwork and innovation but in negative direction. The value standardized coefficient beta is (β=-2.13 p<0.05). Thus, it can be concluded that hypothesis 3: Reward moderates the relationship of teamwork and innovation is accepted even though in negative impact.

5. Conclusion and Discussion

This study found that teamwork has impact on innovation and reward significantly affects innovation. Thus, firms should keep maintaining and improving innovation and reward in the firms. Nevertheless, reward significantly impact the relationship of teamwork and innovation in a negative way. This research reveals interesting findings that reward contributes negatively to teamwork and innovation. The possible explanation of this situation is, SMEs in Indonesia usually distribute rewards individually where teamwork reward is not particularly prioritized in the companies. Individual rewards will lead to competition among the teamwork members therefore and it has not provided secure feelings in collaborate among the members. Individual reward may reduce teamwork cooperation in improving company innovation. Reward that has not accommodated teamwork is the most common of the teamwork failure in organization (Woodman, et al., 1993). Teamwork that has been running well can be negative if the reward system implemented by the company does not support trust or beneficial for each member of the teamwork. Therefore, in addition to

awarding incentive individually, the company should add and develop incentive that can be received by teamwork members as a result of cooperation in the company.

Entrepreneurship for All: An Exploration of the Impact of Entrepreneurship Education across Disciplines

Angela Hamouda
Dundalk Institute of Technology, Ireland
Angela.hamouda@dkit.ie

Abstract: Increasingly, international entrepreneurship education policy has been attracting research attention (Smallbone & Welter, 2010). Entrepreneurship education has been pushed to the top of socio-economic and political agendas, and is currently a high priority imperative for government policy makers (Mitra and Matlay, 2004). It is widely recognised that the benefits of entrepreneurship education are not limited to the creation of new business ventures and subsequent new jobs, but will also develop key competencies of students, encourage innovative mind sets and as a consequence enable them to be more creative and self-confident in whatever they undertake. It has been highlighted by (Hytti & Kuopusjärvi, 2004, p.6) that there is also a distinction between preparing people to be enterprising/entrepreneurial and preparing them to be entrepreneurs. Additionally, there is an increasing role for entrepreneurship in a complex world where there are constantly changing needs of a very diverse population due to changes in society, technology and the economy. The design of specific entrepreneurship modules for non-business disciplines are key to making students more employable, giving them skills and knowledge required across all disciplines (Hamouda and Ledwith, 2016). The aim of this paper is to investigate the impact of the integration of entrepreneurship across third level programmes and explore its impact on the development of entrepreneurial mind-sets amongst undergraduate students. The findings are based on results of 137 surveys from graduates from across ten programmes in the Schools of Business and Humanities, Engineering and Applied Science and Nursing at Dundalk Institute of Technology, Ireland. The findings indicate that an entrepreneurship programme specifically designed for non-business students has had an overwhelming positive impact on their entrepreneurial attitudes and intentions. In particular, they have an increased entrepreneurial awareness and their level of confidence towards the consideration of starting a business as a viable career option has increased. The paper provides an innovative approach to entrepreneurship education and creates a framework for other third level institutions to develop similar initiatives to help lay the foundations for entrepreneurship to be the norm, and as such will also be of interest to researchers in this space.

Keywords: Entrepreneurship Education, Non-Business Disciplines, Impact, Culture, Graduates

1. Context and Rationale

In recent years, entrepreneurship education has increased both as a practice and as an area of study. The understanding and teaching of entrepreneurship is informed by a belief that the development of entrepreneurial capacity will bring economic and social benefits to regions, increasing both the quality and levels of employment. Entrepreneurship has been highlighted as 'one of the cornerstones of a modern, fully developed economy' Forfás (2007, p.5).

It is now widely accepted that the competitiveness and future prosperity of the Irish economy depends on the application of knowledge, innovation and entrepreneurship. There is a need to provide a sufficient quantity of skills to fill the emergent employment opportunities; to develop entrepreneurial skills which are relevant to all disciplines in an intrapreneurial context. In business, there is a need to provide the quality of skills required to drive growth and provide the diversity of skills to reflect the complexity of business.

In the Department of Jobs Enterprise and Innovation (2015, p.46) 'Action Plan for Jobs', the Government has set out a vision for Ireland to be among the most entrepreneurial nations in the world and acknowledged as a world-class environment in which to start and grow a business. It is vital that the role of entrepreneurship is optimised as an essential source of employment and wealth creation, thereby positioning entrepreneurship as a key element in the economic growth agenda. Hisrich et al., (2013, p.6) states that entrepreneurship plays an important role in the creation and growth of businesses, as well as in the growth and prosperity of regions and nations, however, they also recommend that in order to recognise, evaluate and exploit opportunities enterprising individuals are required.

There has been a call for entrepreneurship education to be embedded in all courses at third level to help develop and nurture entrepreneurial mind-sets (Fitzsimons and O'Gorman, 2013). Furthermore, it has been suggested third level programmes should take a multi-disciplinary approach to support the entrepreneurial ideas that emerge outside of business faculties (O'Keeffe, 2013). The Hunt report (2011, p.56) on the National

Strategy for Higher Education to 2030 in Ireland suggests that creativity and entrepreneurship must be encouraged to a much greater extent at undergraduate level.

Botham and Mason (2007, p.9) suggested that the widespread teaching of entrepreneurship is perhaps one of the reasons for the entrepreneurial nature of the United States economy. The call for culture and education to support entrepreneurship in Ireland is recognised in Forfás (2007, p.57). Ideally it suggests that culture and education will be mutually re-enforcing and complementary in fostering a spirit of enterprise throughout society, strengthening the motivation and capacity of entrepreneurs and potential entrepreneurs.

2. Entrepreneurship Education

It is widely recognised that the benefits of entrepreneurship education are not limited to the creation of new business ventures and subsequent new jobs, but will also develop key competencies of students, encourage innovative mind sets and as a consequence enable them to be more creative and self-confident in whatever they undertake. Mwasalwiba (2010), reviewed literature on entrepreneurship education and found that the most common definition for entrepreneurship education is that of an educational process designed to influence individuals' attitudes, behavior, values or intention towards entrepreneurship. He found there was relative agreement among academics that the main rationale for entrepreneurship education is more economic than social, with entrepreneurship being seen as a solution to economic problems, in particular employment.

However, there has been a move towards a behavioral view with a focus on entrepreneurship education to influence attitudes, values and a general culture. In this way, scholars are reluctant to associate entrepreneurship education strictly with new venture creation as a sole educational objective. It has been highlighted by (Hytti and Kuopusjärvi, 2004, p.6) that there is also a distinction between preparing people to be enterprising/entrepreneurial and preparing them to be entrepreneurs. The EU's position, in common with the OECD adapts a wider view of entrepreneurship and encourage the adaption of this in an educational context:

> *"Entrepreneurship refers to an individual's ability to turn ideas into action. It includes creativity, innovation and taking calculated risk, as well as the ability to plan and manage projects in order to achieve objectives. This supports everyone in day-to-day life at home and in society; makes employees more aware of the context of their work and better able to seize opportunities, and provides a foundation for entrepreneurs establishing a social or commercial activity."* (European Commission, 2008)

As entrepreneurship plays such a vital role in the development of an economy and the creation of wealth and jobs, the question for the educational sector is how to develop training programmes which will instill the necessary skills in students to allow them to operate as graduates in an entrepreneurial manner. Henry et al., (2003, p.196), asserts that at the individual level, students who have completed entrepreneurship programmes are more likely to:

- create more businesses and employment
- generate more business contacts
- have a broader range of skills and knowledge
- possess greater self-confidence in their entrepreneurial abilities
- test the commercial viability of their idea
- improve their employability even if they do not start a business

The European Commission (2008 p.26) has specified the importance of the development of entrepreneurship education at third level. It suggests that there are features of entrepreneurship education that are common within all disciplines and programmes and courses should be geared to the acquisition of generic and horizontal skills, aimed at making students:

> *'…. more creative/innovative; highly motivated; pro-active; self-aware; self-confident; willing to challenge; better communicators; decision-makers; leaders; negotiators; networkers; problem solvers;*

team players; systematic thinkers; less dependent; less risk averse; able to live with uncertainty; capable of recognising opportunities.'

The same report recognises that the teaching of entrepreneurship needs to be tailored to the specific needs of different fields of study. Volkmann (2004, p.185) states that entrepreneurship taught and learned on the basis of an interdisciplinary approach at universities, introduces new forms of knowledge and teaching methods as well as new problem-solving skills for students. Terms such as "multidisciplinary" and "interdisciplinary" entrepreneurship education are being used to explain models where collaboration occurs between different disciplines. The extent to which the collaboration occurs can range from side by side delivery of lecture material to the total integration of the different disciplines in a programme or a module or a single assignment project. Technological and Business disciplines are well suited to such collaboration.

3. Methodology

The overall objective of the study was to explore the impact of entrepreneurship education on the development of the students from across disciplines, in particular their understanding, attitudes to and interest in entrepreneurship as a result of engaging with entrepreneurship as part of their programme. An exploratory research approach was used to identify and investigate new insights suggested by the results of the study within the context of public policy and current practice in Ireland in the area of multi-disciplinary entrepreneurship education. An exploratory study is a valuable means of 'what is happening; to seek new insights; to ask questions and to assess phenomenon in a new light' (Robinson, 2002, p.59).

The primary research was designed to gain a perspective from graduates across disciplines at Dundalk Institute of Technology. The intention was to consider entrepreneurship education from a demand-side (both the attitudes towards and interest in entrepreneurship and impact and experience of entrepreneurship education from the students' perspective).

Programmes were identified from across disciplines at Dundalk Institute of Technology (DKIT) which included entrepreneurship as part of their programme. These students (a total of 356) were surveyed electronically in March 2018 using Survey Monkey sent out via e-mail (see www.surveymonkey.com) which collated the results and provided the means for analysing the responses. A survey provides an efficient tool for collecting background, quantifiable data from a specific sample, as well as gathering qualitative information from respondents in the form of experiences and views (Saunders et al., 2018). The survey response rate was 38%. The survey was broad in its application and was designed to collect both quantitative and qualitative information. The survey was structured into the following sections:

1. Sought to establish information regarding graduates' profile to include; their age, gender, nationality, background in family business, discipline, current stage of their programme, and also to confirm they have or are currently taking an entrepreneurship module as part of their programme.
2. Sought to determine their perception of the relevance of entrepreneurship to their programme.
3. Sought to elicit their perception of how entrepreneurship education (EE) has impacted the development of their entrepreneurial characteristics and skills
4. Sought to explore their understanding of and attitude towards entrepreneurship and how this has been impacted by their engagement with an entrepreneurship module.
5. Sought to investigate students' perception of the impact of the entrepreneurship module on their employability and career development.
6. Students were also asked how confident they feel to start a business at some stage in the future.
7. Finally students were asked to highlight what have they gained from their experience of participation in entrepreneurship as part of their programme.

4. Findings and Discussion

The survey was administered via e-mail to 353 participants across 10 undergraduate programmes at Dundalk Institute of Technology (outlined in Table 3). A total of 135 surveys were completed and analysed using Survey Monkey.

4.1 Profile of Survey Participants

Of the 135 respondents, 43 are male and 94 female. The age profile is spread across 4 categories as outlined in Table 1 below. The majority, 110 (81%) are Irish with the remaining students representing the international community which is reflective of the colleges growth and internationalisation.

Table 1: Age Profile of Participants (n= 135)

Age Category of Participants	**Male 43**		**Female 94**	
18-22 Years	20	47%	44	48%
22-26	10	23	27	29
27-39	8	19	8	9
40-50	1	2	11	12
50-65	4	9	4	4

Table 2: Nationality of Students (n=135)

Nationality	**Number of Respondents**	**% of Respondents**
Irish	110	81
European	9	7
Chinese	6	4
Malaysian	1	0.77
Saudi	6	5
Other*	4	3

* included; US, Czech and Kazakhstan

Table 3: Students' Area of Study (n=135)

Area of Study	**Current Year of Study**	**Number of Respondents**	**% of Respondents**
Community Youth Work	7 Y3, 3 Y4	10	7
Social Care	Y4	19	12
Business and Management	Y3	39	29
Marketing PR and Communications	Y4	6	4
Digital and International Business	Y4	9	7
Business and Technology	10 Y3, 3 Y2	13	10
Hospitality Management	7 (Y4), 3 (Y1)	10	7
Engineering Entrepreneurship	Yr4	7	5
Agricultural Science	11 Y3, 3 Y4	14	10
Early Childhood Studies	2Y3, 6 Y4	8	6

Students come from across a broad range of disciplines, Business, Social Science (Humanities), Engineering and Science. All of the students have either already taken or are currently taking an entrepreneurship module as part of their programme.

4.2 Students Attitude Towards and Understanding of Entrepreneurship

It is positive that the majority perceive entrepreneurial skills as very relevant (31%) and somewhat relevant (50%) to their area of study (as outlined in Table 4). There are comparisons across disciplines with the majority (90%) of those from Business disciplines considering these skills to be of relevance whereas this drops to (59%) amongst the Social Science disciplines and increases (91%) amongst the Science disciplines. Furthermore, the majority indicated that they have a very good (19%) or a fairly good (51%) understanding of entrepreneurship prior to taking the module. This understanding varied across disciplines; 48% amongst Social Science students and 80% amongst Business and Science disciplines.

Table 4: Students' Perception of the Relevance of Entrepreneurial Skills to their Area of Study (n=135)

Level of Relevance	**Number of Respondents**	**% of Respondents**
Very Relevant	42	31
Somewhat Relevant	68	50
Not Relevant at all	15	11
Unsure	10	7

Furthermore, it should be noted that the majority (70% had a very good (19%) and fairly good (51%) understanding of entrepreneurship prior to engagement with EE. This highlights exposure to entrepreneurship through other channels. However, it is interesting that 54% of students from Social Science indicated a poor (35%) or very poor (19%) understanding of the topic prior to taking the module.

Table 5: Students' Understanding of Entrepreneurship Prior to Engagement with Entrepreneurship Module (n= 135)

Level of Understanding	Number of Respondents	% of Respondents
Very Good	25	19
Fairly Good	69	51
Poor	30	22
Very Poor	11	8

4.3 Impact of Module on Student's Understanding and Awareness of Entrepreneurship

Students were asked to gauge their level of understanding and awareness of entrepreneurship and how this has changed since engaging with EE. This is detailed in Table 6. The majority (76%) have an increased understanding and awareness which indicates a positive impact. This rises to 81% amongst the Business students. However, it is interesting to note that for 33% of the Social Science students, they have no significant understanding and awareness of entrepreneurship since taking the module.

Table 6: Extent to which Students' Understanding of and Awareness of Entrepreneurship has Changed since Engaging with Entrepreneurship Module (n=135)

Level of Understanding and Awareness	No. of Respondents	% of Respondents
I now have a much greater understanding and awareness	50	37
I now have an understanding and awareness	52	39
I have no significant understanding and awareness	21	16
Unsure	12	9

In order to probe this area further, students were invited to highlight how key entrepreneurial characteristics and skills have developed since engaging with entrepreneurship education. The results are outlined in Table 7. It is considered that the areas of communication and presenting/pitching skills, teamwork and leadership skills have been well developed by the majority. Students felt that other core skills such as confidence, creativity and innovation, being an independent thinker had only increased a little (or perhaps are more cautious in their consideration of the development of these core skills during this timeframe). It is interesting that many felt that negotiation (58%) and persuasiveness (45%) had not changed at all.

Table 7: Perception of the Development of their Entrepreneurial Skills/Characteristics (n=135)

Characteristic/Skill	Increased a Lot	Increased a Little	No Change at all	Decreased a Little	Decreased a Lot
Confidence	28 (21%)	68 (50%)	35 (26%)	2 (1%)	2 (1%)
Creative/Innovative	28 (21%)	63 (47%)	40 (30%)	1 (0.75%)	2 (1%)
Determined/Driven	29 (22%)	49 (37%)	42 (31%)	10 (7%)	4 (3%)
Persuasive	17 (13%)	52 (40%)	59 (45%)	2 (1%)	2 (1)
Communication	35 (47%)	37 (50%)	26 (35%)	0 (0%)	2 (3%)
Independent Thinker	25 (34%)	43 (57%)	30 (40%)	1 (1%)	1 (2%)
Team Player	29 (39%)	32 (43%)	32 (43%)	6 (8%)	1 (2%)
Leadership	29 (39%)	36 (48%)	32 (43%)	1 (1%)	1.5 (2%)
Problem Solver	22 (29%)	43 (57%)	32 (43%)	1 (2%)	2 (3%)
Presenting/Pitching	35 (47%)	32 (43%)	29 (39%)	2 (3%)	2 (3%)
Networking	15 (20%)	44 (59%)	39 (53%)	0 (0)%)	2 (3%)
Negotiation	16 (21%)	39 (52%)	43 (58%)	1 (2%)	1 (2%)
Decisive/Assertive	19 (26%)	40 (54%)	39 (52%)	1 (1%)	1 (2%)

4.4 Entrepreneurship and Career Development

Students were asked to indicate how important they perceived Entrepreneurship Education (EE) to be for the development of their career as outlined in Table 8. It is reassuring to see that the majority (78%) perceive it to be important. The majority (90%) of those from Business disciplines have a positive perception towards linking EE to their career development. This contrasts with 60% from Social Sciences.

Table 8: Importance of Entrepreneurship Education for Career Development (n=135)

Level of Importance as perceived by the Students	Number of Respondents	% of Respondents
Extremely Important	42	31
Somewhat Important	64	47
Not Important at All	19	14
Unsure	10	7

They were subsequently asked to indicate the level of impact they feel (EE) has on key skills/characteristics for career development as detailed in Table 9. It is interesting to note that the majority feel that EE impacts positively on key skills and characteristics, in particular, creativity/innovation, developing new ideas, team management, planning, leadership and the pitching of new ideas to a panel. This reflects their perception of the impact of the module on the development of these core skills. It should be highlighted that 46% of Social Science students do not feel that their EE will help to make them more employable. Of this same group 41% did not feel their EE was important for their career development.

Table 9: Perception of Impact of EE on key Skills/Characteristics for Career Development (n=135)

Characteristic/Skill	Will have a Significant Impact	Will have an Impact	Will have No Impact at All
Creativity/Innovation	34 (46%)	46 (62%)	20 (27%)
Problem Solving/Critical Thinking	30 (40%)	49 (65%)	22 (29%)
Developing New Ideas	38 (51%)	44 (59%)	18 (24%)
Team Work	44 (59%)	35 (47%)	25 (29%)
Team Management	41 (55%)	40 (54%)	19 (26%)
Calculated Risk Taking	27 (36%)	45 (61%)	25 (38%)
Planning	39 (52%)	42 (57%)	20 (27%)
Leadership	32 (43%)	48 (65%)	20 (27%)
Networking	29 (39%)	47 (63%)	24 (33%)
Presenting and Pitching	44 (60%)	36 (48%)	20 (27%)
Negotiating	27 (36%)	47 (64%)	26 (35%)
Marketing	41 (54%)	36 (48%)	36 (48%)

Table 10: Perception of Impact of Entrepreneurial Skills on Employability

Statement	Number of Respondents	% of Respondents
I feel it will help make me more employable in the future	85	63
I do not feel it will help make me more employable in the future	35	26
I am unsure	15	11

Table 11: Perception of Importance of Entrepreneurship Education for Future Career Development (n=135)

Level of Importance	Number of Respondents	% of Respondents
Extremely Important	42	31
Somewhat Important	64	47
Not so Important	19	14
Not Important at All	10	7

4.5 Level of Confidence in Starting their own Business in the Future

Participants were asked to indicate how confident they feel about starting a business in the future. They were given three statements and asked to indicate which best describes them individually in terms of how confident they feel to start a business. Results are displayed in Table 12. The majority feel confident (22%) or very confident (44%) that they will start a business at some stage in the future. The majority (75%) of Business students feel confident about starting businesses while in contrast the majority (60%) of Social Science Students do not feel confident they will start businesses in the future.

Table 12: Level of Confidence to Start a Business in the Future (n=135)

Statement by Student	Number of Respondents	% of Respondents
I feel confident that I will start a Business at some stage in the future	30	22
I now feel very confident that I will start a Business at some stage in the future	60	44
I do not feel confident that I will start a Business at some stage in the future	45	33

4.6 Students' Experience of Entrepreneurship Education

Students were asked to indicate their experience of the module. This was left an open question in order to gauge opinions, attitudes and experiences further. There was a mix of responses which indicated a positive experience and included; an increase in confidence, development of team work skills, creativity and problem solving skills and other broad business development skills.

4.7 Increase in Confidence

Many students highlighted that their confidence has been increased through the process of researching and developing an idea through to pitching to a panel and speaking in public which developed a level of professionalism they may not have experienced before. It was also mentioned by some students that their confidence to pursue their ideas has increased:

'…I gained confidence, just because I am not an expert on a subject does not mean that I cannot pursue it!!'

4.8 Teamwork Skills

It was highlighted that one of the core skills to be developed was that of team work and team management as many of the tasks and projects initiated were team based. For many students, their course work to date had been at individual level so this experience offered the opportunity to develop a core skill necessary in both an intrepreneurial and entrepreneurial context.

'…. it gave me a great experience of leading a team and make sure the group is productive and the goals achievable.'

4.9 Creativity and Problem Solving Skills

Many students across all disciplines highlighted that the module provided an opportunity to develop their creative potential, critical thinking and problem solving skills. Some of the comments included:

'…I learned to think out of the box, how to create something from nothing.'

'..there are no rules, everything is possible!!'

'..it has helped me not only come up with ideas but actually flesh them out and realise whether or not they are viable.'

4.10 Business Development Skills

Students developed core business development skills such as networking, planning, communication and business acumen that will not only make them more employable and help with their career development but provides them with a toolkit that they can use for developing projects regardless of their discipline. Some students commented:

'…I gained a greater understanding of how business works and a gained a good overview of business development.'

'…an incredible increase in the understanding of how a business operates.'

'…from develop an idea, looking at all aspects in relation to that idea, how to market and pitch that idea.'

'..I do not intend to start my own business but the theory of learning will have a great impact when planning things like fundraisers or starting up a new activity group.'

'…I've always wanted to have my own business; I just needed the building blocks and some guidance to put me in the correct patch in able to achieve it'.

'.. gave me an insight into what employers and customers look for in an individual.'

4.11 Social Science Students

It is interesting that students from this discipline had a similar experience to the other cohorts as well as highlighting specific experience of social entrepreneurship:

'..I now know there is an opportunity for social entrepreneurship.'

'… I learned what social entrepreneurship is all about, how it impacts on society in a pro-community setting'.

' ….initially I wasn't sure how applicable this was to me, ..now after doing a rocket pitch, I feel more capable to create and plan ideas that will help me in youth work. It also let me identify and analyse what I actually want to do in the future.'

5. Discussion and Conclusions

The results indicate significant benefits for the graduates of all programmes across disciplines. Graduates are more confident, are experienced in idea generation and resourceful in pursuing opportunities to commercial value. These skills have obvious application in the setting up of a new business but are equally valuable in all organisations where the need for innovation is becoming more compelling. Furthermore, many students highlight they are confident they will start a business at some stage in the future. This is significant as it indicates that students are confident in their ability to pursue entrepreneurship as a viable career option going forward after graduation. This reflects a positive impact of entrepreneurship education across disciplines. This also indicates that a sizeable cohort have embraced the culture of entrepreneurship. This concurs with Mwasalwida (2010) in his review of entrepreneurship education literature which reveals a process designed to influence attitudes and intentions towards entrepreneurship.

Additionally, this study shows that students are not only developing a business idea for the purpose of earning their qualification, but are interested in the further development of their idea and application of the skillset acquired. These findings concur with Henry et al., (2003 pp 196-197) who highlighted that students who have completed entrepreneurship programmes yield certain direct benefits, for example; having a broader range of skills and knowledge; possessing greater self-confidence in their entrepreneurial abilities and improving their employability even if they do not start a business.

At higher education level, a central purpose of entrepreneurial education should be to develop entrepreneurial capacities and mind-sets. Research highlights the benefits of providing entrepreneurship education to those students outside the business school (European Commission, 2008). With a change in employment structures and sources, there is an ideal opportunity to introduce new sources of employment and present self-employment as an attractive and profitable alternative to the conventional career prospects for graduates.

The literature shows strong support for a multi-disciplinary approach to entrepreneurship education. The report of the European Commission (2008, p.29), states that traditional educational methods do not correlate well with the development of entrepreneurial traits and attributes and that multi-disciplinary collaboration is an essential element of building enterprising abilities. The strategy of 'Entrepreneurship for All' disciplines responds very well to the distinct aims of the Department of Jobs Enterprise and Innovation (2014), National Policy Statement on Entrepreneurship in Ireland which is to:

- Build the pipeline of entrepreneurs
- Build entrepreneurial capability
- Build the right conditions for entrepreneurship

In order to understand further the long term impacts of such a programme, a longitudinal study will be required to track the progression of the participants and understand the influence and benefits of entrepreneurship education post-graduation. This paper provides an example of an innovative response to the challenges presented by an ever changing global economy. The results clearly indicates the strategy of entrepreneurship education being offered to all students regardless of discipline is successful in making students more employable, giving them skills and knowledge required and in the long term generating an entrepreneurial culture which is a pre-requisite for sustainable economic growth.

From Mind to Market: Innovation insights from the Welsh Life Sciences and Health Ecosystem

Thomas Howson[1] and Gareth Davies[2]
[1] Swansea University Medical School & the Life Sciences Hub Wales, UK
[2] Swansea University School of Management, Wales, UK
900817@swansea.ac.uk
G.H.Davies@Swansea.ac.uk

Abstract: As a nation, Wales faces a number of social and economic barriers to the improved health and wealth of its population. Health innovation can play a key role in overcoming these challenges, providing improved patient health outcomes, reducing health system in-efficiencies and catalysing wider economic growth. Despite this, attrition rates of Life Science and Health SME's in the UK are high, with a multiplicity of barriers to successful innovation existing. Efficient innovation management processes are regarded as an indicator of successful innovation outcomes. Early intervention via the analysis of innovation characteristics can help assess both strengths and weaknesses, highlight barriers and enablers and provide an insight into the future direction and developmental requirements for the innovation. To overcome many of the barriers identified, access to appropriate knowledge, expertise and resource is imperative. This is reflected in the international rise of open innovation models, first popularised by Chesborough (2003). Innovation in health consists of a complex web of interaction between public and private sector actors. Ecosystem transparency plays an important role in facilitating collaborative relationships among actors of the Quadruple Helix, allowing entrepreneurs and firms to identify and access external sources of knowledge, expertise and resource. This paper describes the development and use of an innovation analytic tool, referring to case studies from a clinical innovation programme in Wales. This is coupled with an extensive mapping exercise of the Life Science and Health ecosystem across Wales. In combination, the approach promotes the creation of a trans-disciplinary open innovation environment, and mediates the creation of bespoke commercialisation pathways. Ultimately, the paper develops a framework to facilitate the co-creation of health innovation amongst actors from the Quadruple Helix in Wales.

Keywords: Innovation, Life Science, Health, Tool, Ecosystem, Collaboration, Translation.

1. Challenges facing Wales

Wales, once a power house of the industrial revolution, providing coal and steel to fuel industrial expansion globally, has witnessed a struggle in its transition from traditional industries to a new knowledge-based economy. The economic performance of Wales is seen to lag behind many of its national and international counterparts. The Gross Value Added (GVA) per capita in Wales, a common measure of economic output per head of population, ranked lowest across the four regions of the UK in 2015 (Office for National Statistics, 2017). Patterns of low economic output are supported by long term higher than UK average unemployment rates (Welsh Government, 2018).

Alongside the challenges facing the Welsh economy, the National Health Service in Wales (NHS Wales), faces significant challenges in providing high quality, consistent levels of healthcare in a sustainable manner. This is driven by an ever ageing population, increasing burdens of chronic disease in both young and elder populations and rising patient expectations (Bevan Commission, 2013) amongst other factors. Currently, the Welsh Government spends 48.4% of the £15bn devolved national budget allocated to Wales from the UK central government on Health, Wellbeing and Sport (Welsh Government, 2016). Of concern, is the current trends that growth in spending on Health and Care in Wales is beginning to outstrip wider national economic growth (UK Parliamentary Review, 2018). In 2014, The Nuffield Trust identified a growing financial gap between the services the NHS in Wales is expected to provide and what it can afford to provide. This financial gap in Wales is predicted to be in the region of £2.5bn by 2025/2026 (Roberts & Charlesworth, 2014). As a result, the current model of healthcare provision in Wales is considered unsustainable (UK Parliamentary Review, 2018), with a recognised need to re-evaluate service provision models.

2. The Life Science Sector in Wales

The Health and Life Sciences sectors are inherently inter-connected and play important roles in co-creating innovative solutions to health care challenges facing modern society. Globally, The Life Sciences sector possesses an exemplary history in the development of ground breaking medical

innovation. The Life Sciences sector is defined by the Welsh Government (2013) as: 'Pharmaceutical, Biotechnology and Medical Technology with wide ranging activities including research, testing, manufacturing and the provision of specialist services'. In Wales, the Life Sciences sector currently consists of over 350 companies and employs over 11,000 people (Welsh Government, 2018).

3. Theoretical Context

Innovation can be defined as the 'successful exploitation of new ideas' (Cox, 2005) or in layman's terms taking ideas 'from mind to market'. Innovation in multiple forms, is associated with increased productivity levels (Hall *et al.,* 2009), which is considered to drive increased performance and efficiency, which in turn can manifest itself through both organisational growth and cost efficiency savings. Healthcare innovation is defined by Omachonu & Einsprach (2010) as the "*introduction of a new concept, idea, service, process, or product aimed at improving treatment, diagnosis, education, outreach, prevention and research, and with the long term goals of improving quality, safety, outcomes, efficiency and costs."* Thus innovation from the Life Sciences and Health sectors will play a critical role in ensuring the sustainability of NHS services, improving patient health outcomes and driving wider economic growth in Wales.

However, health innovation is renowned for its challenging nature. Barriers to success commonly include significant capital requirements (DiMassi *et al.,* 2003), a complex and uncertain regulatory landscape (Wagner *et al.,* 2006) and often long developmental time frames (DiMassi *et al*., 2003), amongst many others.

Consequently, on average, only 17% of innovation processes (not specific to health) are considered successful (Strategyn, 2010), with project failure having a detrimental effect on the survival and growth of firms (Cefis & Marsili, 2005). The difficult nature of innovation in the UK Life Sciences sector is reflected by a three-year failure rate of 39% for SME's in 2011, highlighted by the UK Department for Business, Innovation and Skills (2011).

The innovation process is considered hard to manage (Cormican & O'Sullivan, 2004) with the initial stages described as 'Fuzzy' (Kim & Wilemon, 2002). Well managed innovation processes are considered to have a significantly positive influence on organisational competitive success (Adams *et al.,* 2006), however Small and Medium Sized Enterprises (SME's) commonly pursue a less structured approach to innovation (De Toni & Nassimbeni, 2003), which may offer insight into the high attrition rate of smaller companies identified previously. Frankel *et al.,* (2000) describe how established management practice competencies associated with increased performance, including the ability to quantify, evaluate and benchmark technological capabilities, often poses a significant challenge to contemporary organisations. Benchmarking is a common management practice associated with improved performance (Camp, 1989) which is described by Borsi *et al.* (2004) as "*an analytical management technique, which may be used to compare internal performance with the best external performance to identify strengths and weaknesses".*

Work by Cooper & Kleinschmidt (1995), identifies a high quality new product process, a clear well communicated new product strategy and adequate resources as the three greatest drivers of improved innovation performance. Findings are supported by Salomo *et al.* (2007) who identify that proficiency of project planning and process management are important determinants of ultimate new product development (NPD) success. Success factors identified throughout the literature also highlight the importance of external influences on the success of innovation efforts (Chang, 2003). The "liability of smallness" is a term used by Aldrich & Auster (1986), to describe the challenges SME's face with regards to a lack of resource including both financial and human capital, with small firms reported to commonly lack the multi-disciplinary skills base required for successful innovation activity (Bianchi *et al.,* 2010). Having linkages with actors who possess complementary assets is regarded to play a critical role in successful innovation with two main network benefits of resource sharing and knowledge spill overs described by Ahuja (2000). Acquiring knowledge and skills through collaboration is thus considered an effective and efficient way of successful innovation (Adams *et al.,*1998).

Open Innovation, a concept first popularised by Henry Chesborough (2003), refers to "*the use of purposive inflows and outflows of knowledge to accelerate internal innovation and expand the markets for external use of innovation*" (Chesborough, 2006). Knowledge creation is considered a social process (Nonaka and Takeuchi, 1995) and plays a central role in innovative activity (Cohen & Levinthal, 2000). Innovation thus emerges as a result of social interaction, when a diverse range of actors share complementary knowledge (Blomqvist and Levy, 2006). The Triple Helix Model described by Etzkowitch & Leydesdorff (1995) supports this view, proposing a co-evolutionary approach to technological development amongst actors from academic, industrial and governmental spheres.

4. Aims of this paper:

The positive influence the adoption of both strong innovation management practices and open innovation approaches by SME's can have on innovation outcomes has been outlined. This paper presents a framework to support the Health Innovation management process, utilising an integrated mapping methodology for the planning and implementation of knowledge transfer and commercialisation activities. The approach combines the use of an innovation analytic tool, and a Health Innovation ecosystem mapping exercise. In combination, the two outlined mapping processes facilitate the identification of actors and resources and the construction of bespoke commercialisation pathways for Health Innovation in Wales. This approach aims to increase the success rate of the translation and adoption of Health Innovation in Wales, increasing the pace and efficiency at which innovation is taken from 'Bench to Bedside'. The approach has application for practitioners, policy makers and wider Life Sciences and Health ecosystem stakeholders, promoting the co-creation of health innovation between ecosystem stakeholders.

5. Innovation Analytic Tool

Many tools have previously been designed to make managing the innovation process more simple (Cormican & O'Sullivan, 2004), however no single tool appears to have been widely adopted. Prior to the onset of innovation, it is important to assess the innovation capabilities and resources that exist. Learnings from such tasks generates Actionable Knowledge relating to the current and future requirements of specific innovation projects. This permits managers or practitioners to pinpoint areas of strength and weakness in their innovation armory when benchmarked against known best practice, and thus ensures often restricted project resource is allocated in the most efficient manner, to areas where intervention may be most effective. The use of Maturity Matrices (or otherwise referred to as star charts or radar charts amongst other terms) to assess innovation is not new, and is a methodology used across a broad range of subject areas (Arundel & Hollanders, 2005; Kohler *et al.,* 2013; Kaczynski *et al.,* 2008; Miguel *et al.,* 2017). Maturity Matrices allow the visual examination of multiple metrics simultaneously, permitting users to identify strengths and weaknesses through observations relating to the symmetry or the uniformity of data points (Atanassova, 2010). The use of Maturity Matrices also permits users to benchmark performance across multiple data sets. Further, Maturity Matrices permit the user to assess temporal changes between data sets, offering an effective way to demonstrate time series data (Atanassova, 2010). Consequently, the innovation analytic tool presented utilises a maturity matrices methodology to visualise performance indicators against identified best practice, aligning with the innovation audit technique suggested by Tidd *et al.,* (2005).

The Innovation analytic tool is designed to assess innovation capabilities and characteristics of in-vivo innovation projects, teams and organisations, that may enable or present a barrier to successful innovation outcomes. The result of such analysis provides a strategic blueprint which can subsequently be used to guide the future direction of the innovation planning process. The factors, against which innovation projects are assessed, were developed by identifying common Critical Success Factors relating to Innovation projects throughout the associated literature. Literature utilised in the design of the analytical model included work by Adams *et al.,* (2006) who outline seven broad themes of innovation management measurement including: Inputs Management, Knowledge Management, Innovation Strategy, Organisation and Culture, Portfolio Management, Project Management and Commercialisation. Rothwell (1992) identifies eight key characteristics related to successful innovation including, amongst others: High quality internal and external communication, Careful planning procedures, the presence of technological gatekeepers and high quality

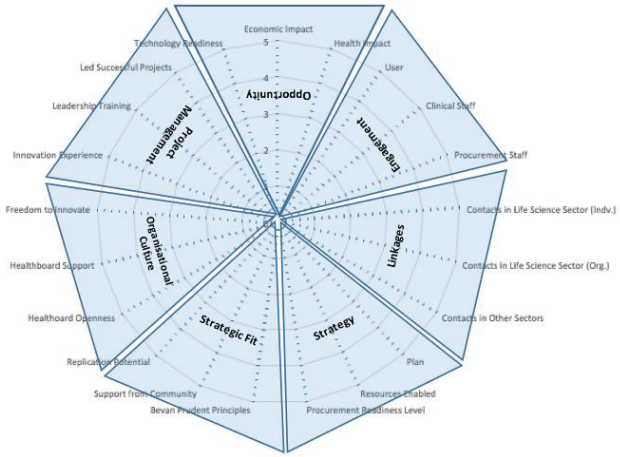
management. Other literature utilised in the design of the evaluation metrics included work by Cooper & Kleinschmidt (1995) and Pinto & Slevin (1988).

However, a 'one size fits all approach' seems unlikely to be most effective, as different forms of innovation across different industries possess differing developmental requirements and are governed by different external factors. This view is supported by Baker *et al.* (1983) who identify that critical success factors associated with projects vary according to business and project nature. The analytic tool therefore ensures the measurement variables are most appropriate to assess Health Innovation projects by incorporating perspectives of actors from the Life Science and Health sectors in Wales, using the findings of an exploratory questionnaire examining the barriers and enablers of the translation and adoption of Health Innovation.
The innovation analytical tool developed (Figure 1), was based around the work of Chiesa *et al.,* (1996) and Tidd *et al.* (2005), which latterly focusses around auditing innovation management. Tidd *et al.* (2005) suggests that "*organizations with no clear innovation strategy, with limited technological resources and no plans for acquiring more, with weak project management, with poor external links and with a rigid and unsupportive organization would be unlikely to succeed in innovation*". The auditing process used by Tidd *et al.,* (2005), utilised a scale based approach to assess innovation competencies in five different areas including: Strategy, Processes, Organisation, Learning and Linkages. The work then applies the information acquired to a maturity matrix, to produce a visualization of innovation forms, an approach which was adopted in the development of this analytical model.

The innovation analytic tool was initially piloted using the Bevan Commissions Exemplars Programme. The Bevan Commission Exemplars programme was designed to encourage NHS staff in Wales to develop, try out and test at speed, new ideas and ways of working within the Welsh NHS. Programme data was collected using questionnaires exploring self-assessed competencies in seven areas considered influential in determining innovation outcomes as well as assessing the opportunity trajectory and the strategic fit of the project (see Figure 1a and 1b). Question topic areas focused around: the proposed opportunity, participants engagement with stakeholders, participants linkages, participant innovation strategy, project strategic fit, organisational culture and participant project management. The questionnaire used a self-evaluative approach issued at three points (onset, mid-point and conclusion) throughout the 12-month programme duration. The questionnaire utilised a Likert or Summative-type scale, an objective measure used frequently across health research (Hartley, 2014). This approach aligned with that of the innovation audit methodology proposed by Tidd *et al.,* (2005). Results presented in Figure 1 illustrate the use of the Maturity Matrices methodology and innovation analytic tool for the Bevan Exemplars programme. Figures 1a and 1b show the construct of the innovation analytic tool, and Figures 1c and 1d demonstrate the use of the innovation analytic tool to assess the strengths and weaknesses of individual projects and to examine the overall cohort development.

a)

b)



Figures 1a and 1b show the construct of the innovation analytic tool used in the Bevan Commission Exemplars programme, which examines innovation characteristics around twenty-one indicators categorised into seven themes.

c)

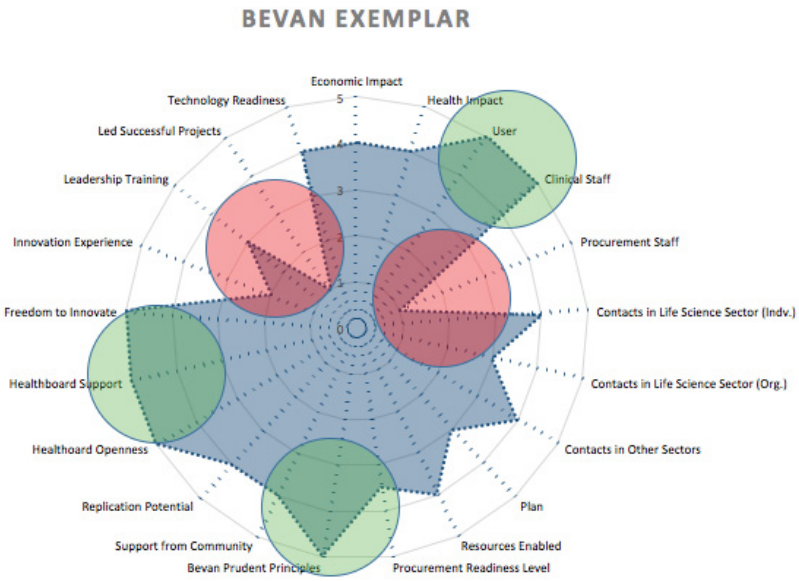


Figure 1c shows a representation of use of the innovation analytic tool to benchmark participant innovation projects, highlighting project strengths (green) and weaknesses (red).

d)

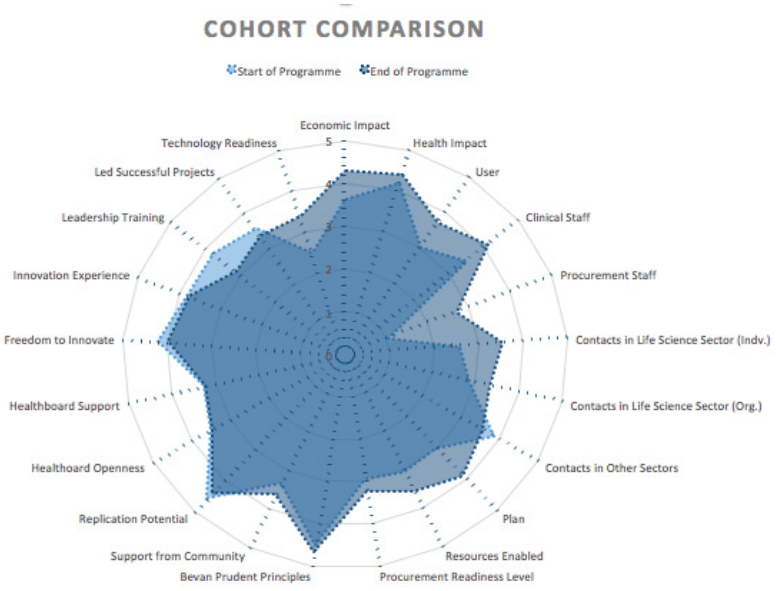

Figure 1d shows a representation of use of the innovation analytic tool to compare cohort development progress at the onset and conclusion of Bevan Commission Exemplars programme

Figure 1

To demonstrate the practical application of this tool, two case studies from the Bevan Exemplars are presented. The project described in Figure 2, focused around the *design and implementation of a palliative care educational programme in nursing homes, which sought to improve the quality of end of life care.* b)

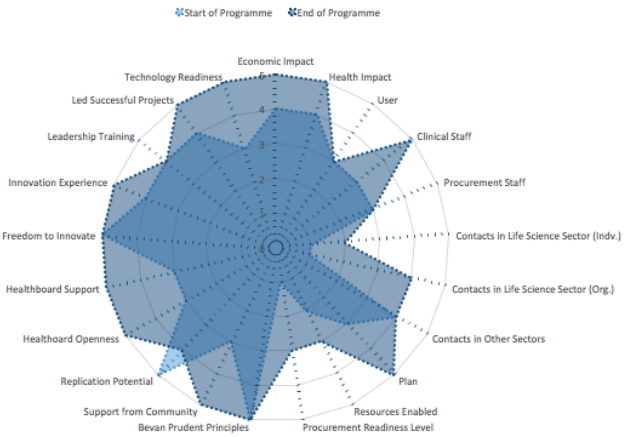

Figure 2: Representation of the use of the Innovation Analytic Tool in the assessment of participant projects on the Bevan Commission Exemplars programme. The Innovation Analytic tool shows innovation forms of participant at the onset (light blue) and conclusion (dark blue) of the Bevan Commission programme.

The initial innovation form identified at the onset of the programme (light blue) provided a source of insight and Actionable Knowledge relating to the needs of individual innovation projects and innovation teams. The project outlined in Figure 2, showed particular weaknesses when compared to best practice in areas including organisational culture and strategy (planning). This actionable knowledge allowed programme leads to adjust both the general design of the programme to trends reflected across the cohort as well as providing more personalised support to overcome individual project needs. Results recorded at the conclusion of the programme represented by the darker segment on the radar, highlighted significant improvements in multiple areas, including in areas such as project maturity, organizational culture and strategy.

The same approach was applied to the project described in Figure 3, which focused around the development of a “postcard scheme”, aiming to prevent multiple attendance at acute medical facilities relating to self-harm attempts.

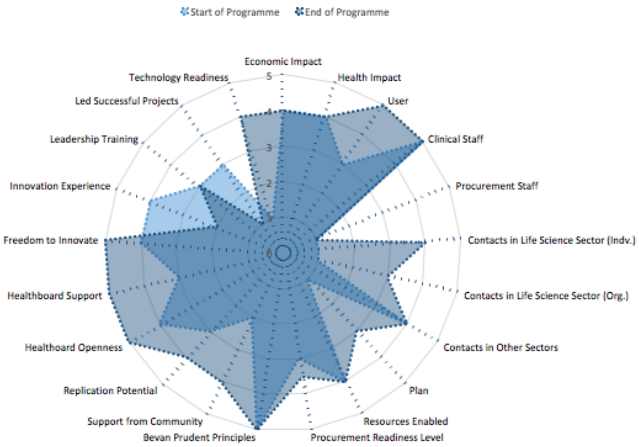

Figure 3: Representation of the use of the Innovation Analytic Tool in the assessment of participant projects on the Bevan Commission Exemplars programme. The Innovation Analytic tool shows innovation forms of participant at the onset (light blue) and conclusion (dark blue) of the Bevan Commission programme.

At the onset of the programme, the project described in Figure 3 demonstrated a lack of maturity in areas including project planning and Technology Readiness. At the conclusion of the programme, the innovation form produced by the Innovation Analytic Tool demonstrated improvements in the areas suggested.

Participant perspectives at the conclusion of the programme further support the notion that the use of the Innovation Analytic Tool had a positive effect on the quality of support provided by the Bevan Commission. The Bevan Commission was regarded as the key enabler to the development of Exemplars healthcare innovation projects with innovators acknowledging the "excellent support, resources and ideas" offered, as well as a "fantastic opportunity to gain knowledge and skills" facilitated through the structure provided by the programme, training and workshops.

6. Ecosystem Mapping:

As evidenced through the use of the Innovation Analytic Tool with the Bevan Commission Exemplars Programme, the Actionable Knowledge obtained from use of the Innovation analytic tool allows the construction of an innovation opportunity blueprint. This blueprint or innovation form provides a structural framework from which managers or practitioners can effectively design strategic approaches to support the translation and adoption of specific innovation projects aligning with the identified needs. As alluded to previously, innovation in Health requires a multitude of different expertise, knowledge, resources and services, not universally available from internal sources in many organisations.

Technological collaboration networks allow organisations to access such resource and to achieve a higher degree of innovativeness (Nieto & Santa Maria, 2007). Innovation in Health requires the interaction between multiple systems, involving both public and private sector organisations and their formal and informal networks. Such systems incorporate actors from Governmental, Industrial, Academic and Clinical spheres as well as third sector organisations and end users. Further, Health Innovation involves actors positioned at both the core and the periphery of their respective sectors, each playing varying roles to service the combinatorial nature of innovation. Considering Health Innovation in this broad multi-actor context the term Innovation Ecosystem is deemed more appropriate. A (21st Century) innovation ecosystem is described by Carayannis & Campbell (2009) as

> *"a multi-level, multi-modal, multi-nodal and multi-agent system of systems. The constituent systems consist of innovation meta-networks (networks of innovation networks and knowledge clusters) and knowledge meta-clusters (clusters of innovation networks and knowledge clusters)……..which in turn constitute agglomerations of human, social, intellectual and financial capital stocks and flows as well as cultural and technological artifacts and modalities, continually co-evolving, co-specialising, and co-opting…'.*

As this definition suggests, innovation ecosystems are complex and dynamic in nature, consisting of both tangible and intangible sources of resource and expertise. According to Walker *et al.,* (2008), complex problem solving tasks including stakeholder management, can benefit from mechanisms that increase the clarity of the problems through visualisation techniques. In order to facilitate Open Innovation approaches, thus enable actors to identify complimentary external sources of expertise, knowledge, resources and services, ecosystem transparency is required. Mapping of the actors and resources that exist amongst ecosystems offers a way of providing this clarity, and thus promoting open innovation approaches. The rest of this paper will describe an approach taken involving the mapping of the Life Sciences and Health ecosystem in Wales. Mapping of the Life Sciences and Health Ecosystem in Wales utilised a two-tiered approach. Initially, organisations were identified and latterly classified according to primary business activity using a model developed by Cooke, Kaufmann *et al.,* (2006) to describe the Life Sciences cluster in Munich, which was subsequently adapted and used by Davies *et al.,* (2011), to describe the Life Science and Health innovation ecosystem in South West

Wales (Figure 4). This allows actors to identify complementary collaborative partners across a wide reaching spectrum of business activity including supply chain partners, existing knowledge and expertise and sources of finance. It also provides actors with an understanding of their competitive landscape and allowing the identification of gatekeepers, of whom can facilitate access to desired markets.

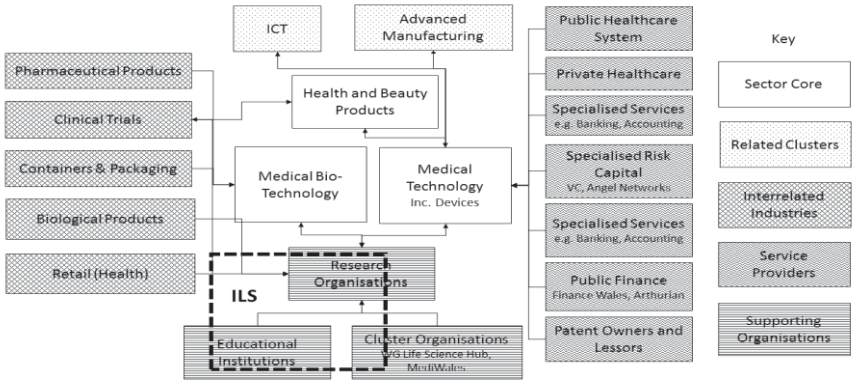

Figure 4: Model used to categorise Life Science and Health sector organisations in Wales taken from Davies et al., (2011) whom adapted an initial model by Cooke, Kaufmann et al., (2006) to describe the Life Sciences cluster in South West Wales.

According to Dovey (2009), innovation between collaborative partners is highly contingent upon trust.

Many constituent parts of the innovation process including creativity and idea sharing, depend on a high degree of trust existing between actors (Dovey, 2009). Consequently, the second stage of the outlined mapping approach involves the examination of the relational ties existing between organisations according to actor's perceptions on relational strength and the nature of such partnerships. This multi-dimensional approach to ecosystem mapping facilitates the creation of bespoke commercialisation pathways (demonstrated in Figure 3) based upon trusted relationships, reducing the amount of wasted time and resources of organisations.

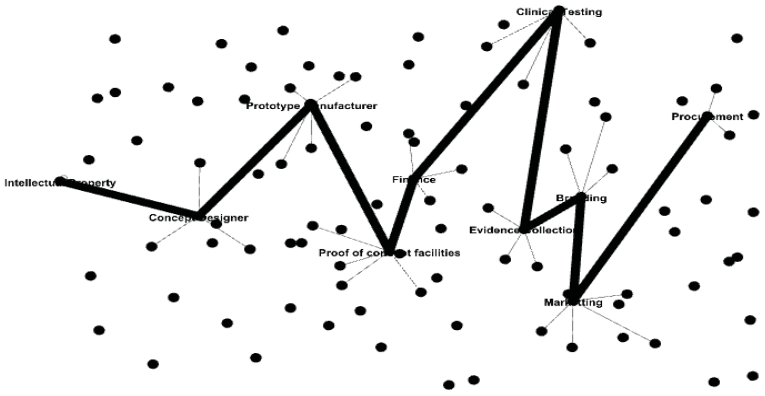

Figure 3: Representation of the use of the ecosystem mapping approach to create bespoke commercialisation pathways for the development of innovation utilising knowledge of actors and the relationships existing between them. Actors are represented using black nodes with edges (lines) used to describe relationships existing between actors. A representative commercialisation pathway is illustrated by the denser black line.

7. Conclusion:

This paper has outlined a novel approach to health innovation management using an integrated mapping technique. In combination, the use of both innovation opportunity mapping and ecosystem mapping approaches working in synergy promotes the translation and adoption of innovation.

Through identification of innovation characteristics and areas of weakness in innovation approaches, together with knowledge of actors, expertise and resources existing within the Health Innovation ecosystem, bespoke commercialisation pathways can be tailored to the needs of the innovation. This approach promotes an integrated ecosystem-centric approach to innovation, reducing the fragmented culture currently existing between Life Science and Healthcare delivery sectors in Wales. This approach aims to provide transparency and reduce the requirement for co-location, whilst promoting a trans-disciplinary, cross-sectoral approach to Health Innovation. Implementation of this approach stands to improve the success of health innovation in Wales, driving improved patient health outcomes and economic growth by supporting organisations throughout the innovation process.

Collaborative Learning in Entrepreneurship Education in a Japanese Business School

Yuko Inada
Kwansei Gakuin University, Hyogo, Japan
yukoin@kwansei.ac.jp

Abstract: Entrepreneurship education is important for successful economic and social development. Business schools all over the world have become increasingly aware of the importance of entrepreneurship education and collaborative learning to expand global markets. Some previous studies assert that collaboration is a factor for success in higher education. Students improve their attitudes and communication skills by collaborative learning. Other studies argue that individual performance depends on team performance. Although entrepreneurship programs in business schools are often designed as team-based courses, research is scarce on collaborative learning in entrepreneurship education. This study examined the perceptions of collaborative learning in a sample of 17 international and 5 Japanese students taking an entrepreneurship course as part of an MBA program taught in English at a Japanese business school. Japanese students had more than 10 years of work experience. On the other hand, international students of eleven different nationalities had never worked full time or had less than three years of work experience. Semi-structured interviews were conducted in English for international students and in Japanese for Japanese students in June and July 2017. Data comprised 34,685 words in English and 17,433 words in Japanese. The KH Coder text-mining tool was used for qualitative content analysis to visualize concepts in the large text dataset and create a collocation network of linear connections. Results revealed that students reported that class participation and teamwork were important. Both Japanese and international students tend to participate more in group work and engage in class participation. However, their perception of the sessions, awareness of becoming an entrepreneur, and objectives in the course differed by nationality: international students focused on certain sessions such as business model, marketing, and entrepreneurship, although Japanese students remembered most sessions. International students think being an entrepreneur is difficult, but Japanese students thought that becoming an entrepreneur is an experience. Furthermore, international students focused on obtaining employment in Japan, whereas Japanese students focused on international collaborative learning experience and improving their English language skills. Collaborative learning for diverse classes of students should be enhanced in future courses.

Keywords: Entrepreneurship education, Entrepreneurship, Collaborative learning, Diversity, MBA, KH Coder

1. Introduction

The demand for entrepreneurship education in business schools has grown and internationalization has increased student body diversity (Deuchar, 2004; Keogh and Galloway, 2004; Tan and Ng, 2006; Vos, Celik, and Vries, 2016). Business schools around the world improve their entrepreneurship programs with the goal that students become entrepreneurs or develop entrepreneurial perspectives in their future careers (Koning, 2016). Collaborative learning is one way to enhance students' attitudes and performances in marketing, accounting, and management courses (Bacon, Stewart, and Silver, 1999; Caldwell, Weishar, and Glezan, 1996; Deeter-Schmeltz and Ramsey, 1998; Hampton and Grudnitski, 1996; Miglietti, 2002). It is vital in the workplace that workers skilfully collaborate on projects, share information, and help each other to meet the demands of increasingly diverse markets and clients (Janz, 1999; Mikkelsen and Gronhaug, 2000; Vos, Celik, and Vries, 2016).

1.1 Entrepreneurship and entrepreneurship education

Entrepreneurship is a key driver of economic and social growth because it improves economic efficiency, yields innovation, and creates jobs (Shane and Venkataraman, 2000). By offering entrepreneurship education, educational institutions support students' efforts to become entrepreneurs or to use entrepreneurial skills in their careers (Koning, 2016). Entrepreneurship is widely defined to mean personal development, creativity, self-reliance, resourcefulness, and dynamism used to become *entrepreneurial* (Lackéus, 2015). The definition of entrepreneurship in a narrow sense applies to recognizing opportunities, business development, self-employment, creative ventures, and growth to be *an entrepreneur* (Fayolle and Gailly, 2008; Mahieu, 2006; QAA, 2012). Jones and English (2004: 416) defined entrepreneurship education as 'a process of providing individuals with the ability to recognize commercial opportunities and the insight, self-esteem, knowledge and skills to act on them'. Lackéus (2015) suggested that value creation is a common core in entrepreneurship education. The European Commission (2008: 10) defined entrepreneurship education as comprising four elements:

1. Developing personal attributes and skills that form the basis of entrepreneurial mindset and behaviour (creativity, initiative, risk-taking, autonomy, self-confidence, leadership, team spirit, etc.);
2. Raising the awareness of students about self-employment and entrepreneurship as possible career options;
3. Working on concrete enterprise projects and activities;
4. Providing specific business skills and knowledge of how to start a company and run it successfully.

These four elements address entrepreneurship in its wide and narrow sense. Regarding the topics in entrepreneurship education, business plan is one of the most common approaches to teaching entrepreneurship (Honing, 2004; Solomon, 2007).

1.2 Entrepreneurship and entrepreneurship education in Japan

The Global Entrepreneurship Monitor (GEM) is a well-known research project involving a comparative measurement of entrepreneurial activity in the world. It began in 10 countries, including Japan, in 1999, and as of 2016, it compares the impact of entrepreneurial activity on the national economy of 66 countries. The objective of GEM research is to clarify the growth process of venture companies, to understand the factors that activate entrepreneurial activity, and to make important policies with policymakers in each country on issues such as national economic growth, competitiveness, and employment (Mizuho Information & Research Institute, 2017). Among the seven major countries (the United States [US], Japan, Germany, the United Kingdom [UK], France, Italy, and China) in a survey in 2016, the US, the UK, and China were in the top in terms of total entrepreneurial activity (behavior and attitude). In other words, people in these three countries tend to recognize business opportunities and choose an entrepreneurial occupation more and are evaluated higher on entrepreneurial social position than those in other countries.

Meanwhile, the overall entrepreneurial activity (behavior and attitude) in Japan was extremely negative among the seven countries (US, Japan, Germany, UK, France, Italy, and China). The result was not temporary, but it was applicable to a long-term period of over five years. This survey clearly shows that Japanese entrepreneurial activity is in a serious situation.

The Ministry of Education, Culture, Sports, Science and Technology has been promoting the EDGE-NEXT (Exploration and Development of Global Entrepreneurship for NEXT generation) project, which is aimed at fostering human resources to support entrepreneurship and new business creation based on research and development in higher education and establishing ventures and ecosystem by stakeholders or related organizations. Moreover, the Ministry of Economy, Trade and Industry has been involved with the Venture Challenge 2020 project, which leverages an ecosystem of universities, research centers, and big companies to foster venture businesses. The expectation of MBA entrepreneurship education in Japan is high. However, as of 2013, more than 85 per cent of higher education institutions in Japan did not have an entrepreneurship course (Deloitte Touche Tohmatsu, 2014). Entrepreneurship education in higher education in Japan remains under developed.

1.3 Collaborative learning and the outcomes of team performance

Collaborative learning is a learning method in which students interact in small groups or project-based teams. An advantage of collaborative learning is that it improves students' involvement, problem-solving, and communication skills (Yazici, 2005). Entrepreneurship programs are often structured to include team-based projects (Man and Farquharson, 2015). Glăveanu (2010) demonstrated that the trend of collaborative learning in entrepreneurship education should shift from a focus on 'I' to an emphasis on 'we'. Previous studies have found that successful teamwork in higher education courses includes collaboration (Riebe et al, 2010; Scott-Ladd and Chan, 2008; Teo et al, 2012; Yazici, 2005). However, teams might not be successful when individual team members' performance is low or where the gap between active members and free riders is large (Brooks and Ammons, 2003; Siciliano, 2001). Thus, to date, the findings on entrepreneurship education with collaborative learning are mixed. Moreover, although there is general agreement that entrepreneurship education in higher education is a key driver of economic and social growth and that collaborative learning is important, few studies have focused on entrepreneurship education that includes collaborative learning.

Therefore, this study examined attitudes towards collaborative learning in a diverse sample of students in entrepreneurial education and differences between international and Japanese students.

1.4 Research hypotheses

H1. Entrepreneurship education with collaborative learning improves students' entrepreneurial learning process.

H2. International students' and Japanese students' perceptions of entrepreneurship education with collaborative learning are different.

2. Methods

A Japanese business school launched the New Global Venture Creation (NGVC) course, which is an entrepreneurship course in an English-language MBA program in 2017. Table 1 presents the details of the 14-session course. The NGVC course has a practical focus on the global aspect of entrepreneurship in a course of Japanese and international students. Its goal is to develop students' entrepreneurial attitudes, behaviours, abilities to create and implement business plans, strengthen students' competitive presentation skills, and support international students' efforts to start businesses. During the course, students from various backgrounds collaborate on projects to identify tasks, create business ideas using human-centred design thinking, build teamwork skills, and devise effective solutions as global leaders for better societies. The course contains 60 per cent lectures and discussions and 40 per cent group work. From sessions 3 to 12, in each session, two or three students present an inspiring product or service to their classmates. Moreover, in session 11, we invited a German entrepreneur who had launched his business in Japan with a Japanese partner and received a prize in a business competition in Osaka, Japan.

The instructors provide conceptual frameworks and conduct class discussions and workshops to help students to create innovative ideas, business strategies, market analysis, and financial statements regarding complex global issues. Students have opportunities to launch new businesses, such as social service businesses or businesses specific to their home countries or Japan. The course identifies ways to improve students' business skills, not only as entrepreneurs but also as project managers. Students work in groups for more than half of the course: 60 per cent of the final grade is based on the students' created business plans, which are collaborative assignments during class with additional time spent outside class, and 40 per cent of the final grade is based on individual participation during class periods and a written report.

Table 1: The syllabus of the New Global Venture Creation course

Session	Type of content	Content
1	Lecture	Welcome, introductions, and course objectives and goals; presentations of trends in entrepreneurial activity in Japan and around the world
2	Group work	Business plan (brain storming)
3	Lecture	Design thinking and establishing a new business
4	Group work	Team building (marshmallow challenge)
5	Lecture	Business plans (creating innovative ideas, business concepts, company strategies, market analysis, financial statements) and business model canvas
6	Group work	Business model canvas
7	Lecture	Marketing plans (STP, SWOT, 4P) and Internet strategies
8	Group work	Idea presentation
9	Lecture	Prototype
10	Lecture/ Group work	Business competition and presentations
11	Lecture	Stories about entrepreneurs
12	Group work	Business plan
13	Competition	Business plan competition
14	Competition	Business plan competition, positive feedback activity, summary of the course

Semi-structured interviews were conducted with 21 students in an English MBA program at a Japanese business school to explore their attitudes towards collaborative learning. Participants were 5 Japanese students with more than 10 years of experience, and 17 international students (11 nationalities) who had never worked full-time or had fewer than 3 years of work experience. About 61 per cent of the sample was male. Regarding age, 68 per cent was 20–29 years old, 18 per cent was 30–39 years old, and 14 per cent was 40–49 years old. About 68 per cent of the sample was from Asia, 14 per cent was from North or South America, 9 per cent was from Europe, and 9 per cent was from Africa. Regarding nationality, 24 per cent was Japanese, 14 per cent was Chinese, 14 per cent was Thai, 9 per cent was Indonesian, and 5 per cent was Filipino. The United States contributed nine per cent, and five per cent was from the Commonwealth of Dominica. Denmark, France, Liberia, and Cameroon each comprised five per cent of the sample (Figure 1).

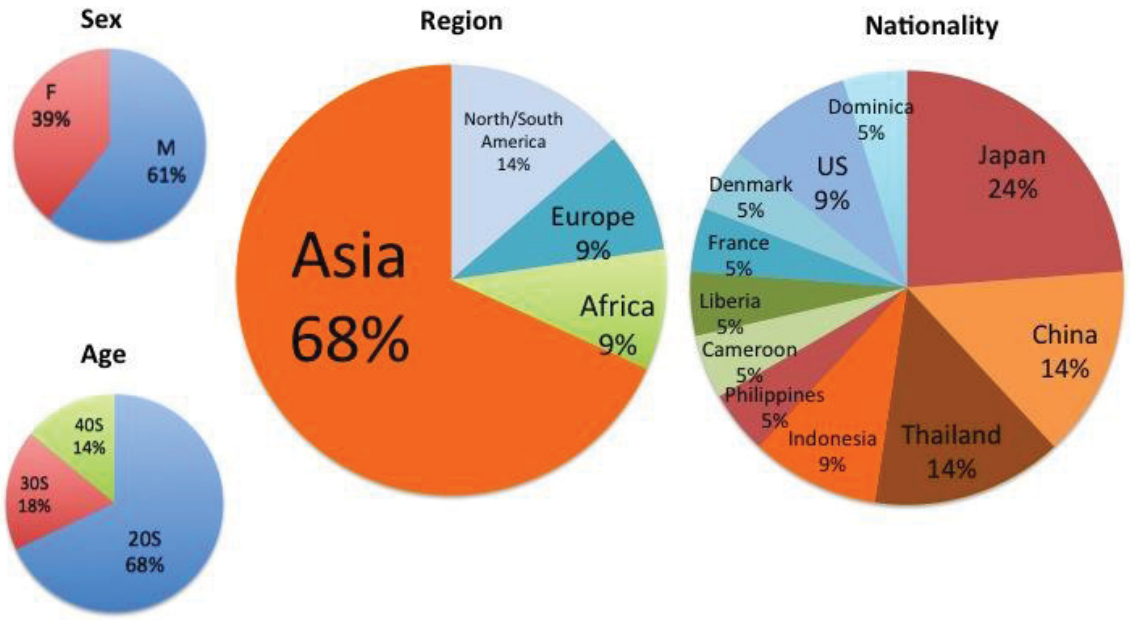

Figure 1: Sample characteristics as proportional distributions

The semi-structured interviews were conducted in English for international students and in Japanese for Japanese students in June and July 2017. The students were asked the following types of questions.

1. Personal background regarding education and career
2. Reasons for participating in the NGVC course
3. Learning during the NGVC course
4. Thoughts on the experience of collaborative learning

The interview data comprised 34,685 words in English and 17,433 words in Japanese. KH Coder was the text-mining method used to qualitatively analyse the content. KH Coder enables visualization of concepts embedded in huge text datasets. The tool extracts apparently related terms, organizes them in circular patterns, and draws collocation networks connected by lines. Large numbers of related words have big circles, and thick lines indicate strong connections (Higuchi, 2014). One advantage of KH Coder is that it avoids researcher bias that tends to arise during qualitative data analysis because it retrieves and analyses the precise word structures in the data (Higuchi, 2013). This study focused on the sizes of the circles, which indicated the number of words, and the thick lines that indicated strong co-occurrence relationships.

3. Results

KH Coder performed the co-occurrence network analysis, which found the number of occurrences of the terms and their similarities. The extracted and specialized terms of the Japanese students were categorized into nine groups of related terms (Figure 2). Group A included ‘business’, ‘plan’, ‘competition’, ‘canvas’, and ‘model’. Group B comprised ‘impression’, ‘entrepreneurship’, ‘design’, ‘website’, ‘story’, ‘remain’, ‘marshmallow’, ‘challenge’, ‘Number 1’, ‘last’, ‘reason’, and ’come up’. Group C was ‘input’, ‘output’, ‘think’, ‘feel’, ‘myself’, ‘opinion’, ‘present’, ‘lecture’, ‘theory’, and ‘practice’. Group D contained ‘presentation’, ‘skill’, ‘change’, ‘team’, ‘interaction’, and ‘interesting’. Group E included ‘Japan’, ‘Japanese’, ‘itself’, ‘culture’, ‘different’, and ‘search’. Group F comprised ‘young’, ‘foreign’, and ‘language’. Group G had the terms ‘English’, ‘class’, ‘understand’, ‘keyword’, ‘group’, ‘work’, ‘personal’, and ‘participation’. Group H had the terms ‘starting a business’ and ‘experience’. The last group (Group I) had the terms ‘fun’ and ‘speak’. The network that emerged suggested the following: (1) ‘students retain an impression of the sessions on business model canvas, business plan, business competition, Internet strategy, design thinking, entrepreneurship story, and marshmallow challenge in entrepreneurship’; (2) ‘students identify themselves to present their opinions and practice during lectures’; (3) ‘team interaction is interesting and presentation skills are developed’; and (4) ‘young international students encounter a different culture and need to search for information of Japan—understanding English is important in group work and individual participation in class’; (5) ‘starting a business is an experience’; and (6) speaking is fun.

The extracted and specialized terms of international students were categorized into eight groups (Figure 3). Group A included 'Japanese', 'work', 'company', 'school', 'Japan', and 'come'. Group B was 'entrepreneur', 'want', 'maybe', 'difficult', 'say', and 'really'. Group C comprised 'think', 'time', 'feel', 'know', 'people', 'idea', 'good', 'team', 'work', 'experience', 'learn', 'lot', 'talk', and 'different'. Group D included 'participation', 'class', 'input', 'output', 'lecture', 'presentation', 'per cent', 'plan', 'write', and 'evaluation'. Group E included 'entrepreneurship', 'challenge', 'remember', 'day', 'marketing', and 'model'. Group F comprised 'job' and 'look'. Group G comprised 'English' and 'speak'. The last group (Group H) had the terms 'try', 'understand', 'point', 'actually', 'thing', and 'like'. The network that emerged implied the following: (1) 'students retain an impression of the sessions on business model, entrepreneurship challenge, and marketing'; (2) 'maybe I want to be an entrepreneur, but it is difficult to make it happen'; (3) 'people are different—good teamwork is required to know ideas and think business, and a lot can be learnt by talking with different people'; (4) 'one of the reasons to come to Japan is to work at a Japanese company, and I will look for a job'; (5) 'class participation in lectures and presentations is required input and output related to my grade'; (6) 'I need to speak English'; and (7) 'I actually like to try, think, and understand the points'.

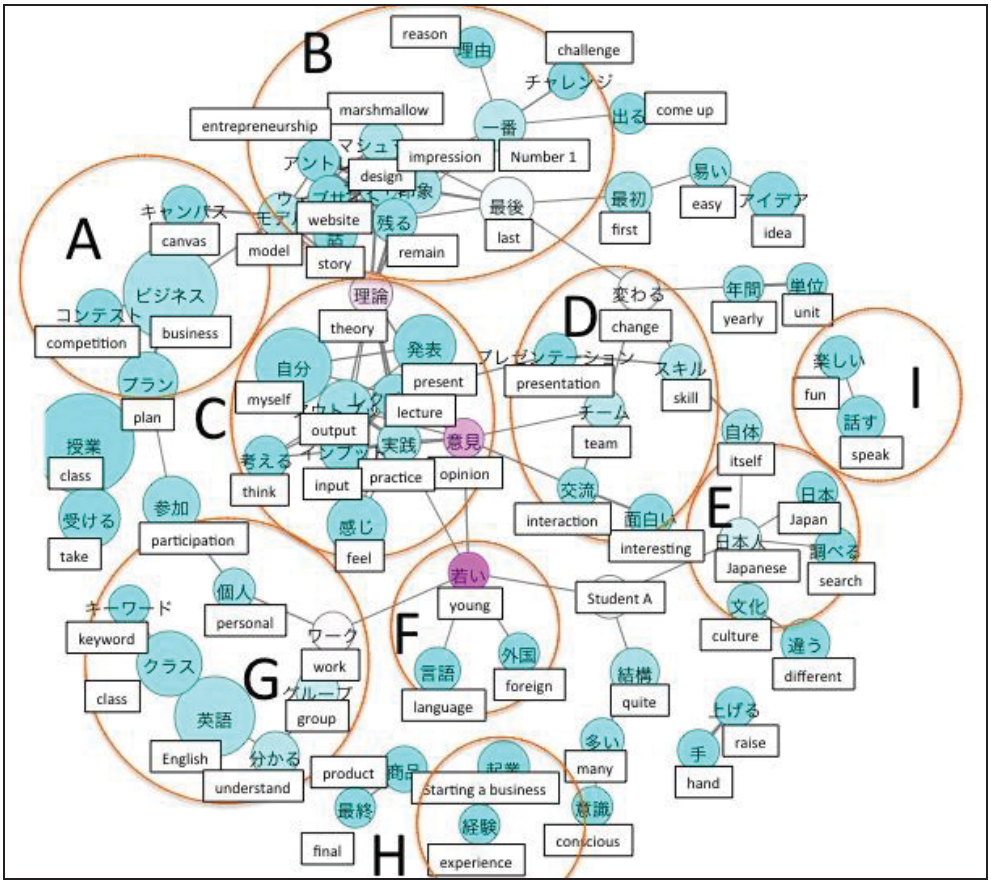

Figure 2: Japanese students' co-occurrence network analysis results

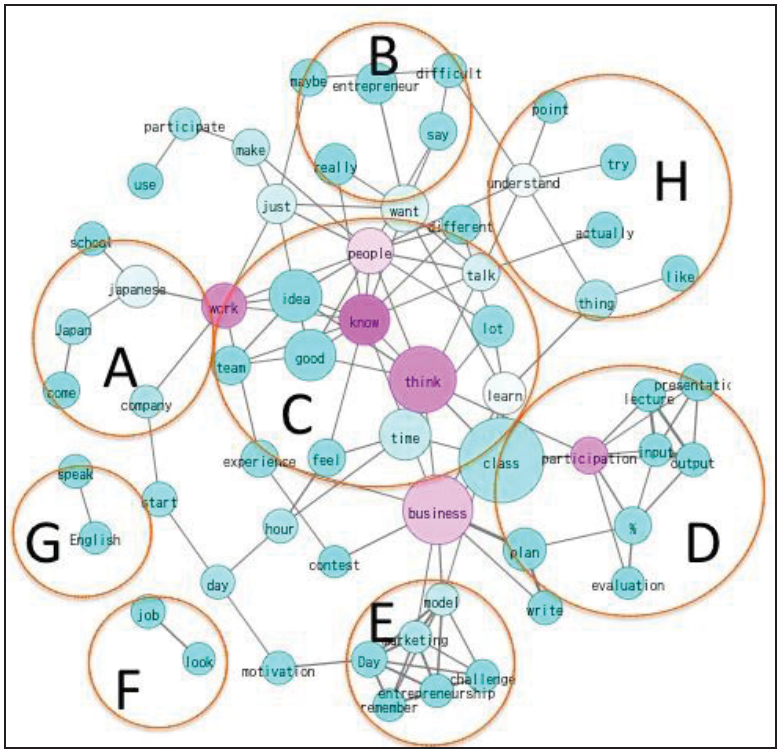

Figure 3: International students' co-occurrence network analysis results

4. Discussion

This study aimed to determine whether entrepreneurship education with collaborative learning improves students' entrepreneurial learning process, and whether international and Japanese students' perceptions of entrepreneurship education with collaborative learning are different.

The results revealed that it positively affects students' perceptions of entrepreneurship education with collaborative learning, in terms of 'speak fun', 'interesting', 'change', 'challenge', and 'understand English' as shown in Figure 2, and 'good team or idea', 'I like', and 'talk a lot' as shown in Figure 3. There are similarities and differences between Japanese and international students' co-occurrence network analysis results. In terms of similarities, both Japanese and international students stated the importance of class participation and teamwork. Japanese students reported that interacting in a team was interesting. They seemed to identify themselves as Japanese in an international collaborative learning experience based on the network circle in Figure 2 (Group B), content of 'Japan', 'Japanese', 'itself', 'culture', 'different', and 'search'. Comparing with a regular Japanese MBA course, international students were younger and had less work experience and a different culture. Japanese students might require a different strategy to explain their opinions during group work because their point of view in business discussions with international students could be different. Moreover, Japanese students require more explanation and presentation skills in English. As for international students, they stated that working with Japanese students had a positive effect in terms of finding good ideas on the process of making a business plan, because it was a good experience to have a rich conversation with their well-experienced Japanese classmates and have a different perspective during group work. The business plan could be developed practically from deep insights. Yazici (2005) states that collaborative learning improves students' involvement, problem-solving, and communication skills; the NGVC course especially affects their involvement and communication skills.

As for differences, there were three major ones. First, the impact of the sessions was different between Japanese and international students. Japanese students remembered the sessions on business model canvas, business plans, business plan competition, Internet strategy, design thinking, entrepreneurship story, and marshmallow challenge. On the other hand, international students remembered the ones on business models, marketing, and entrepreneurship. International students indicated that class participation during lectures and presentations was important to their grades. Japanese students thus remembered more sessions than international students. International students focused on a couple of sessions and grades.

Second, their awareness of being an entrepreneur was different. Japanese students remembered the session on entrepreneur story. They recognized that starting a business is an experience. They did not show any negative attitude. On the other hand, international students stated that entrepreneurship is challenging and becoming an entrepreneur might be difficult. In terms of barriers for becoming an entrepreneur, international students seemed to have more than Japanese students. One reason is that they have less work experience. Another reason is that, in the 11th session on stories about entrepreneurs, international students felt that becoming an entrepreneur in Japan is difficult. The guest speaker from Germany talked about the difficulties he faced in terms of legal and financial support without Japanese assistants when he launched his business in Japan.

Lastly, one particularly interesting finding was that Japanese and international students' objectives in the course differed. Japanese students apparently wanted to improve their English skills, according to the network circle in Figure 2 (Group G): 'English', 'class', 'understand', 'keyword', 'group', 'work', 'personal', and 'participation'. As for international students, most students are not native English speakers. They mentioned 'English' and 'speak' (Figure 3, Group G). However, they usually take an English MBA course. Their class objectives do not involve English. Japanese students emphasised more on speaking English as being one of the vital aspects in group work and class participation. On the other hand, international students were apparently interested in working in Japan. The network analysis found 'job' and 'look' (Figure 3, Group F), and 'Japanese', 'work', 'company', 'school', 'Japan', and 'come' (Figure 3, Group A). Therefore, it might be helpful to include activities in entrepreneurship courses in which Japanese students with 10 or more years of entrepreneurial experience share their work experiences with Japanese organizations to help international students generate ideas. Furthermore, it would be practical for students in the NGVC course to work with Japanese companies to make business plans together. This opportunity will enrich Japanese companies and help them discover business opportunities in different nations and learn how to work with diverse team members. As Janz, (1999), Mikkelsen and Gronhaug (2000), and Vos, Celik, and Vries (2016) mention that the demands of diverse markets and clients has increased, collaborating learning on projects is vital in the workplace.

5. Conclusion

This study explored entrepreneurship education with collaborative learning improves students' entrepreneurial learning process in a sample of diverse students and investigated the differences between international and Japanese students. The KH Coder methodology used in this study demonstrated the value of visualizing text in large text datasets, which made it possible to obtain these qualitative results. The results found that Japanese and international students identified class participation and teamwork as important aspects of the NGVC course. They seem to enjoy their interactions and show a positive reaction during the process of making a business plan. However, their perception of the sessions, awareness of becoming an entrepreneur, and goals in the NGVC course differed. Japanese students remembered almost all sessions and thought that starting a business is an experience. Further, they seemed to be seeking collaborative learning experiences with international students and opportunities to improve their English language skills. As a result, they identified themselves as Japanese in an international collaborative learning experience. On the other hand, international students remembered a couple of sessions such as business model, marketing, and entrepreneurship challenge. They felt that it would be difficult to be an entrepreneur in Japan. Furthermore, working in Japan could be one of the course objectives of international students. This study suggests that this course should be modified to accommodate Japanese students' ability to share their work experiences with international students in a collaborative learning environment. In addition, it would be a great experience for students in the NGVC course to work with Japanese companies to make business plans together. It is important that collaborative learning in entrepreneurship education comprises students of diverse cultural backgrounds from Asia, Africa, Europe, and the Americas because students tend to share ideas and participate in a course from their cultural perspectives.

5.1 Limitations

This study's results lack generalizability because of the limitations of its sample. Therefore, researchers are encouraged to analyse the student's entrepreneurial learning process of entrepreneurship education in larger and representative samples. Furthermore, this was the first time that a course on New Global Venture Creation (NGVC), which is a practical focus on the global aspect of entrepreneurship, was held with Japanese and international students in an English MBA program at a Japanese business school. Since this is only one course with both Japanese and international student enrollees, there could be wide disparities between first-year and second-year students in terms of entrepreneurial knowledge and skills. It could be interesting to

divide the entrepreneurship courses: one basic course and the advanced course. Also, this research shows only 14 sessions' worth of results. The longitudinal research on entrepreneurship education with collaborative learning will be need to be pursued in a future study.

Commonalities and Differences among Different Forms of Entrepreneurship Education

Alexandros Kakouris
University of Peloponnese, Greece
akakour@phys.uoa.gr

Abstract: Entrepreneurship education undergoes a continuously expanding phase for the last twenty years. Emanated from Business Schools in both US and Europe in 90s, fostering the entrepreneurial mindset penetrates now the curricula of the vast majority of academic institutes across the globe. It also tends to exceed the academic milieu leaking into informal learning settings. Nonetheless, the rapid evolution of entrepreneurship education has differentiated its nature by, at least, three different forms: the 'about', 'for' and 'through' ones. The 'about' mode focuses on information and knowledge transfer relevant to entrepreneurial phenomena in the economy and the society, the 'for' mode focuses, beyond knowledge, to entrepreneurial skills and capacities in order to produce graduate entrepreneurs while the 'through' mode aims at transforming traditional disciplines of all kinds into entrepreneurial ones. Further to the previous classification, 'critical' entrepreneurship education can be added as a distinct form for which there is published description and relevant research. The impetus of the present article is to briefly present the distinct forms of entrepreneurship education, as they appear in literature, and to connect them with entrepreneurial learning. Adopting the Bloomian framework of knowledge, skills and attitudes as fundamental components of learning, the article seeks to reveal which of them are in the spotlight in each distinct form of entrepreneurship education. The present conceptual analysis offers insights regarding the teaching models that could be expected in each of the different forms of entrepreneurship education, relevant assessments and outcomes. Excluding the 'through' mode that is visionary at present, evidence and examples of the rest forms abound in literature due to the many implementations of entrepreneurial courses worldwide. The article concludes that entrepreneurship education evolves rapidly in accordance with modern socioeconomic demands, but it also exhibits internal dynamics and differentiation coherent to the nature of the phenomenon of entrepreneurship that need to be further examined and understood in order to analyse the wider role of entrepreneurship education and the expectations from it.

Keywords: Entrepreneurship education, Entrepreneurial learning, Bloom classification

1. Introduction

What have the expectations from entrepreneurship education been during its evolution from the nineties until now? And how are these expectations confronted by several teaching models that build upon knowledge, skills and attitudes as principal elements of learning? Educational research in the field indicates fragmentation in content and methods (Fayolle 2013, Mwasalwiba 2010, Kakouris and Georgiadis 2016) urging for deeper understandings and typologies (Berglund and Johansson 2007, Kyrö 2000, 2015, Fayolle, 2013, Winkel 2013) for a further deployment of entrepreneurial courses in both formal and informal learning settings (e.g. Kakouris 2017, Preedy 2018). Complementary to the typical cognitive classes of knowledge, skills and attitudes, emotions and values attract recent research in order to holistically discuss the entrepreneurial instruction within the education doctrine (Kyrö 2000, 2015, Lackéus 2014). These perspectives have led to the discussion of multidimensional learning environments in entrepreneurship (Kakouris 2016a).

Tracking the bibliometrics of entrepreneurship education (e,g, Hermann and Bossle 2018, Kakouris and Georgiadis 2016) it emerges that entrepreneurial learning is mostly considered as cognitive or organisational and has also been loosely connected with the outcome of education. Experiential learning appears third, compared to the previous two forms, but also more efficient in inspiring entrepreneurial intentions (Piperopoulos and Dimov 2015). Another finding reveals that research bridging entrepreneurial learning and education with career planning of learners has been scarce (Kakouris and Georgiadis 2016). For sustainability education, as a subset of entrepreneurship education, common issues appear in literature: e.g. a demand for active pedagogies and experiential learning (Hermann and Bossle 2018). The underlying question is whether entrepreneurship education exhibits different forms and if so, what kind of pedagogies might facilitate the different educational perspectives?

The distinction among different forms of entrepreneurship education has been hinted from the very beginning of its various implementations (e.g. Johnson, 1988; Hannon, 2005; Heinonen, & Hytti, 2010). For example, Gibb (2002), based on Chia (1996) and Kyrö (2000), remarks: "*In an educationalist context this challenges the notion (see below), that one can separate 'for' entrepreneurship from 'about' entrepreneurship in an academic sense.*"

After a long period of relevant discussions, three forms of entrepreneurship education have been overriding, namely the 'about', 'for' and 'through' modes of entrepreneurship education (Lackéus 2015). Hannon (2005) has discussed different epistemological assumptions in pedagogy that can be associated to entrepreneurial teaching while Gibb and Price (2014) have summarised a wide set of instructional tools associated to different pedagogies. The aim of the present article is to compare the three distinct modes of entrepreneurship education and more specifically to address which learning components each of them focuses on. In this way, the objectives of entrepreneurship education, whenever implied in either formal or non-formal settings, can be further discussed in a coherent educational frame. Furthermore, scholars have argued that critical aspects of entrepreneurship should be considered in content and methods (Berglund and Johansson 2007, Kakouris 2015, 2017). To include critical entrepreneurship education as a distinct instructional state, the penetration of learning components framework by critical aspects is addressed.

In the rest of the article the three forms of entrepreneurship education are introduced whilst the customary Bloomian framework (Bloom et al. 1956) of knowledge, skills and attitudes is connected with these forms. Under the present interpretation, commonalities and differences among the distinct forms of entrepreneurship education are summarised. Criticality is also discussed in regard to the Bloomian framework.

The consequences and further educational implications of the present analysis are presented in the last section of the article.

2. Differentiating entrepreneurship education

For the needs of an OECD report, Lackéus (2015) summarised the types of entrepreneurship education as they have been developed over time. Three forms appear distinct in objectives and methods. These forms are briefly presented in the sequel, and then, they are analysed towards the Bloomian framework that consists the base for any instructional design.

2.1 Addressing the three forms of entrepreneurship education

According to the relevant literature, the different forms of entrepreneurship education, summarised in Table 1, can be described as follows.

The '*about*' mode aims at educating trainees in regard to business venturing phenomena generally. This has been the oldest form that pre-existed the observed expansion of entrepreneurship after 00s and has offered the paradigm for the development of courses dedicated to business venturing. Depend on the adopted perspective, i.e. management, economics, sociology, etc., the entity of analysis can vary among the firm, an economic region or state, the society, or more rarely, the individual whilst contingent knowledge (Fiet 2001) may come from the aforementioned fields. The learning objective mostly refers to knowledge transfer based on traditional lectures and analyses of case studies (i.e. cognitive approach). Knowledge acquisition is examined by the end of the courses through formal exams. Apparently, this form of courses dominates in formal settings of economics and business faculties often entitled as "Theory of Entrepreneurship". Under such circumstances, there is no given or clear evidence for the entrepreneurial propensity of graduates. The only goal that is examined is knowledge accumulation independently whether this knowledge will be used in new business formation by the graduates. For instance, graduates of such courses may be able to evaluate a business plan (or parts of a business plan) without developing their own business plan ever.

When aiming at inducing new business formation by the graduates, i.e. graduate entrepreneurship, entrepreneurship education entails its '*for*' mode. Therefore, the entity of analysis refers solely to the individual and her/his own capacities. The individual is considered motivated towards starting a new business whilst motivation can exist before her/his enrolment in the course or can be empowered during the course.

Experiential learning pedagogy is followed in the majority of relevant courses where various tools (e.g. business model CANVAS, PEST or SWOT analyses, marketing tools, elevator pitch, financial statements, business plan, etc.) are practiced in the classroom. Mentoring is also used as a supporting supplement to students' work (usually performed in teams). Contingent knowledge is retrieved from management, marketing or psychology fields. The expected outcome is auspicious business plans from student teams that might go further to possible competitions or find a way to funding and lead to new business formation.

Table 1: Three different forms of entrepreneurship education.

	About	For	Through
Objectives	Educate trainees about business venturing phenomena	Inspirit entrepreneurial capacities to become entrepreneur	Fostering the entrepreneurial way of thinking
Entity of analysis	Firm, individual, society	Individual	Individual
Knowledge domains	Economics, Management, Sociology	Management, Psychology	Psychology, Sociology, Economics, Philosophy
Main focus	Knowledge	Skills / Capacities	Attitudes
Trainees	Business and Economics students	Motivated students from all disciplines	All disciplines
Teaching tools	Lectures, Case studies	Practical tools, Exercises, "How to"s, Mentoring	Underdeveloped
Assessment	Typical examinations	Promising Business Plans	Discovering opportunities
Entrepreneurial propensity	Uncertain	Starting new businesses	Likely to become entrepreneurs
Learning effect	Knowledge accumulation	Knowledge exploitation	Knowledge transformation
Expected occurrence	Formal settings	Informal / Non-Formal / Formal settings	Formal settings

The '*through*' mode of entrepreneurship education refers to embedding the entrepreneurial way of thinking into any discipline. The entity of analysis is the individual who enters "an actual entrepreneurial learning process" (Lackéus 2015: 10) relevant to her/his core subject. An example of this type of education is given by Handscombe et al. (2008) for teaching entrepreneurship to science and engineering students at Sheffield University. Lackéus (2015: 8, Fig. 1) categorises the 'through' mode as highly practice oriented, focusing on skills and attitudes, and usually adopted in primary education and in work life and vocational training settings.

Experiential learning offers the base of the pedagogy where knowledge is derived through experience. Any type of knowledge may be considered relevant (psychological, economic, sociological, philosophical, etc.) as far as it concerns the evolving entrepreneurial learning. There are no pre-given and specific objectives for the learners who may be considered as likely to become entrepreneurs since they possess a positive attitude towards business venturing. Since this type of education is new, many of the adopted instructional tools are underdeveloped and created by educators *in situ* for the needs of the specific course. In higher education settings the 'through' mode aims to convert knowledge obtained in each core discipline into entrepreneurial knowledge where uses of this discipline-specific knowledge with market value are conceived. The willingness of the learners to pursue entrepreneurial opportunities typifies the success of this mode of education. In sum, the 'through' mode of entrepreneurship education is visionary, at the moment, leading some scholars (e.g. Kyrö 2015) to promote entrepreneurship education as a new paradigm of pedagogy with transformational potential in the modern uncertain society.

2.2 Associating the Bloomian perspective to the entrepreneurship education forms

Bloom's et al. (1956) taxonomy of learning domains has been the most used framework for instructional design and evaluation. According to the 1956 educational psychology committee, led by Benjamin Bloom, the cognitive, psychomotor and affective domains are distinct in the human learning process. The cognitive domain deals with the acquisition of knowledge, the psychomotor with the cultivation of skills (hard or soft), and the affective one with the development (or moderation) of attitudes. Therefore, within the education field of study it has been widely accepted that participating in any kind of education simultaneously affects the previous learning domains: knowledge, skills and attitudes (hereafter KSA). The embracement of the KSA triptych for the content and outcomes introduces a simple and 'common' understanding for entrepreneurship education and for building teaching models and assessments associated to it. Nonetheless, the entrepreneurial KSA framework has not been fully discussed and theoretically deployed yet. Many scholars define entrepreneurship education as a 'delivery of knowledge and skills' underestimating attitudes and their role despite 'fostering the entrepreneurial mindset' purely refers to an attitude. These three learning domains are closely discussed in the sequel.

It is argued here that there are inherent difficulties in each one of the incorporated learning categories. Beyond the classical debate and criticism about the systemicity of Bloom's learning domains, i.e. KSA are interrelated and evolve together so as changes in one of them affects the other two and the whole of learning, intrinsic questions for entrepreneurship education in academic settings concern entrepreneurial knowledge and skills themselves. Let us suppose that each KSA category can be understood as separate, as the vast

majority of educators and educational designers tacitly accept. What constrains the entrepreneurial knowledge and how many entrepreneurial skills exist? Despite the efforts to answer such questions (e.g. Johannisson, 2016), knowledge encounters the shortage of a genuine theory for entrepreneurship (e.g. Bygrave 1993, Bygrave and Hofer 1991, Fiet 2001) while entrepreneurial skills remain inadequately explored and discussed in a rigorous framework (e.g. Bird 1995). Attitudes are possibly the least explored learning domain and have been predominantly and systematically confronted through the Theory of Planned Behaviour (e.g. Ajzen 1991, Krueger and Carsrud 1993, Krueger and Brazeal 1994), or sporadically elsewhere (e.g. Kakouris 2016b), appearing crucial for the formation of the entrepreneurial intention. They are also recognised as the most affected learning domain from the local culture and other external influences (e.g. Nicholson and Anderson 2005). Remarkably, Shane (2008) has addressed a series of existent 'illusions' for entrepreneurship that can obviously play a significant role in the formulation of entrepreneurial attitudes. Even the massive fostering of the entrepreneurial mindset during the last decades has led to a tremendous increase in the youth population who declare a positive attitude toward becoming entrepreneurs, an issue that may need a more critical approach and analysis (see next section). In sum, the KSA triptych that is widely, and sometimes 'uncritically', adopted in instructional design for entrepreneurship consists the underpinning for the development of pedagogy, teaching models or teaching philosophy, and educational assessment. Any insight that advances each of the three Bloomian learning domains strengthens the theoretical foundation of entrepreneurship education as a distinct form of pedagogy (Kyrö, 2015). The relevant question is how each form of entrepreneurship education builds upon KSA?

To address this question we have first to consider that knowledge is more than skills that are more than attitudes. Contingent knowledge, relevant to entrepreneurship, is abundant and it can be purely entrepreneurial or domain-specific. Skills pertain to what one could do with her/his knowledge, depend on her/his innate abilities, and how much of it could be exploited and in which way; whilst (general) attitudes are fewer and concern how positive or negative is one towards certain actions, motives or needs (e.g. risk-taking, contributing, sharing, well-being, morality, responsibility, achievement, etc.). It emerges from the discussion in section 2.1 (Table 1) that the 'about' mode of entrepreneurship education follows the traditional academic perspective that builds upon knowledge (Figure 1a). As far as enough knowledge is acquired, skills are developed accordingly and depend on knowledge and skills relevant attitudes are formulated or modified.

Thus, the 'about' courses apply to everyone, extend the knowledge base of the individual and assume that entrepreneurial skills and attitudes will appear. The outermost objective is knowledge acquisition (especially business knowledge) and therefore it dominates entrepreneurship education in Business and Economics Schools (Table 1).

Conversely, the 'for' mode of entrepreneurship education builds upon skills (Figure 2b). Starting from what students can do and through experiential learning pedagogies relevant knowledge is acquired through practice. Depend on skills and knowledge acquired, the relevant attitudes are affected. This mode is highly dependent on the skills and capacities of the students since they are asked to take initiatives in order to engage in the experiential learning process. Knowledge is still a learning objective but it is path-dependent and can be different amongst learners or groups of learners by the end of the process. The outermost learning objective is what the students will be able to do by the end of the course that suits to their own skills which will have been enhanced through the process. Learning to learn, for example, is a certain capacity that can be cultivated during this type of courses. The 'for' mode of entrepreneurship education has been spread around in both formal and informal settings aiming at producing graduate entrepreneurs.

The 'through' mode of entrepreneurship education copes with attitudes. It actually starts from attitudes (Figure 1c) and proceeds with skills and knowledge. It needs everyday observations that concern the socioeconomic environment and certain human behaviours to discuss the attitudes of the participants towards these observations. It refers to anyone as a member of the society and exhibits an inclusive character. Rapid changes in the environment and induced uncertainty can trigger the process aiming at encouraging the participants to consider their own skills in order to respond to future situations. Any insights from psychological, sociological, economical or philosophical perspectives are relevant to the examination of the emerging attitudes. The willingness to perceive and pursue opportunities created by the turbulence indicates the outermost objective of the 'through' mode. These opportunities will meet the personal skills of the students that are expected to acquire the relevant knowledge at a later phase. Because attitude is the underpinning of this mode in its very beginning, critical examination of the various facts and arguments is

needed to avoid any external 'false' influences or biases (cf. Shane 2008). Instructional tools to cope with attitudes are known to be scarce and need to be developed (e.g. Kakouris 2015). There are not many examples of the 'through' mode up to now but it apparently possesses a transformational potential.

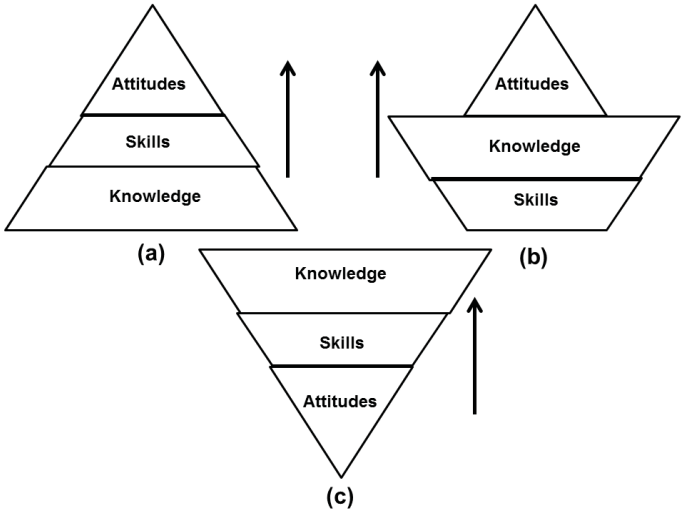

Figure 1: Three different structurations of the Bloomian framework.

In sum, three different hierarchies (structures) and the interplay among the Bloom's learning domains were discussed in this section (Figure 1). The three forms of entrepreneurship education confront the KSA triptych but in different ways and priorities. The present discussion contributes the development of instructional models efficient for each one of them.

3. Critical entrepreneurship education

Within the education field of study, critical education occupies a distinct domain. Critical pedagogy has been originated by Paulo Freire in 1970 and has been differentiated through the time (see Freire 2018).This type of pedagogy applies in cases and subjects where critical questions appear crucial for the learning process. Long-standing unanswered critical questions may cause disorienting dilemmas and disturb entrepreneurial learning (e.g. Kakouris 2015). Critical questions emerge from deep beliefs and assumptions of the individuals revealing the underlying stereotypic considerations.

Entrepreneurship, especially in the individual unit of analysis, appears a-theoretical (Bygrave 1993, Bygrave and Hofer 1991, Fiet 2001) with strong ties and influences from the socioeconomic environment that may induce a series of underlying critical questions. These questions are crucial in the 'for' mode of entrepreneurship education where students are expected to take initiatives and actions to become entrepreneurs. They do not affect the skills and the capacities of the individuals but the type (the relevance and the validity) of the knowledge they have to look for. Remarkably, Shane (2008) reveals various aspects of entrepreneurship that can be 'illusionary' when entrepreneurship is taught. For the 'about' mode similar cases can appear, in a less extent, through unjustified case studies, politically biased theories (e.g. Lackéus 2017) or stereotypic influences from other disciplines and fields. Therefore, critical and thorough examination of the adopted knowledge, case studies and contingent theories are needed to be adopted when entrepreneurship is taught in academic settings.

Criticality affects crucially the 'through' mode of entrepreneurship education. Critical aspects of entrepreneurship that interact with the beliefs and the attitudes of the participants may cause unpredictable situations in the classroom. Critical pedagogy mostly refers to such cases tending to be emancipatory. For example, education that aims to empower female entrepreneurship has to be critical. The same holds for immigrant entrepreneurship. Berglund and Johansson (2007) adopted the Freirean perspective to entrepreneurship and regional development. They analysed a project (DiE) to inspire entrepreneurship in a 'vulnerable' Swedish region where people do not view themselves as entrepreneurs. Kakouris (2017) adopted the constructivist approach to develop informal learning in entrepreneurship based on critical thinking. The latter implementation revealed that various assumptions and beliefs, associated with attitudes, underlie teaching and appear through typical instructional incidents during the process. This kind of teaching has to be

recognised as different and proponent to critical entrepreneurship education that needs to utilise its own pedagogy and methods (e.g. communicative learning, critical discourse).

Critical entrepreneurship education is also expected to confront more efficiently the axiological base of entrepreneurship (Kyrö 2015) – a more central issue in Continental education compared to the Anglo-Saxon one. In this way it will be able to discuss values beyond knowledge, skills and attitudes. Therefore, entrepreneurship education will be better connected with social needs, social cohesion, sustainability and employability. For instance, the last GEM survey in Greece showed that after a continuous increase in the number of young entrepreneurs there is decay during the last year. Such findings indicate that entrepreneurship education has to reflect on its operation and to encompass the social phenomena and needs in a critical manner.

4. Conclusions

The present conceptual article discussed the learning components of the different forms of entrepreneurship education. The 'about', 'for' and 'through' modes have appeared distinct in objectives and methods. These forms have followed the dynamics of entrepreneurship as a phenomenon and a field of research. The 'about' mode is the oldest one, stemmed from Business Schools. The 'for' mode follows the modern demand for an increase of start-ups from graduates; whilst the 'through' mode is visionary for the future of entrepreneurship education. Concerning the Bloomian domains of learning, the 'about' mode builds on knowledge and progresses to skills and attitudes in order to educate students in regard to entrepreneurial phenomena. It follows the traditional academic teaching 'pyramid' shown in Figure1a. The 'for' mode starts from skills and proceeds to knowledge and attitudes. It mostly aims to produce graduate entrepreneurs. The 'through' mode builds on attitudes and progresses to skills and knowledge as shown in the 'reversed pyramid' of Figure 1c. It aims at transforming all disciplines into entrepreneurial ones. Implications of the present discussion concern the teaching models for each entrepreneurship education mode. The 'about' mode follows knowledge transfer and the 'for' one follows experiential learning. Efficient methods and models for the 'through' mode need to be developed further. Apart from the three previous modes, critical entrepreneurship education has to be considered as distinct. Critical aspects of entrepreneurship have to be included in the curricula confronted through critical pedagogies and methods. In this way, entrepreneurship education will be integrated and able to facilitate the emerging social needs.

How French Enterprises Cultivate a Culture of Innovation in their Workplaces

Hady Khalaf[1] and Frank Rouault[2]
[1]Bel, Beirut, Lebanon
[2]Practical Learning, Paris, France
hadykhalaf@gmail.com
p.l.france@orange.fr

Abstract: Every firm strives to be among the most innovative in its industry, but only a very few succeed. According to a report published by BCG (2016), the top 50 most innovative companies share one thing in common: the ability to create a culture that makes them more innovative than their peers. However, an innovation culture is an intangible resource that cannot be explicitly measured (Godfrey and Hill, 1995), and therefore, altering a company's culture is not a straightforward process. To study this, grounded research was used to identify the major themes associated with the innovation culture phenomenon. These were then verified through semi-structured interviews conducted with senior professionals selected from several French enterprises. We found that firms cultivate an innovation culture by introducing new capabilities on top of existing ones and by opening more to the outside. We also found that It is difficult to cultivate an innovation culture if a classical leadership style predominates the organization. The findings concur with the dynamic capability and the transformational leadership theoretical perspectives. They also show that innovation culture is altered through initiatives towards the actors (leadership), the activities (new capabilities) and the environment (openness), building on the anthropological perspective of culture. These findings deepen our understanding of the innovation culture phenomenon, which can provide senior managers in French firms a set of actions to incorporate into initiatives to develop the right ecosystem and capabilities to innovate and sustain their competitive advantages.

Keywords: innovation culture, innovation performance, capabilities, openness, transformational leadership

1. Introduction

Present thinking regarding organisational theory and strategy is shifting from the sustainability of competitive advantage to the capacity to manage innovation and change (Brown and Eisenhardt, 1997; O'Reilly and Tushman, 2008). Most factors affecting innovation performance are beyond the firm's control, including the firm's intangible innovation culture, which can be viewed as the invisible hand that affects the firm's entire innovation performance.

This paper focuses on the cultivation of innovation culture by exploring themes derived mainly from the dynamic capability perspective. A multiple-case analysis across different industry sectors in France was conducted using semi-structured interview techniques. The findings and the limitations of the research and its contribution to practice and theory are then discussed.

2. Literature Review

Two definitions of culture, based in anthropology and management, seem to have gained general acceptance (Wines and Napier, 1992). Anthropologists view culture as an intangible phenomenon specific to the very nature of individuals, nations, and organisations. Jones (2006) referred to it as "invisible baggage" that crosses oceans, national borders, and language communities. Singh (2004) noted culture is internalized at the most basic level in the form he calls "Habitus", which is formed by learnings from the extra-personal world of everyday practices and experiences. According to Schwartz (1992), culture consists of the derivatives of experience learned or created by the individual and is transmitted from past generations. Leung *et al.* (2005) described culture as a fuzzy set of basic assumptions and values, orientations to life, beliefs, policies, and behavioural conventions shared by a group of people. The management perspective considers how to build, develop, and put into practice the innovation culture phenomenon (Angel, 2006; Coffman, 2006). We intend to answer this question through four propositions derived from the literature that are subsequently discussed.

2.1 Innovation culture and innovation performance

The relationship between specific explanatory variables and innovation performance has received much attention. Denison, Hooijberg, and Quinn (1995) explored the relationship between leadership and innovation performance, and Kanter (2008) associated culture with innovation performance. Further exploration of the

innovation culture (IC) phenomenon shows IC combines factors related to leadership, strategy, organisational structure, and people's capabilities and their mindsets.

Most authors agree that innovation culture can either drive or hamper organisational performance (Christensen and Raynor, 2003). Ahmed's (1998) study of 21 cross-industry cases showed a positive relationship between innovation culture and innovation performance. Similarly, Le Bas and Laužikas's (2010) study of Lithuania's information technology sector and Padilha and Gomes's (2016) focus on 16 textile firms in the state of Santa Catarina in Brazil concurred.

This association shows innovation culture should not be treated as an abstract phenomenon or an invisible hand that has an unclear effect on innovation performance. Instead, it should be viewed as a management entity (McCormick, 2008) influencing incremental and disruptive innovation performance. Incremental innovation performance focuses on minor improvements or simple adjustments in current technology (Munson and Pelz, 1979). It represents the firm's capability to adapt its products and services to market trends without changing the rules of the game. In incremental innovation, the element of risk is contained.

Conversely, disruptive, or radical, innovation performance involving new product creation undermines the capabilities on which conventional players have built their success (Markides, 2006). Disruptive innovation performance is not achieved in the classical way; it requires an independent system of thinking along with a dynamic learning process (Markides, 2006). Disruptive innovation is accordingly concerned with a different set of behaviours, skills, and organisational habits; thus, it requires a different innovation culture. The relationship between innovation culture and innovation performance is consequently positive.

- **P1:** There is a positive relationship between innovation culture and innovation performance.

2.2 Innovation culture and dynamic capabilities

The foundations of the innovation phenomenon are built on change. Innovation culture literature pairs a static phenomenon, like culture, with a dynamic phenomenon, like innovation. Therefore, to analyse "innovation culture", one must consider the stability-change dilemma (Jucevicius, 2007).

The dynamic capability perspective has been linked with the innovation phenomenon to address how to effectively execute innovation activities and influence a firm's innovation performance. A firm's dynamic capabilities take the form of organisational structures, processes, infrastructures, and other mechanisms that enable the firm to enhance its innovation performance. They also govern how it integrates, builds, and reconfigures internal and external competences to address changing business environments (Teece, Pisano, and Shuen, 1997). Dynamic capabilities enable firms to create new products and processes to respond to shifting market dynamics (Teece *et al.*, 1997). According to Daher (2016), the fundamental elements of most definitions of innovation are based on an organisation's dynamic capability to initiate, develop, or implement new ideas, products, or technologies.

Zollo and Winter (2002) distinguished between operating routines and dynamic capabilities (the patterns of generating and modifying routines). A firm can deconstruct and eliminate the capabilities, routines, competences, and skills that block its adaptability to a changing environment (Hall and Andriani, 2002). Identifying the hierarchal organisation of dynamic capabilities helps in understanding how they influence the firm's innovation culture. Collis (1994) defined the first hierarchical capability category as the firm's ability to perform basic activities; the second and third categories as its ability to improve on these activities; and the fourth category as a high-order meta-learning capability. Danneels (2002) differentiated between first-level and zero-level capabilities, which illustrate the firm's ability to learn new domains. However, Winter (2003) viewed zero-level capability as ordinary operating capability that incorporates the core functions firms use to earn its current living.

First-order capability addresses how firms build basic capabilities, competences, or routines to sustain present performance. However, innovation culture is influenced by higher-level capabilities that drive incremental and disruptive innovation performance. New, more flexible organisational forms (Ahmed, 1998; Martins and Terblanche, 2003), simplified decision-making processes (Jiménez and Sanz-Valle, 2012), cross-functional project teams (Crossan and Apaydin, 2010), and innovation champions are examples of capabilities that stimulate and support the firm's innovation culture's operating framework. Drivers of an innovation culture

fall into three primary clusters: 1) identification, development, co-development, and assessment of technological opportunities and threats related to customer needs (sensing); 2) resource mobilisation to address needs and opportunities and capture value (seizing); and 3) continued renewal (transforming) (Teece, Peteraf, and Leih, 2016).

Innovative organisations are agile and dynamic by default and can make timely, effective, and sustained changes when required (Winby and Worley; 2014) by acquiring new skills and knowledge and new organisational structures to execute their innovation strategy. A key feature of an agile innovative organisation is its ability to accelerate its innovative activities to respond quickly and successfully to change, thus building a time-based competitive advantage (Kumar and Jaideep Motwani, 1995). These organisations introduce novel working practices to avoid wasting resources (Winby and Worley, 2014), and they build routines, capabilities, or behaviours on top of existing ones to adapt faster to changing environments (incremental innovation) or to create new environments and markets (disruptive innovation).

In this paper, we simply refer to these capabilities as "new capabilities" that influence the firm's capacity to change, continuously renew itself, and innovate. French companies that are challenging their current capabilities and are building higher level of capabilities to innovate are seriously working on their innovation culture. By default, new capabilities challenge the classical habits and influence the firm's innovation culture.

- **P2:** There is a positive relationship between new capabilities and innovation culture.

2.3 Innovation culture and firm's openness

The continuous renewal and transformation of a firm's capabilities is a cornerstone of the dynamic capability perspective. Higher-level capabilities today are not only built from inside the firm but also sourced from outside their boundaries.

The innovation process has become collective and combinatorial (Coombs and Metcalfe, 2000). Open innovation uses purposive sourced knowledge inflows to accelerate internal innovation and facilitate outflows to expand the markets for external use of the innovation (Chesbrough, 2003). The main difference between an open and closed innovation is a cultural one. With open innovation, firms accept not only to externally source ideas from but also to learn and co-create with the outside. By building learning networks with other members of their value chains, firms establish high-value relationships and access to a wide range of company-to-company linkages that enable the free flow of information to continuously renew and update their knowledge.

The innovation game today has become a multi-player one, and companies like Amazon, Airbnb, and Uber have disrupted the overall value chains of the trading, services, and public transport sectors. Progressing from the classical linear innovation models (Chapman and Corso, 2005) to network or collaboration-focussed innovation (Chesbrough, 2003) is viewed as an evolution in the firm's innovation culture. Innovative enterprises are now oriented to their customers, wherever they may be (Martins and Terblanche, 2003). Thus, innovative companies include suppliers, customers, start-ups, and innovation clusters in their strategy and co-create ideas with them. For instance, France is considered to have a mature start-up ecosystem, but the deal flows between start-ups and traditional corporations are still limited. Co-creation is enabled by open working spaces in which employees collaborate with each other and their customers and suppliers, which is a model shown to enhance innovation performance. A recent study on a large South Korean e-commerce company showed bringing individuals' workspaces closer led to more individual-level exploration resulting in higher organisational performance (Lee, 2017). In Europe, France is the fourth largest country in number of co-working spaces (Deskwanted.com, 2013), which mostly consist of start-ups and young entrepreneurs, but the linkages with traditional French organisations are still weak. Innovative companies leverage diversity, seeing multi-cultural project teams as an opportunity to expand their knowledge base (Wenger and Snyder, 2000) and stimulate innovation behaviour.

Co-opetition is an open innovation model that drives firms to collaborate and share knowledge with their competitors (Bengtsson and Kock, 2000), and this openness phenomenon can influence the entire innovation culture of the firm.

- **P3:** There is a positive relationship between openness and innovation culture.

2.4 Innovation culture and leadership

Innovation ability rests in the skills of the workers, but it also depends on how motivated the workers are to try something new and challenge the status quo. The organisation's leadership style is the starting point in building a disruptive innovation culture. Transformational leadership theory provides an understanding of how leaders can stimulate innovation: transformational leaders tap into followers' intrinsic motivations and drive them to think bigger, serve the organisation's collective interests beyond the ordinary limits (Bass, 1985), and challenge the prevailing culture. According to Bass (1985), transformational leaders are distinguished by four behavioural "I's": idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration, and each of these either directly or indirectly influence the firm's innovation culture.

Leaders who use various motivational techniques to provoke and push their teams to innovate are the engineers of an innovation culture. Employees who are intrinsically motivated are inner directed and do not expect a financial reward in executing the task; they are interested and engage in a task because of its nature (Utman, 1997). Moreover, intrinsic motivation is a well-established predictor of creativity (Shalley, Gilson and Blum, 2000).

Transformational leaders empower their teams by putting the innovation task at the centre of the way their teams should work, and this empowerment is assumed to be a cause of intrinsic task motivation and satisfaction (Spreitzer, 1995). It may cause workers to accept tasks in addition to their daily routines because they enjoy inventing something new or challenging something that exists. Thus, a positive relationship is established between meaningfulness, self-determination, and intrinsic task motivation (Gagne, Senecal and Koestner, 1997).

In intrinsically motivating their teams by extending the opportunity to engage in entrepreneurial tasks, transformational leaders recognize risk-taking behaviour is perceived as an opportunity to disrupt, create, and succeed or to try, fail, and learn. The importance of promoting entrepreneurial behaviour at work is gaining increasing attention in the literature. Sicotte, Delerue and Drouin (2015) emphasized entrepreneurship appears to contribute the most to performance and innovation portfolio management. Daher (2016) discussed the values that promote innovation, such as value novelty, breaking traditions, autonomy, results oriented, mistake tolerance, adaptability, empowerment, and others. Thus, employees must act more like entrepreneurs and intrapreneurs (Leybourne, 2010), and by intrinsically motivating teams to engage in entrepreneurial behaviour, transformational leaders build an innovation culture that can enable incremental and disruptive innovation performance. Good managers think creatively, act entrepreneurially, and, if necessary, override routines. However, the dynamic capability perspective has paid little attention to the role of leaders in driving change, which is addressed in the fourth proposition.

- **P4**: There is a positive relationship between leadership and innovation culture.

3. Research Method

Our initial exploration is qualitative and relies on the five features of qualitative research proposed by Yin (2011, p 7). It is subjectivist and exploratory and follows a constructivist and problem-oriented research theory (Lawrence, 1992). It combines an EMIC–ETIC perspective (Pike, 1967) via a semi-structured questionnaire.

Eleven cases of leading French enterprises across different sectors, including telecommunications, banking, leading retail chain, pharmaceuticals, construction, real estate, travel, insurance, media, service to individuals, and organisations, were analysed. The interviewees are all French leaders with local and/or international responsibilities.

The data generated was reviewed borrowing coding techniques in the grounded theory approach to empirical research (Glaser and Strauss, 1967; Hernandez, 2009). Saturation was addressed in terms of content and process through the 7+/-2 Miller model (1956). The combined business experience of the two authors made them comfortable sharing the initial findings and acknowledging that further cases are planned to address reliability and validity.

For ethical and confidentiality reasons, we have chosen not to present the names of the organisations we have explored. However, four are in the CAC 40, and seven employ from 100 to 10,000 employees.

4. Data Analysis

We will review our initial findings towards the four propositions and discuss the limitations and the further research needed.

- **P1:** There is a positive relationship between innovation culture and innovation performance.

As proposed by the literature, the relationship between innovation culture and innovation performance is not questioned: most of the leaders interviewed agreed that innovation culture is positively related to innovation performance. Some interviewees even positioned culture as a prerequisite to innovation performance:

"If you have the means and conditions, but not the culture, innovation will not happen. But a culture and limited means will generate innovation." (pharma enterprise interviewee)

Most of the interviewees were dissatisfied with their firms' overall innovation performances, seeing their companies as neither disruptive nor fast moving due to cultural reasons. One of the interviewees explained French enterprises do not tolerate failure; moreover, they are afraid to fail, and therefore do not recruit employees based on their capacity to create and change. Consequently, they are stuck with conventional generations, making it difficult to establish a culture in which innovative behaviours are dominant.

Interviewees from companies agreed innovation culture should touch all domains and functions (not only exclusive to marketing). They recommended following a 360° approach treating acceptance of mistakes as a core organisational value that defines the firm's innovation.

"When you create and you are not afraid to fail, you have a culture of innovation." (online travel agency interviewee)

In the cases observed, licensing failure was a core theme that can alter firm's innovation culture. However, this transformation is not simple because it touches on the "perfectionist culture" of French enterprise. It may not mean lowering the standards but making them more adaptable to market needs in the present and the future.

The interviews conducted pave the way to deeper explorations around the "Perfectionist-Success" dilemma that may be hindering French enterprises from building an innovation culture. The notions of "Perfection" and "Speed" must be explored in line with the notion of market orientation.

- **P2**: There is a positive relationship between new capabilities and innovation culture.

The qualitative and intangible nature of the innovation culture phenomenon makes it difficult to quantitatively measure its impact on innovation performance. However, the positive relationship between innovation culture and innovation performance has steered the discussion towards how to build an innovation culture. Some interviewees viewed it as a question of process and stressed the need for French enterprises to enhance the practice of processes like Six Sigma. Others highlighted the importance of collaboration and information exchange and the need to encourage diverse team building to connect people with different jobs in various geographical locations. This would combat the silo effect and French enterprises' monocultures. Examples from the UK, where diversity is considered a competitive advantage, were given that demonstrated how classical capabilities and maintaining old ways are serious barriers to innovation. However, a leading French brick-and-mortar retailer does not feel threatened by the e-commerce disruption, especially if employees are neither equipped with innovation capabilities nor feel any urgency to become so.

"The organisation culture does not allow to work in project mode, to go fast and move forward." (leading brick-and-mortar retail chain interviewee)

These types of enterprises should be the first to be disrupted because they are neither proactive nor able to quickly react to external threats.

The themes "we are very late" and we "fear to fail" were serious concerns voiced by most of the interviewees.

One can conclude French companies like to take their time (we are very late) in perfecting capabilities that reduce the risk factor (fear of failure). In today's context, failure to anticipate future capabilities is considered a dangerous behaviour that exposes the firm and its industry to disruption. Of the companies we explored, only one, a leading telecom operator, is earnestly working on future capabilities. Building future capabilities should however be the concern of every company across all industries. One of the interviewees noted some of the major multinational French firms, from the smallest SMEs, start-ups, and scale-ups and whether local or regional, are experiencing disruption today. For instance, innovative financial technology (FinTech) is already competing with and disrupting the banking industry. The French banking industry has a choice: it can take a leading stance on FinTech innovation or it can be disrupted by it. The former is only an option if banking enterprises dynamically transform themselves as expressed during the interview with a regional banking firm in France:

"Innovation is incremental on an ongoing basis, and we prepare for disruption in the future." (regional bank interviewee).

In the past, being big was an advantage. However, one interviewee noted, today, big companies that fail to transform and renew themselves, which they can only achieve through rethinking their existing organisational structures and moving to be more flexible and agile, can be at risk. But, agile structures are only achieved by breaking individual and functional silos and working collaboratively. Many interviewees stressed the need to somehow democratize the innovation process, with innovation carried out by all managerial functions and levels. This consequently requires building innovation capabilities within various functions and teams led by innovation champions who carry out the innovation process by helping teams think differently. As an example, an interviewee recommended designing temporary structures that can operate in a "commando project mode" either to react to a challenge or to initiate and drive a new idea.

A new structure deployed without an innovation-enabled infrastructure could be a failure. Therefore, establishing a digital infrastructure to connect various teams and encourage sharing best practices and new ideas is important. One company we explored, for instance, has addressed this and developed internal technology labs to explore potential technologies and anticipate future trends, and another company is reviewing the interior design of its workplace. A question raised, however, is how the new knowledge created can be activated.

"French are very innovative; they have many ideas, [but] our problem is the ability to implement." (leading retailer interviewee)

Following the dynamic capability approach and examining the interviews conducted, it is apparent only by building new capabilities will French enterprises succeed in effectively implementing innovation activities. An innovation culture can act as a safety net in times of digital and technological disruption if firms succeed in renewing themselves. The positive relationship between new capabilities and innovation culture is thus confirmed.

- **P3**: There is a positive relationship between openness and innovation culture.

The dynamic capability perspective also looks at how firms leverage external capabilities. Although France is one of the most mature of start-up countries, little evidence on serious external collaboration initiatives with the corporate sector has been collected. Interviewees acknowledged the importance of collaborating with the outside and stressed the need to co-create with customers and suppliers. Building relationships with universities and scientific research centres is a common practice of pharmaceutical companies and can be more effective than developments in internal R&D, stressed the interviewee from a leading French pharma company. Corporate social responsibility program co-innovation is greatly practiced by the telecom company interviewed, but collaboration with its competitors is not a common practice.

This raises a question about French firms' willingness to open up and engage in co-opetition activities; although, the added value of collaboration may not yet be justified. However, in the grocery retail business, major French retailers' buying alliances are effective in exercising buying power over suppliers. One of the interviewees suggested these alliances may go beyond negotiation to the exploration of innovation initiatives that drive growth.

Although few practices were shared, interviewees agreed that by opening up, companies build new learning capabilities for quicker and better innovation. As one interviewee noted, companies must have the right internal capabilities to manage an open model; for example, the telecom company successfully established a dedicated structure to drive external collaboration initiatives.

- **P4**: There is a positive relationship between leadership and innovation culture.

The interview results confirmed the literature review conclusion of the usefulness of the leadership theory in understanding the dynamic capability perspective. All the interviewees identified leadership behaviour and style as a barrier to innovation culture development, which suggests the leadership qualities inherent in the transformational leadership theory (e.g., competence in engaging and intrinsically motivating employees) are important to driving a culture of innovation. Entrepreneurship cannot succeed if it is not endorsed by management and does not cascade across the organisation, remarked an interviewee.

Another dominant theme that emerged in interviews but was not discussed in the literature review was leaders encouraging employees' "curiosity at work". Curiosity drives learning and exploration, and the propensity to change will be accordingly affected. Likewise, leaders must manage and animate diverse teams, and the leadership quality determines how diversity can be turned into an asset that influences innovation culture. The inspirational trait of the transformational leadership theory seemed to be missing in most of the cases explored. Many sub-themes associated with who should drive an innovation culture were grouped under the theme of Transformational Leadership Community, which includes innovation and initiative sponsors, innovation champions, agents of change, and any organisational member who exhibits the mind-set to positively influence transformation and innovation. This community also creates "transformational movements" to influence the firm's overall innovation culture. The larger this community, the higher the propensity to change and innovate. However, having or committing to the means to transform and innovate may moderate the influence of transformational leadership on innovation culture as expressed here:

"*Giving the space, freedom and means to people is key to innovate.*" (media enterprise interviewee)

Innovation cannot be managed in conventional and classical ways. People's well-being and having fun at work are important, commented a director from a major travel agency firm in France. Leadership in the technology sector seems more attuned to innovation practices, and an interviewee from a leading French telecom company emphasized training people in design thinking and giving them the space to speak and explore are all important enablers. The pharmaceutical director focused on the importance of a sponsor at a senior level developing ideas.

Individuals' daily activities and basic routines also influence the organisation's innovation culture: innovation must be anchored in human realities, and people must be supported across the organisation.

The interviewees identified transformational leaders' qualities and habits as influencers of the firm's innovation culture and proved to be positive. The influence of other leadership styles, like transactional and autocratic, on innovation culture will be investigated in the future.

5. Discussion

The innovation cultural of French enterprises seem paradoxical. France has, as one of the interviewees stated, the most advanced start-up ecosystem in the world; however, not many unicorns have originated in France. Innovative corporate companies are indeed found in France, but the traditional enterprise model with companies governed by bureaucracies remains nationally dominant, and although there is a high concentration of academic institutions and high R&D spending, France still lags other countries in innovation.

The qualitative approach helped in exploring the key themes associated to innovation culture. However, a quantitative research is required as a next step, to more reliably frame the innovation culture of French enterprises in association to the four propositions defined by this paper. A sample of the questionnaire that the authors intend to apply in future research is presented in the appendix. Another investigative avenue is how innovation cultures differ among small, regional, or international enterprises. Other European countries

may be facing similar challenges, and French enterprises' stand on innovation culture might be compared to them.

For managers who would like to influence their firms' innovation cultures, this paper discusses areas on which to focus. Two important drivers for this include the introduction of new capabilities and a focus on transformational leaders. French firms must learn to be more tolerant of mistakes and understand how to strike a compromise between perfection and speed. Lastly, this paper shows that today, opening up may be an option, but tomorrow, the ability to learn from capabilities the outside world has mastered will be a necessity.

Appendix

Questionnaire

Name: Optional: -----

Company Name:
Work context:

- Industry
- Transports/Communication
- Commerce/Retail/Wholesale
- Finance/Insurance/Banking
- Services
- Health
- Education
- Public services
- Others

Position

- Farmer
- Shop owner, small entrepreneur
- Manager and knowledge worker
- Trader
- Employee
- Worker
- Retired
- Others

Geography:

- France Only
- Europe
- International

Company size:

- Less than 10 employees
- Less than 100
- 100 to 999
- 1,000 to 9,999
- More than 10,000

Professional experience:

- Less than 5 years
- 5 to 9 years
- 10 to 19 years
- 20 to 30 years
- more than 30 years

Impact of Innovation Culture on Innovation Performance

	1	2	3	4	5
	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
Innovation plays an important role in our industry.					
I am satisfied with the innovation performance of our firm.					
Our firm is able to launch breakthrough Innovation.					
Our firm is able to react fast on innovation.					
Our firm has built the right innovation culture.					
In general, there is a strong relationship between innovation culture and innovation performance.					

Innovation Culture & New Capabilities

	1	2	3	4	5
	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
We have a flexible organization structure.					
We motivate creative people.					
We have incentivized people for innovation.					
We have a budget that motivates people to test new ideas.					
All functions are involved in innovation.					
Only marketing and R&D are involved in innovation.					
We challenge the classical way of doing things.					
We explore new ways of doing things.					
Innovation culture is enabled by new capabilities.					

Innovation Culture & Openness

	1	2	3	4	5
	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
We have strong networks within our ecosystem.					
We have an innovation program with universities.					
We have an innovation program with accelerators and startups.					
We co-create with customers and suppliers.					
We collaborate with our competitors.					
We learn from external sources.					
We constantly challenge what we know.					
We motivate our teams to collaborate with external parties.					
Innovation culture is enabled by opening up to the outside.					

Innovation Culture & Leadership

	1	2	3	4	5
	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
We are constantly stimulated by top management to innovate.					
Our management inspires us to think big.					
We are allowed to take risks.					
We encourage our teams to take risks.					
We are encouraged to learn new things.					
We motivate and support our teams to learn new things.					
We encourage our teams to think for the future.					
We separate between short-term and long-term results.					
We are encouraged our teams to act like entrepreneurs					
Our management gives us support & means so we act like entrepreneurs.					
We are encouraged to change and explore new ways.					
We have prospective transformation projects.					
We feel empowered to innovate.					
We are curious to explore how others do things.					
We feel constantly intellectually stimulated.					
We accept delivering products that are not perfect.					
We accept compromise between product quality and speed.					
We encourage our teams to think creatively.					
We feel more confident with classical ways.					
We focus our energy on delivering the yearly results .					
Leaders play a role in cultivating an innovation culture.					

Perceived Importance of Innovation, Knowledge Management Maturity, Returns Management Knowledge and Internal Integration

Alena Klapalová and Radoslav Škapa
Masaryk University, Brno, Czech Republic
klapalov@econ.muni.cz
skapa@econ.muni.cz

Abstract: The aim of this paper is to determine relationships between the perceived importance of innovation (PII) by managers, knowledge management maturity (KMM), returns management knowledge (RMK) and internal cross-functional integration and coordination (CFIC) among Czech firms. Returns management (RM) used to be the most neglected process in business (Norek, 2002) due to the dominance of forward-based thinking in value creation processes (de Brito, 2004). Innovative practices are highly recommended for managing returns and reverse logistics (RL) especially owing to many specific features of RM and limited space for making foresights (Richey et al, 2005; Bernon, Rossi and Cullen, 2011). High variability and complexity of tasks and, more difficult coordination of processes inside and across the firms related to manage returns requires increased information management needs, proper knowledge sharing and adequate KM (Meade and Sarkis, 2007). Schoenherr and Swink (2012) proved that CFIC is positively associated with the ability to transform and exploit knowledge obtained from the external partners (what is extremely important in the case of RM). In our model we test relationships between the PII, existed RMK, KMM and the level of the internal CFI. Based on a survey of 232 managers from the same number of firms from various industries and sectors in the Czech Republic, this study applies the structural equation modelling (SEM) to investigate proposed research model. Results show that the perceived importance of innovation has a positive link with KMM, RMK positively influences KMM, KMM has a positive link to the CFIC and the CFIC has a positive link to the PII.

Keywords: perceived importance of innovation, knowledge management maturity, internal cross-functional integration, returns management knowledge

1. Introduction

For many decades innovation has been acknowledged as one of the most important factors influencing substantially the sustainable economic and market success and competitivness of firms (Deshpande et al, 1993). Innovation as an item is the result or output of both the innovation as a process (innovation as a process is itself a type of innovation) and innovation as an organizational attribute. The latter connotes specific characteristic, feature or quality which may distinguish between the organizations. Ability, capability, capacity to innovate, technological capacity and willingness and commitment to change, (cultural) readiness to follow new ways and to be creative, tendency to engage in, support and realize new ideas or simply organizational creativity and open-mindedness or openness to new ideas belong to the descriptions of understanding what innovativeness, resp. innovation orientation might be in the organizational practice (Hult, Hurley and Knight, 2004).

There is very close relationship and interdependence between innovation, innovativeness and another factor from the list of the antedecents of business success and growth, namely knowledge and specifically KM (Hung et al, 2010). The prevalent view on this relationship is represented in the cause and effect mechanism where innovation and innovativeness are the consequences of KM (Alavi and Leidner, 2001; Darroch, 2005).

However, there are several identical conditioning factors affecting both organizational issues – innovativeness and effective KM, among which organizational culture or climate, leadership, managers´ commitment and organizational structure pertain to (Janz and Prasarnphanich, 2003; Chen et al, 2010). Research also emphasizes that sharing and integrating and coordinating knowledge and knowledge flows (KF) is extremely necessary for the both effective innovation endeavour and KM and its maturity (Ettlie and Reza, 1992; Pagell, 2004). Internal integration fosters better intra-firm goal alignment, in particular if there is a shared understanding of its value and importance (Pagell, 2004). Individual percieved importance is one of the fundamental preconditions of behaviour in general (Ajzen, 1991). Analogy can be made to the collective perceived importance (PI) of some object or task that drives organizational processes (Kelly, 1993). PI and its impact on behaviour has been studied in several fields, but to the best knowledge of the authors of this paper, not in innovation-related studies yet.

There is one specific area of business life with many negative impacts on several stakeholders, which is RM. The volume of reverse flows (RF) of products, packaging and waste has been dramatically increasing over the last few decades globally (Shaharudin, Govindan and Zailani, 2015). Existing knowledge from the forward processes is seldom applicable to more complex problems and processes with high level of uncertainty regarding the time, the amount, the quality, the requests for settlement and with the extreme demand on maintaining the relationships inside and outside the business as RM can be assigned as the cross-functional domain spanning the boundaries of a firm through the relationships with customers, distributors and suppliers (Mollenkopf, Russo and Frankel, 2007). Handling of all these requirements expects creativity, flexibility and innovative solutions (Huang and Young, 2014). More and better knowledge and competencies as well as skills of RM are considered to be a distinct competitive advantage owing to the ability to create more value for interested parties (Jayraman and Luo, 2007). People dealing with RM in the environment where this area is demanding can have specific position and power and may push to manage knowledge across the organization to make KF in harmony with their needs and for the profit for the firm.

Although there is a number of arguments that confirm the above outlined reality, academic research shows extreme inattention to investigate the aforementioned areas. This paper tries to fill the gap and give the answers to several research questions indicated above. We want to find out if PII (as a specific construct) may have a positive effect on the level of KMM. If this is approved, implication for management in the sence of the communication improvement about the role of innovation exists. Another issue for our exploration is the effect of RMK on KMM. We also want to test if the KMM positively affects the CFIC. If the results confirm our assumption, we can claim that if knowledge is managed on the strategic level, infrastructure and space for knowledge sharing and learning environment is provided and if KM is the integral part of every organization process, the CFI yields better knowledge and KF and so it is supportive element for KM. Finally we want to explore if the level of the CFI is positively linked to the PII. Our argument for this expectation lies in the fact that sharing the knowledge about needed innovation of products, processes or even of organization across the functional units may increase pressure to view innovations as beeing more important.

2. Theoretical foundations

Unlike the general recognition of the importance of innovation for business success there is no concensus what innovation is due to the different perspectives of different disciplines which deal with innovation (Baregheh et al, 2009). Research shows that it is not the innovation itself but an organizational climate, spirit and energy which is grounded in deep understanding of the meaning, purpose, significance and value of beeing innovative and that stands behind the success and competitiveness of an organization which is able to develop and realize desirable innovation performance and outputs (Deshpandé, Farley and Webster, 1993).

Several terms and constructs try to grasp the purport of this factor. Innovativeness, innovation spirit, openness to innovation or innovation orientation are the few and concurrently the most frequent representatives. Based on the works of Manu (1992) and Siguaw, Simpson and Enz (2006) this characteristic feature strategic in its nature (and multiple construct for the researchers) of the organizational behaviour encompasses: already mentioned openness to the innovation and to new ideas – as a part of organizational culture; total innovation programmes; offensive strategy; research and development expenditures; energy to invent and refine products; capacity to innovate; strength of the emphasis on innovation; mix of entrepreneurial intent (strategic intent to innovate) and innovation climate (human resources practices related to the employee´s new ideas encouragement, support and sharing); recognition and appraisement of creativity and innovation and communication and reinforcement of the innovation-focused shared values. Siguaw, Simpson and Enz (2006, p. 559) conceptualize innovation orientation as *"an overarching, organization-wide knowledge structure".*

Not only Siguaw et al work but also many other studies confirm that innovation and innovative organizational behavior is positively related to KM (Choo, 1996; López-Nicolás and Meroño-Cerdán, 2011). Knowledge is to some extent and level managed in every organization (also unconsciously), however as it is the same with every aspect of management, knowing the level of maturity enables to improve, to avoid some harmful influences and to support positive factors (Pee, Teah and Kankanhalli, 2006). There are several models for measuring KMM but no unique agreed approach has been established yet (Khatibian et al, 2010). Among numerous factors which show the quality of KM, strategically managed and planned knowledge, KM implemented into the whole organization and its processes and provision and support of the infrastrucutre

and culture for sharing knowledge belong to the most emphasized ones (López-Nicolás and Meroño-Cerdán, 2011).

Leaders – through culture and climate - play critical role in shaping employees' values, guiding beliefs, understandings, ways of thinking, attitudes, perceptions and behaviour (Pagell, 2004). Especially attitudes and perceptions are forces that lead to some specific behaviour. In organizations, also attitudes and perceptions of individuals may be integrated into the unique entities (Elsbach, 2014). If all or most of employees have a positive attitude towards a concrete object and the object is perceived as important, the effort focused on achieving the goal related to the object will be more intensive in comparison with the situation if attitudes and perceptions are negative and disperse (Awey et al, 2008). Understanding the importance of innovation for organization and of the own personal well-being (for instance through the reward system linked to the innovation market success) may be connected to the higher willingness to share tacit knowledge of an individual and to actively participate on knowledge processing (Bock and Kim, 2002). Thus, we hypothesize that PII should serve as a stimulus for more intensive and more effective KM and results in KMM. In line with this idea we propose to test a new construct "perceived impotance of innovation"

RM is extremely demanding for knowledge integration not only in the internal environment but also with the external parties, in particular with customers, suppliers and distributors (Ramírez, 2012). "Knowing this knowledge", i.e. to have right information right time, of the right quantity and at the right place from the right people and using it to solve multiple problems and tasks (e.g. how to avoid product returns, how to deside about the disposition (Kokkinaki et al, 2004) is very complex issue for management and decision making.

Notwithstanding, in comparison with the amount of reseach on the information need and provision in RM (or RL) KM theory in this context is almost absent (Wadhwa and Madaan, 2007; Ramirez, 2012; and Ramirez and Girdauskiene, 2013). Muniz et al (2017) in the latest existng literature review on inteconnection of reverse logistics (so not specifically focused on product returns), knowledge management and strategic managementsupport this fact. There is no current research related to linkages with innovation management and the internal inegration which integrates also knowledge flows and thus promote innovativeness. Hovever, it is obvious from other - not product returns studies – that high level of such knowledge can be a proof of proactive approach and accepted role of RM in a firm and thus influence promotion and developemnt of KM. Such assumption has never been explored in RM theory.

Knowledge-driven environment enables knowledge capture, knowledge acquisition, knowledge creation, knowledge storage, knowledge sharing and diffusion and knowledge exploitation (Paarup Nielsen, 2006) and serves as the rudiments for innovativeness. If all these processes work well, there is the probably an urge to be more integrated – internally as well as externally. This presumptiom stems from the Hirunyawipada et al (2010, p. 657) who postulate CFIC to be tacit-to-collective knowledge transformation mechanism. Integration and coordination of people and processes and knowledge embedded in functional departments may open the shutters to the bigger flow of joint need to innovate and so to boost perceived importance to innovate. Our paper reacts to the call of the authors for future research in this issues and we examine KMM impact on the CFIC and potential impact of the CFIC on the PII.

Based on the above discussion the following hypotheses for the expected effects are proposed:

H1: The PII contributes positively to the KMM.
H2: The KMM positively affects the CFIC.
H3: Higher internal CFIC increases the PII.
H4: The RMK stimulates KMM.

3. Methods

3.1 Research design

Because the set of hypotheses H1 to H4 constitutes a model of complex relationships, the empirical validity of hypotheses was not tested separately, but the whole model was validated at once using structural equation modelling (SEM). The SEM gained intense popularity in empirical research due to its ability to test complex relationships and to include latent variables (Babin et al., 2008; Schreiber et al., 2006).

Our model combines three observed (PII, CFIC, RMK) and one latent variable (KMM - reflected in three items – directly observed variables). The items of KMM were adapted from Chang Lee et al. (2005) and McKeen et al. (2006). The PII was inspired by Bharadwaj (2000) and was measured using a single-item scale that rated innovation's importance to the organization on a seven-point scale. The remaining two observed variables are adapted from authors´ previous research (Klapalová et al., 2013). The wording of questions and variables names are in Table 1.

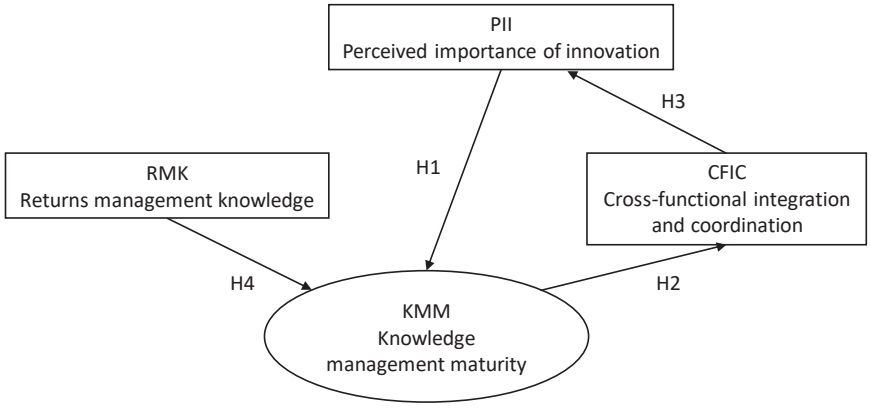

Figure 1: Structural model

Table 1: Description of variables and items (N = 217)

Variables	Items (scales)	Median	Mean	Std. Dev.
KMM	KMM1: Knowledge is managed as a strategic asset. *(strongly disagree – strongly agree)*	5	4.49	1.72
	KMM2: KM is planned and integrated into all corporate processes.	4	4.22	1.77
	KMM3: We have systems and venues for people to share knowledge and learn from each other in the company.	4	4.14	1.98
PII	What is the role of innovation in your firm? *(no need of innovation – an existential necessity)*	5	4.87	1.87
RMK	What is RM and/or RL related knowledge in your firm compared to forward logistics? *(substantially lower – subs.higher)*	3	3.31	1.39
CFIC	What is the level of internal CFIC in your firm? *(very low – extremely high)*	5	4.37	1.97

Note. Scale description in italics.

3.2 Data collection and the sample

The six variables employed in the paper come from a survey realized by authors in 2015/16. The survey explored ambitions, approaches, and practices of firms towards RM. In other words, the survey asked firms representatives (higher management, specialists in logistics/operations/after-sales) to find out some inormation about RM and RL on the one hand, and management system on the other (its characteristics, including the approach to knowledge and innovation).

Out of 232 collected questionnaires, the final sample shrank to 217 cases, because we removed the cases with missing values (casewise deletion). For SEM, a sample size above 200 is the minimum advised by literature (for further discussion see Wolf et al., 2013). If we take into consideration that the number of distinct parameters to be estimated in our model, is 13, then the sample size can be regarded as appropriate (based on the rule of thumb: 10 cases for one estimated parameter).

4. Analysis of results

The statistics of central tendency and variability for each of variable are presented in Table 1. The Kolmogorov–Smirnov test rejected the idea about normal distribution of data; however, the histograms did not show any cardinal difference from a normal distribution, so the further calculations were done on non-transformed data.

In the first step, the validity of the latent variable of KMM was checked in terms of its convergence by indices proposed by Hair et al. (2009): The standardized regression weights of three items (KMM1, KMM2, KMM3)

were higher than the recommended cut point of 0.5 and are of statistical significance ($p < .05$). Next, Cronbach alpha, Joreskog rho as well as AVE were above the thresholds of 0.7, 0.7 and 0.5 respectively (see Table2). All the three indices allow us to accept KMM as valid.

Table 2: Measures of convergence validity

Indicators` names	KM
Cronbach alpha	0.803
Joreskog rho	0.838
Average Variance Extracted	0.645

After ensuring convergence validity of KMM, the structural model was computed by applying maximum likelihood method in SPSS AMOS and assessed by indicators of χ^2, CFI, RMSEA. The graphical form of the model is depicted in Figure 2.

The value of χ^2 test (8, 217) = 9.845, p = .272 speaks in favor of the proposed model; in statistical terms, the model does not differ from the structure of empirical data. The more conservative model fit indices support the conclusion: their values (comparative index fit = .995 and RMSEA = .033) are in harmony with the recommended thresholds (Hair et al., 2009). Because the model as a whole can be accepted, it is reasonable to analyse the model's elements and relationships.

Table 4 summarizes the detailed results: The hypotheses H1 to H4 are statistically significant at $p < 0.05$ (H2, H3, and H4 at $p < 0.01$) and appropriate regression weight are positive, which corresponds to our expectation of positive relationships among variables (see Table 3). All in all, the findings allow us to accept the H1 to H4 (provisionally, of course). Despite ambiguity in the interpretation of regression weights, the higher regression weights are usually interpreted as an indicator of stronger links between variables. In this respect, the strongest relationship was found between KMM and CFIF (i.e., H2; $\beta = 0.369$); the remaining H1, H3, and H4 are of similar strength.

The quality of the statistical model is also assessed by its explanatory power, as measured by the explained variance of the dependent variable. Because the model works with three dependent variables that are independent at the same time (the model has a form of a loop), we can only report the explained variance (r^2) for each variable without implying further conclusion regarding the model (r^2 for PII, KMM, and CFIC equals 0.06, 0.1 and 0.16 respectively).

Table 3: Regression Weights

			Estimate	**S.E.**	**C.R.**	**P**	**St. regression weights**	**Hypothesis**
KMM	<---	PII	.106	.043	2.487	.013	.190	H1
CFIC	<---	KMM	.686	.148	4.643	***	.369	H2
PII	<---	CFIC	.185	.069	2.679	.007	.192	H3
KMM	<---	RMK	.160	.054	2.973	.003	.213	H4
KMM3	<---	KMM	1.000				.523	
KMM2	<---	KMM	1.597	.198	8.048	***	.935	
KMM1	<---	KMM	1.469	.181	8.114	***	.887	

5. Limitations, discussion and implications

The main methodological limitation of presented research relates to the single informant approach. The view of just one person on a complex system - the firm - can be distorted by diverse factors such as job position, knowledge, experience, etc. This issue is more relevant in the context of RM/RL because firms often lack precise monitoring/measuring systems in this field and the informants cannot rely on "hard" data.

Another limitation is with constructs and variables. Three of four construct are one-dimensional ones and so they cannot offer rich and more explanatory picture of the reality. Here is the space for the research implications and for a call to test different dimensions of PII, RKM and CFIC. Very common conclusion can be made with the KMM construct where only three dimensions were measured. Further only CFIC was measured and no interest was devoted to the external integration. Also, number of usable questionnaires limited analyses and does not enable to test more and mutual relations as well as involvement of other answers (and constructs or variables) to enlarge context of investgated situation.

Our research has several implications for managers and for research. First, it shows the linkage and effect between KMM and CFIC. This is challenging finding and should be explored into more depth. Simple and logical explanation could be that the integration and coordination element in KM is strong and KMM– at least if it is reached through those three practices as it is in case of our firms - requires also practices that lead to and enable proper integration and coordination. Second, results proved the expected effect of the PII on KMM. This finding recommends firms to promote innovation spirit. If there is a mutual understanding why to be innovative is important and a shared awareness exists of which specific innovation processes and factors result in successful innovation, proper decision making can be realized on the strategic, tactical and operational level throughout whole firm. Such mutual understanding creates shared beliefs, attitudes and perception of importance. In our research we pay attention especially to the perception construct relying on the study of Bahamonde-Birke et al (2015) which proves that perception strongly affect decision making. Third, this study shows that CFIC is an important determinant of the PII. It means that sharing, mutuality, interconnections serve as drivers for collective understanding. This might be powerful way to maintain common spirit. However, in our survey we did not separate integration and coordination. Thus, in the future research this variable can be manipulated and explored as two seperate measures. Forth, survey also shows another influence – of one area of specific KM on the more general one. From our survey it is not clear if this is so due to the integration and coordination effect, nevertheless, this point is worth of deeper interest.

6. Conclusions

This study, despite its limitations, tries to focus attention of academic to several areas of business practice, which stand in the shadows or even in the darkness of interest regardless the fact they they belong to those domains or fields where enormous concern for the exploration and investigation exists. Understanding also these relatively small pieces of mosaic and especially how they influence whole and more complex view may be important for further development of the "parent" fields. More questions and more answers can be raised, and answers and new or improved processes may be initiated through new knowledge about how important perceived importance is – both of individual employees and as a collective or group perception Which right stimuli should be developed and how to use them for sharing not only some pieces of knowledge but be really involved. So, domain of human resource management, organizational communication, innovation management and knowledge management can see some new ways. Also, power of some specific knowledge need and body of knowledge in this area should be studied in more depth, specifically how this power may be consciously managed and positively utilised for knowledge management and potentially even for other "managements as well as for strategic and organization and network level.

Multichannel Distribution in the Process of Delivering Value for Banks' Customers

Monika Klimontowicz
University of Economics in Katowice, Poland
mklimontowicz@ue.katowice.pl

Abstract: The Polish banking market if thought to be one of the most dynamic developing in Europe. Its characteristic features are high competitiveness and innovativeness. Concurrently, banks and credit institutions dealing on this market are assessed as stable and, in general, have no problem with fulfilling new regulatory requirements. Polish customers' openness for novelties and their usage of new technologies in various fields result in the change of their expectations concerning banks and other financial products' suppliers. Contemporary, delivering value for customers means not only understanding customers' needs but also following their preferences on a place and time when they use them. The purpose of the paper is to present the changes in the way of delivering value for banks' customers. The paper describes the importance of the value creation ability for building and maintaining competitive advantage, characterises distribution channels used today for delivering those values, presents prerequisites and forecasts of multichannel distribution's development on banking market.

Keywords: multichannel distribution, value for customers, banks' business models, banks' distribution channels

1. Introduction

The banking sectors play the crucial role in the economy. They respond to different kind of external factors. Economic, political, social, technological and legal environment influences banks' market policy and behaviour.

There is no common agreement what kind of factors are the most significant ones. Undoubtedly, the increased number of new acts, directives and supervisory recommendations let many authors state that the regulatory pressure is the most important factor influencing not only the retail banking market but the whole economy (Marcinkowska et al., 2014; Kasiewicz and Kurkliński, 2012). For others, the most important are those that allow banks to create sustainable competitive advantage. Today building and maintaining market position is impossible without long-term relations with customers resulting from the ability to match the offer with their clients' needs and expectations. Creating, delivering and capturing value for customers is mostly influenced by social and technological factors (Sullivan, 2008; Świtalski, 2005, Ernst & Young, 2016).

For last few decades, different kind of technological innovations has a profound effect on retail banking services in Poland and all over the world. As a result of systematically increasing the complexity of new technology, development of information and communication's techniques, economy's networking, social revolution have already happened and changed customer behaviour and expectations concerning banking services.

The primary motivation for using modern technology has been to reduce costs (Delafrooz et al., 2013, Persson 2013), increase efficiency, speed, and control the customer-bank interactions (Honebein and Cammarono, 2006). The unlimited access to financial services and their remote management have delighted both customers and banks. The benefits of technology centre around the fact that the clients can access services whenever and wherever they want without the necessity of interpersonal contact and the technology potential to add value to the overall customer experience (Blount, 2010). After the first period of technology admiration, retail banks have realised that there still a large group of clients who prefers face-to-face interactions. Balancing the need concerning service functionality and individual approach to customers focused on relation remains a challenge for banks (Davis, 2013). In recent years, the development of social media has enriched technological landscape and has influenced markets, companies, institutions and customers' behaviour and expectations (Mayfield, 2008, Ahlqvist et al., 2008, Kaplan and Heinlein, 2010, Weinberg and Pehlivan, 2011, Hanna et al., 2011, Papagiannidis and Bourlakis, 2015, Durkin et al., 2015). As a result, banks have attempted to deploy new technology in their market strategies to be more communicative, more customer-centric and innovative.

This paper argues that following customer expectations in the field of creation, delivering and enhancing value for customers as a core part of the business model will require implementing new solutions concerning banks' distribution channels.

The purpose of the paper is to present the changes in the way of delivering value for banks' customers. The paper begins with an analysis of the value creation process as a part of banks' market activity. It further discusses the values delivered by selected kinds of banks' business models and banks' distribution channels used for delivering those values to their customers. Finally, it concludes with the prerequisites and forecasts concerning the multichannel distribution's development on banking market.

2. Creating value for customers as a part of banks' market activity

The primary objective of banks' market activity is to gain a competitive advantage over their rivals and maintain their market position. The successful market strategy combines all bank's internal tangible and intangible resources that are the source of its strengths and weaknesses with all threats and opportunities that have arisen on the banking market. It must allow creating value for all stakeholders. Since the 1950s, when the first attempts to describe the value creation process have appeared (Casadesus-Masanell and Ricart, 2007; Magretta, 2002), a long-term method of using disposable and potential resources in the process of value creation for customers or other stakeholders is called a business model. According to many authors, a business model is just a simplified way that explains the relation between internal and external factors influencing reaching organisation's objectives and value creation (Saebi and Foss, 2014, Zoot and Amit, 2010, Santos et al., 2009, Zott and Amit 2008, Magretta, 2002). Others focus on the philosophy of organisation's market activity and state that it is a conceptual tool that enables to express business logic of an organisation (Nosowski, 2012) and to determine precisely the strategic assumptions in the area of value creation (Pyka, 2013). The business model is also defined by describing its particular components. The review of business model's definitions and components allow to state that the ability to create and deliver the original value proposition for customers is its core foundation. This component reflects firms' ability to fulfil customers' needs and expectations and match firm's product and services with these requirements. Among other elements, authors usually indicate the importance of defined market segments of customers, tangible and strategic resources, and strategic processes including the way of communicating and delivering value to customers (see Table 1).

Table 1: The business models' definition and components in selected concepts

Author	Definition	Business Model's Components
Zott, Amit (2001)	The content, structure, and governance of transactions designed to create value through the exploitation of business opportunities.	Transaction content, transaction structure, transaction governance
Magretta (2002)	Stories that explain how enterprises work; a good business model answers Peter Drucker's age-old questions: Who is the customer? Moreover, what does the customer value? It also answers the fundamental questions every manager must ask: How do we make money in this business?, What is the underlying economic logic that explains how we can deliver value to customers at an appropriate cost?	Customer definition, value to customer, revenue and economic logic
Dubosson-Torbay et al. (2002)	The architecture of a firm and its network of partners for creating, marketing and delivering value and relationship capital to one or several segments of customers to generate profitable and sustainable revenue streams.	Products, customer relationship, infrastructure and network of partners, and financial aspects
Morris et al., 2005	A concise representation of how an interrelated set of decision variables in the areas of venture strategy, architecture, and economics are addressed to create sustainable competitive advantage in defined markets.	Value proposition, customer, internal processes/ competencies, external positioning, economic model, and personal/investor factors
Shafer et al. (2005)	A representation of a firm's underlying core logic and strategic choices for creating and capturing value within a value network.	Strategic choices, create value, capture value, value network
Osterwalder et al. (2005)	The blueprint of how a company does business.	Value proposition, target customer, distribution channel, relationship, value configuration, core competency, partner network, cost structure, revenue model
Johnson et al. (2008)	The business model consists of four interlocking elements, that, taken together, create and deliver value.	Customer value proposition, profit formula, key resources, key processes

Source: Own work based on Zott et al. (2011).

All business models' components can be grouped into four core areas (Ballon, 2007, Osterwalder and Pigneur, 2005): creating value for customer, building relations with customer influencing customers' satisfaction, loyalty, and engagement, delivering value by proper infrastructure, managing costs and revenues of areas mentioned above. The fields of the business model and their components should be considered as a potential

means through which banks can fulfil their objectives and gain outcomes such as financial performance, risk profile, and contribution to financial stability as well as the economy, which can change over time. Searching for competitive advantage requires analysing these components from the perspective of their potential to create value for customers (Deloitte, 2012). The process of business model creation should thus be based on the knowledge concerning customers' market behaviour, habits, needs and expectations.

Today the dominant generations active on the banking market are Generation X, Generation Y, and Generation Z. They are the leading retail banks' market segments. Each of these generation has different, unique expectations, experiences, generational history, lifestyles, values, and demographics that influence their buying behaviours (Klimontowicz and Harasim, 2017). Thus preparing the adequate value proposition should incorporate knowledge on their core value, technology usage, preferred way of communication and financial needs and expectations (see Table 2).

Table 2: The characteristics of selected generations

Criterion	Generation X	Generation Y	Generation Z
Core values	Time	Individuality	Connectivity
Technology	Assimilated	Integral	Digital natives
Preferred way of communication	Prefer personal interactions and communication.	Commonly use telephone communication and the Internet, active on social networking sites.	Communication via smartphones, active on social networking sites, create own documents and databases, use the web to research and network.
Communication media	Cellar phones	The Internet, picture phones, e-mails	Smartphones, tablets and other mobile devices
Financial needs and expectations	· cautious and conservative, · looking for mortgages, investment insurance, saving programs · money is means to and the end, · used to ingrained status quo banking · some find their bank's existing mobile interface difficult to work with · display some willingness to adopt mobile banking, but they lack the enthusiasm · security concerns about new technology · declare the openness to the idea of mobile banking	· earn to spend, · money is today's payoff, · looking for first car loans, first mortgages, credit cards, student loan · a half of them would switch banks to mobile payments capability from their primary bank	· looking for savings and payment accounts, first credit cards, student loan, · more conservative, more money-oriented, more entrepreneurial and pragmatic about money compared to Millennials, · elusive to traditional financial services providers, · use mostly mobile devices like smartphones, tablets, and laptops for communication · expect everything to be digital · expect seamless cross-channel customer service

Source: Own work base on Williams and Page, 2011, BMO Wealth Institute, 2014, First Data Corporation, 2010

Concurrently, the business model should allow creating value for a bank. The traditional business models that divided banks into universal and specialised ones do not correspond to generations value directly. They represent product orientation and focus on banks' objectives. The contemporary business models have already tried to combine both an ability to create value for customers with an ability to create value for banks (see Table 3), but their value propositions still correspond only with financial needs and expectation excluding behavioural characteristics of generations. They deliver some general values but have not implemented the strategy allowing to deliver specific values to particular customer segments (Deloitte, 2012).

Table 3: The value proposition and creation in banks' business models (Capgemini, 2008)

Model	Value proposition for customers	Value creation for banks
financial advisor for mass affluent customers	Niche positioning leveraged by delegated marketing promotion Main strength is the confidence relationship with the brand, and with a strong belonging feeling.	Intensifying client's relationship by upgrading the value of service. Eventually collecting a greater volume of financial flows and assets.
community bank model	Specialised service provider to a specific community (travellers, military, migrants). Closest to personal affinity, recognised by "buzz" network.	Niche positioning leveraged by delegated marketing promotion. Main strength is the confidence relationship with the brand, and with a strong belonging feeling.
discount bank model	The most economic without minimising security or quality. The lowest prices on the market.	Marginal revenues without additional fixed costs (provided existing systems and back offices may be shared). Acquisition or retention of self-directed new customers who have little interest in advisory or proximity services.
trust operator model	One-stop shopping for customers, including all kinds of personal or family services: domestic chores, bills management, employment research, real estate, mobile phones, journeys, sports and other tickets	Capturing additional business flow Increasing cross-selling opportunities Optimising the return on assets (physical network)

Regardless of the particular value proposition selected by a bank for gaining competitive advantage and the market success, it requires developing channels serving delivery of that value to bank's customers.

3. Banks' contemporary distribution channels

Today delivering value for customers in a better way than competitors has become one of the most significant factors of competitive advantage and a crucial element of bank's market strategy. Banks' distribution is a profit-oriented activity that includes planning, realisation and control of value flow from a supplier to a final purchaser. The primary condition for managing the efficient distribution system is maintaining the equivalence between the needs and interests of a bank, customers, and intermediaries (see Table 4).

Table 4: The needs of banks' distribution system participants.

Customers	Banks	Intermediaries
· product satisfaction · procedures satisfaction · service quality satisfaction · fee and charges satisfaction	· sale increase · development of market position · customers' loyalty · intermediaries loyalty · the control over distribution system · all distribution channels penetration	· satisfactory conditions of cooperation · high level of margins and commissions · independence · bank's loyalty and respect

The starting point for planning a distribution policy is answering the question what customers' expectations are and what competitors offer in this field. Deciding on the number and sorts of the distribution channels must also consider the range of banking products and bank's financial and human resources. Distribution channels are the pipelines that deliver products and services to consumers, and revenue to banks and credit institutions. The assessment of distribution channels concerning the adequacy of time, place and costs should be made from customers perspective because any distribution system concurrently allows both to maximise the level of service quality and minimise costs.

Distribution channels have been developed mainly in response to changing markets and technologies. Today banks usually use direct and indirect distribution channels that offer personal, face to face contact (referred by customers as branches) as well as remote channel including Automatic Teller Machines (ATM), payment cards, the Internet access to banking products and mobile solutions.

During the last decade, the number of banks' branches operating in Poland has exceeded the level of 7000. It has been increasing till 2012. Since then it has been slightly decreasing but it is still quite large in comparison with other European countries. Analysing the number of other points of sales the similar tendency can be observed. At the same time, the number of banks' employees per branch and another point of sales has decreased from 18,2 in 2007 to 8,2 in 2017 (see Figure 1 and 2). To a large extent, it is the result of mergers and acquisitions. However, the trend reflects retail branch revolution that has been underway for several years. The tradition branches are evolving in response to migration to new distribution channels. The universal or relationship banker (also called a "universal agent" or "relationship agent") model is shaping up to be the dominant type for a branch. Relationship bankers are expected to have a different skill-set to the traditional

employees, with versatility, a personable sales-orientation, and confidence in educating customers how to use modern banking technology. Universal bankers working in dialogue towers with cash recyclers constitutes an Assisted Full-Service option. Additionally, the rise of the so-called "micro-branch" has occurred in response to consumer demand for convenience and expanded services. Frequently located in shopping centres, micro-branches transform from full-service branches. They usually have 24-hour Automatic Teller Machines (ATM) lobbies, secured behind an airlock or security grill for the night, where customers can perform transactions.

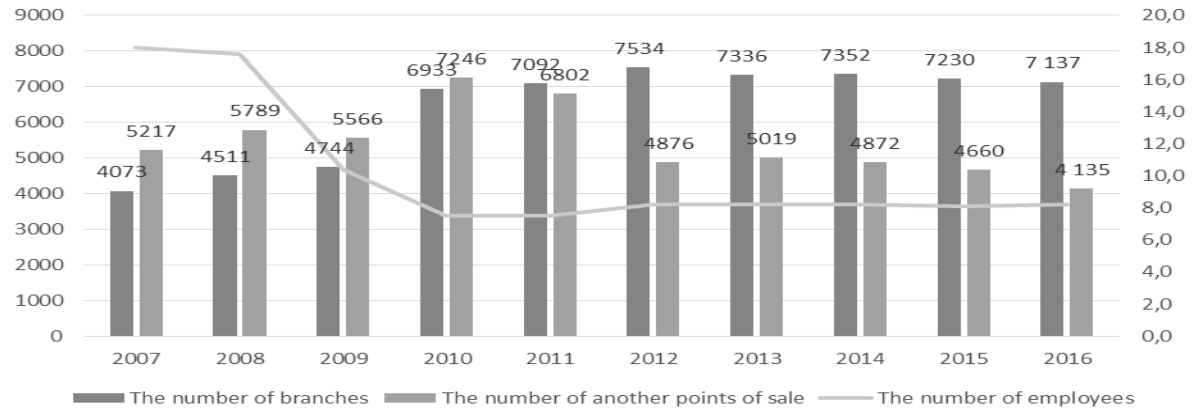

Figure 1: The number of branches, another points of sale and employees per an point of sale in 2007-2016

Source: Own work base on KNF data.

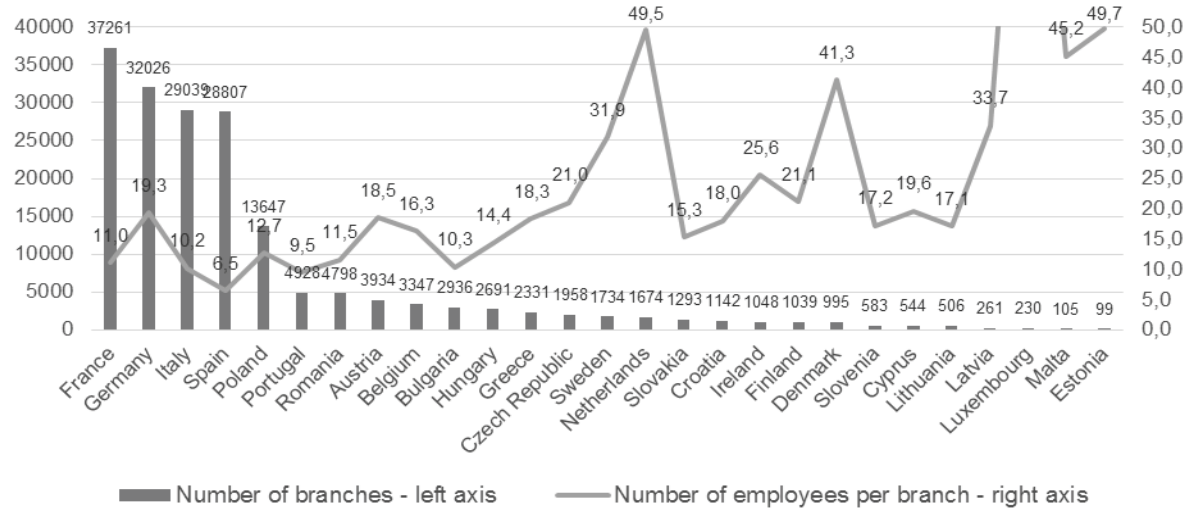

Figure 2: The number of branches and employees per branch in 2016

Source: Own work base on ECB data.

The ATM channel is still maintaining its central role as a core banking touchpoint with the consumers. ATMs are essential for access to cash and bank experience. In some markets, their role has evolved to be a channel complementary to branch, mobile and Internet banking (Accenture, 2016). In Poland, they still play a traditional role. During the period considered, the ATM's number in Poland had been systematically increasing. The same tendency is observed in Europe (see Figure 3).

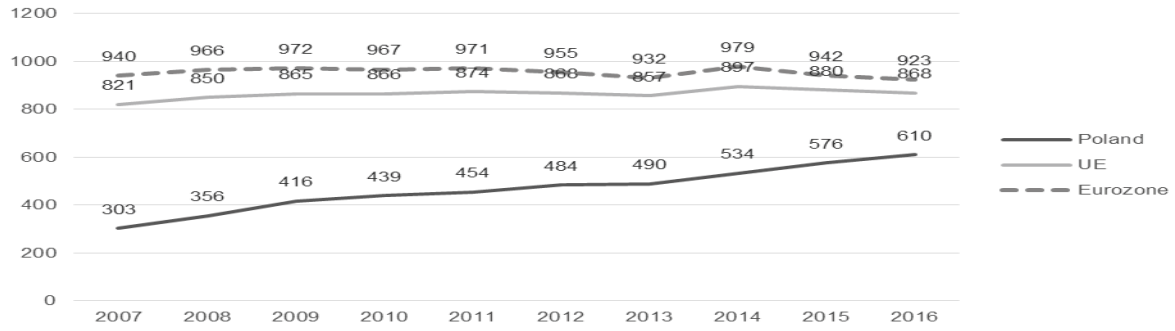

Figure 3: The number ATM's in 2007-2016

Source: Own work base on NBP and ECB data.

The next becoming more and more popular distribution channel is Internet banking. The number of customers who has access to Internet banking and uses this distribution channel at least ones a month has almost doubled since 2012 (see Table 5). At the end of 2016, almost 31 million clients have access to e-banking. The first position of PKO BP concerning the number of customers and dynamics remains stable (PR News, 2017).

Table 5: The number of customers who has the access to and use internet banking in 2012-2016.

The increasing number of smartphones and tablets and the broad spectrum of their possible usage have caused the dynamic development of mobile banking. The ING International Survey on Mobile Banking 2016 revealed that almost 47% of the global population use such a devices for banking and the next 15% is going to use mobile banking during the next 12 month. In Poland, 43% responders have declared using mobile banking and next 20% plan to use mobile banking in the nearest future. The number of m-banking active users is growing very fast. The data gathered by PR News shows that during the last five years has reached the level of 7,6 million users. Similarly to e-banking, PKO BP holds the leader position (see Table 6).

Table 6: The number of customers use mobile banking in 2012-2016.

Almost a half of internet users has already installed a banking application. For them making a money transfer is the second most commonly managed activity (the first is sending and receiving e-mail). Over 80% transactions is done using internet and mobile. This channels are also used for sending loan, credit, account and deposit applications (Kurowski, 2017). The popularity of mobile banking is growing all over Europe and additional customer expect to join mobile banking (see Figure 4).

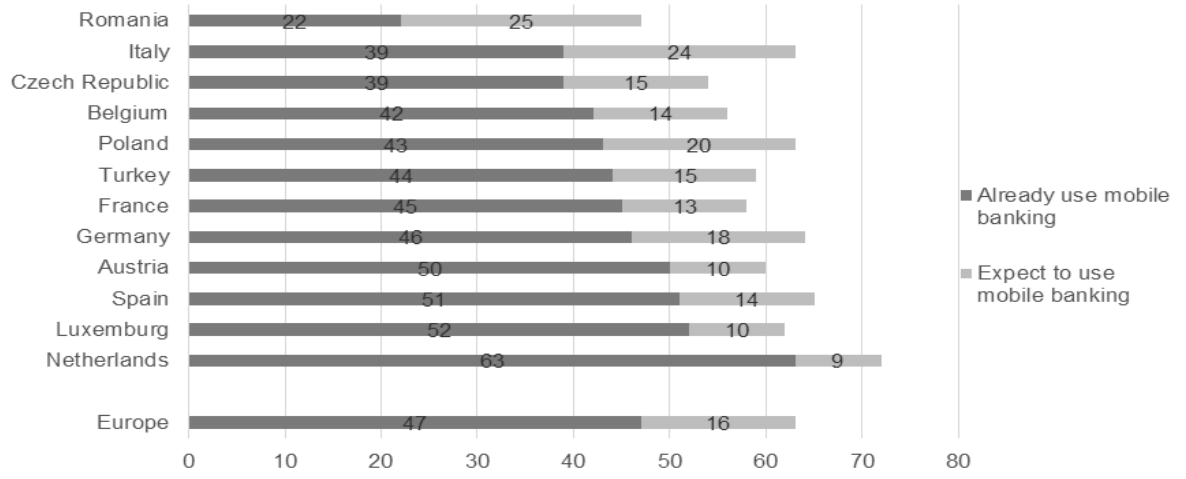

Figure 4: The mobile banking usage in 2016

Source: ING International Survey (2016).

The further development of mobile channels will make bank to search for new solutions. Traditionally they treat other banks' distribution policy as a benchmark for the market decisions. However, in this case, the leading innovative market players have been established outside the banking system. They consist of mobile operators, virtual payment services, and FinTechs (Solarz, 2005, Wawrzyniak, 2012). As a result, in the nearest future, the competition concerning the internet and mobile banking will be pervasive.

4. Prerequisites for the further development of multichannel distribution on banking market

The last few decades brought significant changes on banking market. Due to increasing complexity of new technology, a massive development of information and communication's techniques, economy's networking, globalisation and growth of customers' expectations combined with regulatory requirements banks face new challenges. Among them the crucial for delivering value for customers are (Kumar et al., 2016):

- the threat of new entrants resulting in increased competition from Fintechs and neo-banks - non-banking service providers in the form of Fintech players are causing disruption and disintermediation, often targeting discrete highly profitable segments of the banking value chain,
- changing customer demographics and expectation that are driving the need for innovation to meet customers' demand,
- the increasing risk of cyber threats –facing the unprecedented challenge of data breaches banks are forced to strengthen their security and authentication systems,
- development of cloud services for core business activities as a key enabler of increased agility and improved cost efficiency to support banks' business strategy,
- the need for the transformation of banks' legacy systems enabling to drive agility, achieve better time to market, and develop competitive differentiation,
- the development of distributed ledger technology that is expected to eliminate banks' need for managing multiple databases and reconciliation structure and enhance the transpiration of transaction into the future,
- the necessity of full integration of banks' risk management and compliance,
- the implementation of advanced analytics to deliver insights about customers focused on detection and mitigation of risks associated with frauds,
- financial inclusion and financial awareness.

Today's banking customers want more transparency, more simplicity and easy access. Above all, they seek a seamless experience as they move from one channel to another. Customers are interacting with multiple channels, both physical and digital. More and more, they rate banks according to the experience they have working across those channels. Banks that communicate effectively with customers across multiple channels not only enhance the customer experience but also improve the efficiency of bank distribution networks. Effective multichannel sales and servicing are achieved through:

- multichannel integration, especially creating and optimising a seamless experience that bridges physical and digital channels,
- next-generation branch networks that include 'cookie-cutter' branches and differentiated branches that are specialised for a particular territory,
- innovative relationship management, with a particular focus on customer experience and customer feedback management.

The integrated multichannel architecture must be powered by analytics as a real-time event management, advanced digital advisory and need-based offerings optimised by channels. Additionally, banks will base building long-term relations with customers on their engagement where they spend their time (e.g. on social media), following their interests, leveraging influencers, and co-creation based on increased customer intimacy. The future success depends on the ability to create a digital ecosystem. In such ecosystem, banks will serve as trust centre with an extended proposition (financial and non-financial) wherever the customers leverage the power of mobile and offer m-payment services (Accenture, 2012). Successful banks will concurrently leverage direct channels to generate sales and high-value traffic in branches.

Implementing those changes will result in redefinition the term of the multichannel distribution. It should not be understood just as using many different distribution channels (van Bommel and Edelman, 2015). Today multichannel distribution means synchronisation of all technological solution and information available in various channels and offering integrated communication and sales platforms that look similar regardless the device and technology. Taking into account the dynamic development of social media and their impact on society and enterprises new distribution policy should incorporate those media into strategy not only as a communication channel but also as a channel enabling the usage of banking products.

Most of the banks operating in Polish banking market offer their customers only selected products and functionalities using the Internet and mobile technology. New solutions should not only match all features to a platform but also be ergonomic and well-designed. Concurrently, banks should develop new products and services designed for particular sales platforms. In this process, the key success indicator is understanding the context and using additional technology such as geolocation by beacons (Kurowski, 2017).

Focusing on particular segment requires designing the right propositions for the right customers. This task involves identifying target segments of the market and crafting propositions and experiences to delight them what means designing products and services that offer a genuinely captivating value proposition and generate genuine customer enthusiasm. That ability requires understanding bank's target customer segments in detail and focus on them with precision (Symons et al., 2007). It is of particular importance because some clients' needs are not evident. For example, the higher income, the lower interest in functionality enabling arranging advisory meetings by Internet or mobiles what is frequently the only one offer differentiator for affluent customers (Kurowski, 2017).

The entire bank, from a boardroom to the front line, should focus on delivering value proposition with an early and ongoing emphasis on cross-functional and multichannel collaboration. Through a carefully crafted after-sale process, banks will capitalise on the new customers' enthusiasm by arranging an initial welcoming call in the first week and initiating a month-by-month follow-up program to help customers better understand offer features. They should monitor customers' activity to determine how customers are using the bank's services and systematically track any potential problems. Managing the client's relationship needs following the experience of the customer day by day and delighting customers again and again (Symons et al., 2007). Real customer-focused solutions do not just take the pulse of consumer opinion. They use the findings to correct shortcomings, fine-tune product and service offerings, and, by tying improvements to compensation, motivate employees. By delivering a seamless, personalised customer experience across all channels, banks can achieve competitive differentiation.

Banks remain the most trusted provider of Internet and mobile payment applications, but third-party offerings such as Apple Pay and Google Wallet are gaining ground. Across Europe, 84% of respondents in 2015 choose their bank as the most trustworthy provider. That share shrinks to 75% in 2016. While "other banks", "other suppliers" and "social media" have all garnered a more significant share of support this year, trust is increasing faster for Apple Pay, Google Wallet and other named groups. These third-party mobile app brands add six percentage points to their share in 2016. (ING International Survey, 2016). The competition of non-bank providers is going to be one of the most threats in the nearest future.

Maintaining bank's market position seems to be impossible without implementing multichannel distribution model. Despite advantages for customers, there are also many benefits for banks. Accenture experience shows that, in comparison with other distribution models, offering multichannel distribution brings better results regarding cross-selling, retention index, cost reduction and efficiency improvement (Wolanin, 2013).

The establishment of Internet commerce, smartphone technology, and improved marketing communications has created new possibilities for the banking distribution channel model. The Polish customers adapt new solutions quite quickly, but still, most of them are willing to have access to traditional branches if needed. The attempts to shift all distribution channels to digital world have failed. Banks have already understood that they have to offer both possibilities. The next challenge is to integrate all distribution channels and provide the same functionality regardless of the place, time, device and platform.

5. Conclusion

The remarkable development of technology, a new generation of customers entering the banking market and the threat of non-bank financial service suppliers catching customers interest and money are the key market challenges for banks and credit institutions. Today's distribution models seem to be insufficient to follow all contemporary needs and expectation of customers. Multichannel distribution model, understood as synchronisation of all technological solution and information available in various channels, offering integrated communication and sales platforms that look similar regardless the device and technology and enabling the analysis of all customers activity, seems to be banks' future. Such a model allow delivering value proposition in any place and time required by customers. Maintaining the market position on banking market will be impossible without matching banks' market behaviour with customers' expectation in this field. Banks should design the personalised proposition to each client, deliver those proposition in the right place and at the right time using preferred communication channels, develop those proposition by everyday analysis of customers behaviour and activity for delighting him and building long-term relationships.

Technology Entrepreneurship Attributes on Enterprises from Aviation Valley in Poland: Fuzzy Sets Approach

Piotr Kordel
Silesia University of Technology, Gliwice, Poland
piotr.kordel@polsl.pl

Abstract: hitherto accumulated research output within the area of entrepreneurship confirms the great significance of entrepreneurial processes, in particular entrepreneurial orientation, for the effective development of high-technology enterprises. At the same time, there are not many research reports concerning the category of technology entrepreneurship and the configurational approach to the development of an organization. The aim of this article is to fill this gap by describing the technology entrepreneurship attributes as behavioural indicators of high-technology enterprises in the light of a configurational approach.The goal of the paper is to characterize the influence of organizational attributes of technology entrepreneurship phenomenon on the development of high – technology enterprises. The qualitative comparative analysis with the use of pairwise comparison and fuzzy set methods was the methodological base of the research. Twenty enterprises from the Aviation Valley in Poland, divided symmetrically into two groups according to lifecycle (i.e. start - up and growth companies), were the subject of research. Companies in the Aviation Valley in Poland constitute a good laboratory for studying the phenomenon of technology entrepreneurship due to: (a) their affiliation to the industry called in accordance with the OECD nomenclature "high-tech industry" which means conducting directly or indirectly R&D works; (b) high development dynamics of the aviation industry in Poland, including establishment and development of new companies. Organizational attributes of technology entrepreneurship are measured by entrepreneurial orientation of high – tech enterprises and the perception of environmental uncertainty. Organizational development is measured using the multidimensional concept of high performance organization. The empirical research results indicates that organizational attributes of technology entrepreneurship of high performance enterprises are characterized by strong entrepreneurial orientation based on proactivity, innovativeness, risk taking and high environmental uncertainty based on dynamism. High performance enterprises on two following stages of development, i.e. start – up and growth, has specific profiles of organizational attributes of technology entrepreneurship. Both are based on three dimensional strong entrepreneurial orientation and perceiving the environment as very dynamic, but start-ups as opposed to growing firms ignore the env. complexity and negate the env. hostility.

Keywords: technology entrepreneurship, entrepreneurship organizational attributes, qualitative comparative analysis, fuzzy sets method, high – technology companies, avio-industry.

1. Introduction

On the one hand, the phenomenon of technology entrepreneurship that manifests itself in practice in the establishment and development of new technology companies, is crucial from the point of view of building economy based on know-how and it is more and more visible on the Polish market, but on the other hand, there is no clear and coherent theory of technology entrepreneurship as an workshop supporting an effective establishment and development of such companies.

Companies in the Aviation Valley in Poland constitute a good laboratory for studying the phenomenon of technology entrepreneurship due to: (a) their affiliation to the industry called in accordance with the OECD nomenclature "high-tech industry" which means conducting directly or indirectly R&D works (Hatzichronoglou, 1997); (b) high development dynamics of the aviation industry in Poland, including the establishment and development of new companies (Kordel & Machnik – Słomka, 2016).

The phenomenon of technology entrepreneurship has been described in the article in the form of an epistemological concept on effectiveness, attribute and a process levels. The structure of the paper is divided into three following parts: the first part describes technology entrepreneurship as a mechanism for development of high-tech enterprises; the second part details two basic categories, i.e. entrepreneurial orientation and environmental uncertainty, as attributes of technology entrepreneurship; the third part includes methodology and results of empirical studies.

2. Technology entrepreneurship as a mechanism for development of high-tech enterprises

Technology entrepreneurship is a type of entrepreneurial strategy, according to which the key element of development of an organization is the development of technology. In other words, an organization, as an

entity of technology entrepreneurship strategy, is a catalyst for technology ventures, ranging from a technological idea to the market product. A model of technology entrepreneurship is a mechanism for development of an organization and its environment, the main logic of which is a constant recognition and use of technological development opportunities (Bratnicki, 2004; Kordel, 2014; Stachowicz, 2016).

When analyzing technology entrepreneurship in the perspective of strategic organizational development, it should be considered as a motor mechanism and it can be understood in three ways: (a) at the functional level, as a process of technological entrepreneurship, (b) at the attribute level, as specific features of internal and external environment of technology entrepreneurship, (c) at the level of results, as various perspectives of technology entrepreneurship performance. Figure 1 displays the three levels concept of technology entrepreneurship.

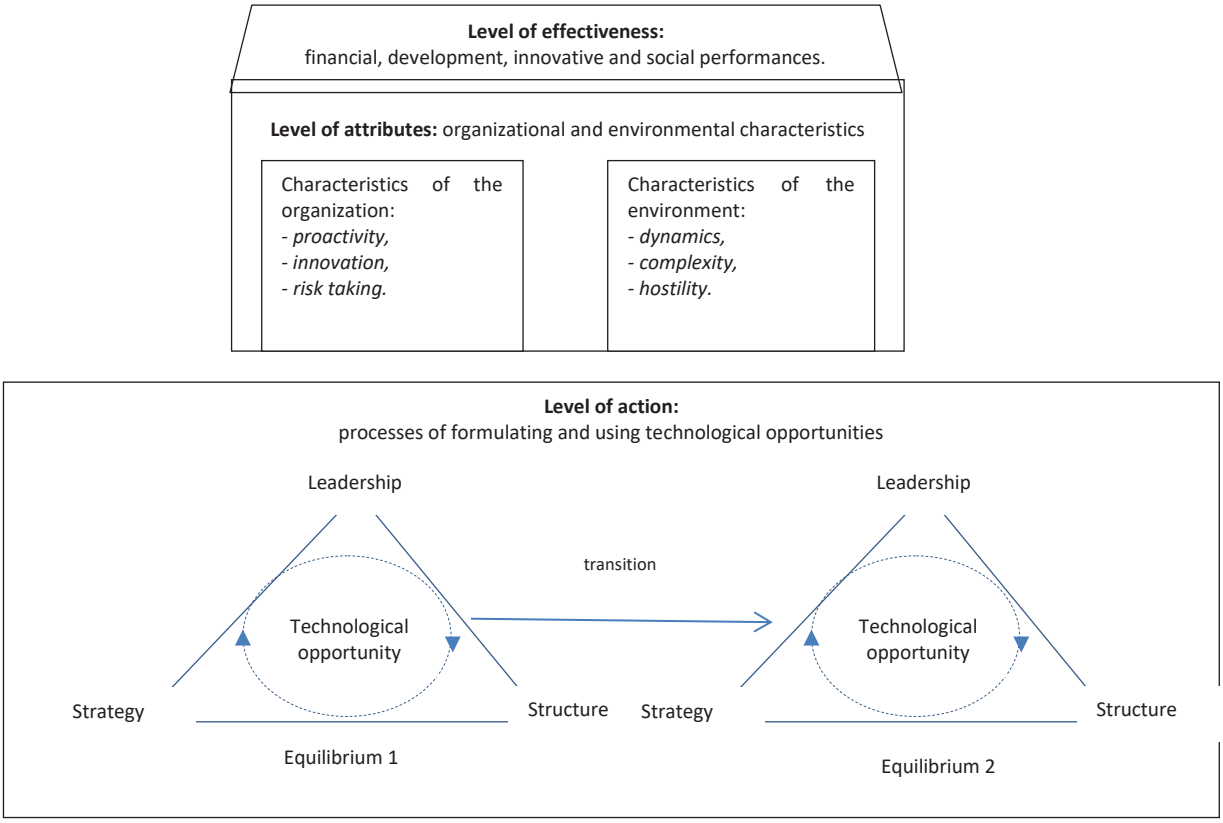

Figure 1: Results, attributes and processes of technology entrepreneurship

Source: Own study

At the process level, according to the configuration approach (Dess, Newport & Rasheed, 1993), technological entrepreneurship is understood as a configuration of elements of managerial leadership, organizational structure and development strategy. At the attribute level, in the light of the concept of entrepreneurial orientation of the organization (Jeffrey & Lumpkin, 2011), we can distinguish three characteristic features of an entrepreneurial organization, i.e.: proactivity, risk taking and innovation. The characteristics of organizational environment can be determined based on the following attributes (Dees & Beard, 1984): hostility, complexity and variability. At the level of results, according to the concept of high performance organization (de Wall, 2012), an entrepreneurial mechanism of the organization's development should reflect in its superior development within a given time perspective. Entrepreneurship in the context of organizational learning is the organization's ability to cope under conditions of uncertainty.

From the point of view of studies on entrepreneurship, two early stages in the development of technological undertakings are crucial, and they characterize with different configurations or development patterns, including (Kazanjian, 1998): (a) stage of early development at which the organizations aim to create an innovative product; (b) stage of sustainable development at which the organizations strive to increase sales and create a stable product portfolio. The stages of development of high-tech organizations are understood as

configurations of an organizational project that represent adjustment of an enterprise to a particular business context in a given time window.

3. Entrepreneurial orientation and environmental uncertainty as attributes of technology entrepreneurship

Technology entrepreneurship is inseparably associated with the process of managerial decision making, which means selection of one of many alternative actions under the conditions of uncertainty. Uncertainty of the technology entrepreneurship environment is related to spontaneously occurring events in the further environment of the enterprise, in particular its technological sphere and closer environment of the enterprise, in particular in the area of customer needs and behavior of competitors. Uncertainty, understood as unpredictability of environmental conditions, is a prerequisite for entrepreneurship strategy.

Since the reality is a mixture of uncertainty and determinism, making managerial decisions involves a subjective category of hesitation. All forms of uncertainty lead to discontinuation of actions due to the occurrence of hesitation. Uncertainty in the context of actions triggers a hesitation reaction, which in turn causes uncertainty of behaviors or even decision paralysis. Attributes of an entrepreneur as an identifying unit and using development opportunities through actions under the conditions of uncertainty are manifested in two perspectives, i.e. weaker and more positive perception of uncertainty areas (in particular the effects of uncertainty) and ability of constructive dealing with uncertainty, and even an ability to use it. Three uncertainty dimensions mentioned most often in the literature are: (Dess & Beard, 1984; Sharfman, 1991): variability, complexity and hostility of the environment. Variability refers to the rate of changes, innovation of the environment as well as to the degree of predictability of actions of competitors and customers. Complexity is defined as a level of knowledge required for understanding the organization's environment. In other words, complexity is related to the number of variables describing a given environment. Hostility describes the availability of resources at the disposal of entities in a particular environment. A high level of these three dimensions of uncertainty results in the unpredictability of the environment that is its uncertainty.

As the uncertainty of organization's environment increases, the importance of entrepreneurial managerial decisions that create a supporting structure for entrepreneurial behavior of the organization also grows. Entrepreneurial behavior of the organization can be characterized by the following three features (Lumpkin & Dess, 1996): innovations of behavior, proactivity of behavior and risk taking behavior. In other words, the main features of development ventures of high-tech entrepreneurship organizations are innovation, proactivity and risk taking. Organizational entrepreneurship is a consequence of the ability of the managerial staff to make decisions for the implementation of proactive, innovative and risky development projects (Rauch, Wiklund, Lumpkin & Frese, 2009; Sharfman & Dean, 1991). Innovation of development projects consists in experimenting and improvisation with the use of creative processes for introduction of new ideas to the market and improvement of processes. Specifically, organizational innovation means the predisposition of the managerial staff of the company to make decisions concerning the involvement of resources in creative processes of experimentation by introducing new products and services to the market and continuous improvement of value creation processes. Proactivity of development projects consists in creating development opportunities by creating technological development, anticipation of competitors' behavior and predicting client's expectations. In other words, proactivity is an attitude of managerial staff to the continuous identification of development opportunities and adoption of an anticipatory perspective consisting in introducing new products before the competitors as well as anticipation of future demand. Taking risk means the tendency to invest resources of the organization in activities that characterize with results uncertainty. In other words, taking risk means undertaking actions and investing resources in uncertain areas of business activity.

In the context of an uncertain environment, companies must be more entrepreneurial, which means greater innovation of products, services and processes as well as greater proactivity compared to competitors; additionally, the activities of entrepreneurial companies are characterized by risk orientation. In the context of technology entrepreneurship as a type of entrepreneurship (Lindelof & Lofsten, 2006), rapid technological development of the company's environment strengthens the competitive pressure and creates fields of technological opportunities that encourage companies to entrepreneurial behaviors. A positive impact of entrepreneurial behavior of organizations on the effectiveness under conditions of uncertainty is confirmed in the literature (Fauzul, Takenouchi & Yukiko, 2010; Hoq & Chauhan, 2011; Fauzul, Takenouchi & Yukiko, 2010).

4. Methodology and results of empirical studies

The aim of empirical studies was to develop attribute profiles of high-tech enterprises being on two successive stages of development as temporary equilibrium states, i.e. birth phase and phase of consolidated development, in the context of their impact on the effectiveness of the enterprise. The attribute profile of a company was described by its innovative and proactive behavior as well as risk taking. The attribute profile of a company was analyzed in the context of uncertainty of the environment described by dynamism, hostility and complexity. The effectiveness of a company was described by multidimensional construct of a high performance organization.

Empirical studies were carried out on the group of companies from the Aviation Valley in Poland. The Aviation Valley is an excellent laboratory for studying the effectiveness of processes of technology entrepreneurship. It concentrates companies characterized by high intensification of R&D works (Khilji, Mroczkowski & Bernstein, 2006) mainly belonging to the so-called group of high-tech companies according to the OECD classification.

Implementation of the assumed research aim has been divided into two stages. The first stage of the research process consisted in a multidimensional analysis of effectiveness of two groups of organizations, the first group of companies at the stage of entering the market and the second group of companies at the next level, i.e. stage of consolidated growth. The criterion distinguishing these two groups of companies was the level of stabilization of income from sales of the product portfolio. The companies at the stage of entering the market focused on the development of a product and strengthening its position on the market. The companies at the stage of sustainable growth focused on the intensification of sales of the existing products and introduction of new products. The second stage of the research process consisted in the analysis of attribute profiles of two groups of companies subject to the study, in the context of their impact on obtaining an extraordinary performance. The attribute profiles referred to the entrepreneurial behavior of the companies and uncertainty of the environment.

The empirical studies were carried out at the turn of 2015 and 2016 on a group of companies from the Aviation Valley in Poland. The studies were of a qualitative nature, based on the methodology of comparative case study (Rialp, Urbano & Vaillant, 2005). The selection of companies for the study was deliberate, the main criterion for the selection of cases was the occurrence of technology entrepreneurship processes, understood more or less through the prism of using the latest technologies as the development core of a company. The group of companies at the stage of entering the market belonged to the Pre-incubator of the “Podkarpackie Science and Technology Park”, and the group of companies at the stage of development belonged to the “Podkarpackie Science and Technology Park”. The size of the survey sample, after verification of obtained study results, eventually amounted to twenty companies divided equally into two study groups, i.e. ten companies at the stage of entering the market and ten companies at the stage of sustainable development.

The respondents in both surveyed groups of companies, due to the necessity of having strategic knowledge, included the highest level management staff, in the group of companies entering the market these were mostly the owners of the examined organizations.

The process of carrying out the empirical studies was a multi-stage process, composed of the phase of direct interviews with the management staff of pro-innovative structures, i.e. “Aviation Valley Association in Rzeszów, Poland”, “Pre-incubator of the Podkarpackie Science and Technology Park” and the “Podkarpackie Science and Technology Park” as well as the management staff of companies affiliated in the Aviation Valley.

The aim of this stage was to verify the assumptions and research model for its detailed operationalization in the form of a research tool. The next phase of the empirical studies was to conduct a questionnaire research with the use of a designed research tool on the selected group of companies. The research was carried out either directly in the companies or by a telephone interview, depending on the time capabilities of the management staff.

The research tool was composed of an introductory part concerning a short characteristics of the company under study and the main part describing the multidimensional construct of effectiveness, construct of entrepreneurial features of the organization’s behavior as well as the construct of uncertainty of the

environment. The introductory part contained open questions concerning the name of the company, its website, classification of business activity and the ownership structure of the company. The main part of the questionnaire consisted of eleven statements selected on the basis of a theoretical construct of four perspectives for measuring the organizations' performance (Audretsch, 2012), the construct of entrepreneurial orientation of organizations (Jeffrey & Lumpkin, 2011) and the construct of uncertainty of organizations' environment (Dees & Beard, 1984). All questions were evaluated in relation to the last three years of company's operation. The first five statements concerned a multidimensional measurement of performance, the next three - entrepreneurial orientation of the organization and the last three referred to the uncertainty of the organization's environment. The statements concerning the analysis of performance related to the following aspects: sales profitability in the perspective of financial performance of the company; increase in total income from sales of products and services as well as employment growth, both were describing the perspective of the performance of the organization's development; income from the sale of new or radically modernized products and services in the total sales income in the perspective of innovation; general engagement of employees in the activities of the organization in the perspective of social performance. The statements in the field of analysis of entrepreneurial orientation of the organization included the following characteristics of the organization's behavior: preferring research and development, technological leadership and innovation as an innovative behavior; initiation of activities in the organization's environment as a proactive behavior; preferring high-risk activities and high return activities as risk taking. Statements in the field of analysis of features of the organization's environment concerned: high rate of changes describing the dynamics of the environment; expert knowledge required for understanding the external environment of the organization as the comprehensiveness of the environment; mutual reluctance of external entities of the organization's environment as hostility of the environment. All questions were evaluated based on the seven-point Likert scale.

The structure of the studied group of companies by ownership criterion is presented in Table 1.

Table 1: Ownership structure of researched companies

Group of companies	Owner - inventor	Owner - tradesman	Owner - VC
Start -up	10 (100%)	10 (100%)	0 (0%)
Mature growth	6 (60%)	10 (100%)	0 (0%)

Source: Own study

The analysis of the ownership structure proves that the companies at the entry phase are managed by the authors of technological ideas, and the companies at the mature growth phase are managed together by the authors of technological ideas and marketers. The effectiveness of the surveyed companies at the stage of entering the market is entrenched with the technological competencies of owners, and the effectiveness of the surveyed companies at the sustainable development phase is grounded in technological and marketing competencies. There were no high risk funds among the owners of both groups of surveyed companies.

The method of pairwise comparisons was used for the analysis of obtained statistical data from the main part of the questionnaire in the area of multidimensional analysis of performance (Shields, 2015; Bernardin & Wiatrowski, 2013; Ragin, 2014). In order to evaluate the differences between the examined cases according to particular performance criteria, the predominance function, defined according to the following logic formula:

F(x)= - 1, when-6 <= x <=- g
F(x)=(x+D)/(G-D), when –G<x<=-D
F(x)=0, when -D<=x<=D
F(x) = (x-D)/ (G-D), when D<=x<=G
F(x) =1, when G<x<=6
$R(i,k) = \sum_{j=1} f(P(i,k) - P(j,k))$; P(j,k) - evaluation of i-th company, acc. to k-th criterion.
$O(i)=\sum R(i,k)$ - a synthetic assessment of the effectiveness of the i-th company.

where: x is the difference of assessments of two compared companies, D is the threshold of indistinctness, G is the threshold of predominance. In the analyzes carried out, the indistinctness threshold was one and the threshold of total predominance was six.

Afterwards, to switch to the analysis according to the logic of fuzzy sets, the membership function for particular variables of the research model were defined. Synthetic assessments of the performance of surveyed companies were subject to calibration to obtain the function of membership of a company to the set of highly performance companies.

μ_E (i) – function of membership of the i-th company to the set of highly efficient companies - E.

Individual assessments concerning the entrepreneurial orientation of the organization and characteristics of the organization's environment were also subject to calibration.

μ_{Cj} (i) – function of membership of the i-th company to the set of companies with particular characteristics describing their entrepreneurial orientation and their environment - Cj.

Afterwards, on the basis of the functions μ_E (i) and μ_{Cj} (i) based on logic of fuzzy sets and Bool's algebra, the impact of belonging to particular sets C_j and to the set E was analyzed. These analyzes can be formalized in the following form:

$Y \Leftrightarrow F(x_1,x_2,...)$

where: Y means that a company belongs to the set of effective companies, and x_j means that a company belongs to the set of companies with the j-th feature (however, instead of x, its negation may occur). F means the logic formula which is the sum of products of logic simple sentences (each of which expresses the belonging of a company to one set C_j).

The Table 2. presents results of empirical studies on the impact of the feature of entrepreneurial orientation of a company and its environment on the performance in the group of companies entering the market.

Table 2: Attribute profiles and the effectiveness of high-tech companies at the stage of entering the market

Model	Row coverege	Unique coverage	Consistency
Construct: f_perform. = f_(innov., proactiv., risktak., dynam., complex., hostility)			
(M1):~f_hostility * f_dynam * f_risktak * f_proactiv * f_innov	0.71	0.05	0.85
(M2): f_ complex * f_dynam * f_ risktak * f_proactiv * f_innov	0.78	0.12	0.63
(M3): ~f_ hostility * f_ complex * ~f_dynam * f_ risktak * ~f_proactiv * ~f_innov	0.14	0.09	1.00
Solution coverage: 0.92; solution consistency: 0.67			
Frequency cutoff: 1.00 ; consistency cutoff: 0.60			

Statement	Model 1	Model 2
Entrepreneurship of the organization:		
Innovation: the organization prefers research and development, technological leadership and innovations	•	•
Proactivity: the organization initiates activities in the environment	•	•
Risk taking: the organization prefers high-risk activities and high return activities	•	•
Uncertainty of the environment		
Dynamics: there is a rapid pace of changes in the organization's environment	•	•
Comprehensiveness: understanding of the organization's environment requires an extensive expert knowledge.	*o*	•
Hostility: behavior of entities of the organization's environment is characterized by mutual reluctance	~	*o*
Explanation of symbols: • occurs, o does not occur, ~ negation.		

Source: own study with use of fs/QCA 2.5/

Both obtained attribute profiles of the companies at the phase of entering the market show an unambiguous entrepreneurial orientation of the high performance companies. This orientation finds its unequivocal basis in all three types of behavior indicating the entrepreneurial orientation of the organization, i.e. innovation, proactivity and risk taking. However, the obtained attribute profiles of examined organizations differ in terms of the uncertainty of environment perceived by the management staff. In the first model, the uncertainty of environment is perceived based on the dynamics of changes in the environment. In the second model, the uncertainty of environment is perceived based on the dynamics of changes in the environment and its complexity. In none of the obtained profiles there is hostility of entities as a carrier of uncertainty; in the first profile, hostility is negated, in the second profile, hostility does not occur.

In summary, the first attribute profile of high performance companies at the phase of entering the market is based on a strong entrepreneurial orientation and perception of the environment as dynamic and friendly. The second attribute profile of high performance companies at the phase of entering the market is based on a strong entrepreneurial orientation and perception of the environment as dynamic and comprehensive.

The Table 3 presents results of the empirical studies on the impact of the feature of entrepreneurial orientation of the organization and its environment on the performance in the group of companies with sustainable growth.

Table 3: Attribute profiles and the performance of high-tech companies at the stage of mature growth

The obtained attribute profile of companies at the stage of sustainable development with high performance shows a clear entrepreneurial orientation. This orientation finds its unequivocal basis in all three types of entrepreneurial behavior, i.e. innovation, proactivity and risk taking. The profile of perception of environment uncertainty of companies with high performance is characterized by a rapid pace of changes and comprehensiveness, the feature of hostility does not occur.

The comparison of the obtained attribute profiles of high performance companies at various stages of development is presented in the Table 4.

Table 4: Profiles of high performance organization: start – up vs. mature growth

The attribute profile of high performance organization at the stage of entering the market	**The attribute profile of high performance organization at the stage of sustainable development**
P1: - highly entrepreneurial orientation: innovative, proactive as well as risk taking behavior; - perception of uncertainty of the environment: rapid pace of changes P2: - highly entrepreneurial orientation: innovative, proactive as well as risk taking behavior; - perception of uncertainty of the environment: rapid pace of changes and high complexity	P1: - highly entrepreneurial orientation: innovative, proactive as well as risk taking behavior; - perception of uncertainty of the environment: rapid pace of changes and high complexity

Source: own study.

All obtained profiles of high performance companies are based on highly entrepreneurial orientation. The differences occur with regard to the perception of uncertainty of the environment, in particular they concern the hostility of behavior of its entities. In all profiles, the environment is perceived as highly variable. In the first attribute profile of high performance companies at the stage of entering the market, there is a negation of the hostility of environmental entities, which is accompanied by lack of complexity of the environment. The

second profile of high performance companies at the stage of entering the market is similar to the profile of high performance companies at the stage of sustainable development. Both are based on the highly entrepreneurial orientation and perception of the environment as highly variable and complex while not recognizing any hostility of entities within the environment.

5. Conclusion

The attribute analysis of technology entrepreneurship confirms that high performance enterprises on early stages of development must behave very entrepreneurial taking into account all three entrepreneurial orientation attitudes. The perception of env. uncertinty by high performance enterprises is based mainly on perception of rapid pace of changes, high complexity and without environmental hostility. It means that high performance enterprises must be able both to manage env. changes and complexity by strong entrepreneurial orientation and to format environment as rather friendly then hostile. The start - up companies comparing with mature growth ones have more different configurations of technology entrepreneurship to succeed in uncertain environment. Concluding the results of empirical research, it should be emphasized that the research was of qualitative and exploratory nature and was carried out in the form of a comparative case study. In other words, they provide a good basis for formulating introductory theoretical assumptions of the category of entrepreneurship and they need to be complemented by representative research to create the basis of a comprehensive theoretical framework of the phenomenon.

Abstract: Due to increasing competition, what companies need to do is as important as how they do business. For this reason, companies are focusing on getting better ideas ahead of their competitors and passing them on quickly. Models developed for innovation management, such as technology push, market pull, coupling, interactive and network are being applied and developed in different sectors with different add-ons. The aim of this study is to propose and apply the innovation management framework in an international insurance company and evaluate its results. This framework includes interactive model as the innovation management approach; brainstorming as the creative thinking method, and Delphi as group decision-making method. The volunteers selected from employees of the company among those who are more closely related to the customers. Although 37 of 510 employees are applied to the program, only 22 of them are approved. The volunteers were provided with detailed information on technological trends and trained in innovation management and creative thinking methods. Later, 328 innovation ideas were produced by using brainstorming method. These ideas were presented and consolidated into 62 different ideas, and then the participating volunteers were requested to score the ideas in terms of 5 criteria. The scored ideas were ultimately evaluated by a couple of joint meetings and the 6 ideas are decided by using Delphi method to be offered to the executive's of the company with the detailed feasibility reports and project proposals and those who find sponsors from the executives will be initiated in a program. In this study, the interactive innovation management model was extended to the insurance sector in a novel approach by combining a set of well known methods in an order for different steps. According to the literature, this study is the first in the insurance sector in Turkey, and a subject of study in the world is also increasing. The results obtained in this study are considered to be a guide for researchers working on this field. For further research, it is suggested to consider of granting individual mentorship to employees who are volunteers throughout the innovation management process.

Keywords: innovation management, interactive innovation model, insurance, digital transformation, brainstorming

1. Introduction

1.1 The Role of Innovation in Corporations

With the impact of globalization, the world quickly began to become a single market. The number of firms and consumers who produce and demand similar products is increasing. For this reason, the market is filled with similar and commodity products. Consumers, in this case, prefer price, quality, convenience and ease of payment and delivery, and choose the product that suits them best. For all these reasons, one of the most important factors in the preference of firms is that they constantly innovate and attract consumers with their unusual practices.

Innovation is seen as an important tool for companies that want to survive and grow in competitive conditions (The Boston Consulting Group, 2006). But for companies that want to gain a competitive edge, innovation is not a one-time tool. There is a need for managing the innovation so that innovation can be implemented continuously at every stage of the enterprise and an environment suitable for the realization of innovations. So that the sustainable competition and success depend on innovation management of an organization (Cooper, 1979; Rothwell, 1992; Benedetto and C.Anthony, 1999).

As an important requirement of innovation management, institutions should not expect innovation to come into being spontaneously, but should proactively plan an environment that will lay the groundwork for innovative thinking and work that reveals industry market trends, competition conditions, customer expectations and trends in order to create this environment (Preez and Louw, 2008).

Innovation can be realized in many different areas such as product, process, organization, marketing, etc. However, the innovations are seen very often product and technology-centric. This approach is most probably a result of defining innovation as "the ability to create new value at the intersection of business and

technology" (Davila, Epstein and Shelton, 2007). According to the Oslo Manual, innovation is *"a new or significantly modified product (goods or services) or process; a new marketing method; or a new organizational method in business practice, workplace organization or external relations"* (OECD, 2005). Although this definition includes organizational and marketing innovations, one of the most basic points in innovation is still focusing on new or improved ideas which can be sold and marketed. On the other hand, measuring and evaluation of innovation are as a complex issue as it is important for companies (Frenkel, Maital and Grupp, 2000).

1.2 The Innovation Management Models

There are many models of innovation management processes in the literature from idea creation to product commercialization (Rothwell, 1992; Trott, 2005; Ning, 2017). Six of them are widely accepted and used in innovation management field such as technology push, market pull, coupling model, interactive model, network model and open innovation.

Technology Push Model usually provides research and product development without making market research, using newly discovered technologies. Touchscreen technology on smartphones is an example of this. Touch screen technology has emerged as a result of work done by EA Johnson in the 1960s. As a result of a series of R&D (Research & Development) activities made in the 1980s, Hewlett Packard introduced a touchscreen computer, and nowadays many touchscreen technologies such as the Apple PDA and the 1996 Apple Palm series are used (V.Ryan, 2013).

Market Pull Model is the innovation process that is triggered by a request for a new product coming from the market or the necessity of resolving a problem. According to this model, the need for innovation is; market research is determined by the requirements of the end or potential customers. Market pull is also starting with the desire of customers to make improvements in existing products. In the 1990s, there was a market requirement for a camera that could take an infinite number of pictures and instantly see the pictures we took. The requirements for this market had led to the development of digital cameras, and the existence of digital cameras has led to the development of photo editing software. Every requirement in the market brings with it the next innovation (V.Ryan, 2013).

Although technology and the market are two distinct driving forces to create innovation, it appears that most of the innovations are formed by the combination of technological and market factors in a creative context. Additionally, most of the failures in the process of creating innovation are based on inability to follow technological trends and to evaluate the market correctly. Although the relationship between science and technology and the constantly changing market is quite complex, it is assumed that it is possible to achieve the success by setting a good balance between technology and market with ***Coupling Model*** of innovation management (Dodgson and Rothwell, 1995). This balance between technology and market requirements is important at every stage, from the first thought of the idea of innovation to the end of research, design and development work, to the presentation of a new product or process market (Dodgson and Rothwell, 1995). It is a model that recognizes the interaction and feedback systems between different elements and tries to combine R&D (Research & Development) and marketing studies (Preez and Louw, 2008).

Interactive Model suggests that new knowledge has been brought to the point with the help of knowledge already existing in the company (R&D studies, etc.) (Clark and Guy, 1997). Innovation management process emphasizes the importance of relationships among the departments within the company and it is argued that innovation can come from all departments of the company. For this reason, it is stated that the interaction between the units in the company is very important. If the company is looking for technological solutions, it will look at the existing solution proposals, and if this solution does not satisfy the proposal, it will try to bring new information to the market (Fischer, 2001).

The interactive model is a framework that connects "Technology push" and "Market pull" models. There is no clear starting point for the interactive model, like the simultaneous coupling model. Interactive innovation is emerging with the latest developments in science and technology, needs in the society and in the market, and organizational skills. Innovation is not just between R&D or production and marketing, but between science technology and all functions linked to the market (Trott, 1998).

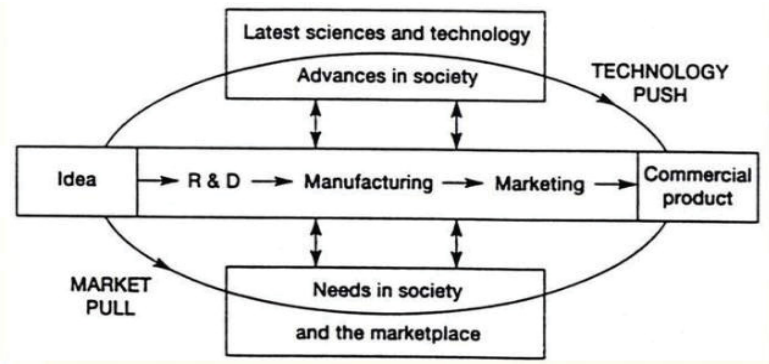

Figure 1: Interactive Model (Rothwell and Zegveld, 1985)

Network Model: According to this model, it is not enough to cooperate only with internal departments for innovation like the interactive model. In addition to internal departments, links with other institutions, universities, research centers, suppliers, and consumers should be established. According to Freeman, the network model *"establishes open connections with a group of complementary forces operating on the field, in order to reduce all the great dynamic and static uncertainties that may arise"* (Freeman, 1991).

Finally, according to the *Open Innovation Model*, a company aims to make the best use of the ideas of internal and external sources. Companies have the thought to be successful if they only they can best use of internal and external ideas (Preez and Louw, 2008). This model argues that establishing a better business model is more important than entering the market first. In the open innovation model, companies take their technology from many different sources. It is important to be able to benefit from using outsourced information by allowing it to use its own ideas in external institutions as well as by protecting the intellectual property rights. It combines internal and external ideas to advance the development of new technologies for the market.

1.3 The Role of Creative Thinking in Innovation

There are three key points to be aware of during the innovation process, i) identifying and understanding the problem, ii) finding ideas that can solve the problem, and to selecting the most appropriate one among all ideas (Modlin, 2015). In order to solve a problem, it is necessary to determine the possible solutions to the problem that can be detected and identified first. At this point, there is an important role of creative thinking methods. When it is necessary to be decided as a group, the brainstorming method is used when the group members are concerned about not being able to express their ideas freely due to the hierarchy and when we have little time to make a decision (Rawlinson, 2017). Some researchers have argued that brainstorming is the best tool for group idea production (Isaksen and Gaulin, 2005). Other popular group decision-making methods include Delphi (Chan et al., 2001), Rank Order Centroid (RoC) (Edwards and Barron, 1994) and Ratio Method (Weber and Borcherding, 1993). One of the important elements of creative thinking is to get support from methods of finding unique and new ideas during individual thinking. At this point, methods such as lateral thinking (Bono and Zimbalist, 2010) and morphological analysis (Hubka and Eder, 2012) may play an important role as well.

The aim of this study is to apply the interactive innovation management model in a case study with the selected employees who have close relation with the customers after supporting them with detailed information and trainings to enable them to produce innovative ideas in an effective way.

The next organization of the paper is as follows. Chapter 2 emphasizes the necessity of the insurance sector as well as the fact that it is in other sectors to establish a culture of innovation management. It is mentioned that the importance of innovations in the insurance sector is increasingly recognized today and the studies in this domain have been included. It is pointed out that the number of studies in insurance domain is still low and more information needs to be revealed. In Chapter 3, our case study in the insurance domain has been elaborated in detail. The results obtained were analyzed in Section 4.

2. Problem Definition

As in other domains of the sector, the insurance domain is in search of development and improvement of methods, processes, tools, and products because of the dynamic natures of the environmental factors such as

consumer, customer, competitor, and technology (Mills and Tubiana, 2013). It is clear that the spread of innovative thinking culture in insurance institutions is necessary to provide these innovations and to catch up the time.

Today, the insurance industry seems to be moving slowly but steadily on innovation management. Most insurance companies are very concerned about the innovation management stage in order to make long-term investments (Modlin, 2015).

It is observed that studies on innovation management in the insurance domain are very few. In a small number of these studies, Preez and friends aimed to sell innovative insurance products through new distribution channels (for example using smartphones), targeting low-income markets in an effort to innovate in the insurance industry. They have used the brainstorming method to find innovative ideas for this purpose. By combining ideas from different categories, they have defined various new concepts. They have taken a feasibility report for each of the concepts that they have developed and tried to develop the project by way of these concepts. Since the projects have not yet ended at the time of publishing, there is no clear information about the results of the work. But they say that they have come a long way since they first described innovation (Preez and Louw, 2008).

In the literature, no other studies related to innovation management have been found in the insurance sector, indicating that there is very little work to be done in this area. This study was carried out in an international insurance company in Istanbul, Turkey (Sompo Japan Insurance, Turkey) and proposes a practical framework for innovation management that we hope will contribute to the lack of innovation management in the insurance domain.

3. Methods

Our study consists of 8 steps covered in the following headings, are shown in Figure 2.

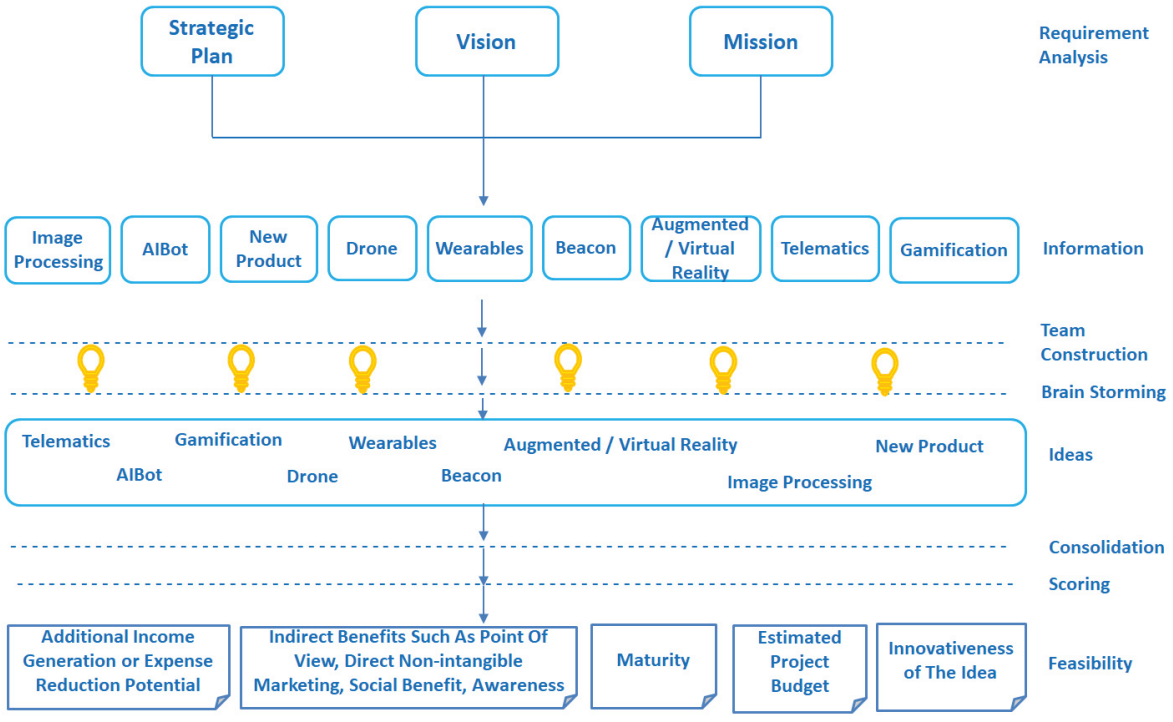

Figure 2: The framework of the extended interactive innovation management model

As described in the literature for the interactive innovation management model; the latest developments in society and technology should be determined and the expectations of the society and the market should be perfectly met. The produced innovative ideas should be in the technological areas which can be determined after a requirement analysis (Rothwell and Zegveld, 1985).

Basically in this study, first by considering the strategic plan, vision, and mission of the insurance company, the current situation and requirement analysis are carried out. As a result of the requirement analysis, the technological areas are determined by which there should be innovative studies will be made. Then we have informed the employees about the 9 technologies that we have set as a result of the negotiations we had with company executives at the beginning. They employees are asked to produce ideas that they can apply in their businesses. After a couple of trainings, teamworks and brainstorming, 328 ideas were produced. Then the ideas were scored with respect to the criteria based on strategic objective of the company and then consolidated. Finally the feasibility reports were issued for the selected most appropriate ideas. The result of these stages brings 6 ideas to be applied, produced and/or commercialized. Since the production and commercialization process will take too much time, we have not included this part in our study.

3.1 The Requirement Analysis with Executives m

Every new project, product, and activity in the workplace comes to meet a business requirement (Business Requirements Analysis, 2015). Many studies show that the main reason for project failure is the lack of product requirements or the lack of necessary support (Kumar, 2006). Today, many organizations believe that management requirement analysis will increase the likelihood of project success.

Requirement analysis also referred to as requirement engineering in the literature, aims to meet customer expectations with new or significantly modified products (Wohlin and Aurum, 2005). It is believed that making decisions by conducting requirement analysis before management of any project will contribute significantly to meet business objectives by managing project scope and costs.

Although direct involvement of excecutives in the process of creating a vision for innovation is an important element, it is more valuable for companies to work as widely as possible in their innovation development work (Mills and Tubiana, 2013).

For this reason, in our study, we first performed a comprehensive requirement analysis with the company executives. During the requirement analysis conducted by the executives, it was discussed the expectations of the customers and what they could do to meet these expectations. During these meetings, it is confirmed that the employees rather than executives who are directly conducting with the customers are more capable of understanding and describing the customer expectations in detail. For this reason, the interactive innovation management model (Fischer, 2001) has been preferred by providing an effective communication and interaction environment among all departments.

3.2 Increasing the Knowledge Capacity of Employees

Another characteristic of the interactive innovation management model is that it acknowledges that innovation will build on the company's existing knowledge (Clark and Guy, 1997). In addition, it is very important that employees are willing to contribute the study in terms of productivity. For this reason, weekly technology bulletins such as Telematics, AIBot, Gamification, Drone, Wearables, Beacon, Augmented / Virtual Reality and Image Processing were prepared and shared with all employees for 2 months in order to increase the knowledge of the employees and to identify the volenteers. On this page, although an interactive model was chosen as the innovation management model, it also benefited from some elements in the Coupling innovation management model (Preez and Louw, 2008), by providing information on technology trends for employees with extensive knowledge of customer expectations.

All those studies are coordinated by the digital transformation office of the insurance company. It is often reminded by the same office via e-mails that the purpose of preparing the bulletins is to produce and implement innovative ideas in these areas. Apart from this, all employees were asked to think about innovations in technological areas that said 'how good it would be if this innovation was done on this field,' and these ideas were collected through an online questionnaire. This method is very similar to the recommendation of constructing a sentence with *"I wish ..."* as a catalyst by La Sella (Salle, 2008) in order to create innovative ideas.

It is anticipated that the ideas of innovation to be revealed will be in line with the institution's strategic objectives. For this reason, the vision, mission and strategic objectives of the company have been shared with all employees during this stage.

3.3 Selecting the Candidates

The on-line questionnaire mentioned above is used to identify candidates who will voluntarily participate in innovation management activities. Employees in the questionnaires were asked whether they wanted to be included in the innovation study and were asked to select one of the technological themes previously announced in the bulletins for innovation work. Employees are also given the opportunity to choose this technology and write it down if there is a proposed innovation in the technology field.

Following the collection of these preliminary requests, the approvals are requested from the managers of the employees for spending the required time for the relevant work.

Being able to experience a comprehensive innovation management process has been an important motivation for employees in this study. In addition, a number of in-house and out-sourced training opportunities to contribute to personal development were also presented.

The number of applicants to participate in the first stage is 37. 5 of candidates are interested in drone technology, 10 in gamification, 4 in AIbot, 4 in wearables, 6 in new products, 4 in telematics, 3 in image processing, and 1 in beacons technology.

3.4 Training and Workshops on Creative Thinking Methods

22 of 37 volunteers are accepted to involve in two training sessions, called "Innovation Groups Initial Training". In the first session of the training, science, technology and innovation concepts, technology and innovation management issues were discussed and types of innovation (based on Oslo Manual (OECD and EUROSTAT, 2005)) were explained. There was also an interactive training on creative thinking techniques. In the second session, the technological newsletters were sent back to the participant readers, and the details of the technology and examples of applications in the world were shared. In this way, both the conceptual plane of the participants has strengthened; as well as the knowledge about the technology they would produce innovative ideas.

3.5 Gathering the innovation Ideas

In order to obtain more concrete and valuable suggestions from the voluntary employees involved in the innovation management process, the brainstorming method has been applied.

Brainstorming is the best tool known for group idea production (Isaksen and Gaulin, 2005).The brainstorming method is preferred since we try to make the search for solutions easier by starting from the maximum creative ideas that will be released during the group discussion method.

Basic idea behind the brainstorming method; the greater the number of ideas about a given problem, the more likely it is to find the most appropriate solution (Litchfield, Fan and Brown, 2011).

A comfortable, peaceful and authentic environment was created for the participants to the idea production phase. In order to conceal their ideas, they are guaranteed that they will not be subjected to inappropriate or unfavourable criticisms, even if their unconventional ideas are absurd to other members and executives.

The study was applied in a medium-sized meeting room. Elements to distract the participants were removed from the room. In order to make them feel comfortable, a friendly atmosphere was created and tea and coffee treats were offered.

In addition to the 4 moderators, two different sessions were organized with 17 volunteers as 4 groups using the idea sheet method in the brainstorming study. In the first session, ideas about AIbot, telematics, gamification and drone technologies were produced; while ideas about wearables, beacon, image processing, new products, and Augmented / Virtual Reality technologies were produced in the second session. The ideas produced after the two sessions were put together in an online environment.

As a result of brain storming, 328 ideas were produced. Of these ideas, 59 are about AIbot, 35 are telematics, 32 are Gamification, 33 are Drone, 11 are Wearables, 40 are Beacon, 34 are Augmented / Virtual Reality, 45 are Image Processing technologies and 39 are New Product.

3.6 Consolidating the Innovative Ideas

During the brainstorming sessions, it is possible to produce similar ideas by different groups for the same subject. Even so, this situation has been taken to ensure diversity. However, this situation requires a good consolidation of ideas produced. To do this, 328 ideas produced primarily are classified according to technologies. The ideas have been read by the moderators and the similar ideas are merged.

After the process of consolidating ideas, 62 different ideas were obtained. Of these ideas, 7 are about AIbot, 5 are telematics, 5 are Gamification, 8 are Drone, 5 are Wearables, 4 are Beacon, 6 are Augmented / Virtual Reality, 8 are Image Processing, and 14 are New Product.

3.7 Scoring the Innovation Ideas

After the ideas were consolidated, the digital transformation office also asked from the volunteers to evaluate all consolidated ideas based on the following criteria by an online questionnaire:

- Potential of Additional Income Generating or Expense Reduction (Multi / Medium / Low).
- Indirect Benefits such as Marketing, Social Benefit, Awareness (High / Medium / Low).
- Estimated time period to apply (Long: 18 + Month / Medium: 6-18 Months / Short: 1-6 Months).
- Estimated project budget (Much: > 500,000TRL / Intermediate: 500,000-100,000 TRL / Less: <100,000 TRL).
- Innovativeness (Very / Medium / Less).

After this online evaluation, all candidates were invited to evaluate the scored ideas again. In this evaluation, the scores of the ideas were shared with the participants. So that the most innovative, the most revenue-generating, the shortest time requiring, etc. ideas can be sorted and then discussed and re-scored very easily by the volunteers.

3.8 Feasibility Studies of the Innovation Ideas

The projects are then sorted with respect to the ranks which were created with respect to the above criteria. The Digital Transformation Department of the company made a feasibility study on the top 10 of the innovative ideas and found 6 of them feasible to be projected and offered to the executive of the company.

4. Result and Discussions

Innovation studies are crucial in order to grow and survive in today's competitive conditions (The Boston Consulting Group, 2006). The importance of innovation for companies in the world is being recognized day by day, and the development and applications of innovation in different sectors are increasing.

As is the case in other sectors, the insurance industry also recognizes the need to disseminate innovation culture and the need for innovative practices (Insurance Industry Innovation Consulting Solutions, 2017); (Mills and Tubiana, 2013). But despite that as a result of the extensive literature search, the lack of studies in the insurance sector is noteworthy.

In the field of innovation, studies are carried out in various sectors. There are various innovation management models (technology push, market pull, coupling model, interactive model, network model and open innovation) and these innovation methods are applied differently in different sectors (du Preez and Louw, 2008).

Interactive innovation management process in this study was applied to an international insurance company that has been serving the insurance industry; preliminary steps for the implementation of innovative ideas are carried out.

Our work with volunteers working at SOMPO Japan-Turkey Company was completed in 10 weeks. The company has a total of 510 employees and 22 people volunteered working in different departments.

The most important feature that differentiates this study from other innovation applications is that the interactive innovation model has been implemented in an insurance company with the collaboration of executives and employees by using a set of well-known methods in a special order starting from the

requirement analysis and idea generation to the evaluation of the ideas. Additionally, the idea generation is based on only the predetermined technologies which are decided with respect to the requirement analysis. Later ideas were scored and a feasibility report was presented again from the most appropriate ones. As results of all these studies, 6 of 328 ideas are determined that can be realized. These 6 ideas are in the process of passing on to the company.

Table 1: The numbers of ideas in different stages of the study

	Gathering the Ideas		Consolidation and Scoring	Feasibility
Technologies	**Suggested Ideas In the on-line Survey**	**Generated Ideas by Brainstorming**	**Scored and Evaluated Ideas**	**Feasible Ideas Presented to the Executives**
Image Processing	3	45	8	0
AIBot	4	59	7	2
Beacon	1	40	4	1
Gamification	10	32	5	2
Drone	4	33	8	0
New Product	5	39	14	1
Telematics	4	35	5	0
Virtual Reality	0	34	6	0
Wearables	4	11	5	0
TOTAL	**35**	**328**	**62**	**6**

It has been observed that volunteers have a high level of motivation during the whole stages. After this study, the company has initiated a series of training activities for improving the capacity of the employees in different skills, such as customer relations, effective communication, marketing, etc.

The interactive innovation management model that is proposed to the company will be continuously applied by the digital transformation office of company by considering the policy and strategic objectives in the coming years.

This study is the first study based on literature in the insurance sector in Turkey, and one of the rare examples in the world began to appear recently. From this point of view, this study is considered to be a guide for the researchers who will work in this domain.

However, according to our observations during the study, it is evaluated that it would be beneficial to offer individual mentorship to volunteers about technology and innovation management, creative thinking methods and commercialization will be very beneficial in the future works.

Abstract: The knowledge of the Portuguese public regarding smart cities is still limited, such knowledge being more present in the technological and business environments. Portuguese cities are starting to invest in smart issues as a response to their complexity and challenges. The ENABLE Consortium's INTELPARK Solution (fictitious names given for anonymity purposes) described herein is an example of a smart parking solution that, through the combination of hardware and software, provides key information about the parking area being managed (for example, occupancy or vehicle infraction information). This technological solution, focused on optimizing and making the management of parking areas more efficient, will serve everyone involved: from the driver to the manager. This article aims to focus on the prospective user (in this case, the driver who will park his or her vehicle in the parking area), since the consumer / traveller driving a vehicle is the main reason for the success or failure of any product and service, such as this one, in the marketplace. In addition, we are living in times of profound digital transformation in which access to information, oftentimes down to the second, becomes increasingly important for the user as well as the search for solutions that increase well-being, quality of life and comfort. Thus, 209 valid online survey answers were received, with structured questions, responses which were gathered from drivers or end users and in a non-probabilistic sampling research process. The main goal was to know how the mobile application INTELPARK, associated with this smart solution, was perceived by the end user, and to understand the potential interest in it and how frequently it would be used. The data collected was analysed through descriptive statistics and via the chi-squared test, in order to find associations between variables. The research concludes that future end users of this mobile intelligent parking application will have the following profile: they will be older, highly literate and with a higher gross monthly income. Moreover, these results also show that parking is seen to be an issue of citizenship and which promotes quality of life rather than simply being a source of revenue.

Keywords: smart cities, smart solutions, smart parking, traffic, mobile application

1. Introduction

Cities occupy only 3% of the land area, but consume 60% to 80% of the energy and are home to half of the world population (3.5 billion inhabitants) (United Nations, 2015). Cities account for 70% of CO2 emissions, and up to 30% originate in the search for parking (Parking Network, 2014). Due to the demographic, social and environmental importance of cities, the investment in new management models, and in innovative solutions (e.g. the usage of information and communication technologies) is increasing and smart cities are being born, supporting cities' competitiveness, quality of life, development and sustainable growth.

One of the major challenges of these urban centers is mobility and the number of vehicles on public roads, emitting polluting gases, leading to road congestion and affecting quality of life (*The Guardian*, 2015). In Europe, the technological solutions for an efficient urban area management have increased, helping to reduce the negative impact of cars. For example, solutions include the pre-booking of facilities (parking lots) and mobile applications with information about available parking places.

An example of a technological solution, a smart parking solution, is ENABLE Consortium's INTELPARK Solution (fictitious names given for anonymity purposes) that focuses on solving the difficulty for drivers in finding a vacant parking space. It is implemented in the infrastructure of the city and brings advantages for citizens, managers and cities.

The present research intends to study the suitability of this new technology to the needs of the user, as well its adoption. To this end, an online survey was conducted involving potential users and focusing on their interest in the mobile application, its future impact on their life, the possible usage frequency, among others.

Therefore, we seek to contribute to the broader discussion on welfare, quality of life, sustainability of the planet and on the efficient management of resources.

2. Innovation, product diffusion and adoption

2.1 Innovation: definition, dissemination and adoption

In the 1930s, Joseph A. Schumpeter, the initiator of the innovation dialogue, defined innovation as "the process of doing something that is already being done, but in a different way" (Schumpeter, 1947, p. 151). For Eurostat & OECD (2005, p. 46), it "is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational method in business practices, workplace organisation or external relations".

Rogers (1995) states that the decision-making process for adopting innovation comprises five steps:

- Knowledge (when the individual is exposed to and absorbs knowledge about the innovation);
- Persuasion (when the individual forms an attitude, favourable or not, towards the innovation);
- Decision (when the individual engages in some form of activity that leads him to accept or reject the innovation);
- Implementation (when the individual uses the innovation);
- Confirmation (when the individual seeks reinforcement of the decision he or she made and may even go back on the decision taken).

Moore (1991), in turn, presented the Technology Adoption Lifecycle Model, representing the market penetration of any technological product, according to the user's response to the innovation. There are five classifications for consumers: innovators (technology is central to their lives and they are eager to try new ideas), early adopters (although not tech savvy, they adhere to new products soon and easily understand the benefits of the new technology and relate it to their concerns), early majority (guided by their practical sense they prefer to first see how the product is working with other people and only then invest in it), late majority (more sceptical and reticent, requiring additional proof that the product works) and laggards (not technology friendly, only having a connection to technology when forced to buy a product in which the technology is so well hidden that they do not even notice it) (Moore, 1991; Rogers, 1995).

However, the model has three gaps, each one representing the difficulty that a technological innovation faces when going from one segment of users (buyers) to another. Therefore, there is a gap between the innovators and the early adopters, between the early adopters and the early majority, and between the early and the late majority. The first gap occurs when a technological product cannot demonstrate any core benefit, making it difficult for people to understand why it is being used. The second gap is related to the lack of technological knowledge of the second group. At this stage of product development in the market, some attention is needed to make the product easy to use so that it may continue to succeed, otherwise it will not go forward and will never reach the late majority. The gap between the early adopters and the early majority is called the chasm (or abyss) and it is the most difficult gap to be overcome by the innovation, given the difference between the two groups and their size. Finally, let it be stated that for an innovation to become a "household name" and for its creators to become rich the innovation must make it over the chasm and into the early majority segment, soon to be followed by the conquering of the late majority segment of buyers.

Although attention must be paid to all of the groups of consumers described above, there are other details that the company has to be aware of, such as the transfer of ideas between individuals that inevitably ends up influencing the success of a certain innovation. This transfer or sharing of ideas can be influenced by several reasons. One is the degree of similarity between individuals in terms of attributes such as education, beliefs or even social status. Consequently, the more similar they are, the more fluid the exchange of ideas.

3. Smart Cities

A smart city is a city interconnected by communication and information technologies, with the aim of increasing innovation, efficiency, sustainability, competitiveness and economic growth, while improving quality of life and providing for a wiser management of natural resources (Batty et al., 2012; Joshi, Saxena, Godbole, & Shreya, 2016; Komninos, Pallot, & Schaffers, 2013). Smart cities have different areas of activity depending on the urban areas and on the technological intervention that may be required: smart economy, smart people,

smart governance, smart mobility, smart environment and smart living (Batty et al. 2012; Komninos et al., 2013). From these, smart solutions/products/services are created and integrated (e.g. air quality monitoring, traffic monitoring).

4. The ENABLE Consortium's INTELPARK Solution

Parking plays a key role in road traffic, and eventually all vehicles need a parking space. Uncertainty and the lack of information regarding the location of available parking spaces makes the whole process complicated, causing many drivers to lose a significant percentage of their time searching for adequate parking (Thompson & Richardson, 1998).

The INTELPARK solution created by the ENABLE Consortium was the answer supplied by the three founding Portuguese companies, specialized in R&D, to solve the need for increasing the efficiency of parking management and to transform it into a more accurate tool to improve urban mobility and, ultimately, quality of life.

The INTELPARK solution is a smart parking solution, inserted in the Smart Mobility area and composed by hardware - magnetic sensors (installed in the parking space), communication gateway (which connects the hardware and the software) and an occupation indicator (informing about parking availability) - and software - a management platform (aggregating all of the information) and a mobile application (informs drivers of parking availability and how to get there) - that complement each other. The smart parking solution supports the management of parking areas in big cities and helps drivers to find a parking place or even to pay or book in advance.

The ENABLE Consortium's system, installed in the infrastructure itself, allows for interoperability, providing real-time information (Oliveira & Ferreira, 2014). This predictive power is the unique selling point of the ENABLE Consortium. In addition, the mobile smartphone application for drivers, adds value to the offer.

Therefore, the solution is transversal to all those involved: private and public entities and drivers (the end users).

Ultimately, the end users' parking experience will improve due to the information available. Payment is made more flexible, making it more convenient and faster given the various payment options available (mobile application and even kiosks). The driver will be able to save time, fuel and other associated costs, decreasing the frustration associated to the vehicle parking process as well as reducing CO2 emissions for which he or she is responsible.

5. Methodology

This research is exploratory, following a quantitative methodology through the administration of an online survey using Google Forms, which was shared on Facebook and sent via e-mail to the researchers' network of contacts and the database of students of the Department of Economics, Management, Industrial Engineering and Tourism of the University of Aveiro. The sample for the survey is classified as being a non-probabilistic convenience sample.

In the survey, structured questions were used: multiple choice questions and sentences with a Likert scale of 5 points.

The survey was divided into three main sections:

- Socio-demographic data: age group, gender, education, nationality and gross monthly income.
- Parking habits: related to owning a car, where the respondent usually parks and how often he or she pays fines;
- The mobile smart parking application: regarding the prior use of a similar mobile application the respondent had to rate certain statements;

There were 219 responses to the survey in total, but only 210 were considered valid. In order to analyse the quantitative data, JMP software was used for the descriptive statistics and the calculations for the chi-squared test and association between categories were done manually and according to Oakshot (2016).

6. Analysis of the surveys

6.1 Descriptive statistics

The analysis of the surveys was based on a total of valid 210 responses.

The sociodemographic information, parking habits and opinion on the mobile application of the Smart Parking Solution of the sample is presented in tables 1-3 below.

Table 1: Sociodemographic responses to the survey

Question	Answer
Age	18-24 years old – 60% 25-40 years old – 18.6% 41-50 years old – 15.2% 51-65 years old – 5.2% >65 years old – 1%
Gender	Female – 66.67% Male – 33.33%
Qualifications	Basic education – 0% High school – 21% Bachelor's – 51.9% Master's – 19.5% PhD – 7.6%
Nationality	Portuguese – 98.56% European but not Portuguese – 0.48% South American – 0.48% North American – 0.48% Asian – 0% African – 0% Oceania – 0%
Gross monthly income	I do not have my own income – 52.4% Minimum wage – 5.2% More than the minimum wage but less than € 1,000 / month – 11.9% 1,000€ - 1,500€/month – 10.5% 1,500€ - 3,000€/month – 12.8% 3,000€ - 5,000€ / month – 4.3% > 5,000€ - 2.8%

6.2 Chi-squared tests - Association between categories

The chi-squared test is a non-parametric test, that is, it does not test a parameter or a ratio (Oakshot, 2016, p.10). In this case, the chi-squared test is used to test the associations between categories. In it we have two options for each hypothesis: the null hypothesis (when the association is not confirmed) and an alternative hypothesis (when the association is confirmed). According to the social sciences, the alternative hypothesis is normally tested at the 5% of level of significance. In total, twenty-four associations were tested, using the chi-squared test. Of these twenty-four associations, six showed a positive association. These are shown below (due to space limitations the calculations are only shown for the first association found).

Table 2: Parking habits

Question	Answer
Do you own a car?	Yes - 62.9% Car sharing - 25.7% No - 11.4%
Do you usually park in paid parking?	Yes (5 and 4) - 2.4% and 17.6% Neutral (3) - 32.4% No (2 and 1) - 38.6% and 9%
Where do you usually park?	City center - 69.5% Around the city/Suburbs - 30.5%
Have you been fined for being badly parked / in violation in the last 12 months?	No - 76.7% Yes, I was fined one or a few times - 22.9% Yes, I was fined many times - 0.5%

Table 3: Opinion on the mobile application of the Smart Parking Solution

Question	Answer
Have you used any mobile smart parking application yet?	Yes – 7.6% No – 92.4%
I am / would be interested in an application like this	I completely agree (5 and 4) - 38.1% and 31.4% Neutral (3) - 21% I strongly disagree (2 and 1) - 7.1% and 2.4%
I do / would regularly use the application	I completely agree (5 and 4) - 37.2% and 31.4% Neutral (3) - 22.3% I completely disagree (2 and 1) - 7.03% and 2.16%
The application changes / would change how we look for parking places and how we pay	I agree completely (5 and 4) - 38.41% and 38.41% Neutral (3) - 16.52% I strongly disagree (2 and 1) - 5.12% and 1.54%
The application is / would be useful for my day	I completely agree (5 and 4) - 33.76% and 32.07% Neutral (3) - 23.21% I strongly disagree (2 and 1) - 7.88% and 3.09%

6.3 Qualifications of the respondent x being fined for being badly parked / in violation in the last 12 months

The first category association is between the qualifications of the respondent and the question "Have you been fined for being badly parked / in violation in the last 12 months?". The answers to it were "Yes, I was fined one or a few times.", "Yes, I was fined many times." And "No, I did not." To simplify, the data of the two positive answers were added, leaving only the "Yes" and the "No" options. The null hypothesis is that there is no association between the categories, that they are thus independent. The alternative hypothesis is that there is an association between the categories, that they are thus dependent. Please see the tables and calculations below.

Table 4: Qualifications of the respondent x being fined for being badly parked / in violation in the last 12 months

	Yes	No	Total
High school	7	37	44
Bachelor's	20	89	109
Master's	16	25	41
PhD	6	10	16
Total	49	161	210

Table 5: Frequency table (qualifications of the respondent x being fined for being badly parked / in violation in the last 12 months)

	Yes	No
High school	10.267	33.733
Bachelor's	25.433	83.567
Masters	9.567	31.433
PhD	3.733	12.267

Table 6: Chi-squared test (qualifications of the respondent x being fined for being badly parked / in violation in the last 12 months)

	Yes	No
High school	1.04	0.316
Bachelor's	1.161	0.353
Masters	4.326	1.317
PhD	1.377	0.419

Degrees of freedom = 3

1. Calculated value = 10.309; 2) Critical value = 7.815
2. < 1), therefore we accept the alternative hypothesis at the significance level of 5%, which means that the variables are dependent and there is an association between the qualifications of the respondent and being fined for being badly parked / in violation in the last 12 months.

6.4 Gross monthly income of the respondent x being fined for being badly parked / in violation in the last 12 months

The second category association is between the gross monthly income of the respondent and the question "Have you been fined for being badly parked / in violation in the last 12 months?". To simplify, the answers were aggregated into two groups: "Yes" and "No". The null hypothesis is that there is no association between the gross monthly income of the respondent and being fined for being badly parked / in violation in the last 12 months, that is, they are independent categories. The alternative hypothesis is that there is an association between gross monthly income and being fined for being badly parked / in violation in the last 12 months, that is, they are dependent categories.

1) Calculated value = 14.445; 2) Critical value = 7.815
2) > 1), therefore we accept the alternative hypothesis at the significance level of 5%, which means that the variables are dependent and there is an association between the gross monthly income of the respondent and being fined for being badly parked / in violation in the last 12 months.

6.5 Gross monthly income of the respondent x habit of parking in paid parking areas

The third association between categories is for the question classified through a 5-point Likert scale: "Do you park in paid parking?" and the gross monthly income of the respondent. To simplify, the answers were aggregated: "Don't agree" (1 and 2), "Agree" (4 and 5) and "Neutral" (3). The null hypothesis is that there is no association between the monthly gross income of the respondent and the habit of parking in paid parking lots, that is, they are independent categories. The alternative hypothesis is that, in fact, there is an association between the monthly gross income of the respondent and the habit of parking in paid parking lots, that is, they are dependent categories.

1) Calculated value = 20.211; 2) Critical value = 12.592
2) < 1), therefore we accept the alternative hypothesis at the significance level of 5%, which means that the variables are dependent and there is an association between the monthly gross income of the respondent and the habit of parking in paid parking lots.

6.6 Age group of the respondent x car ownership

The fourth association between categories is for the question "Do you own a car?"; to which three options were given: "Yes", "I share a car with other people (for example, with my parents)" and "No"; and the respondents' age range. The null hypothesis is that there is no association between the age group of the respondent and car ownership, that is, they are independent categories. The alternative hypothesis is that, in fact, there is an association between the age group of the respondent and car ownership, that is, they are dependent categories.

1) Calculated value = 17.387; 2) Critical value = 5.991
2) < 1), therefore we accept the alternative hypothesis at the significance level of 5%, which means that the variables are dependent and there is an association between the age group of the respondent and car ownership.

6.7 Qualifications of the respondent x car ownership

The fifth association between categories is for the question "Do you own a car?"; to which three options were given: "Yes", "I share a car with other people (for example, with my parents)" and "No"; and the qualifications of the respondent. The null hypothesis is that there is no association between the qualifications of the respondent and car ownership, that is, they are independent categories. The alternative hypothesis is that, in fact, there is an association between the qualifications of the respondent and car ownership, that is, they are dependent categories.

1) Calculated value = 20.818; 2) Critical value = 12.592
2) < 1), therefore we accept the alternative hypothesis at the significance level of 5% which means that the variables are dependent and there is an association between the qualifications of the respondent and car ownership.

6.8 Gross monthly income x car ownership

The sixth association between categories is for the question "Do you own a car?"; to which three options were given: "Yes", "I share a car with other people (for example, with my parents)" and "No"; and the gross monthly income of the respondent. The null hypothesis is that there is no association between the gross monthly income of the respondent and car ownership, that is, they are independent categories. The alternative hypothesis is that, in fact, there is an association between the gross monthly income of the respondent and car ownership, that is, they are dependent categories.

1) Calculated value= 47.375; 2) Critical value = 12.592
2) < 1), therefore we accepted the alternative hypothesis at the significance level of 5%, which means that the variables are dependent and there is an association between the gross monthly income of the respondent and car ownership.

Proven from previous calculations, there are six associations between variables, indicated by the arrows in figure 1.

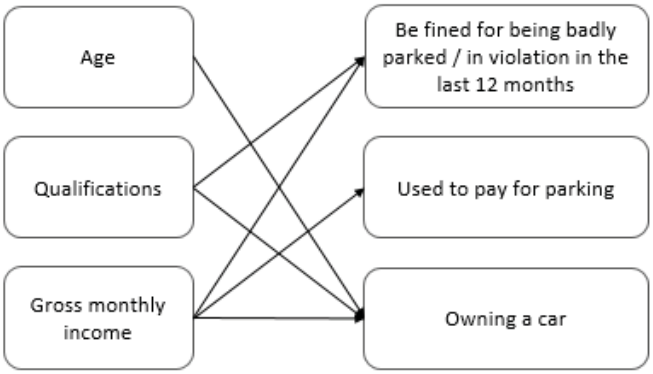

Figure 1: Dependent associations between categories

From figure 1 we can verify that the age group is associated with:

- Owning a car.

The respondents' qualifications are associated with:

- Being fined for being badly parked or in violation in the last 12 months;
- Owning a car;

In addition, gross monthly income is associated with:

- Being fined for being badly parked or in violation in the last 12 months;
- Owning a car;
- Being used to paying for parking.

7. Discussion

This research sought to add to the knowledge on the Portuguese public regarding smart cities and smart parking. We thus verified the degree of adoption of a smart parking solution, by drivers, as well as the influence of several sociodemographic factors related to the same issue and application.

From the descriptive statistic results we can state that the majority of our sample has never used a similar smart parking mobile app (92.4%) and this may be explained by smart solutions not having been implemented on a large scale in Portuguese territory or, at least, in the residential area of the respondents. However, the majority of the sample shows an interest (69.5%), would make regular use of the app (68.51%) and believes it would change the way they look for a parking place and pay for it (76.82%). In addition, only 11.43% of the respondents said they did not have a car, which makes this sample more prepared to respond appropriately, since the remaining 88.57% of the respondents drive and need parking.

The younger respondents (18-24 and 25-50 years old) showed more interest in the app, but the older respondents are the ones who pay more often for parking and the explanation for this might be their

qualifications (older respondents were found to have higher literacy) but also their higher gross monthly income. According to the survey data, the two are related since those with higher literacy occupy higher-paying positions (the percentage of respondents receiving a gross monthly income of more than €1,000 increases with age).

Contrary to what one might think, the data collected shows that there is a tendency for men and women to behave equally in relation to parking, since no gender-dependent relationships were found. Despite this, there was an indication that women are more receptive to innovation (according to the descriptive statistics, but not according to the inferential statistics, the latter referring to statistically significant associations between categories), since they showed more interest in the smart parking mobile application. However, men are the ones who usually pay more for parking, and their gross monthly income can be considered as an explanatory factor. On average, the men in the sample receive higher salaries: the percentage of male respondents receiving a gross monthly income above €1,000 compared to the female respondents is almost twice as high.

Trying to explain this difference using the literacy argument, according to the data obtained, does not make sense, since 77.71% of the female respondents and 75.52% of the male respondents have a bachelor's, master's or doctoral degree. This is, therefore, a curious fact, and may be indicative of the existence of gender inequality in the workplace.

In addition, the gross monthly income has an influence on the payment of parking fines, paying for parking and owning a car. Engel's Law can help explain this phenomenon, asserting that the income spent on primary goods will decrease as wages increase, so individuals with higher incomes will spend more money on luxury items (Houthakker, 1957). Thus, the ability to pay fines is seen to be a “luxury”, since a higher income is related to the payment of more fines. For example, individuals who are late or in a hurry, apparently prefer to pay a fine rather than fail to arrive on time. Therefore, it can be assumed that individuals with higher literacy also pay more fines, countering the idea that higher literacy rates are synonymous with a more civic-type behavior. Those who have lower incomes cannot afford to pay fines and therefore have a more civic-type behavior, perhaps for the wrong reasons. Money is effectively seen to be a great conditioner of behavior.

However, it is important to say that this conclusion cannot be generalized to all situations.

8. Conclusion

We share the perspective that smart cities and the technology associated to them will have a major impact on urban planning and policies (Batty et al., 2012). The city, as we know it, is turning into a place where the use of Information and Communication Technologies (ICT) is complementing physical actions. Real-time information is increasingly available to citizens making it possible to reduce resource consumption, improve the utilization capacity of the existing infrastructure, leading to the creation of new services, subsequently improving commerce, while improving also city management and increasing resilience (Harrison & Donnelly, 2011).

Technological solutions must always adapt and even merge with the flows and dynamics of each city and its citizens. New technologies tend to polarize and divide at different levels, so it is necessary to explore and investigate in a number of areas (e.g. urban policies or economic development) how they can be improved on to better fit citizens and their needs (Batty et al., 2012; Joshi et al., 2016).

The number of cars sold increases annually, accentuating the difference between the number of cars in circulation and the number of available parking spaces. A technology solution such as the INTELPARK smart parking solution will simplify drivers’ parking experience. However, this type of technology will only work if there is user adoption and acceptance. Thus, it is necessary to understand what influences and matters to drivers in order to create the right technology (and the right marketing campaign to communicate its benefits).

The research concludes that future end users of this mobile intelligent parking application will have the following profile: they will be older, highly literate and with a higher gross monthly income. Thus, marketing efforts for the parking application should be directed at this segment. However, with the benefit of the general population in mind, city councils could also create special pricing conditions for younger individuals in order to encourage them to adhere to smart parking solutions. Such conditions could include special pricing for parking for young citizens who could access such benefits through face recognition technology – much as the Apple

iPhone X uses, in 2018 – and as a way to control who is actually benefitting from the special reduced-price conditions.

9. Limitations and Future Research Suggestions

It would be interesting to do an international study (e.g. cross cultural) and / or a study of other technological solutions – as was done in previous studies – see for example Gonçalves & Oliveira (2010) and Gonçalves, Martins, Branco, Perez-Cota, & Oliveira (2016). Additionally, studies with specific samples which are appropriate to the objectives of the study should be performed; relating this to the case in hand, future studies should include more higher-income citizens. It is also imperative that we increase our understanding of how consumers behave, and how they adopt other smart solutions – applied to other domains of public life (e.g. smart waste management, smart air quality). Furthermore, there is the possibility that we may do additional field research based on a technology acceptance and usage model so as to understand the true determinants of the adoption of this type of technology by users. Another possible avenue for future research is the utilization of an organizational technology adoption model so as to understand the factors which may influence the adoption, by organizations, of such a system (be they car park managers or firms which use the service).

10. Compliance with Ethical Standards

This study is based on part of a master's internship report done by one of the authors (Lima, 2017). The initial work has been translated from Portuguese to English and has been summarised to include herein the main highlights of what was a larger and more in-depth study. New material has also been added. Publishing master's dissertation / project / internship results, to reach a wider audience, is one of the objectives of the Master's in Management at the University of Aveiro.

The Information Problem on the way to Becoming a "Gazelle"

Ekaterina Litau
ITMO University, St. Petersburg, Russia
science@blcons.ru

Abstract: In the context of globalization, the relative share of small enterprises is constantly increasing. The purpose of the study was to identify the factors determining the growth or stagnation and fall of small enterprises, the impact of entrepreneurs' personality on business success, and possible ways to influence a company to improve its performance. A longitudinal study was conducted which involved monitoring of 68 small enterprises in the North-West region of the Russian Federation for more than 15 years. Direct observations were supported by interviews, which enabled us to compare the independent monitoring with comments by direct participants as well as to gain insight into the causes and consequences of certain situations. The variance in entrepreneurs' response to similar situations showed difference in their psychological traits and the effect it has on companies' performance. At the same time, it demonstrated the impact of the fundamental laws of human psychology. The findings confirmed the key role of entrepreneurial personality for the growth of small businesses. Furthermore, for the first time in this field of research, the study identified the "Information Problem" as a major factor hindering the robust development of small high-growth firms managed by talented entrepreneurs and preventing their transition into the category of medium-sized businesses. The proposed solution to the Information Problem implemented as a software tool allows entrepreneurs to cope with the challenges of growth. The implementation and use of the product does not require significant intellectual and financial resources; therefore it could become the "penicillin" for potential "gazelles" to overcome the crisis of transition.

Keywords: entrepreneurship, small business, high-growth firms, "gazelles"

1. Introduction

Over the last few years, the issues and trends of small business development have been at the center of public discussions among both academics and policy-makers. Despite Marx's predictions that capitalism would result in the dominance of a handful of large-scale companies, which would in turn divide society into giant corporations' owners and employees, one sees an opposite pattern. A steady increase in the number of small enterprises witnessed since the 1980s, a greater fragmentation of markets and industries, and a rapid rise in self-employment in small business demolish this hypothesis.

In the OECD area, small and medium-sized enterprises (SMEs) are nowadays the backbone of national economies. Being the predominant form of enterprise, they account for approximately 99% of all firms (OECD, 2016). SMEs provide the main source of employment, accounting for about 70% of jobs on average, and are major contributors to value creation, generating between 50% and 60% of value added. In developing countries, SMEs contribute up to 45% of total employment and 33% of GDP (OECD, 2017).

Russian economy was always driven by large enterprises and government entities, not startups. Entrepreneurship was not a formal part of the Soviet culture, and entrepreneurs were not held in particularly high esteem. The lingering effects of this heritage on the national culture still often lead to misconceptions about the nature and value of entrepreneurship. Technical capabilities are traditionally quite high, but business skills lag behind, and their improvement will take time. SMEs, startups, and nimble innovative companies have only recently been trying to make a significant contribution to the economy. As of today, SMEs represent just 21% of GDP (OC&C, 2018).

In many countries, including present-day Russia, governments concur that small businesses can be important drivers of inclusive and sustainable economic growth, job generators and incubators for innovation. In addition, it is widely recognized that their development can contribute to economic diversification and resilience. Furthermore, boosting SME potential is especially relevant for stabilizing the economy of developing resource-rich countries like Russia that are vulnerable to commodity price fluctuations.

Recognizing the importance of small businesses for economic growth prompts national governments to establish policies that support SMEs as a strategic priority. The policies include a wide array of support programs, tax incentives, subsidies, looser credit terms and other benefits for entrepreneurs.

However, with all the heavy investments into such programs, governments do not necessarily achieve the expected result. There are certain limits to what public policy and direct government intervention alone can achieve. There is empirical evidence to suggest that these attempts sometimes produce even counterproductive results for high-growth entrepreneurship (Van Stel et al., 2004).

The objective of the study was to identify the reasons why many small enterprises are incapable of growth — and to offer a problem-solving algorithm. We present the "Information Problem" concept, confirm the importance of internal factors in small enterprise development and present the author's methodology that helps to meet the challenge.

2. Literature review

A transition of a small enterprise into a medium-sized is akin to the adolescent period for people. Many, if not all, have to face "puberty" difficulties at a certain phase of maturation. At every stage of life, one encounters a particular problem inherent to this period, but it is the pubertal period that we pay enormous attention to as it determines the whole subsequent life of the individual. In terms of enterprise evolution, the move from a small into a medium-sized business seems to be the most significant period, as it sets up foundations for the firm's successful development. The enterprise experiences transition from informal processes within the enterprise to formalized ones (Davila, 2005; Greiner, 1972). That is why the study of factors contributing to the success of this process (as well as the ones impeding it) is extremely important.

The above given data indicate that the process of small enterprise development is not as dependent on external factors as is commonly believed and that the reasons preventing the progress are also of internal character. One of the key internal factors is the entrepreneur's personality as it largely determines the chances of success at the initial stage of the venture development.

Although views on entrepreneurship have transformed over the years, so far the most accepted definitions are those proposed by Schumpeter (1911), Knight (1921), and Kirzner (1973). Knight defined an entrepreneur as a person who decides to take an action that involves risk for the sake of reward, while Kirzner emphasized the entrepreneurial role of an intermediary who facilitates market creation. Both views rest upon general equilibrium theory, i.e. the neoclassical model of the economy which is limited to resource optimization in a stable environment and considers upheavals such as new ventures giving rise to whole new industries as external developments over which the management does not exert any influence.

Schumpeter, in contrast, focused on the power of creative destruction associated with the entrepreneur-innovator and highlighted the relationship between entrepreneurship and economic growth. He was the first to stress the importance of entrepreneurs as the main vehicle to move an economy away from a state of equilibrium through innovations. Aghion and Howitt (1992) attempted to further develop Schumpeterian theory of growth through creative destruction, where innovators drive out previous inefficient enterprises. Other authors focus on Schumpeter's assumption that innovation-based economic growth requires an effective selection among high-skill entrepreneurs (Acemoglu, Aghion & Zilibotti, 2006; Michelacci, 2003). These theories establish a direct link between entrepreneurship and economic growth and consider innovations to be a key to entering the market.

Thus, despite some differences, research indicates that entrepreneurship is a key component of innovation creation. In other words, it is the entrepreneur fulfilling his or her potential through new venture creation who ultimately enables economic growth.

There has been a substantial amount of research on the entrepreneur's personality. Scholars attempt to identify particular individual attributes that would enable one to describe a successful entrepreneur and in this way outline general patterns of small enterprise development. According to researchers, entrepreneurs are characterized by such features as risk-taking propensity, creativity, ambiguity tolerance, autonomy, self-confidence, persistence, alertness, opportunity recognition, etc.

Admittedly, the existence of such traits does increase a person's chances of establishing a successful business and can be seen as a kind of a gift similar to a talent for music or arts (Gardner, 2011). In this connection, the seminal work of Birch (1987) is of considerable interest, demonstrating that only 4% of all enterprises are able

to show sustained growth and exert a deep, if not decisive, influence on macroeconomic outcomes. Birch coined the term "gazelles" to refer to this type of fast-growing, dynamic enterprises (Birch, 1987; Birch & Medoff, 1994). Among other enterprises, Birch distinguished large companies called "elephants" and small companies called "mice". These company types differ in size, but are both characterized by slow growth and a low contribution to employment (Tachiki, 2014).

Along with a relatively small percentage of "gazelles" in the whole population of companies, it is found that most of them cannot maintain their status for a long time. Existing research on "gazelles" in Russia provides evidence that stable growth rates are shown only by a small number of enterprises. According to Yudanov (2010), 40–48% of the enterprises observed in this status failed to keep it and soon slipped out of the category. A similar picture is seen in the Western economies. What prevents "gazelles" from maintaining high growth rates observed at the initial stage?

3. The problem statement

Focusing on personality traits that distinguish successful entrepreneurs from the herd and on their impact on enterprise growth, researchers often ignore the influence of attributes and patterns inherent to each individual due to the fundamental laws of human psychology. Yet, it seems that these primary laws, abilities and limits (such as the human brain's memory-storage capacity and the capacity to perceive and process information) directly affect entrepreneurial success, i.e. the ability of "gazelles" to maintain a given rate of growth and move into the category of medium and large companies.

According to Miller (1956), who uncovered the basic patterns of perception and processing of information, the human brain's short-term memory is able to hold and process an average of 7±2 items of information (the famous Miller's magical number) with no loss in quality. In other words, an individual is able to consider no more than five to nine factors when making decisions, can directly work with no more than five to nine people, etc.

To get an idea of how basic psychophysiological characteristics of the entrepreneurial manager, and, in particular, the limitation deduced by Miller, influence the performance of a small enterprise, one should trace its life cycle. At the initial stage, there is no professional management. All daily activities tend to be at the sole discretion of the entrepreneur. Being the business owner, its manager and often employee at the same time, the entrepreneur is directly involved in all routine processes of his or her venture.

If we look at the small enterprise as a system where each process (e.g., relations with suppliers and customers, advertising, production, etc.) is an information flow, we will see that at the early stage of development all flows inevitably pass through the entrepreneurial manager. The situation is natural given the small scale of operations and the absence of complex managerial tasks. The attributes more or less inherent to all entrepreneurs, such as the drive for success, risk taking propensity, creativity, self-confidence and ability to act under uncertainty, enable them to successfully overcome challenges. At the stage of the enterprise establishment, these qualities are of critical importance and exercise a decisive influence on the development process.

However, as the enterprise grows, many changes occur, and with regard to "gazelles", they occur rapidly. The scale of operations increases: the number of orders and the volume of purchases grow, production expands, the staff size increases, and the tasks become more challenging. This implies complication and a significant increase in the number of information flows. Apart from that, the situation remains the same, with almost all flows, regardless of their urgency and importance, passing directly through the entrepreneurial manager. At a certain stage, it becomes obvious that the volume of incoming information starts to well exceed his/her ability to perceive and process it. The entrepreneurial manager continually experiences time shortage and is unable to fully control business operations. With more and more failures to process incoming information and make timely and proper decisions, he/she begins to hamper the development of the company.

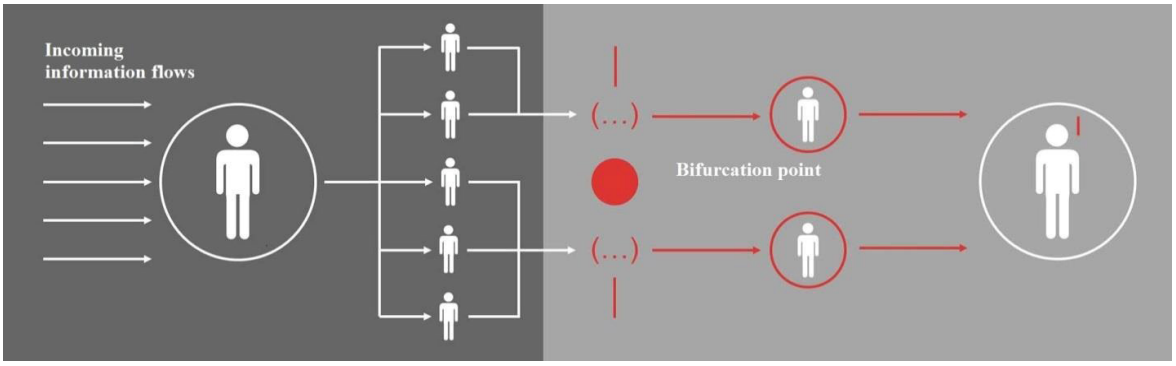
Thus, the entrepreneurial manager is faced with what we call the Information Problem. With no appropriate measures taken, the business begins to stagnate and lose competitiveness. As we can see, the Information Problem is, on the one hand, an indicator of the enterprise growth, and on the other hand, an obstacle for its further development.

4. Research model

For the purpose of the study, a longitudinal study was performed which involved monitoring small enterprises for more than 15 years. The sample was comprised of 68 micro and small businesses (according to the Russian Federation law, these are the firms that employ up to 100 persons and have an annual turnover not exceeding RUB 800 million) from the North-West region of Russia. The same location ensured that enterprises were exposed to equal political, economic, geographic, socio-cultural, environmental and other external influences; they had almost the same funding options available and their owners served as top managers. The sample included startups and young companies as well as more established enterprises operating in different industries (manufacturing, trade and services) and led by entrepreneurs of varying gender and age.

Over the period of the study, some enterprises went out of business (62%), while others moved to the category of medium-sized. Various aspects of business operations were studied, including daily activities, external and internal management issues faced by the entrepreneurs and the ways to handle them, entrepreneurial performance, etc. Special attention was given to the entrepreneurs' actions and their response to certain situations. Direct observations were supported by interviews, which enabled us to gain insight into the entrepreneurs' views on the problems accompanying companies' development and to analyze their response to external effects. The variance in the entrepreneurs' response to similar situations showed difference in their psychological traits and the effect it has on companies' performance. At the same time, it demonstrated the impact of fundamental laws of human psychology.

To generate a problem-solving algorithm, the findings were analyzed in terms of the fundamental laws of human psychology and, in particular, an individual's ability to perceive and process incoming information. As a result, the author developed a small-enterprise management approach which allows for efficient redistribution of information flows and, thereby, allows entrepreneurs to cope with the challenges of growth. Redistribution of information flows is based on authority delegation and/or automation of the tasks that do not relate to direct enterprise management and can be performed by employees without the entrepreneur's participation (see Figure 1).



Entrepreneur as a subject who receives all information flows.

Entrepreneur as a subject who receives ever-increasing information flows.

At this stage, an enterprise may undergo various changes in its management structure.

Supervisor with a function of filtration and transformation of information flows.

Entrepreneur as a subject who receives transformed information flows.

Figure 1: The informational Problem and its solution

The algorithm for the developed methodology consists of the following steps: making a "snapshot" of information flows, measures estimation, data analysis, and reassignment of responsibilities. The algorithm was successfully built into the developed web service.

To make a "snapshot" of information flows, a concept of external and internal factors affecting an enterprise was used. When external (environmental) factors enter the enterprise, they launch processes in which internal flows are formed (see Figure 2). Generating a "snapshot" of information flows includes three main stages: (1) making a list of external flows that go through the entrepreneurial manager; (2) making a list of employees participating in the processes of formation and transformation of internal flows that go through the entrepreneurial manager; (3) description and visualization of information flows routes between the entrepreneurial manager, employees and the environment.

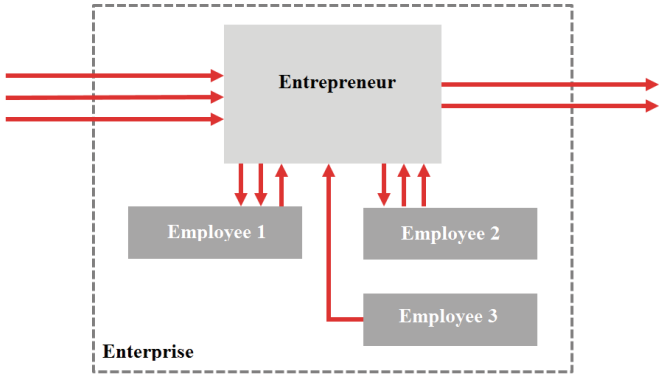


Figure 2: A "snapshot" of entrepreneur's information flows

To effectively redistribute information flows, it is necessary to measure them in terms of time and priority. The estimation of time consumption does not require mathematical accuracy, as long as it is aligned with subjective perception of the entrepreneurial manager. Prioritization of information flows might also be intuitive or might depend on certain criteria. Combining time consumption estimates and priority level of each task gives a comprehensive view of information flows at an enterprise.

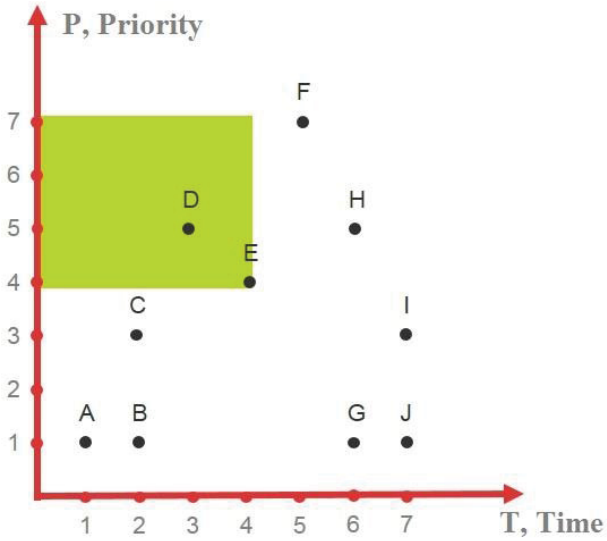

Figure 3: The "transmission corridor" of information flows

It seems reasonable to first process information flows with the highest priority and the least processing time. We assume an information flow to be appropriate if its time value is 1–4 and its priority level is 4–7. We refer to this range of values as a "transmission corridor" (see Figure 3). For example, the information flows D and E in Figure 3 are the most appropriate and require a direct involvement on the part of the entrepreneur.

5. Results

To implement the proposed approach we developed a specialty software product — Smart Management of Information Flows (SMIF) tool. To test the tool, we selected companies that meet "gazelle" criteria, i.e. young (not older than 5 years) fast-growing dynamic companies that annually increase their revenues by at least 20% (Audretsch, 2012). The sample included 30 companies.

The introduction of the developed tool in the surveyed companies helped their executives make timely decisions regarding necessary structural changes and enabled a more systematic and meaningful authority delegation process. In the course of this transformation, the entrepreneurial managers started to develop a consistent view of enterprise management and to recognize a need for business processes reorganization. This enabled the enterprises to promptly respond to market needs and ensured greater competitiveness.

The Podpisnyje Izdanija ("Subscription Editions") bookstore represented one of the most prominent success stories. It should be noted that the retail book industry in Russia is going through a major crisis. The last 5 years saw a 12% drop in book sales. However, the revenue of the named store increased greatly over the same period. Within a short time, the up-and-coming entrepreneur who had took the reins in 2012 was able to build a new team (the headcount increased from a handful of employees to 25) and optimize business process performance. The entrepreneur disengaged himself from excessive information flows associated with routine operating activities, which enabled him to focus on more value-adding creative tasks related to development and production of tasteful, but inexpensive souvenirs and gifts. The launch of the new line of business accounted for the rapid growth in revenue and offered the small individual retailer opportunities to penetrate new regional markets. The revenue increased by 49.7% in 2015 and by 68.9% in 2016. Another example is the Probka ("Cork") restaurant founded by a famous chef in 2000. The early success of the business led to an expansion, with 7 more projects launched over the next 10 years. Although employee engagement was always a priority for the entrepreneur, he eventually came to a point where the task of managing an increasingly large team became too overwhelming. He thus faced the Information Problem. Financial performance declined accordingly: the network experienced consistent losses for 4 years since 2010. In 2014, the founder made a key decision to withdraw from operating control of all restaurants at once, built a high-quality management system and focused on managing a single favorite restaurant. The company soon achieved break-even and started making money. The revenue increased by almost 100% in 2015.

Out of 30 studied enterprises, 26 successfully overcame the crisis by timely introducing of a new management system and maintaining the growth dynamics. The remaining 4 enterprises went out of business, and their founders have no intent to continue an entrepreneurial career.

6. Discussion

In earlier studies, researchers tended to consider entrepreneurial personality traits as the main, if not the only, significant inherent factor affecting business development. Nevertheless, it is impossible to deny that continuous successful development of an enterprise and its transition to a new level proves to be a challenge even for a talented entrepreneurial manager. Experience indicates that entrepreneurs can perfectly adjust to unfavorable conditions and cope with various difficulties, but are not able to manage their own enterprise in an efficient way when it comes to successful growth and development in the presence of the Information Problem. Thus, the critical point in enterprises' development is, ironically, business success, rather than a lack of resources, administrative hurdles or insufficient information support.

The Information Problem directly associated with the entrepreneur's personality and determined by the fundamental laws of human psychology has not so far been suggested as a research topic. Yet, real-life cases indicate that it is due to the very nature of his/her personality that the entrepreneur facing the problem is generally incapable of identifying and overcoming it. This elucidates why "gazelles" taken to a certain level of growth eventually drop out of the race as their managers do not find a solution to the Information Problem.

An obvious answer to this problem is information flows redistribution that makes it possible for the entrepreneur to free up some time to focus on strategic issues. In this case, (s)he keeps managerial functions, but the management activity becomes more conscious, structured and, hence, efficient. However, in the course of business routine, the implementation of this solution may face a number of difficulties. To begin with, the entrepreneur is often not aware of the degree of complexity of the task at hand, not able to stand back and make a sound judgment and, therefore, does not take timely measures to help the enterprise out of the Information Problem.

The situation is complicated by the fact that even being aware of the Information Problem, the entrepreneur may experience difficulties in solving it due to his or her personality. Apart from the positive qualities that contribute to business success, talented entrepreneurs tend to exhibit such traits as the lack of consistency,

narcissism, intolerance of dissent, obsessive desire to control, etc. that cause a pathological unwillingness to delegate. Considering all tasks to be equally important, the entrepreneur is often simply not able to delegate properly. As a result of spontaneous redistribution of responsibilities, a paradoxical situation often occurs, where employees solve critical tasks relating to finance, marketing, etc., whereas the entrepreneur is immersed in irrelevant matters of little significance for the enterprise development.

The good news is that the Information Problem is quite solvable if entrepreneurs are aware of the pattern of its occurrence and the ways to overcome it. Adherence to the proposed methodology algorithm could help identify the problem in a timely manner and take the necessary steps for its solution.

7. Conclusions

The findings of the study justify the importance of the fundamental laws of human psychology in any business transition phase. They also provide a new way to look at issues of small enterprise development and factors that contribute or impede its success.

For the first time in this field of research, we identified the Information Problem as a key factor hindering the robust development of small high-growth firms managed by talented entrepreneurs and preventing their transition into the category of medium-sized businesses. The Information Problem concept explains why even talented entrepreneurs are unable to cope with processes typical for enterprises experiencing a period of rapid growth. Tackling the Informational Problem is a necessary condition for the development of “gazelles” — the companies that are of critical significance for national economies.

Special personality traits, such as entrepreneurial talent which allows the enterprise to become a “gazelle”, are not sufficient for the company to maintain this status. After reaching a certain limit, the enterprise, suppressed by the entrepreneur him/herself, is unable to continue its development. A very small percentage of “gazelles” succeed in coping with this challenge.

One of the possible solutions could be to use specialty software such as the tool proposed by the author for small enterprise information management. The tool allows for efficient redistribution of information flows and, thereby, enables entrepreneurs to cope with the challenges of growth. The implementation and application of the product does not require significant intellectual and financial resources and hence is affordable to almost any enterprise. Therefore it could become the “penicillin” for potential “gazelles” to overcome the crisis of transition and continue successful development.

Abstract: This study followed a mixed methodology – five semi-structured interviews were performed, and transcribed in full, with four senior lecturers and one administrative employee at the university; and a survey with 124 valid responses, answered by students of the university, was also conducted. The research question was the following: how does the University of Aveiro achieve its competitive advantage, in view of its competition in Porto, Coimbra and Lisbon, which are the three main geographical areas nearby? The University of Aveiro may also be seen, however, to be competing with other international universities, as the University of Aveiro is highly placed in the international rankings for young universities (the University of Aveiro was, in 2017, ranked 81st in the Times Higher Education Young University Rankings, for universities aged under fifty years). The resources, capabilities and key competences of the University of Aveiro, founded in 1973, were analysed. The results of the study indicate that 76% of the respondents of the survey chose the University of Aveiro as their first choice in their applications, which means that these students are following their first choice for their careers. The University has constructed its attractiveness around value innovation: its low price (not only for its annual fees, but also concerning the cost of living in the Aveiro area – in central Portugal), coupled to its superior and highly recognized teaching practices, its highly recognized research around its 18 research centres, its start-up incubator, its creative science park, its cooperation and knowledge transfer to society (via its many partnerships with different organizations), its multicultural environment (the University of Aveiro is a favourite of Erasmus students), its award-winning campus (in architectural terms), and its organizational culture geared towards the satisfaction of its students, as well as its organizational structure in a matrix format whereby the university is built around different and unique departments (for different functional areas of study) with each having a degree of autonomy, though being managed centrally by the university rectorate. The University of Aveiro is thus seen to be very entrepreneurial as it has remained flexible, dynamic, and principally open to new teaching methods.

Keywords: Strategy, Resources, Competences, Competitive Advantage, Innovative Teaching Methods, Entrepreneurial University

1. Introduction

> *"Universities need to evolve from teaching and learning, research and engagement to being drivers of innovation and entrepreneurship. And they need to work with all stakeholders in the innovation and entrepreneurship system – in the best interests of the nation and citizens."*
>
> (MacGregor, 2015)

There are several factors, including the swift development of Internet skills and globalization, which make it increasingly harder for organisations to establish a long term sustainable competitive advantage (Hitt, et al., 2011). The question is, how does one forge that advantage? In the case of the University of Aveiro (UA), what sets it apart from its rivals? Which are its competitive factors in the higher education sector? This case study about the UA focuses on the analysis of the resources, capabilities and key competences that differentiate and sustain its position in the market. We see the UA as being highly entrepreneurial. That is, the UA puts into practice certain leadership and governance principles that categorise it as being entrepreneurial. We start this case study by briefly introducing the target institution – the UA, followed by a review of the literature, which is focused on the relevant key concepts for the analysis of the case study. We then end the study with a discussion of the results obtained and a conclusion.

2. University of Aveiro

The UA was established in December 1973, officially starting its activities in 1974, with merely 46 students (Universidade de Aveiro, 2014). Currently, around 14 600 students attend its facilities which are located at the Campus Universitário de Santiago (Universidade de Aveiro, 2017). Its Rector, Professor Manuel António

Assunção, can count on a Rectoral staff formed by four Vice-Rectors and six Pro-Rectors (Universidade de Aveiro, 2017a). According to the Rector's Strategic Plan, the UA is defined as being a public foundation of private law (Universidade de Aveiro, 2012) and its mission is:

> *"To create knowledge, expand the access to learning in benefit of the people and society, through research, teaching and cooperation; adopt a global development program for the individual, partake in the creation of a European research and educational space and of a regional development model based on innovation and scientific and technological knowledge"* (Universidade de Aveiro, 2017).

As for its organisational units the UA encompasses, as stated by its Web page (Universidade de Aveiro, 2014a) the following, as portrayed in Figure 1.

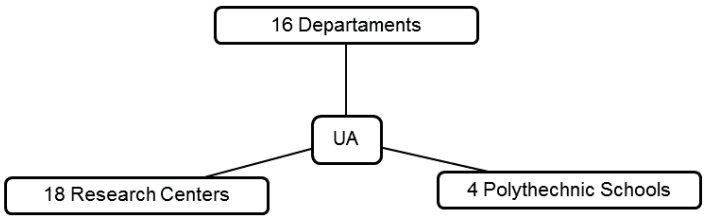

Figure 1: Organizational Structures of the UA

Source: Own personal research

According to article 35, number 1 of the University of Aveiro's by-laws/charters, the organisational units have "(…) scientific, pedagogical and cultural autonomy corresponding to their scope of intervention and experience/maintain management/regulatory autonomy mitigated in the conditions foreseen in the current by-laws/charters." (Universidade de Aveiro, 2009). Its matrix structure allows an interdisciplinary approach and cooperation between the several departments, and also provides for a bigger variety of teaching methods (Universidade de Aveiro, 2012).

In Figure 2 we present the 2017 numbers referring to Courses, Human Resources and Students.

14 574 Students				
184 Undergraduate and Postgraduate Courses	**294** Postdoctoral scholarships	**903** Teaching Staff	**635** Technicians and administrative personnel	**118** Researchers

Figure 2: UA in numbers (2017)

Source: Adapted from the UA Web Page (Universidade de Aveiro, 2017)

In the research field the UA is scored as being one of the best knowledge producers nationally and internationally, bringing together researchers from different backgrounds and nationalities, with advanced research projects on behalf of the society we live in (Universidade de Aveiro, 2012a).

It also includes the UNAVE, translated to being the Association for Professional Training and Research of the University of Aveiro, and also the IEUA, the University's Business Incubator. Nine firms lodged in this Incubator were present at the Web Summit 2017 that took place in Lisbon (UA-Online, 2017). These two facilities show the effectiveness of the UA in cooperating with the entrepreneurial environment while also offering services to the community through its commitment to research and innovation in all the different collaboration programs it has joined, such as the Creative Science Park – Aveiro Region (Universidade de Aveiro, 2012a).

Internationalisation through exchange programs is an increasingly used method by higher education institutions. In the UA's case, it is present in various international forums and it participates in several mobility programs like the Erasmus Program, for instance (Universidade de Aveiro, 2013). Thus, it provides a University network based on the sharing of teaching methods, cultures and interdisciplinary realities, not only at the European level but also globally.

Therefore, a university's position in international rankings allows them not only to have enhanced visibility but also to evaluate their performance in different categories by means of specific indicators. That said, according to the Times Higher Education World University Rankings, the UA is in the 81st position in the Young Universities Rankings 2017, being the best classified Portuguese university to appear in the list, and is consequently considered as being one of the 500 best universities in the world as far as general performance goes (Times Higher Education, 2017).

3. Literature review

An entrepreneurial university is one which is adaptive and which has individuality and a unique local flavour (Clark, 1998). Universities "that have willed themselves to change" (Clark, 1998, p.3) rather than "those that remain entirely encapsulated in a traditional mode" (Clark, 1998, p.3) are defined herein as being entrepreneurial. "An entrepreneurial university, on its own, actively seeks to innovate in how it goes about its business. It seeks to work out a substantial shift in organizational character so as to arrive at a more promising posture for the future." (Clark, 1998, p.4).

In MacGregor (2015), six key elements of an entrepreneurial university are indicated, as follows: "good leadership and governance, capacity incentives, entrepreneurship in teaching and learning, a culture of entrepreneurship, stakeholder partnerships, and internationalization." Furthermore, entrepreneurial universities consistently address "problems such as unemployment, poverty, low economic growth and inequality" (MacGregor, 2015).

The object of this study also concerns the concept of competitive advantage; the aim is to understand how it is achieved. According to Porter (1985) it may be said that a firm has competitive advantage over another when it obtains and maintains profits that surpass those of their rivals – what a firm desires is for it to be sustained over time. This concept can also divide itself into two sub-concepts for a better understanding: cost advantage and differential advantage. This competitive advantage only exists when a firm can produce the same benefits as another firm, but with a relatively lower cost (cost advantage), or the benefits of its products were able to surpass those of its competitors (differential advantage): in that way, competitive advantage can be achieved once a firm can generate higher value for its customers and superior profits for itself (Santos, 2009).

The development of this advantage depends on several resources that should be superior to those of its competitors. As reported by Barney (1991) cited by Santos (2009) resources can be patents and registered brands, proprietary know-how, the set of defined clients or the company's reputation; capabilities are what allows firms to exploit their resources in a successful way – this combination is considered as being part of the firm's nuclear competences, which enable the "innovation, efficiency, quality and response of clients, that may be used to create cost advantage or differential advantage" (Santos, 2009, p. 12).

Therein, the concept of competitiveness is essential. Note that it does not only have a meaning attached to it – its idea depends largely on the context it works in (Paulo, 2009). Looking at Porter, in his book *Competitive Advantage* (1985), competitiveness or competitive strategy consists in a consistent pursuit of a favourable position in the market, which should be profitable and sustainable. According to the author, there are two issues that underpin the choice for the best competitive strategy: the first one is "the attractiveness of industries to long term profitability and the aspects that determinate it" (Porter, 1985, p.1) and the second one refers to the "determinants of the relative competitive position inside an industry" (Porter, 1985, p.1). In order to delineate a good competitive strategy to and within a firm, Porter also designed a world-renowned model that defines the competitive intensity of a sector and that depends on five basic forces, as follows:

industry rivalry, threat of new entrants, threat of substitutes, bargaining power of buyers and the bargaining power of suppliers (Porter's Five Forces Model). Sustainable competitiveness, which is a connection and important link between productivity, sustained development and corporate competitiveness is bundled in all this and emerges increasingly and with more strength.

In a world getting progressively closer (and perhaps thus getting ever smaller) due to the effects of globalisation (and ever more facilitated air travel) a more scrutinized approach is imperative also associating it to the concept of internationalisation. Globalisation is a multi-level process that is spurred on by external pressures and the influence they carry in society (be it markets, politics and/or values) – due to the

"acceleration, massification, diffusion, and expansion of transnational people, products, finance, image and information flows" (Castro, 2015, p.7). In other words, constant access to a tremendous and unprecedented amount of information, anywhere and by anyone has allowed the world to become a "global village", where communication and knowledge flows are steadfast and unstoppable. The terms globalisation and internationalisation were considered, for a long time, as synonyms and later came the conclusion that they were complementary: internationalisation is perceived as a consequence of the current globalisation, which is evident, among other areas, also in higher education (the best example is the Erasmus Program). The phenomenon of "global village" led us to believe that with so much information circulation the effortlessness in which one witnesses the evolution of time is immense, and in that way innovation becomes something that is impossible not to happen.

All these changes are contributing to transforming current society into the so-called knowledge society. This concept is specifically designated in the literature as being the "third industrial revolution" – where the most important capital is knowledge (Etzkowitz, 2001). Here is where Universities play a big role, seeing as they are part of the biggest "engine" for the development and production of knowledge. Generally speaking, in order to create this society, there is a junction of knowledge and information which provide "structural mechanisms in which social coordination merges with economic interactions and political control and management" (Pais, 2007, p.5). The role of Universities does not end here for they are much more than a body that simply produces and relays knowledge: they belong in an organisational culture with values, beliefs and norms that they adopt and seek to follow. Furthermore, according to Gomes (2000) the organisational culture has certain tasks that are decisive: "contact, integration, motivation, involvement, commitment or implication, identification, performance, success or organisational excellency" (Araújo, 2014), and they are aimed to be performed by Universities to their stakeholders, in this case their students, who are looking not only for personal, individual and professional growth but also to credit the institution that gives them the necessary tools to fulfil their goals.

4. Methodology

This study followed a mixed methodology. Five semi-structured interviews were performed (in November 2017), recorded in audio and transcribed in full, with four senior lecturers and one administrative employee at the university. The interviews aimed to understand not only the strategic orientations of the organization, the intended positioning in the industry and the perception of competitive advantage, but also the existing organizational culture, and in that context, employees with different functions and responsibilities were selected. Since the students constitute a primary stakeholder for any educational institution, it was considered pertinent to confront what the institutional aspirations are, with the students' perceptions. In this sense, a questionnaire was carried out (in October and November 2017), aiming to understand not only what leads the students to choose the UA, but also their degree of satisfaction and current perception of it. The questionnaire was anonymous, executed and disseminated online, and obtained 124 valid answers.

5. Results

5.1 Interviews

When the question about what distinguishes the University of Aveiro from other higher education institutions in the country is raised, the quality of research, education, networking with the labour market, the university campus and the academic community are highlighted. In the interview with Professor Carlos Costa, Head of the Department of Economics, Management, Industrial Engineering and Tourism (DEGEIT), Professor Carlos Costa said that a great factor of differentiation is quality – both scientific and in terms of relationships established with companies and organizations. A specialization in research, namely "the search for excellence in very specific areas", was also pointed out by Dr Ana Dias, as a key differentiator. The fact that the UA is a young university and already holds relevant positions in international reference rankings, also distinguishes and confers it a competitive position. In fact, the Pro-Rector for Internationalization, Dr Marlene Amorim, indicated that "the UA has consistently ranked among the top 100 universities in the world under the age of 50 years". Dr Manuel Oliveira, Director of the Master's course in Management, also stated that "the University of Aveiro, because it is younger, is more agile, more entrepreneurial and closer to students." Another aspect that distinguishes the UA is internationalization: "it currently has more than 70 nationalities in its *Campi* (among students, lecturers, researchers and administrative staff)", the Pro-Rector stated. Dr Marlene Amorim also emphasized the environment and infrastructures "that offer national and international students a degree of

modernity, security and hospitality that have been repeatedly underlined and which are of fundamental importance for the attractiveness of the UA and for the academic success of its community".

In relation to key competences, three major axes have been identified. "Point number one – to teach, this is why we exist, our mission is to teach, to train students," Professor Carlos Costa specified. In this context, Dr Manuel Oliveira referred to the importance of having a qualified and specialized teaching team, indicating that "there is a lot of concern to hire people with very specific knowledge" that meet the needs of the students; he also referred to the meritocracy environment and the fact that students have a role in the quality of teaching through feedback provided within the quality management systems which have been implemented. The second point enumerated by the Director of DEGEIT was research - "to do good research, quality research that allows the university to grow, but also allows society to evolve". Finally, Professor Carlos Costa referred to cooperation with society, to guarantee that the “teaching and research will be useful externally".

At the internal level, Deolinda Lopes, a collaborator in the academic management services since 1978, listed three strengths of the university, namely, "organization, professionalism and quality". Dr Ana Dias emphasized "the opportunities for development and sharing of knowledge", an aspect also addressed by Dr Manuel Oliveira, when he referred in the interview to an environment of mutual aid, not only between and with students, but also among colleagues. This lecturer also elevated the internal organization, where human capital is competent, qualified and experienced, and where "there is a lot of transparency" and willingness to collaborate and support in solving problems. Dr Manuel Oliveira also emphasized the importance of having "good managers and good directors in key places". Professor Carlos Costa, as the Head of DEGEIT, stated that "the university is managed in a democratic way and with total autonomy" and Dr Marlene Amorim clarified that the university is regulated by its own rules and that "advisory bodies exist to support the activity of the rectory and management teams”; furthermore, there are "mechanisms that ensure the representativeness and voice of departments and other organizational units in the UA's internal discussions and decisions”.

Regarding competitive dynamics, Professor Carlos Costa began by noting that the competitors of the University of Aveiro are generally "all universities and all polytechnics". However, he also indicated that the analysis of competition should consider aspects such as the level of development or the specializations. In turn, the Pro-Rector Marlene Amorim, informed that the UA competes at the national and international level, in several areas, such as "the recruitment of students, or the raising of funded research projects”. From the point of view of methodologies for monitoring and evaluating the industry, the Director referred to the final results, mirrored in the reference rankings. Internally, the Pro-Rector mentioned methodologies of evaluation at the academic level, for example, with the monitoring of the level of first-entry candidates or entry-level ratings, and the level of research, where metrics such as the number of publications in relevant databases, the number of citations of publications of UA faculty and researchers, the number of registered patents and the international projects and their amount of financing are applied. From the standpoint of monitoring the industry, there is also the concept of benchmarking. "Benchmarking is an important alternative which the UA uses (...) to guide its innovation and management to the best levels," Dr Marlene Amorim stated. She also mentioned that this assimilation and incorporation of best practices takes place at the personal level, of lecturers and researchers, and also at the institutional level, for example, arising from the participation of the university in national and international networks of higher education.

The evolutionary perception for Deolinda Lopes was very positive; she affirmed that there was a "great development in structures”, “a significant increase of the student community" and she also referred to the diversification of the quality education offered. Lecturer Dr Ana Dias also highlighted "the ability to reach other markets and attract new students and new audiences" over the years. Since the UA was just over 40 years old, Dr Manuel Oliveira pointed out that the university was now reaching maturity, and alerted as to the uncertainty of keeping its young spirit or the possibility of becoming “heavy and similar to other older Universities – it may be inevitable”. However, the Senior Lecturer reinforced the existing academic environment, and expressed his opinion - "at the University of Aveiro, I note that the students are happy", considering that "the students of Aveiro are well on their way". To continue with the young and innovative spirit that distinguishes it, he considered that it is clear that the university “will have to change” and “to make progress along with society". Furthermore, the Head of DEGEIT stated that the UA “has all the skills of the future"; warning, however, of the need for change not only in universities but in education in general; the goal is to prepare the students and "create the conditions for each one to make his way, learn and find solutions".

Dr Marlene Amorim envisioned the UA of the future "with an even more international component, with a greater diversity of publics than the current ones, and therefore with social concerns, of integration and increasing plurality". The Pro-Rector also expected "a strong focus on applied research, and in its connection and integration with teaching methods".

5.2 Survey

5.2.1 Sample Data

The sample is made up of 124 students from the University of Aveiro – 71.8% female and 28.2% male, with the majority (80.6%) aged between 18 and 25 years. Regarding the study cycles, the sample is made up of Master's students (55.6%), Bachelor's students (32.3%) and PhD's (12.1%), coming from different areas of knowledge.

***5.2.2** Survey Results*

Initially, we sought to understand the motivation of the students to choose to study at the UA. First, it was found that, for the majority of the respondents (75.8%), the UA was their first option. The aspects that had more weight in their choice were:

- 1st. The reputation/ UA's teaching of excellence;
- 2nd. Geographical proximity to the place of residence;
- 3rd. Course contents.

Research plays an essential role in teaching and developing, improving and structuring knowledge and society. In this sense, we sought to know if the students had knowledge of research projects developed in the UA, and if they would be interested in working in this area. Most students (80.6%) reported having knowledge of research projects developed by the university, however, only 21% would be effectively interested in working in this field, 26.6% considered this possibility, and the majority (52.4%) had no such interest at the moment.

In a third phase, the objective was to assess students' opinions, not only on what they considered to be the great differentiating factor of the UA compared to other Portuguese educational institutions, but also on what they considered to be strengths and weaknesses of the university. Regarding differentiation, the environment and university campus, including the resources and interconnection between the different departments, the quality of teaching and the proximity between teachers and students, research and the fact that it is a young and dynamic university that focuses on innovation and entrepreneurship, stand out. The three strengths most identified by the students were the quality of teaching, the teaching team, both for their training and their proximity to the students, and the university campus, not only for the centralization of the departments, but also due to the infrastructures and all the surrounding landscape. On the other hand, the three weaknesses most frequently enumerated were the slowness and bureaucracy inherent to the academic services, the lack of maintenance in some departments and the variability of the teaching staff (very good teachers and others below expectations).

Finally, an evaluation scale of different components of the UA was proposed, in order to perceive the degree of student satisfaction. The scale adopted was from 1 to 5 (where, 1 - "Not satisfied" 2 - "Indifferent" 3 - "Satisfied" 4 - "Very satisfied" 5 - "Exceeded expectations"), and applied to the quality of teaching, research, student support services, the academic community, the university campus, and the resources available to the students. The results are shown in Figure 3.

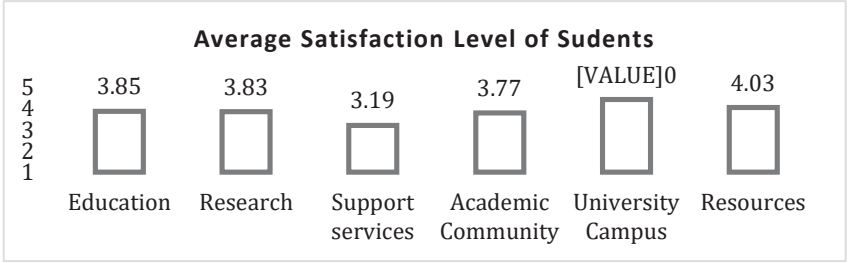

Figure 3: Average Satisfaction Level of UA's Students (November, 2017)

Source: Own personal research

Figure 3 indicates that, on average, students are satisfied with the University of Aveiro. The University Campus is among the components most appreciated by the students, presenting an average level of satisfaction of 4.4 out of 5, and for the majority (54%), it exceeded expectations. Furthermore, concerning available resources, the average degree of satisfaction is high. As concerns education, 75% of the students are very satisfied or considered that their expectations were exceeded. Research, with an average level of satisfaction of 3.83, is subject to great satisfaction or exceeding expectations by about 65% of the students. About 44% of the students are very satisfied with the academic community and, lastly, regarding support services, about 66% of the sample is satisfied or very satisfied.

6. Discussion

Competitive advantages and the differences they produce in organizational performance are often related to the resources that organizations have and how they are managed (Hitt, et al., 2011). Resources, capabilities and key competences form the basis for creating a competitive advantage. This notion is critically important to the success of organizations, because the combination of what they can do (through their resources, capabilities, key competencies and competitive advantages) with what they could do (depending on the external environment) allows them to develop their vision, achieve their mission, and select and implement their strategies (Hitt, et al., 2011).

The University of Aveiro establishes its competitive advantage in terms of both cost and differentiation. The following illustration (Figure 4) represents a proposal for the UA's "creation of competitive advantage" model, based on all the consulted information and field work.

At the resources level, the UA presents solid tangible resources, highlighting its Campus, with all its infrastructures and equipment – pointed out as a factor of differentiation, attractiveness and satisfaction.

Furthermore, at the organizational level, we conclude that both the fact that the organizational structure has a matrix nature and that there are internal processes of quality assurance, provides favourable conditions for the establishment of a competent and healthy organizational culture. The UA also possesses and develops the technology necessary for its activity, both at the level of teaching and research, as well as at a more operational level. As intangible resources, human capital is understood as a key factor for guaranteeing organizational quality (Universidade de Aveiro, 2017). Innovation is also a central concept in the UA, in terms of education, scientific production, entrepreneurship and the dynamization of events, among others. At the level of reputation, which has emerged as the main decision factor for students when opting for the UA, several strands are considered, such as quality teaching, research excellence, the UA brand itself, cooperation and internationalization.

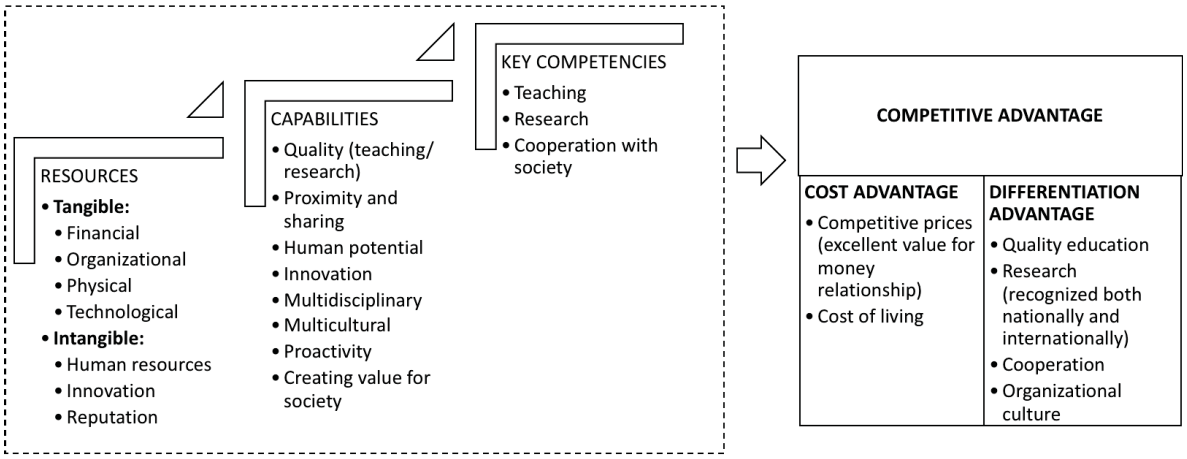

Figure 4: Proposed model of the UA's competitive advantage building process

Source: Own personal research

The capabilities of the UA result from the strategic integration of its resources in order to achieve its mission. Particularly noteworthy are the ability to offer quality training and education, being able to maintain an environment of proximity between teachers and students, the capacity for quality scientific production, the

development of human potential, both at the academic and personal level, as well as concerning the integration in the labour market, the multidisciplinary nature and multiculturalism, proactivity and capacity to innovate, and the capacity to create value for society.

Key competencies are capabilities that give an organization an advantage over its rivals, distinguishing it and reflecting its personality (Hitt, et al., 2011). In the case of the UA, these are based on three major areas – teaching, research and cooperation with society. It is a young and dynamic university, which focuses on quality teaching, proximity, interdisciplinarity, exchange, innovation and cooperation; at the level of research, it is based on recognized quality in international reference rankings, registered patents, publications and citations for UA faculty and researchers; finally, at the level of cooperation with society, it acts at the level of employability not only through the dissemination of opportunities and integration of students in internships, but also in the organization of events and projects integrated with the community.

The combination of all these elements makes it possible to observe that the UA manages to establish its competitive advantage, both at the level of cost, offering quality training at an acceptable (competitive) cost, and at the level of differentiation, not only for its key competencies, but by what supports them, thus revealing value innovation – as described by Kim and Mauborgne (2005, p.13):

> *"Value innovation is a new way of thinking about and executing strategy that results in the creation of a blue ocean and a break from the competition. Importantly, value innovation defies one of the most commonly accepted dogmas of competition-based strategy: the value-cost trade-off. It is conventionally believed that companies can either create greater value to customers at a higher cost or create reasonable value at a lower cost. Here strategy is seen as making a choice between differentiation and low cost. In contrast, those that seek to create blue oceans pursue differentiation and low cost simultaneously."*

It is necessary to consider that the condition of a competitive advantage is not a static one, and in that sense, the key competences that give rise to it must be supported and monitored. They should not, however, be transformed into fixed competences, since they are only a source of competitive advantage if they really allow the creation of value for the organization. If, on the other hand, they are no longer differentiating factors relative to rivals, organizations should naturally focus on identifying, selecting or developing other capabilities that will enable them to achieve a sustainable competitive advantage (Hitt, et al., 2011).

In this context, new studies arise from the increasing variability and instability of the market and of the whole external environment, which indicate the need to move away from the term "sustainability" and to adopt concepts such as "flexibility" in relation to competitive advantage (Sołoducho-Pelc, 2014). Thus, the challenge arises concerning the strategic planning of the ideal competitive advantage, resulting from the combination of sustainability, temporality and differentiation (Sołoducho-Pelc, 2014).

7. Conclusions – An entrepreneurial university

We conclude that the UA is an entrepreneurial university. According to the European Commission and OECD (2012), an entrepreneurial univeristy is one where, among others: "entrepreneurship is a major part of the university strategy; […] the faculties and units have autonomy to act; […] the university is a driving force for entrepreneurship development in the wider regional, social and community environment; […] there are mechanisms in place for breaking down traditional boundaries and fostering new relationships – bringing internal stakeholders together (staff and students) and building synergies between them; […] the university invests in staff development to support its entrepreneurial agenda; […] staff take an entrepreneurial approach to teaching in all departments, promoting diversity and innovation in teaching and learning; […] the university provides access to business incubation facilities". The guiding framework provided by the European Commission and OECD (2012) seeks to advise and inspire, as regards cultural change. By providing a means through which universities may assess themselves the European Commission and OECD (2012) provide a valuable tool to help universities fulfill their vision for the future. We hope with our study (and with our interviews and survey) to have given a detailed perspective of what an entrepreneurial university seeks to achieve. As a suggestion for future research we encourage universities to assess themselves, on a scale of 0-10, as described in the document produced by the European Commission and OECD (2012).

Acknowledgements

The authors would like to thank the interviewees for their time and patience and for having agreed to participate in this research effort. We would also like to thank the University of Aveiro students who decided to participate in this study and who thus answered the survey.

Abstract: The main purpose of this case study was to identify the perception that people with a disability have about the concept of organizational innovation. Therefore, we aimed to provide an answer to the following research question: "How do people with a disability innovate?". The idea for doing this study emerged due to the lack of information and knowledge about the subject. We live in an era when it is easier to see people who suffer from a mental or physical malaise working in institutions or companies – more so than several years ago. Furthermore, people currently have a better understanding about the importance of embracing all individuals in society, and how it is necessary to give them all the same opportunities and to accept them in the business environment. At the same time that companies and institutions are accepting these people there may still be some gaps that make disabled people's work more difficult, resulting in a need to innovate in order to find new ways to overcome some obstacles that appear in their day-to-day lives. The way that people with disabilities modernize and modify some "basic" tasks may lead to a result that may be more productive and profitable for them and/or for the organization where they are inserted. To achieve that productivity and profitability, and also to boost their self-esteem, it is important to make sure that all the necessary tools are provided and that continuous monitoring is implemented to support these employees – creating not only a better understanding of their point of view but also improving their global efficiency. This is a qualitative study based on personal interviews with disabled people as well as being based on interactions with other employees at a major Portuguese university. The intention is to contribute to the increase of information in this area through a direct study with stakeholders while, additionally, adding to the perception of how coworkers and customers face and deal with disabled workers and whether they consider them capable of innovating or driving innovation. This case study concludes with some final considerations about the lack of opportunities given to disabled people which affects the evolution of their work in the workplace.

Keywords: minority groups, organizational innovation, corporate culture, social responsibility, human resources management, employees, practices, integration.

1. Introduction

Over time we have seen a greater interest in people with a disability and in ways to include them in the workplace. We have witnessed a greater concern for the unification of society at the same time as we have witnessed a diversification of the internal organizational environment to also embrace people with certain disabilities. Additionally, some firms, in particular, want to perform a more active role in society, namely by contributing more to the social responsibility aspect of business (Folha dirigida, 2018), the realm under which this study is included.

We found that research is still lacking which involves people with disabilities and especially in Portugal. When one considers research involving Portuguese subjects with disabilities and their link to innovation there is even less academic and scientific knowledge available. We intend to voice some of the opinions of the people we interviewed and who have disabilities.

While performing this research the research team realized that people with disabilities are not naturally seen to be active contributors to innovation activities – also because organisational innovation – which can "improve the quality and efficiency of work, enhance the exchange of information, and improve firms' ability to learn and utilise new knowledge and technologies" (*Oslo Manual*, 2005, p.12) has not been recognized by many people as also being valued innovation activity. The general population tends to view product innovation - which involves "significant changes in the capabilities of goods or services. Both entirely new goods and services and significant improvements to existing products are included" (*Oslo Manual*, 2005, p.17) – as the only valid type of innovation taking place in organisations.

It is fair to say that people with disabilities may be seen to represent a different aspect of business, one which is more complicated. They may not have the knowledge, capabilities or other necessary characteristics to get the work done efficiently and effectively. Furthermore, people with disabilities may represent higher labour costs, due to the necessary adaptations required to accommodate them in the work environment (including costs linked to insurance). Additionally, stereotypes and preconceptions by employers, or even by customers, may result in less of a disposition to hire people with disabilities (Mark et al., 2014).

One may thus conclude that despite there currently being a more positive attitude towards including people with disabilities in the labour market, certain stigmas still exist – related to productivity, performance, and adaptation which may all negatively influence the hiring of such people (*Jornal Expresso*, 2012).

Therefore, to contradict some stigmas, certain institutions exist which seek to provide for a more socially developed society and by way of implementing social action services. As an example of this we have the university being studied herein, which has been defining and implementing protocols with various entities, one of them being CERCIAV, to promote the social inclusion of people with disabilities or incapacities, while at the same time supporting their rights as citizens (CERCIAV, 2014). Thanks to these protocols the university in question has amongst its employees individuals diagnosed with certain disabilities – namely, working in the library, the rectorate and in the campus canteen.

This study is concerned with determining how these employees perceive and understand the concept of organisational innovation and if they have opportunities to innovate; and if they do innovate, how this is achieved.

To maximize the integration of all employees steps need to be taken. To innovate more successfully all employees need to be involved. At a time when social responsibility is at a high in popularity firms need to go beyond what is legally required to provide for fully inclusive workplaces.

The structure of the article, after the introduction, is as follows: a review of the literature comes next, which discusses issues related to the main theme of the article and others such as an inclusive education and the professional future of people with disabilities. We also discuss what expectations people with disabilities have for their careers and how they define organizational strategy and innovation. Furthermore, what does innovation mean to people with disabilities?

The methodology adopted to answer the questions posed was a case study involving a Portuguese State-owned university. Six employees with disabilities and who worked (for a salary) for the university were interviewed. After analyzing and treating the data gathered the results are discussed and the main conclusions presented.

Finally, it is relevant to state that one of the co-authors worked for some time at a training institute for people with disabilities. The mission of the institute was to train people for jobs and to get them job placements in the job market. People who were blind (this group of people was actually relatively easy to employ); or who had perhaps dived from a rock on a beach and broken their spine, in shallow water; or people who had had motorbike accidents and lost an arm or a leg; or people with severe breathing impairments, meaning that they had to always carry round oxygen tanks to stay alive; were the customers of the institute, which was state-run and surviving from subsidies granted – to the value of about 6 million euros, annually, at the time. The issue is that the customers were people who had, generally speaking, the same desires as other people for companionship, self-actualization, fulfillment and love. Do not think that because people look different that they will not have specific desires common to human beings. We thought it relevant to state this as people may be led to think otherwise.

2. Literature review

2.1 Inclusive education and professional futures for people with disabilities

According to Shah (2005), who researched "how education influences the career choices of young disabled people", in Britain, preliminary research revealed that a significant number of people with disabilities also feel that they received insufficient support at school and were not encouraged to pursue their studies in higher education, which led to even less job prospects later on. Special training and experience, as concerns teachers,

was seen to be lacking, in particular in the early stages of the learning process and system. This poor educational foundation affects individuals in subsequent stages of their lives and leads to the first signs of discrimination. School and its effect on people's lives is oftentimes underestimated as in fact this overall experience is essential, in both personal as well as professional terms. Competences and abilities and a sense of responsibility are developed in this school-time period which will affect how people interact with their environments later on in life. A simple fact is that people with disabilities are expected to contribute less to society than people without disabilities and so the former group of people are not seen as needing the same academic qualifications as the latter group of people. In fact, the very opposite is true. Whereby brilliant individuals, endowed with more abilities than the average person, such as Steve Jobs or Mark Zuckerberg or even Bill Gates; may get on very well without a college education; this is not the case for people with disabilities, who need all of the help that society may give them.

Shah (2005) also revealed that the research group of young people (aged 13 years to 25 years old) with disabilities saw their dreams for worthwhile and interesting careers disappear due to a lack of support. "The post-school options of young people in special schools were limited and likely to be more dependent on their physical needs, relating to their impairment, rather than their individual educational and occupational aspirations. Dreams of pursuing a particular career path had to be sacrificed for having support needs suitably met." (Shah, 2005, p.114).

Specialized schools and teachers with specific training are lacking (especially in Portugal) and this means that little opportunities exist for the academic development of certain minorities. The USA is seen to have better prepared schools for diversity (e.g. for the autistic) and for children with special needs. Certain countries and regions are simply not equipped to cater to a diverse set of needs and due to a general lack of funding and awareness of the problem significant adverse effects are the consequence for people with certain disabilities.

In Portugal, due to the financial crisis which hit us in 2011, when we had to borrow 78 billion euros, in order to remain functional, as a society, this meant that many financial cuts had to be put into effect. Minority groups which are not seen to contribute fully to society tend to be the most affected in such periods of hardship. Even outside these extreme periods a poorer country, such as Portugal, will not have extensive funds to help people with special needs be fully integrated in society.

In China, for example, "although China has a civilized history and distinguished Confucian tradition of valuing education, special education as an institution was not established until the 19th century, when Western culture began to influence China. The subsequent development of special education has been slow due to adverse political and economic conditions. After the 1980s, a modern system of special education from preschool to higher education was formed, and since then, China has been moving toward the goals of effective inclusive education in response to global trends and the open-reform policy." (Deng, Poon-Mcbrayer and Farnsworth, 2001, p.288).

Another example is Australia, where there is inclusive education, whereby students with disabilities and special needs are included in classrooms with regular students. A significant problem is that teachers do not feel prepared to deal with the specific issues that inclusive education entails, having been poorly prepared for this (Stephenson, O'Neill, and Carter, 2012).

While business studies, for example, are "in fashion", and able to provide for higher paid salary jobs; degrees linked to social aspects of society – such as those involving people with special needs – are not so popular, though being equally or more difficult in the challenge that they entail.

Despite the increase in awareness, relatively speaking, only a small number of firms hire people with disabilities. Mitchna et al. (2017) reveal that, in Europe, amongst people with disabilities, the employment rate is 27% lower than with people without disabilities. This figure is worse in less developed European countries. Some people with disabilities may not seek employment due to them having low expectations of finding a job. With those companies that do hire people with disabilities what may be verified is that the job settings are frequently badly adapted to the needs of people with disabilities; knowledge is lacking amongst employers as to what is necessary (Mitchna et al., 2017). On the other hand, some employers may be more interested in obtaining the financial benefits of hiring people with disabilities (or interested in being seen as socially responsible), rather than being interested in the inclusion perspective itself. If this is the case, then the

productivity and general performance of the people hired will not be a main concern, if at all. Employers in general are also concerned that people with disabilities may have limited capacities, be prone to disease, or represent an additional responsibility and risk (Mitchna et al., 2017) – as there is a general lack of knowledge and understanding linked to this group in society.

Kaye et al. (2011) refer to the importance of costs related to accommodating people with disabilities in firms as being a deciding factor as concerns the hiring and retaining of people from this job segment. Additional sensibility is also required when dealing with people with disabilities and employers may also be concerned that they may not be disciplined and that if a case goes to court (for example, linked to dismissals) that they, the employer, will lose. Therefore, these aspects also work against the employment and retaining of people with disabilities (Kaye et al., 2011). Performance appraisal expertise of people with disabilities and their [extra] supervision needs are also generally unknown and so also represent an additional barrier to inclusion (Kaye et al., 2011).

The discussion above thus leads to, and explains, the lack of qualified and employable people with disabilities in the workplace.

2.2 Organisational strategy and innovation and people with disabilities

Firms adopt strategies to integrate and coordinate commitments and actions destined to explore essential competences, in view of obtaining a competitive advantage (Hitt et al., 2011). Both internal and external environments need to be researched, analysed and evaluated in order for an effective strategy to be developed. The innovation factor, of the firm's products, services and processes, is what in the end will determine whether the firm will be able to achieve consistent above average returns, or not (Hitt et al., 2011).

NP 4456:2007 defines innovation as being the implementation of a new or significantly improved solution for a firm; a new product or service; a new process; a new organizational method or marketing strategy. The objective is to reinforce an organisation's competitive position, improving performance or knowledge. The rapid and unprecedented evolution of technology has had a significant effect on innovations and on how firms innovate – improving efficiency and productivity, and increasing market shares and profitability for company owners when technology is well leveraged. Organisations are currently increasingly seen as open systems which are constantly adapting to environmental change by following a path of innovation in order to improve performance (Damanpour, 2017).

The link of the above to people with disabilities is not readily made, by most people. People with disabilities are not connected to innovation activities – unless they are able to surpass prejudices, like the late Stephen Hawking was able to. Such is a rare case indeed, even in modern society.

The term disability has appeared to include many different types of disability, limitations and participation restrictions. Oftentimes firms will need a specific strategy aimed at solving the problems linked to disabilities if they are to be inclusive and solve rather than create barriers to inclusion.

A disability is a functional problem or a limiting body structure, such as paralysis or blindness; an activity limitation or other difficulty for an individual to execute a given task, such as eating or walking. Disabilities are distinct from work or other types of discrimination. A disability is thus not just a health problem, but it is rather a complex phenomenon which reflects the interaction between body characteristics and the society in which one resides.

People with disabilities require that environmental as well as social barriers be removed from their daily lives – things as simple as having adapted bathrooms and ramps to get into buildings (rather than there being only stairs available). After all, this needs to occur so that their needs, much as with other people, may be met. Environmental factors may facilitate or make more difficult certain interactions and include what products and technologies, and not only the natural environment, provide for. Other intervening factors include relationships, attitudes, systems, and public policy. Personal factors such as motivation and self-esteem will also affect how people want to actively participate in society. Online accessibility is also important, in the digital age, and websites and e-commerce opportunities need to be available, much as for other individuals (Gonçalves et al., 2013, 2017), though many firms do not know how to achieve this and / or are not interested, due to the additional costs involved. The World Health Organization (2011) warns against generalising in this

area as disabilities and those who have them have a diverse set of different personal factors, are of different genders, age groups, socioeconomic status, sexuality, ethnicity and / or cultural heritage.

As concerns innovation one must recognise that the standard work environment was projected for people without disabilities, and people with disabilities need to trust a variety of product adaptations in their daily lives. Conradie et al. (2017) reveal that more solutions need to be developed, and this will require more participation by all of those involved. Innovation by people with disabilities is not generally communicated and serves to, principally; satisfy their own needs with no further motivation beyond that. Innovation by people with disabilities thus tends not to be commercialized. Note that certain innovations with commercial value serve both people with and without disabilities. Unmet needs are a reason to innovate; however, if the disability is significant this will mean that the probability that an innovation will be created by that person and in a way that satisfies both people with and without disabilities will be small.

Innovation by people with a disability thus, in sum, tends to occur to solve their own very real personal problems and difficulties, which they encounter in society.

Finally, with life expectancy getting ever longer, and the retirement age getting to be ever older, we must realise that people with disabilities will continue to increase and it is imperative that we find ways to include such people in the workplace.

3. Case study

3.1 Methodology

We performed research at a major state-owned (public) and very reputable university in Portugal – the University of Aveiro. There was some surprise in the contacts that led up to the interviews as people we interacted with did not understand why we wanted to interview people with disabilities on innovation, since they were not performing research and development (R&D) activities. The three main departments at the university in which people with disabilities worked were contacted and authorisation was given to go ahead with the interviews in two of these departments.

We thus followed a qualitative methodology in our study and performed semi-structured interviews following an interview script. The objective was to gather qualitative data on a contemporary problem not focused on in the literature. Namely, how people, in Portugal, with disabilities innovate, if at all, at their workplaces in organisations. We also discussed how this target group views innovation, how they view creativity, what they think of change, and if they identify and point out opportunities for improvement.

The interviews were performed between the 14th of March and the 3rd of April 2018. The individual interviews were audio recorded with the consent of the interviewees. Manual notes were also taken. Two groups of three interviewees each were formed. The first group was made up by employees working in the rectorate. The second group was made up by employees working in the library. The rectorate group of employees were blind and their interviews lasted between twenty and thirty-five minutes. In this case the interviewees gave direct and objective answers as they were acquainted with the term innovation. The interviews with the library workers were longer and the disabilities in this case were neurological and linked to movement. Neurological disabilities had to do with less stable and more volatile personalities. The interviews lasted, in this second group, between forty and fifty minutes as some of the concepts had to be explained – namely those linked to innovation – as the academic qualifications of the respondents were also lower.

The interviews were performed until data saturation was reached and until the point whereby no new data was resulting from the interactions.

Table 1 lists some characteristics of the interviewees (age and academic qualifications), as well as the jobs and job tasks that they perform.

Table 1: Some characteristics of the interviewees

Job	Age	Academic qualifications	Job tasks
Library worker	39 years old	4th grade	- Putting books away - Cleaning shelves and carts - Checking shelves
Library worker	42 years old	6th grade	- Cleaning - Providing support to reception desks - Taking care of the plants in the library
Library worker	28 years old	9th grade	- Cloak room - Book quotations - Restoring books - Tidying up
Rectorate worker	37 years old	12th grade	- Telephone – general attendance - Receiving and transferring telephone calls - Sorting themes out
Rectorate worker	34 years old	12th grade	- Receiving and transferring telephone calls - General clarification
Rectorate worker	61 years old	12th grade	- Telephone – general attendance - Clarification on various subjects - Answering e-mails

3.2 Data treatment and the patterns identified in the data

Data treatment involved the identification of patterns in the interview data and in comparing the different perspectives gathered, as espoused in the Business Narrative Modelling Language method (Oliveira and Ferreira, 2010, 2011; Au-Yong-Oliveira et al., 2015). Statements that served to solve the questions posed were considered to be especially pertinent to the analysis.

Patterns identified in the data include the following: **1) Gain information** (Bjork and Holopainen, 2005) – as some of the informants had difficulty in defining what the meaning of innovation was. Though the word was not unknown to them, some of the interviewees were not able to express what it meant. **2) Collaboration** (Bjork and Holopainen, 2005) – people with a disability define themselves as being collaborative, in the workplace. Perhaps due to them not being able to perform a number of tasks by themselves, they see themselves as being actively dedicated to their tasks and demonstrating flexibility and team work. **3) Privileged abilities** (Bjork and Holopainen, 2005) – the people who we interviewed, and with disabilities, view themselves as adapting well to new environments. Evolution, over time, occurs quite easily, as they like to learn and discover new things, and to develop themselves. **4) Rewards** (Bjork and Holopainen, 2005) – the people interviewed feel a sense of self-actualization through their work and feel welcomed in the workplace; they appreciate the support given and like what they do.

As concerns innovating in the workplace, the following additional patterns were identified in the data: **5) Limited set of actions** – "players can only have a few actions to choose from" (Bjork and Holopainen, 2005, p.160). In sum, some of the respondents voiced the perspective that given the tasks that they had to execute and by following the rules and guidelines given, and as they depended on third parties, that there was not much room for [organisational] innovation at all. **6) Handicaps** – there is a need to make "gameplay easier for certain players in order to make all players have the same chance to succeed" (Bjork and Holopainen, 2005, p.396) – in effect, some respondents stated that they felt a fear of the unknown, especially as people with disabilities experience additional difficulties. Change to something different and unrelated is, however, seen negatively (much as people without disabilities may react and feel if changed to something not linked to their experience and preferences). **7) Puzzle solving** (Bjork and Holopainen, 2005) – Change is welcomed as an opportunity for progression, despite being difficult. Change is easier if occurring within the job task and workplace.

Table 2 has some quotes and evidence from the interviews.

Table 2: Quotes and evidence from the interviews

Theme	Objective	Interview evidence
Innovation	Understand how people with disabilities view innovation	"Innovation is a word I have heard of, but I am not sure what it means" (Library worker 1)
		"That word is not new to me but I do not know what it means" (Library worker 2)
		"To innovate is to make things which do not exist" (Library worker 3)
		"Innovation to me means, generally, to evolve, develop, create new expectations and new objectives. It means to develop things increasingly better" (Rectorate worker 1)
		"When we speak of innovation we refer to something which is getting better" (Rectorate worker 2)
		"Innovation is everything which is new" (Rectorate worker 3)
Creativity	Understand whether people with disabilities are creative	"I have a lot of imagination" (Library worker 1)
		"I have some ideas. The most difficult thing is to get the people involved to accept them, to put them in practice" (Library worker 2)
		"I have been motivated to innovate, but more on a personal level" (Library worker 3)
		"There is some disposition for us to be heard" (Rectorate worker 2)
Difficulties	Understand what difficulties people with disabilities face	"Sometimes colleagues are very aggressive when dealing with me" (Library worker 1)
		"We are very limited as concerns work as we cannot do any type of work" (Rectorate worker 1)
		"More accessibility should be created with our telephone consoles" (Rectorate worker 2)

4. A further discussion of the results

For the most part, the interview results confirm the literature. However, organizational innovation, as addressed herein, needs to be communicated in the business environment more, so that certain individual contributions may come to be expected, including from people with disabilities. Our study has shown that people with disabilities may be well aware, and indeed expend much effort, towards organizational innovation.

According to Amabile (1988) creativity is seen to be essential to organizational innovation processes. Creativity is linked to personal characteristics – namely, personality and intellectual characteristics. Certain creative individuals when given the freedom to do so will expend effort and time in the creative process. People with disabilities are no different, as the aforementioned case of Stephen Hawking showed us. People with disabilities, as mentioned above, have the same general desires and needs as other people, and this needs to be recognized – by employers, placed higher up in the organization, but also by fellow employees. In the interviews we saw no evidence to show that the people with disabilities were less creative than people without disabilities. In fact, to the contrary, we saw a strong desire to improve on workplace characteristics, by these individuals, which was very refreshing to the research team. People with disabilities may be very motivated to be productive and exceed the expectations of their employers – on the one hand because jobs are so hard for them to find; on the other because, as they are used to hardship, their minds are continuously working to improve their external environments.

It should be noted however that the job tasks of the interviewees are seen to be repetitive and very routine. Thus, the interview subjects do not feel that they can innovate as concerns their daily routines – which are sequential and methodical. The tasks have been previously defined and so it is difficult to innovate and be creative. Furthermore, as concerns physical and architectural barriers at work, these do exist. These barriers impede better job performance and lead to limitations being felt by the interviewees.

The interviewees do actually think of solutions to improve their work; however these are often never actually voiced to anyone. Financial limitations are also felt as concerns the improving of work stations for people with disabilities. In fact, the interviewees feel that they do not have the ideal resources to innovate. They feel that suggestions to improve on their work spaces and processes are generally not heard and given due attention by their supervisors, mainly due to financial limitations. For the most part the job tends to get done and so improvements are seen as unnecessary. For example, the blind interviewees asked for audio or tactile resources. One blind interviewee in particular stated that job resources need to be adequate and so there exists an incentive to innovate on a personal level, identifying barriers to be overcome.

Relative to job motivation the interviewees are generally imaginative people who want to perform well. There is an effort to do things well at the first attempt. The interviewees revealed themselves to be perfectionists who are in favour of continuous improvement. Innovation occurs with them mainly in their personal job methods which they seek to do the best way possible, depending on the conditions imposed by their superiors.

Resources are generally insufficient and though they possess the creativity and motivation to innovate the techniques available to do so are limited. They do, however, state that they have what they need to perform their daily tasks.

For the blind interviewees answering telephone calls they need the help of third parties, for example, to see missed call information, which they cannot see. Also, they cannot recognize telephone numbers or access them. They need a voice system to be incorporated in the telephones. Furthermore, the Internet pages of the university present some gaps for blind people. Screen readers are needed such as JAWS (accessibility software for blind people) which read the information on screen monitors and transmit that information to a voice synthesizer which aids digital inclusion. Another case mentioned is that these blind employees, when in training at the university, have to use their own personal computers, as the ones available lack voice software.

This leads to a feeling of discrimination as they are not given equal opportunities and resources (concerning access to training). Voice software licenses need to be bought for computers used for training, and this was suggested to senior leadership at the university by one of the blind respondents. Acoustic improvements were also suggested by another blind interviewee as various people speaking at the same time at work affects blind people quite significantly (what they can capture). Therefore, as we have shown above, people with disabilities have a great deal to offer organisations in terms of organizational innovation.

5. Conclusions

Schooling is not seen to be adequate or encouraging of people with disabilities to pursue a higher education degree. Tools are lacking in schools, as is specific training, in order to transfer knowledge better, to motivate, stimulate and provide the necessary competences to progress – both personally and professionally.

Integration is thus difficult. Due to a feeling of being ill-prepared to face higher education and / or the job market many people with disabilities do not seek employment at all. This in itself means that innovation by people with disabilities is occurring to a much lower degree than it could. Some people with disabilities do make it, however, to the job market. These individuals will have found ways to overcome certain obstacles which they have come across, in their paths to employment.

Certain resources which support this job segment are used to gain employment (e.g. CERCIAV). The entities where people with disabilities may find work need to be pointed out to them by organisations such as CERCIAV. Not many options exist and unfortunately this means that jobs need to be accepted which will make use of their capacities, even if the conditions offered are not very favourable. The alternative in many cases is to be unemployed. People with disabilities thus tend to grasp their first real job offers; locations where they will do their best to excel and adapt, often suggesting job improvements (organisational innovation) where appropriate.

We saw a desire to please senior management, much as with people without disabilities, or perhaps even more, as jobs are highly valued. People with disabilities are highly motivated to show that they can get the job done and seek greater responsibility and recognition at work.

Oftentimes supervisors of people with disabilities do not act on suggestions for continuous process improvement given by people with disabilities. The lack of financial resources was pointed out as being important to this outcome. Other reasons pointed out are tradition and how things have been done over the years. Thus, suggestions for improvement often go “unheard” or are outright ignored which means that little space for innovation at work exists, in reality, for this job segment.

The notion that people with disabilities are very capable of doing anything was communicated by all of the interviewees. All people have limitations, whether they have a disability or not. People with disabilities are

elements in society and thus should have the same job opportunities as others. We have found this to be far from reality, currently, in Portugal, but also abroad.

The limitations that people with disabilities may have are seen to be a form of seeing the world differently. These different perspectives may be essential and lead to ways of thinking and functioning "outside-the-box". As one blind interviewee stated, "I am capable of, through the texture of a jumper, to know its colour and you, who can see, cannot do that".

Finally, at a time when one hears a lot about the importance of soft skills, this group of people tends to have a lot of soft skills. Needing other people to get by has made them good collaborators and team players and this in itself is a good reason to employ people with disabilities.

Future research might seek to broaden the research performed to include a larger sample of people with disabilities. Future research may also include people with a more diverse set of disabilities. Additionally, several types of organization may be studied, rather than only a single organization. Different environments and industries may reveal interesting and important information concerning this minority group – which, as mentioned herein, is seen to grow in number, and thus in importance, in years to come.

Abstract: The strategic position of each company does not depend exclusively on the quantity and quality of the resources it has, but on the position it occupies within the network in which it operates. Networking helps reduce transaction costs and business coordination: Valuable information about customers, suppliers, competitors, and good partners is easily shared among network stakeholders, resulting in savings in transaction costs. There may be high transaction costs when there are two different stages of property ownership, and the 4th industrial revolution seeks to challenge the logistical areas for technological digitization and large domain integration and seeks to present a new operational, organizational, and managerial paradigm that will be termed : logistics 4.0. Methodologically, the research is based on a bibliographical review and seeks to find grounds that theoretically justify the reduction of Transaction Costs through Logistics 4.0. Thus, the main objectives of this research are to analyze and understand the relationship between Logistics 4.0 and Transaction Costs, as well as to evaluate the influence of innovation networks in this area. Minimizing these transaction costs is materialized by aligning management structures with the creation of unique structures, thereby reducing the opportunistic behavior of the other party, especially if there is a dependency relationship between the two parties. Logistics 4.0 is based on intelligence and technological equipment and is developed with online tools, seeking to respond to faster, virtual and automatic information systems. Information speed is a major influencer of good results, and improvements in the transmission of information and knowledge seek to improve the management of organizations through their networks and aims to reduce their transaction costs from the new technological and logistical revolutions.

Keywords: Networks; transaction costs; Logistics 4.0; innovation.

1. Introduction

Strategically providing the logistics area with efficient, effective and competent resources, regardless of the institution, has come to be seen as a very important pillar so that they can carry out their activities in a sustainable way so that they reach their most varied objectives (Almeida , 2011).

Logistics in the various sectors as a centerpiece of the company's strategy, over time, becomes a necessity rather than an option and must be applied and managed as a strategic weapon, as like any other industry in the efficient management and effective use of its resources is the most direct way that can exist to assure quality standards demanded by increasingly demanding customers (Carvalho et al, 2017).

Through the work developed by Ballou (2004), Tseng, Yue and Taylor (2005) and Paura (2012) we have to realize that there are three basic activities of logistics: Order Processing (basic factor of identification of the need to be met) ; Maintenance of stock (Ensure that all materials identified as "stockable" always have quantities in stock to meet existing orders) and Transport (whether internal or external should always be ensured so that the necessary goods can be allocated, where necessary correct time). These activities should always be carried out, as rigorously as possible, so that the logistics cycle itself will never be called into question and at the same time the normal operation of the services will not be jeopardized, and there will always be correct and updated information so that has to manage these processes as accurately as possible (Ballou, 2004, Tseng, Yue and Taylor, 2005 and Paura, 2012).

Whatever the methodology from a logistics point of view, institutions should be concerned about how they communicate and how effective they are, since only secure, effective and immediately accessible information systems can circulate correctly, giving meaning to the purpose of the logistics chain, identify the need and satisfy it in the best possible way (Branco, 2013).

The 4th industrial revolution seeks to challenge the logistic areas for a technological digitization and integration of large domain and tends to present a new operational, organizational and management paradigm, which will be denominated: logistics 4.0.

Methodologically, the study is based on a bibliographical review on the themes (1) Innovation Networks, (2) Transaction Costs, and (3) Logistics 4.0 and tries to find grounds that theoretically justify the reduction of Transaction Costs through the networks created in the Logistics 4.0. Thus, in the first place, several studies were done not only in documents indexed in the ISI Web of Science as in Scopus, in order to find literature favorable to the work within the theme of Logistics and Industry 4.0 and with incidence in the costs of transaction and in the theory of networks. Secondly, all abstracts were analyzed, and interesting and important abstracts were selected for the present study. During the reading of the abstracts, articles with a relevant scale were evaluated; little relevant; and less relevant. For the next phase, only the relevant articles were transited. In the last phase, after checking the abstracts of the initial research and excluding the non-relevant articles, the articles were recovered in full and the studies that were truly relevant to the present study were verified.

The main research question is: "Can Logistics 4.0 create cooperative conditions to lower transaction costs?" And as such, the main objectives of this research are: to analyze and understand the relationship between Logistics 4.0 and Transaction Costs as well how to assess the influence of innovation networks on this relationship.

The following chapters address the topics (1) Innovation Networks, (2) Transaction Costs, and (3) Logistics 4.0, then a contribution is made to answer our research question and the main conclusions are presented.

2. Review of Literature

2.1 Innovation Networks

In the organizational environment, the network represents a form of intermediary organization between the organization and the market. The organizational network is comprehensive and generally means that two or more organizations are involved in long-term relationships, with the main objective of revitalizing the various organizational processes to achieve competitiveness in an increasingly turbulent environment (Hakänsson, 1987).

Innovation Networks according to Pyka et al. (2002b), Felman et al. (2006), Braunerhjelm (2008), Huang and Chang (2008), Percival and Cozzarin (2008), Suire and Vicente (2008) and Weber and Khademian (2008) are now widely considered as an effective means of organization complex processes of research and development. The evolution of organizations led to the existence of an approximation in order to strengthen their relations, interconnected by cooperative relations in order to work continuously and together (Franco and Duarte, 2012). Certainly, a single isolated organization will be unable to train all the resources and competencies to fulfill its objectives, as knowledge will always be deficient compared to the knowledge of a network of organizations. Managers thus seek partners who can provide the information, support and advice needed to complete the complex, increasingly diverse tasks they have on the agenda (Franco and Duarte, 2012).

Whatever the distance between the partners, Veciana (2008) and Simões (2009), both affirms that the networks allow a relationship between the organizations in order to concentrate the exchange of experiences between them, as well as the sharing of knowledge, learning, among others (Felman et al., 2006). The intensity and frequency of the relationship between organizations is greater if they belong to the same network.

As for network content, interpersonal and inter-organizational relationships are seen as the means by which actors have access to a variety of resources, including knowledge, made available by other actors (Hoang & Antoncic, 2003). Innovation networks can bring key benefits to logistics, such as:

1. The content of the network: a key benefit of innovation networks is the network's access to a set of information and advice. Relationships may also have reputational or signaling content (Krackhardt & Stern, 1988; Hoang & Antoncic, 2003; Marouf, 2007);
2. Network management: another key benefit of innovation networks is their management mechanism that manages and coordinates the exchange relationships in the network. Trust among network actors

is, for the most part, seen as a critical element that can influence the quality of shared resources. Trust, as well as the depth and richness of exchange relationships, particularly with regard to the exchange of information, will be the critical elements (Granovetter, 1973; Nelson, 1989; Hoang & Antoncic, 2003; Marouf, 2007);

3. Network structure: it is defined as the pattern of relationships that result from strong and weak relationships among the actors that make up the same network. A general proposition is that the different positions that the actors occupy in the network structure have an important impact on the flow of resources and, consequently, on the results of the entrepreneurial activities (Granovetter, 1973; Hoang & Antoncic, 2003; Marouf, 2007). The most intuitive unit of measurement is the network size, defined as the number of direct connections between the focused actor and other actors. The analysis of the network dimension measures the extent to which resources can be accessed at the level of entrepreneur and organizations (Aldrich & Reese, 1993; Baum et al., 2000).

Thus, knowledge diffusion is the form of transfer of knowledge, directly or indirectly, from one part to another (Deeds et al., 1997; Malecki, 1985; Gilbert et al., 2008).

In the Logistic context, the cooperation represents a relationship between partners, finding the development of joint activities that are a source of performance improvement in the organizations that interact in this chain. For Barnes and Liao (2012) it is the skills and competencies of each organization that perform best, not only depending on the organizations' cooperation, but also on internal cooperation (between departments) (Stank et al., 2001) of synchronizing the work of the organization leads to greater efficiency (Jagdev and Thoben, 2001). The non-synchronization of the work in the execution can condition the performance of the Supply Chain, being not only important to share information, but also it is necessary to develop coordination mechanisms (Carvalho et al, 2010).

Christopher (2005) introduces the term interdependent to define logistic cooperation between organizations, presenting them as a network of interdependent organizations working together to manage and improve together flows of materials and information. Organizations when they understand that they do not control all the conditions necessary to individually achieve a given goal (Handfield and Bechtel, 2002) become interdependent with others and seek cooperation as a basic requirement for the creation of value and profitability of organizations (Moura, 2006).

But, innovation networks have flaws, or barriers, to integrate a network of innovation, identified by Pyka et al. (2002), Felman et al. (2006), Braunerhjelm (2008) and Huang and Chang (2008). The actors who wish to integrate this network must have the following requirements: (i) Autonomy; (ii) Social skills; (iii) Reactivity; (iv) Proactivity. Failure to meet some of these requirements will hamper integration and participation in the network.

2.2 Transaction Costs

Transaction Costs were first discussed by Coase in 1937, which awarded him the Nobel Prize for Economics in 1991, by questioning under what circumstances organizations produce for their own needs. Coase (1937) cit. in Barros (2012) states that companies exists because of the existence of a cost of using prices, thus arising the idea of the existence of transaction costs. This relationship sees the company as an alternative way in coordinating production, where it will choose how to organize production based on what will translate into lower transaction costs (Barros, 2012).

The transaction costs are according to Pondé (1996) cit. in Fagundes (s.d.) the consumption of economic resources resulting from adapting, structuring and monitoring the interactions between the different agents, ensuring compliance with contracts.

The theory presented by Coase argues that transactions do not only entail costs, but the attempt to minimize these costs ends up influencing the way economic activities organize themselves (Rocha, 2002). As can be seen, all the theories of transaction costs are associated with negotiation costs with other organizations, which are essentially contractual relations costs, resulting from market failures (Rocha, 2002). This theory argues that transaction costs are not only important, but also provide an important tool for understanding certain forms of economic organization (Rocha, 2002). In this way, transaction costs are defined as: "... costs not directly related to production, but which arise as agents interact with each other and the problems of coordination

that emerge" (Azevedo, 1996, pp. 28 -29). According to Williamson (1994), the minimization of these costs materializes through the alignment of management structures with the elaboration of unique structures, thus reducing the opportunistic behavior of the other party, especially if there is a dependency relationship between the two parties.

The various factors that influence market failures make it almost impossible for companies to pass on the specific information they need at a reasonable cost (Foss, 1993), and this is due to four main factors: high opportunism, limited rationality, uncertainty / complexity (contractual and organizational) and high presence of specific assets (Moschandreas, 1994).

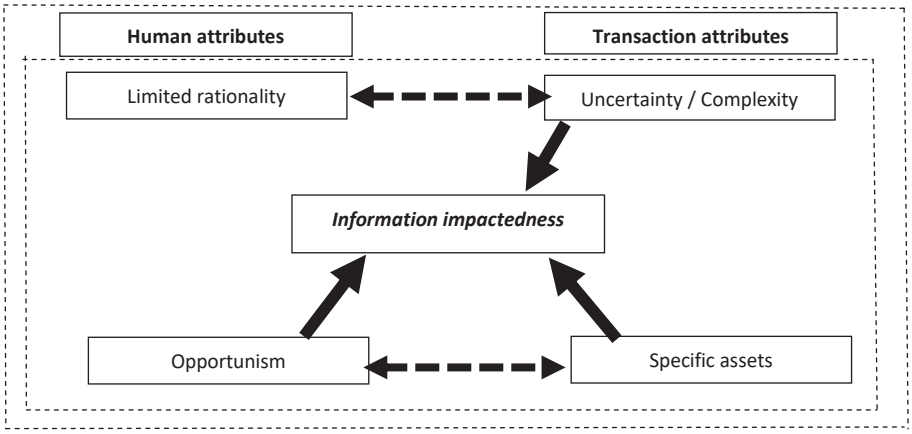

Figure 1: Information impactedness - Adapted from Moschandreas (1994).

As can be seen in the figure above, Information Impact, a definition that comes from Oliver Williamson (Nobel Prize in Economics - 2009), is a derived condition that arises when agents are interested to act opportunistically in the presence of uncertainty / complexity and arises when one participant in the transaction is better informed than the other (adverse selection and moral hazard) (Moschandreas, 1994).

Asset specificity is one of the most important factors contributing to high transaction costs and thus to integration. There are other factors leading to market failures that are also relevant to vertical integration. One of these flaws identified by Moschandreas (1994) is limited rationality, which in turn presupposes decision making using simplifying rules that extract key aspects of the problem without capture all its complexity. Since the rationality of economic agents is limited, this leads to incomplete contracts in the sense that it is impossible for them to project all future events (Kato & Margarido, 2000). According to Kreps (1990) cit. in Kato & Margarido, (2000) limited rationality means that it will be very costly for individuals to predict and contract for every eventuality that may arise throughout the transaction.

Considering that the rationality of the economic agents is limited, since they are not able to elaborate a model that can perfectly predict future events, this necessarily implies that contracts pertaining to any transaction are incomplete (Kato & Margarido, 2000). Although the economic agent's rationality is limited, they are aware that their contractual relations need adaptations and negotiations to safeguard their interests (Kato & Margarido, 2000).

Eiriz (2004: 126) mentions that "a strategic network, in order to be economically efficient, has to offer its actors lower transaction costs than can be obtained internally", and this is a way of knowing if the network will be relatively attractive the benefit / cost ratio.

Networking helps reduce transaction costs and business coordination: valuable information about customers, suppliers, competitors, good partners, etc., is easily shared among network stakeholders, resulting in transaction cost savings (Braunerhjelm, 2008).

Braunerhjelm (2008) argues that networks created to promote innovation among actors can show the following benefits:

- Networks facilitate the exchange of relevant information and knowledge;
- Networking helps reduce transaction costs and business coordination;

- The network transaction leads to rationalization of production;
- Networking increases the ability of companies to exploit economies of scale.

Given this, if there is an informational impact (or problems of asymmetry in complex contracts), opportunism and specific assets, we may be faced with influential determinants of integration.

2.3 Logistics (4.0)

Logistics by itself is defined by USAID (2012, p.13) "*as an operational component of supply chain management, including quantification, procurement, inventory management, transportation, fleet management, data collection (... .) Supply chain management includes logistics activities as well as the coordination and collaboration of workers, levels and functions. The supply chain includes international manufacturers and the dynamics of supply and demand (...)".*

Stressing the origin of logistics we have to go back quite a bit in time, since it is associated with a historical figure: Alexander the Great. He was the first, at military level, to adopt strategies (which without being denominated as logistical) promoted the success of military actions developed (Rodrigues, 2007; Dobroruka, 2009 and Rocha, 2012).

Noting that over the centuries this type of strategy has been improved and adapted to the different sectors of activity we can verify that around 1901 it was recognized academically as a research area when the first study about it was published, which study (Leite, Souza, Silva and Oliveira, 2015).

More recently, around the 70's and 80's, new methodologies were applied to the logistics area that shaped this strategic area and its applicability to the business reality and endowed it with the capacity to adapt to the needs that the constant technological and business evolution in the various sectors of activity, culminating in logistics techniques such as Just in Time (maximum stock minimization and continuous flow of product movement) or Kanban (use of visual indicators for distribution control) (Serio, Sampaio and Pereira , 2006; Adnan, Jaffar, Yusof and Halim, 2013 and Oliveira, Almeida and Sousa, 2013).

A logistic cycle is influenced by several vectors, inseparable and influenced from each other, which lead us to changes in momentary, unforeseeable and specific needs, and the responsible service must be prepared to respond to these needs in a timely manner so that never in any case the quality, safety and speed in the provision of the service or product are called into question.

Through the work developed by Ballou (2004), Tseng, Yue and Taylor (2005) and Paura (2012), we have to realize that there are three basic activities of logistics:

1. Order Processing: basic factor of identification of the need to be satisfied;
2. Stock maintenance: Ensure that all materials identified as "stockable" always have quantities in stock to meet existing orders;
3. Transportation: whether internal or external must always be guaranteed so that the necessary goods can be allocated, in the place necessary in the correct time;

These activities must always be carried out, as rigorously as possible, so that the logistics cycle itself is never called into question and at the same time that the normal operation of production is not jeopardized and there is always correct and updated information so that has to manage these processes as accurately as possible (Ballou, 2004, Tseng, Yue and Taylor, 2005 and Paura, 2012).

Conceptualizing the area under study, it is important to elucidate the concept of Supply Chain Management (SCM), and this integral part of logistics can be defined as the synthesis, maintenance and operationalization of the processes that constitute the supply chain, that as the objective of eliminating the needs of the end consumer identified previously, as well as equipping the institutions with competitive factors that allow them to distinguish themselves from the others (Besugo, 2011; Janvier-James, 2012 and Park, Nayyar and Low, 2013).

Using the studies developed by Courtois, Pillet and Bonnefous (2007) and Ayers (2001), the same author, Besugo (2011), characterizes SCM as having its main impact on the value chain management, fostering its

success, through the management of processes that go from the supplier to the final consumer, characterizing this chain as essential when looking for an integrated management of materials, since it has such a scope that encompasses areas such as the acquisition of goods and services (where includes not only purchases but also stock management, storage activities and distribution) (Roldão, 2002 and Besugo, 2011).

From the historical point of view, according to Serio, Sampaio and Pereira (2006) based on the study developed by Boyson, Cors, Dresner and Harrington (1999), subdivide the evolution of logistics in four recent chapters:

1. Underdeveloped logistics (until 1970): centralization of transport actions, inventory control, identification of needs and distribution;
2. Incipient logistics (between 1970 and 1980): Focus on transport and storage, starting to look at logistics as a process with integrated management needs of its stages;
3. Integrated Internal Logistics (up to 2000): integration of the notion that logistics can be a factor of competitiveness through not only managing the internal logistics of the institution, but also as a way of organizing them with a focus on the objectives and provision of its services with the best possible quality;
4. Integrated External Logistics (from 2000 to the publication of the article): at this stage of Logistics History, the most recent one, was the moment when it realized that it would not make any sense to look at the logistic cycle without there being a clear what the institutions' objectives are and how it could act in order to be as effective and efficient as possible. In this way, a greater emphasis was placed on forecasting needs (demand), information systems and, above all, how to interconnect all the phases that provide a better logistic performance;

Referring to the previous point, the need arises to frame Logistics 4.0 as an ability to integrate the company with the outside through the information systems. Logistics 4.0 brings increased business-to-business competitiveness, increased revenue and productivity, and process optimization (Dais, 2014).

Industrial evolution has directly influenced Logistics and the capacity of material flows to adapt to revolutions: the first industrial revolution works towards the mechanization and the hydraulic force; the second with mass production and assembly lines and electricity; the third with computing and automation; the fourth focuses on the breakthrough that allows machine-to-machine communication without human intervention (Kagermann et al, 2013 and Dais, 2014).

With the fourth industrial revolution, that is, with Logistics 4.0, the main innovative focus is the ability to develop communication between equipment and machines, through the Internet of Things (IOT), reducing time and costs (Kagermann et al, 2013 and Dais, 2014). In the industrial sphere, the IIOT, or internet of things in Industry, also ensures greater transparency in the supply chain, through the ability to verify the movement of cars, pallets and all the various materials in the supply chain.

In the new industrial era (4.0), the deployment of robotic solutions with less need for manpower will be evident (there are human-robot interaction robots) (Kagermann et al, 2013 and Dais, 2014).

In the context of Logistics 4.0, information transparency is an important factor: with a large number of connected objects and equipment, working in tandem and providing real-time information, it is necessary that communication and transmission standards are efficient, so that information and important data are always prioritized.

3. Logistics 4.0 and the relationship with Transaction Costs

The association of new technologies, at a global level, has assumed over time an extreme preponderance in what is the performance of organizations and their orientation to results. In this sequence, logistics does not escape the rule and given the impact it can have on the daily activity of organizations, it is preponderant that this activity is seen not only as support but as one of the central factors for organizations, so that they can be and to develop their activity in an efficient way.

The concept of logistics 4.0 which, as mentioned previously, associates the use of technology (essentially the internet of things), allowing a large number of activities to be carried out by technological innovations and which may be linked to each other by sharing a real-time information, eventually converging with the identified needs so that transaction costs can be reduced, contributing to the different elements of the movement of goods having useful and timely information, thus contributing to a better take decision-making.

Table 1: Logistics 4.0 and the relationship with Transaction Costs

<table>
<tr><th>Transaction Costs</th><th>Network Cooperation</th><th>Logístics 4.0</th><th>Stakeholders</th></tr>
<tr><td>Transaction implies costs</td><td>Networking should allow economic efficiencies;</td><td rowspan="4">Through Logistics 4.0, with internet mediation of things, there is network cooperation within the organizations and with the various stakeholders, ensuring the dissemination of information among the various actors and the integration of the various sectors / actors, ensuring coordination and management of the logistics cycle.</td><td>Offer your actors lower transaction costs than you can get internally.</td></tr>
<tr><td>Informational impact
Asymmetry of information
Limited Rationale</td><td>The existence of networks allows to improve the flow of information and knowledge.</td><td rowspan="2">Ease of access to information / knowledge.
Ability to know in Logistics, networks, prices and essential information;
Better coordination and balancing of deliveries, collections and logistics processes.</td></tr>
<tr><td>Coordination problems</td><td>The decrease of the distance between actors allows the existence of an improvement in the coordination and in the relation between actors.</td></tr>
</table>

Examples such as robotized warehouses, which allow to optimize the storage space and a fast and efficient access to articles or the technology of georeferencing of loads, that allows to locate in real time and to transmit this information to the client, are associated with this phenomenon of logistics 4.0 and are, when optimized, excellent mechanisms of relationship between the various integrating parts of the value chain, since all these examples allow to optimize the existing resources, reducing the costs associated with the process, which are not necessarily of production and allow, on the other access to real-time information that endows data organizations that influence their decision making, improving intrinsically the management of situations related to this area of activity.

Better management, quick and reliable access to information and optimization of resources (infrastructures or human resources) are some of the benefits that the application of technology to the logistics process can have at the level of transaction costs, since all these improvements allow, to provide organizations with greater capacity for relationship and transmission of information between the various internal levels and above all provides organizations with a greater capacity for knowledge and negotiation with the different external agents that are associated with their activity.

4. Conclusion

Considering the definitions presented by Pondé (1996) or Barros (2012) we see that transaction costs are inseparable from any activity, higher or lower, will always be associated costs and, like all others, should be analyzed and evaluated in a way which can be minimized without affecting the level of service provided. In this case, we can suggest different forms of management that benefit the results of this parameter, but it is important to realize that the implementation of technology that allows organizations to perform better, faster and faster to respond to identified needs and that allows them access the information in a quick way so that its decision making is the best possible allows us, possibly, a better management of the Transaction Costs.

Using the studies developed by Courtois, Pillet and Bonnefous (2007) and Ayers (2001), the same author, Besugo (2011), characterizes Logistics as its main incidence in the value chain management, fostering its success through of the management of processes that go from the supplier to the final consumer, characterizing this chain as essential when looking for an integrated management of materials, since it has such a scope that encompasses area such as the acquisition of goods and services (which includes not only the purchases but also the management of stocks, storage activities and distribution) (Roldão, 2002 and Besugo, 2011). Also observing the study by Carvalho (2004) we have to realize that the issue of communication between the various levels of the institution leads to their prudence, the use of information systems equipped with skills that allow an update and quick access to information.

Thus, the main research question presented was: "Can Logistics 4.0 create cooperative conditions to reduce transaction costs?" Thus, it can be said that the application of technology that is useful and has a direct impact on the performance of organizations, besides being a way to boost this performance, it is also a management tool that allows to be in real time, to receive information that can not only influence the decision making, but above all have data that allow to manage the activity of the organizations of form efficient and effective, as well as endowing them with mechanisms of relationship with the entities with which they relate in the course of their activity. Concluding that Transaction Costs can be influenced directly and positively by the new concept of Logistics 4.0, and this influence will only be noticed if the decision maker realizes that only aligning the human resources of the institutions with their policies and objectives as well as the technology that it implements within the organization is that it can influence positively the same and therefore become a mechanism of reduction of costs among which the Transaction Costs.

Abstract: In an increasingly competitive and dynamic world where globalization, information and technology are commonly accepted as influential and determining factors of organizational culture and performance, it becomes imperative for organizations to stand out and gain an advantage over their competitors. This scenario transformation created a greater and more exquisite demand as concerns the average customer and it is now understood that a competitive advantage gained does not necessarily prevail over time. Therefore, organizations must be flexible and learn to adapt easily and rapidly to changes in order to create a sustainable position. Furthermore, the ability to be different, to be innovative, and to create unique products, services, experiences, or a combination of all three, may be viewed as a booster of competitive advantages. In this context: 1. When does innovation begin or should it begin? 2. Is innovation an organizational goal or a philosophy? 3. What makes an organization innovative? This study focuses on innovation as a precursor and defining agent in the development of a business model. First, a brainstorming session was conducted as an exploratory qualitative research effort, with eighteen participants studying innovation and technology management in Portugal (the participants were probed for their views on the three questions above). Additionally, a questionnaire was administered to Portuguese millennials (171 valid responses), with the goal of perceiving potential changes in the national culture that could impact the national innovation mindset. The results were quite surprising and reveal a significant change since the original questionnaire (led by Hofstede) was administered in Portugal.

Keywords: Innovation, Corporate Strategy, Organizational Culture, Philosophy, Sustainability

1. Introduction

"Innovation is widely regarded as a pinnacle success factor in a highly competitive and global economy." (Rajapathirana & Hui, 2018, p.44). The rapid development of new technologies as well as the globalization phenomena increase the necessity for companies to be flexible to market demands; thus companies' capability to stand-out, by being innovative is considered "the most crucial factor for competitive advantage in highly turbulent market condition." (Rajapathirana & Hui, 2018, p.45). Innovation as a mindset embedded in the organizations' ecosystem is the focus of this research. The main purpose is to consolidate concepts such as innovation and strategy, realizing which factors impact or determine the conditions for success. People are the foundation of any enterprise, people and knowledge are thus critical factors for a company's existence and survival – intellectual capital emerges associated with innovation and organizational performance. In this context, also organizational culture, and in general terms, culture, is a determinant factor as it influences the organizational dynamics and overall philosophy. In par with the literature review, it was considered pertinent to analyse not only applied innovation success cases, but also the perspectives of innovation-related trends for future generations. Therefore, a brainstorming session was organized with a group of students taking a master's degree in management, and an adapted version of the Values Survey Module 2013 Questionnaire (Hofstede & Minkov, 2013) was also conducted with Portuguese millennials, in order to perceive potential changes in the culture that could impact the national innovation mindset.

2. Literature review

2.1 Strategy and innovation

Strategy evolved through time, originated in classical Greece and evolving from a military concept into a business concept in our time (Freedman, 2013). Despite lacking a consensual definition, strategy is commonly called a "plan", a way to achieve a certain objective. Although correct, according to some authors it is an incomplete approach to this complex concept. Strategy needs to be thought of and also to emerge from

possible events that may come (Mintzberg, et al., 1998), requesting more than predictive skills. Thus, strategy involves the capability to adapt, to respond to the unexpected, and also to be able to understand the changes that surround us in order to predict what may come – this is the meeting point with innovation.

Innovation is a complex concept that Henderson (2017, p.1) simplifies as "the introduction of new ideas and methods". This proves to be a valuable asset to a firm in order to keep the customer's attention in a constantly changing world with volatile market needs – according to Gorodnichenko, et al. (2008), globalization pressures companies to innovate: the development of new technologies creates new opportunities and increases competition between firms in emerging market economies.

Innovation is thus resurfacing as a crucial and strategic factor in the differentiation of a company's processes, products or services. It is also perceived as a driving force for the development of a sustainable competitive advantage. Recent studies are emphasising the importance of considering innovation holistically. Chen, et al. (2018) present holistic innovation as being total and collaborative innovation driven by a strategic vision. The authors identify four core elements of holistic innovation, namely, strategic, total, open and collaborative innovation: the *strategic* element requires facing innovation not as a single activity, but as a mindset "embedded in the overall goal of enterprise development and the entire management process" (Chen, et al., 2018, p.5); the *total* elements inherent to total innovation management, consists in "innovation in all organizational sectors and all employees, and covers all time and space dimensions" (Chen, et al., 2018, p.5), which implies the effective integration of internal and external resources in order to "create an enterprise innovation ecosystem" (Chen, et al., 2018, p. 5); *open* innovation "focuses on the interaction between the internal and external knowledge of enterprises, emphasizing that enterprises should go beyond the existing closed innovation mode and achieve the goal of «acquiring knowledge from the outside» and «exporting knowledge» to make up for the lack of internal innovation resources, thereby improving innovation performance" (Chen, et al., 2018, p.6); lastly, the *collaborative* element is centred on knowledge – its acquisition, sharing, integration, production and, in general terms, its management, since knowledge is crucial for decision making and consequently, for the survival of companies in a constantly changing world. Thus, collaborative innovation "emphasizes the integrity of science and technology innovation; that is, the innovation ecosystem is an organic collection of elements rather than a simple summation, and its existence, objectives, and functions all show a unified integrity" (Chen, et al., 2018, p.6), and has a dynamic nature, "which means that the innovation ecosystem is constantly changing" (Chen, et al., 2018, p.6). Furthermore, it is important to mention that the four elements must not be seen independently, but "are interrelated and indispensable pillars within the helix of holistic innovation" (Chen, et al., 2018, p.5), which implies, once more, the incorporation of an innovation-oriented mindset in the organization's philosophy or culture.

The question follows of how to manage or determine a company's innovation performance. Aside from company management and identification of needed technology, "the human and structural adjustment of the organization is also gaining importance in innovation performance" (Dereli, 2015, p.1365). Kalkan, et al. (2014) reinforced the relation between an organization's capability to innovate and its intellectual capital or ability to utilize its knowledge resources. Also, according to Gogan, et al. (2016, p. 195), "the importance of the concept of intellectual capital in the age of knowledge becomes the new core of economic progress, since the influence of fixed assets and financial assets is reduced in comparison to the influence of intangible assets". In this context, three components may be identified, namely, human capital, which "refers to the characteristics and the intellectual qualities of the people from the company who have to react to market changes and customer needs" (Gogan, et al., 2016, p.196), structural capital, viewed as "the component of the organization which can be described as the organization's infrastructure and the organizational processes used to obtain products and services" (Gogan, et al., 2016, p.196), and relational capital, which "refers to the ability to establish relationships with stakeholders and the market in a sustainable and stable environment, the ability to establish interpersonal relationships and the ability to develop relationships based on trust" (Gogan, et al., 2016, p.196).

Intellectual capital is therefore considered as an important activity for organizational efficiency in the market and, consequently, for their ability to obtain sustainable competitive advantage (Gogan, et al., 2016).

2.2 Innovation and culture

It becomes imperative to know what is responsible for innovation. Is it something people can impose? Can it be solved by investing money in research and development? If it is as simple as that, why aren't all firms innovative? According to Shane (1993), the rate of innovation in a certain country can't simply be increased by

spending money in research and development, for innovation is highly influenced by social values. This author also claims that uncertainty avoidance and lack of power distance are important to innovation, and Andrijauskienė & Dumčiuvienė (2017) also state that power distance strongly influences innovation, but also focus on indulgence as an important dimension in the matter. On the other hand, Prim et al. (2016) defend that individualism, long-term orientation and indulgence are the dimensions with the most influence on innovation (not denying the impact that other dimensions may have on the innovation index of countries).

Culture isn't something unshakable: culture variants may change over time (Bentley, et al., 2004). This premise is what conditioned the survey conducted: it would be aimed at millennials. Literature divides itself in the age group which defines the millennial generations: Pew Research Center (2018) defines that millennials are born after 1980 and before 1997; Howe & Strauss (2007) state that millennials are born from 1982 to 2005 and McDonald (2015) defends that millennials are born in the last two decades of the twentieth century.

2.2.1 Hofstede insights - Portugal

Hofstede's model of six dimensions of national culture allows to trace the cultural organizational personality of different countries through six characteristics (Hofstede, 2011):

- Power Distance – how less powerful people accept that power is distributed unequally.
- Individualism – degree of interdependence among the members of the society.
- Masculinity – what motivates people to improve.
- Uncertainty Avoidance – do people feel threatened by new situations?
- Long Term Orientation – maintain link with the past in order to shape the future.
- Indulgence – degree of desire control by people.

Through the Hofstede Insights website in order to evaluate Portugal (ranked 31st in the world by the GII – Global Innovation Index in 2017) according to the six Hofstede dimensions, following Chakravorti, et al. (2017), two high-level digital competitive countries were chosen: Germany (also ranked 9th in the world by the GII in 2017) and the United Kingdom (also ranked 5th in the world by the GII in 2017). The results are shown in Figure 1.

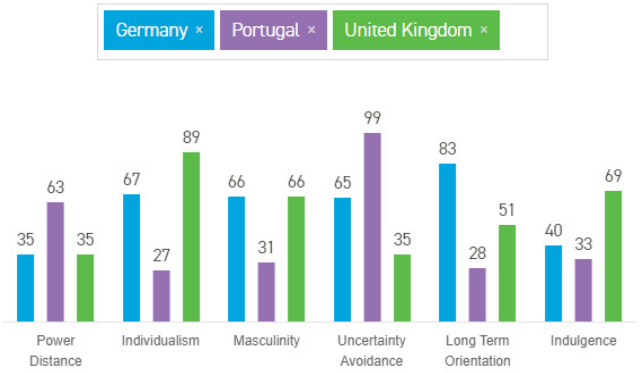

Figure 1: Hofstede's Dimensions - Germany, Portugal & United Kingdom

Source: Hofstede Insights Website – Compare Countries (2017)

Power Distance in Portugal is around 30 points higher than in Germany and the United Kingdom. This dimension reflects that people who are in "lower" positions admit privileges for their bosses - negative information is carefully delivered (in some cases even hidden), which may delay innovation, for it goes against an innovative mindset that should be established in organizations. Rinne, et al. (2012) state that a low power distance index influences innovation positively, for it promotes autonomy in decisions by employees who occupy lower positions in firms.

Individualism is much lower in Portugal when compared with Germany and the United Kingdom. This dimension is acknowledged as influencing innovation positively by Kaasa & Vadi (2008, p.9): "(...) in individualistic societies employees have more opportunities to try something new."

Regarding Portugal's index in masculinity, it marks 35 points less than masculinity in Germany and in the United Kingdom. Knowing that a low index of masculinity indicates that the dominant value in society is quality of life rather than the need to be the very best (Hofstede Insights, n.d.), it is possible to verify that the idea that "having enough to be happy" is what drives Portuguese people, not thriving to be better than anyone, if there is "space for everyone". As stated before, innovation becomes imperative when the need to stand out emerges. Thus, it is possible to verify that there may be a correlation between a low masculinity index and a low innovation index. Although it is applicable to Portugal, some authors state the opposite: Cox & Khan (2017) state that low masculinity is one of the characteristics that contribute to a higher innovation level. On the other hand, and also considering the study mentioned before, Andrijauskienė & Dumčiuvienė (2017) through regression analysis state that this dimension has no significant impact when analysing innovation.

Uncertainty Avoidance strikes the peak in Portugal's analysis: 99 out of 100 possible points, contrasting with 35 points in the United Kingdom and 65 points in Germany. According to many authors, a high index in uncertainty avoidance has a negative influence on innovation and the Hofstede Insights website states: "If there is a dimension that defines Portugal very clearly, it is Uncertainty Avoidance. (...) there is an emotional need for rules (...) innovation may be resisted, security is an important element in individual motivation."

However, once more, Andrijauskienė's regression analysis doesn't recognize an impact on innovation (Andrijauskienė & Dumčiuvienė, 2017).

Regarding Long-Term Orientation, Portugal scores 55 points less than Germany and 23 points less than the United Kingdom. According to Hofstede (2011), short-term oriented cultures tend to focus on the present following traditional guidelines. Hofstede Insights also states that societal change is seen with suspicion in short-term oriented cultures, and according to Prim's regressive analysis, long-term oriented cultures are positively correlated with innovation (Prim, et al., 2016).

In the Indulgence dimension, Portugal scores 33 points, close to Germany's 40 points and less than half of the United Kingdom score (69 points). In this dimension is the meeting point of the regression analysis made by Andrijauskienė & Dumčiuvienė (2017) and Prim, et al. (2016). In both studies indulgence is considered to have an important impact in innovation. According to Hofstede Insights, Portugal has a restraint culture which leads to cynicism and pessimism, and according to Arpaci (2014), more indulgent cultures tend to accept easily new technologies, which may influence the capacity to innovate (as confirmed by the regression analysis of Andrijauskienė & Dumčiuvienė (2017) and Prim, et al. (2016)).

2.3 Applied innovation cases

2.3.1 The impact of innovation on companies

Although innovation in Portugal has improved, the way forward is still long. However, there are companies that have truly managed to "go beyond" and think of innovation as one of their key missions, as is the case with *Stanton Chase* – a company that focuses on identifying, managing, and developing the talent of people and is dedicated exclusively to the provision of new and innovative solutions in Human Capital Management.

This is an international company, present in 46 countries with 73 offices and is one of the 10th largest international companies of Executive Search worldwide, because its processes and methodologies are extremely recognized for their great levels of effectiveness and success (Stanton Chase, 2017).

In addition to this example of Portuguese innovation success, others have become globally acknowledged for the last 40 years (Stanton Chase, 2017):

- *Via Verde*, developed by Brisa, which allows road traffic to occur with greater fluidity, thus avoiding many constraints on motorists;
- The first prepaid mobile phone cards that came to revolutionize the world of telecommunications and allowed the massification of electronic devices and devices, facilitating the whole process (the *Mimo* developed by *TMN*);
- The *Multibanco* system developed by *SIBS* with its range of services (withdrawals, services payment, transfers, etc.);

- *Critical*, a company in Coimbra specializing in the development of software solutions, in which its applications were even acquired by NASA to detect systems testing, detect errors and eradicate them;
- The featherweight gas bottle developed by *Galp*.

Portuguese universities have a significant impact on the creation of new companies based on the innovation pillar:

- *FASTinov* is part of the Faculty of Medicine of the University of Porto that promises to revolutionize the way doctors prescribe antibiotics. FASTinov has received approximately €2.6 million from the European Commission with the aim of launching a clinical diagnostic medical kit which, in a very synthetic way, will allow the susceptibility of bacteria to antibiotics in 60 minutes, allowing a greater speed and efficiency in the treatment of patients suffering from serious bacterial infections, without compromising their health conditions.
- *Veniam* is a spin-off from the University of Porto, IT and the University of Aveiro, which has innovated in transforming buses, cars, trucks and other vehicles into Wi-Fi access points that allow the Internet to be available to all citizens. The concept was tested in Porto, in the STCP fleet, and has already made available 4 million Internet sessions to more than 400,000 users; Veniam is now a part of international markets and the results are very satisfactory, particularly in Singapore and New York.

Unfortunately, history is not only written by strategy and innovation success, as we discuss below.

In 2015, *Nintendo* – an iconic and well-known Japanese company dedicated to the development of video games – faced a major crisis where it was accustomed to being a leader, due to the strong changes that affected the industry. The transformations in the video game market were so intense that the company was unable to cope with or compete with other e-gaming companies around the world, which meant that customers' needs were not met. That combined led to the loss of their fans' loyalty, resulting in a huge decrease in the number of game units sold, the loss of terrain to Sony and Microsoft in the traditional consoles segment and the threat of losing their proficiency in mobile gaming.

The President of the company was faced with a huge blow leading him to even consider the possibility of Nintendo being acquired by another major entertainment company (Kim, et al., 2011).

2.3.2 Innovation: the European Union and Portugal on a global scale comparison

The extremely fast pace of growth in the world means that companies are innovating and renewing in an almost instantaneous way, as the emergence of innovation for business success and economic growth is felt.

According to Eurostat metrics, the most innovative country in Europe is Switzerland and Portugal appears in the third group of most innovative countries.

Although Portugal has tried to stand out by betting heavily on innovation and entrepreneurship in recent years, much remains to be done: the results are not brilliant but don't disappoint. If the analysis is extended beyond the European Union, it is found that research and development investment is still far behind the main competing countries, in descending order, Israel, South Korea, China, Slovenia, Japan, Ireland and the USA, who see their companies investing more in this department. These data are curious because the proportion of business investment in total research and development is high in only two European countries. Portugal ranks in the last third of this list (Janeiro, 2017).

3. Methodology

Bibliographic research was conducted in order to clarify concepts such as "innovation" and "strategy". This research also aimed to connect both concepts in order to understand how far innovation should influence corporate strategy, as practical cases were also studied in which innovation influenced (positively and negatively) organizations' results.

As innovation was researched, it was understood that it was influenced by social values. Therefore, bibliographic research was made regarding Hofstede's six dimensions of national culture and in the Hofstede Insights website data was retrieved to compare Portugal with other countries.

Afterwards, in order to understand the way innovation is seen in a country with a medium technological level, an exploratory brainstorming session was conducted with eighteen individuals taking a master's degree in management at the University of Aveiro. This brainstorming session focused on three questions:

1. When does innovation begin or should it begin? This question aims to analyse the origin of innovation in an organizational context.
2. Is innovation an organizational goal or a philosophy? This question seeks to understand whether innovation is thought of as the main goal of an organization or as a mindset that should be implanted.
3. What makes an organization innovative? This question aims to know what an organization has to do in order to be innovative. This question was also replied to as follows: What leads organizations to innovation?

The brainstorming session analysis contains the common points that the eighteen participants registered, and is followed by quotes that sustain (or not) the answers given.

To add statistical relevance to this study, a survey was created by adapting the Values Survey Module (VSM) made by Geert Hofstede and Michael Minkov which enables researchers to obtain a certain group score in the six dimensions of national culture. To understand whether national culture is changing, the survey was administered online and answered by Portuguese millennials born from 1980 to 1999.

4. Field work

4.1 Brainstorming session

Following the connection between strategy and innovation, a brainstorming session was conducted and some of the common replies are shown and discussed as follows:

4.1.1 When does innovation begin or should it begin?

Focusing on the first part of the question, innovation is known to begin when the firm has to develop a new product/ service or improve an existing one in order to attract the customers' attention – product innovation, as defined by Boer & During (2001, p.84) is: "(...) development, production and commercialization of new products(...)". It was also acknowledged that innovation may appear when the firm needs to lower its costs in order to increase its profit margin – process innovation, which may also appear while a new product is being developed (Boer & During, 2001).

Following the second part of the question, regarding the exact moment when innovation should begin, the session indicates that there is not a moment in the firm's lifetime where innovation should appear - innovation must be in the mindset of the organization, flowing freely. According to IDEO's website (2018): "Building innovation capabilities that are sustainable doesn't happen overnight. Ultimately, it requires a company's leadership to make a bold commitment, and set up the right conditions for creativity to thrive."

4.1.2 Is innovation an organizational goal or a philosophy?

Both. Innovation is seen mainly as a philosophy for it is a tool to achieve the firm's goals and not the objective itself, although in specific cases it stands as an organizational goal – as example, IDEO, among other design and innovation consulting companies.

4.1.3 What makes an organization innovative?

This question was seen in two different ways – as what leads organizations to innovation and what an organization needs to do in order to be considered innovative.

Regarding the first interpretation, an organization becomes innovative when it wants to create competitive advantage by "standing out" in the market it operates. This may happen by innovating in product, service or process.

As to what an organization needs to do in order to be considered innovative, answers indicate that being able to understand what surrounds the organization is crucial – understanding the customers' necessities and the technological evolution.

Also, regarding this question it is understood that the responsibility of innovation is an act of the people inside the organization – an innovation mindset must be implemented, for innovation may come from people and from processes (Ovans, 2015): innovative people may innovate, but it is also possible to create processes that may help less innovative-oriented people to innovate.

4.2 Questionnaire – VSM 2013 adaptation

The VSM 2013 adaptation had 24 questions and we received 171 valid replies (please see appendices 1 and 2).

The data retrieved from the survey was transformed through a descriptive statistical analysis, into the six dimensions model following the form available on the website – the results follow as shown in Figure 2.

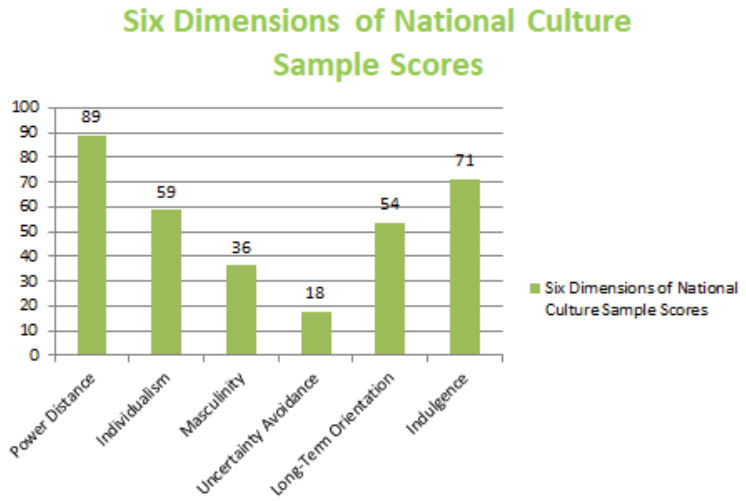

Figure 2: Six Dimensions of National Culture Sample Scores

Source: Own elaboration according to the survey performed

Comparing the scores of the sample with the scores registered in the Hofstede Insights website:

- Power Distance is much higher: 89 points versus 63 points;
- Individualism increased from 27 points to 59;
- Masculinity had a slight increase from 31 to 36 points;
- Uncertainty Avoidance strikes the biggest difference between the index on the Hofstede Insights website and the sample scores. From 99 points to 18 points;
- Long-Term Orientation increased from 28 points to 54 points;
- Finally, Indulgence also registered a considerable increase, from 33 to 71 points.

5. Conclusions

According to the literature, it is possible to understand that innovation and strategy are strongly linked in the twenty-first century. The globalization process created a more volatile world where a firm that might have been successful for many years, can be struggling today and may close in a few months. Therefore, innovation should be acknowledged as an important variable when aiming to achieve a sustainable competitive advantage. As Karabulut (2015, p.1338) stated, "an innovation strategy should be consistent to mission, vision, goals and strategies of a firm", additionally, "firms should be dedicated to invest in research and development, manufacture innovative products and achieve substantial performance to be competitive" (Karabulut, 2015, p.1338). Nonetheless, innovation is more than investing in research and development techniques, it is strongly influenced by the values that drive people inside the organization. Therefore, after studying Portugal in the Six Dimensions' model of Geert Hofstede, it is possible to state that:

- Power Distance in Portugal is strong and influences innovation negatively for it implies that bosses have too much control over their subordinates' tasks and these avoid the providing of negative information – how is it possible to innovate if negative points aren't dealt with? How is creativity possible if a whole department is run by a single mind?

- The low score in Portugal's Individualism might also be a negative influential dimension to innovation, for this dimension is correlated with innovation in some studies. The same follows for the low masculinity index registered in Portugal's score.
- Uncertainty Avoidance is the dimension that defines Portuguese culture the most, for it strikes the highest score of all dimensions. Uncertainty Avoidance is strongly linked to innovation: If changing something is scary, it is better to follow the old practices. However, what if the way things are made is not the best? It is almost an antonym of innovation.
- Regarding orientation, Portugal is considered a short-term oriented country. This may be negative for innovation as short-term oriented cultures don't embrace societal change (which is a sign of innovation).
- Portugal is also understood as a restraint country, which influences innovation negatively: more indulgent societies tend to accept change better.

The examples presented at length help to understand the central role that innovation increasingly occupies in a company's strategy. The situations described refer mostly to the Portuguese case, precisely because we have tried to understand how the country has dealt with such important issues as the development of new processes, technologies and products - in reality, though, the path is still long to "innovate innovation".

The brainstorming session showed that innovation is understood by Portuguese scholars as important to strategy.

Regarding innovation, the results of the VSM 2013 adapted questionnaire to Portuguese millennials show a positive behaviour when compared to the results registered by the whole country in the Hofstede Insights website. Although Power Distance has drastically increased, all other dimensions evolved positively according to the bibliographic research explored in the preceding topics, which may imply that societal change might be evolving positively and that Portuguese culture may become more innovation friendly. It is noteworthy that the Uncertainty Avoidance dimension presented a much lower index, which again means that it is a trend that may be changing and, consequently, may prove very advantageous for the innovation ecosystem of Portuguese organizations.

Appendix 1: Survey (24 questions) administered to Portuguese millennials

Please think of an ideal job, disregarding your present job, if you have one. In choosing an ideal job, how important would it be to you to ... (please circle one answer in each line across):
1 = of utmost importance 2 = very important 3 = of moderate importance 4 = of little importance 5 = of very little or no importance

1. have sufficient time for your personal or home life
2. have a boss (direct superior) you can respect
3. get recognition for good performance
4. have security of employment
5. have pleasant people to work with
6. do work that is interesting
7. be consulted by your boss in decisions involving your work
8. live in a desirable area
9. have a job respected by your family and friends
10. have chances for promotion

In your private life, how important is each of the following to you: (please circle one answer in each line across):

11. keeping time free for fun
12. moderation: having few desires

13. doing a service to a friend
14. thrift (not spending more than needed)
15. How often do you feel nervous or tense? 1. always 2. usually 3. sometimes 4. seldom 5. never
16. Are you a happy person ? 1. always 2. usually 3. sometimes 4. seldom 5. never
17. Do other people or circumstances ever prevent you from doing what you really want to? 1. yes, always 2. yes, usually 3. sometimes 4. no, seldom 5. no, never
All in all, how would you describe your state of health these days? 1. very good 2. good 3. fair 4. poor 5. very poor
18. How proud are you to be a citizen of your country? 1. very proud 2. fairly proud 3. somewhat proud 4. not very proud 5. not proud at all
19. How often, in your experience, are subordinates afraid to contradict their boss (or students their teacher?) 1. never 2. seldom 3. sometimes 4. usually 5. always

To what extent do you agree or disagree with each of the following statements? (please circle one answer in each line across):

= strongly agree 2 = agree 3 = undecided 4 = disagree 5 = strongly disagree

20. One can be a good manager without having a precise answer to every question that a subordinate may raise about his or her work
21. Persistent efforts are the surest way to results
22. An organization structure in which certain subordinates have two bosses should be avoided at all cost
23. A company's or organization's rules should not be broken - not even when the employee thinks breaking the rule would be in the organization's best interest

Appendix 2: Data – calculations

The means were calculated for the responses given. E.g., for the first four questions [where Score = C2*B2 and Mean = SUM(D2:D6)/SUM(C2:C6)]:

Question	Answer	Replies	Score	Mean
1	1	101	101	1,578947
	2	50	100	
	3	14	42	
	4	3	12	
	5	3	15	
2	1	80	80	1,777778
	2	62	124	
	3	20	60	
	4	5	20	
	5	4	20	
3	1	111	111	1,497076
	2	46	92	
	3	8	24	
	4	1	4	
	5	5	25	
4	1	111	111	1,508772
	2	43	86	
	3	11	33	
	4	2	8	
	5	4	20	

Then the index country scores were calculated as follows (more information at: https://www.researchgate.net/post/How_can_we_compute_and_assign_constant_values_to_Hofstedes_Cultural_Dimensions)

Sample Index without **Constant**	Portugal's Index scores according to Hofstede Insights	Correction		Sample Index Scores FINAL
Power Distance Index	63	0	63	88,93937
25,93937

Entrepreneurial Profile and the Level of Individual Entrepreneurship

Kamila Malewska
Poznań University of Economics and Business, Poland
k.malewska@ue.poznan.pl

Abstract: The aim of this article is to confirm or reject assumptions about the existence of a relationship between the characteristics and abilities of an individual which are listed in the literature as characteristics of an effective entrepreneur, and the level of individual entrepreneurship in managerial practice. The paper is both theoretical and empirical in nature and consists of four main parts. The first part discusses the essence of entrepreneurship. Next, attention is focused on entrepreneurship understood as a complex personal competence and on the qualities characteristic of an effective entrepreneur as proposed in the literature. The third part presents the current state of knowledge relating to the influence of personality traits on an individual's level of entrepreneurship, citing the findings of other research in this area. Finally, the results obtained by the author as a result of the conducted pilot study are presented. This paper fully corresponds with the issues undertaken within the scope of the European Conference on Innovation and Entrepreneurship and contributes to expanding the knowledge relating to the existence of a relationship between entrepreneurial profile and the level of individual entrepreneurship. Moreover, it can also provide inspiration for conducting further empirical research in this area. This study was conducted within the research project "The impact of managerial intuitive potential on the effectiveness of decision making processes", financed by the National Science Centre, Poland (funds allocated on the basis of decision No. DEC-2014/13/D/HS4/01750).

Keywords: entrepreneur, entrepreneurship, individual entrepreneurship.

1. Introduction

Entrepreneurship is an extremely important and useful notion both at the level of individuals and at the level of teams, organizations, regions and countries (Oleksyn 2012, p. 23). For this reason, it is a subject that continues to attract the interest of management theoreticians and practitioners. Significant interest in entrepreneurship, however, has not resulted in the formulation of a universal definition of this concept.

According to differing approaches, it is defined as a process, as a type of behaviour, or as a set of personality traits characteristic of an entrepreneur. In the literature, extensive lists of attributes, skills, abilities and predispositions characteristic of an effective entrepreneur can be found. It seems reasonable to try and ascertain whether possessing such features translates into the level of a person's individual entrepreneurship (undertaking entrepreneurial activities in managerial practice). In order to find an answer to the above question, the author has conducted an empirical pilot study in this area.

The aim of this article is to confirm or reject assumptions about the existence of a relationship between the individual characteristics and abilities of an individual which are listed in the literature as characteristics of an effective entrepreneur, and the level of individual entrepreneurship in managerial practice. The paper is both theoretical and empirical in nature and consists of four main parts. The first part discusses the essence of entrepreneurship. Next, attention is focused on entrepreneurship understood as a complex personal competence and on the qualities characteristic of an effective entrepreneur as proposed in the literature. The third part presents the current state of knowledge relating to the influence of personality traits on an individual's level of entrepreneurship, citing the findings of other research in this area. Finally, the results obtained by the author as a result of the conducted pilot study are presented.

2. Literature review

2.1 The essence of entrepreneurship

Formulating a precise definition of entrepreneurship poses many problems. This is due to the fact that it is a multi-faceted and multi-dimensional concept. It can pertain to both individuals and teams, along with entire organizations and communities. In the literature there is no single, universal definition of the concept of entrepreneurship. Table 1 presents some selected definitions of entrepreneurship proposed by leading representatives of research in this field.

Table 1: Selected definitions of entrepreneurship

Author	Definition of entrepreneurship	Key aspects	Approach
J. Schumpeter	It is a process of creative destruction which results in new combinations of production factors, being the sources of entrepreneurial activities (Schumpeter 1990, p. 104).	– innovation, breaking the routine	– entrepreneurship treated as a process
J. Timmons	It is a way of thinking, reasoning and acting focused on seeking opportunities (Glinka 2008, p. 15).	– identification of opportunities	– entrepreneurship treated as a type of behaviour
W. Gartner	It is an act of creation, innovation, creating a new entity (Gartner 1992).	– innovation	– entrepreneurship treated as a process
J. Timmons and H. Stevenson	It is a process of creating and identifying opportunities and exploiting them regardless of the resources possessed. Entrepreneurship is a creative act of an entrepreneur, who starts or builds an enterprise by adopting an active attitude instead of passive observation (Timmons 1999, p. 218).	– generating and identifying opportunities	– entrepreneurship treated as a process
G.S. Mesch and D. Czamanski	It is an adaptive response to changes in the environment, mainly in the labour market (Mesch, Czamanski 1997, p. 597-610).	– adaptation to change	– entrepreneurship treated as a type of behaviour
N. Churchill	It is a process of discovering and shaping opportunities for creating new values through innovation, obtaining the necessary resources and managing the value creation process (Targalski, Falencik 2009, p. 87).	– identifying and shaping opportunities, – innovation	– entrepreneurship treated as a process
A.P. Wiatrak J. Wilkin	It is a set of traits, talents, skills,as well as the system of values, motivation and actual behaviour of a person referred to as an entrepreneur (Wiatrak 2001, p. 21; Wilkin 2008, pp. 57-66).	–the personality traits, predispositions and competences of an entrepreneur	– entrepreneurship treated as a complex personal competence

Source: own compilation.

Summarizing the definitions of entrepreneurship presented in Table 1, it can be noticed that this concept concerns a range of aspects, the most common and fundamental being innovation as well as the creation, identification and exploitation of opportunities. It can also be noted that entrepreneurship is approached in three basic ways:

- as a process (entrepreneurship is treated as a set of interrelated activities, the implementation of which is necessary to obtain a specific result),
- as a type of behaviour (entrepreneurship is perceived as a way of acting in a specific situation; behaving, acting or reacting to stimuli),
- as a set of personality traits (entrepreneurship is defined as a set of specific features, predispositions and abilities characteristic of an entrepreneur).

The understanding of entrepreneurship adopted in this study is one which defines the concept as a complex personal competence, according to which specific personality traits create the specific profile of an entrepreneur.

2.2 The profile of an effective entrepreneur

In the classic perspective, an entrepreneur is a person that is both the founder of a company and its manager, who bears the full risk and financial responsibility connected with running it. With the emergence of increasingly larger enterprises, the unity of these three functions has been disrupted; which can mean that one person founds the company, another manages the company, and still another shoulders the financial risk. The importance of entrepreneurs decreased in the 20th century due to the emergence of professional managers.

Therefore, the capitalism of the 1960s, 1970s and 1980s is called "managerial capitalism." The last two decades of the 20th century, however, saw a resurgence of entrepreneurship and a return to the classical understanding of an entrepreneur.

An effective entrepreneur is characterized by specific features that create a consistent profile. These qualities include the following (Oleksyn 2012, p. 12):

- having passions and interests (activeness),
- mindfulness, ability to notice opportunities,
- creativity,
- ability to assess and take risks,
- apt formulation of mission and vision,
- having a business idea,
- ability to reach the right people and bring them round to one's ideas,
- boldness and tenacity,
- intuition,
- flexibility.

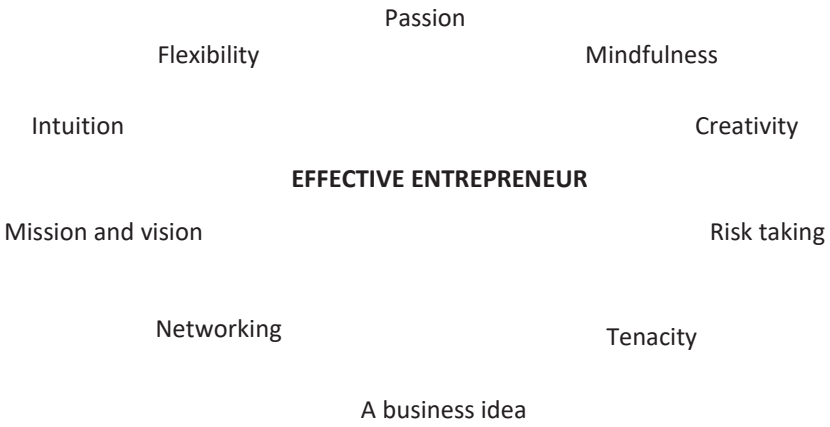

Figure 1: The features of an effective entrepreneur

Source: own compilation based on (Oleksyn 2012, p. 12).

An effective entrepreneur is primarily characterized by passion in their actions, especially when it comes to business operations. The entrepreneur is interested in the sector in which the company operates. Such a person has a positive attitude towards customers and products; hence they are able to become really committed and devote a lot of time to work.

Another important feature of an entrepreneur is mindfulness, also referred to as watchful concentration. This concerns the ability to identify opportunities that appear in the environment.

The next feature which is desirable in the profile of an effective entrepreneur is creativity. It should be emphasized, though, that entrepreneurs themselves do not have to be inventors. However, they should understand the importance of innovations and inventions for the effective functioning of an enterprise.

An entrepreneur's creativity is directly related to having a business idea. An effective entrepreneur must provide the company with a product that will find a sufficient number of buyers. However, it should be remembered that in this approach creativity must have a continuous character. This is because the success of a current business domain does not necessarily mean that it is going to be successful in the future. An entrepreneur's creativity is not limited to specifying the product and the business domain. It also involves the ability to formulate the appropriate mission and vision, as well as building a network of connections both within the company and in its environment.

As no business activity is risk-free, an important feature of an effective entrepreneur is their ability to assess and take risks. People with a strong need for security do not seem to be suitable for undertaking the role of entrepreneurs.

An important element from the point of view of the conduct of business operations is an appropriate, in terms of content, formulation of the mission and vision. If these objectives are defined accurately and honestly, they

unite all the employees around the process of their implementation while fulfilling a motivational and integrative function.

The ability to reach the right people (co-workers, business partners, representatives of the financial sector and the media) and bring them round to one's ideas often turns out to be a crucial feature of an effective entrepreneur. This feature is associated with a high level of social skills, including communication skills, empathy, negotiation skills, tact, patience, and a sense of timing (Poissant, Godefroy 1993, p. 164).

Success in running a business requires time and resistance to failure. Therefore, an entrepreneur should be psychologically resilient, persistent, patient and tenacious.

An entrepreneur's intuition is a factor that largely determines the success of a business. This is because not everything can be measured, calculated and predicted. Sometimes an entrepreneur's conviction about the rightness of decisions made without the support of rational arguments determines their company's advantage in the market.

The final feature of an effective entrepreneur is flexibility, which is essential both in formulating goals and finding ways to achieve them.

2.3 The qualities of an effective entrepreneur in relation to managerial practice

Over the last three decades, many researchers have attempted to determine the impact of selected personality traits on entrepreneurial activities. Table 2 presents selected results of research in this area.

Table 2: Selected empirical studies into the relationship between specific personality traits and the level of individual entrepreneurship

Author and year	Trait/ability/predisposition	Relationship
D. Hull, J. Bosley, G. Udell 1980 C.K. Kay 1986 G. Hills, G.T. Lumpkin, R.P. Singh 1997 S.Y. Lee, R. Florida, Z.J. Acs 2004 A. Ardichvili, R. Cordozo, R. Sourav 2003 D. Dimov 2007 L. Kirzner 2009 J. Heinonen, U. Hytti, P. Stenholm 2011 N. Nicolaou and S. Shane 2015	Creativity	• D. Hull: the author stated that entrepreneurs are characterized by a higher level of creativity than non-entrepreneurs (Hull, Bosley, Udell 1980), • C.K. Kay: according to the author, creativity plays a key role in an entrepreneur's decision-making process (Kay 1986), • G. Hills: research conducted by the author showed that 90% of respondents consider creativity as an important feature in the process of identifying opportunities (Hills, Lumpkin, Singh 1997), • S.Y. Lee: the author proved that people who start a business are characterized by a relatively high level of creativity (Lee, Florida, Acs 2004), • A. Ardichvili, D. Dimov, L. Kirzner, J. Heinonen: summarizing their research, the authors concluded that creative people are more capable of recognizing business opportunities (Ardichvili, Cardozo, Sourav 2003; Dimov 2007; Kirzner 2009; Heinonen, Hytti, Stenholm 2011), • N. Nicolaou and S. Shane: the authors identified the existence of a relationship between having a creative personality and undertaking entrepreneurial activities and starting a business. In addition, they also found a linear relationship between a creative personality and the ability to identify opportunities. According to the researchers, some individuals have a predisposition to enhance their creative personality and at the same time to be entrepreneurs. It should be emphasized that such predispositions are primarily genetically determined (Nicolaou , Shane 2015).
C.P. Neck and C.C. Manz 1992, 1994 N.J. Kruger and P.R. Dickson 1994	Optimism	• N.J. Kruger and P.R. Dickson showed that optimism affects the effectiveness of one's actions. Optimism in this case relates to the ability to achieve ambitious goals rather than being identified with a propensity for taking risks (Kruger, Dickson 1994), • C.P. Neck and C.C. Manz observed that an entrepreneur's effectiveness influences their optimism and results in a greater tendency to see opportunities rather than threats in a given situation (Neck, Manz 1992, 1996).
G. Hills 1997	Networking	On the basis of his research, the author proved that entrepreneurs who have an extensive network of connections with other businesses are able to identify significantly more opportunities than entrepreneurs operating individually (Hills, Lumpkin, Singh 1997).

Author and year	Trait/ability/predisposition	Relationship
W.H. Stewart and P.L. Roth 2004	Risk propensity	Based on their research, the authors formulated a conclusion that there is a relationship between risk propensity and undertaking entrepreneurial behaviours (Stewart, Roth 2004).
H. Zhao and S. Seibert 2006	Conscientiousness and openness to experience	The authors proved that a relationship exists between two personality traits and the level of individual entrepreneurship. These traits are conscientiousness, understood as hard work and motivation in the pursuit of goal accomplishment; and openness to experience, defined as intellectual curiosity, seeking new experiences and exploring novel ideas (Zhao, Seibert 2006).
W.H. Stewart, P.L. Roth 2007	Achievement motivation	In the course of empirical research, the existence of a relationship between a person's internal achievement motivation and their individual entrepreneurship was confirmed (Stewart, Roth 2007).

Source: own compilation.

Summing up the list of empirical studies presented in Table 2 concerning the existence of a relationship between certain personality traits, abilities and predispositions of individuals and the level of their individual entrepreneurship, it can be noticed that although extensive lists of qualities characteristic of an effective entrepreneur have been compiled in the literature, in practice the relationship has only been empirically verified between selected features and the level of entrepreneurship. The relationship between individual entrepreneurship and the level of a person's creativity is the best documented. The authors showed that people with a higher level of creativity are more effective as regards starting a business and making decisions while conducting business operations, as well as generating, identifying and seizing opportunities which appear in the environment. Other features whose impact on an individual's level of entrepreneurship has been verified are an entrepreneur's optimism, network of connections, risk propensity, conscientiousness, openness to experience, and achievement motivation.

3. Research methodology

The aim of this article was to identify the relationship between the personality traits defined in the literature as characteristic of an effective entrepreneur and the level of a person's individual entrepreneurship. In order to verify the above research problem, a pilot empirical study was conducted.

The research involved 48 managers representing all levels of management (the entire management team of one company operating in the food industry) and made use of the survey method. The questionnaire consisted of two principal parts: one part designed to determine the intensity of the personality traits and predispositions typical of an effective entrepreneur, and the second part designed to diagnose the level of individual entrepreneurship. In the first part of the questionnaire the respondents were asked to assess whether and to what extent they possessed the personality features selected by the author. The list comprised 17 traits and abilities, which were evaluated on a scale from 1 to 5. The second part contained a tool for measuring individual entrepreneurship in the form of a test developed by W. Dyduch (Dyduch 2008, p. 55).

The test consisted of 10 questions. For each of the questions the respondent could choose one of three possible answers. In total, each respondent could score between 26 and 100 points. The interpretation of the test results was as follows: the higher the score, the greater the respondent's inclination to undertake entrepreneurial behaviours.

In order to identify the existence of a relationship between having certain personality traits characteristic of a typical entrepreneur and the level of individual entrepreneurship, the Pearson linear correlation coefficient was used to determine the level of linear relationships between the random variables. The value of the correlation coefficient falls within the closed interval [-1, 1]. The higher its absolute value is, the stronger the linear relationship between variables. A value of 0 means that there is no linear relationship between the variables; a value of 1 is interpreted as a positive relationship between the analysed variables; while a value of -1 indicates the existence of a negative relationship between the examined features. In order to verify any potential regularities, one of the most popular and most frequently used statistical methods, analysis of variance (ANOVA), was also used.

4. Empirical research results

An analysis of the results obtained did not reveal the existence of a relationship between the average score for all the assessed features that make up the profile of an effective entrepreneur and the level of a person's

individual entrepreneurship. However, relationships were observed between certain specific features and individual entrepreneurship. The statistical analyses proved that there are weak relationships (correlation strength 0.2-0.4) between 4 out of the 17 assessed qualities and predispositions, and individual entrepreneurship. The four features are the following:

- independence in decision-making (decision readiness – the ability to make decisions even when insufficient information is available),
- proactiveness and strong motivation to achieve goals,
- risk propensity,
- ambition.

It can be noticed that the results obtained partially confirm the findings previously obtained by other researchers. W.H. Stewart and P.L. Roth identified a relationship between the propensity to take risks and the entrepreneurial behaviour of an individual (2004). In subsequent research the same authors also showed the existence of a relationship between internal motivation to achieve goals and the level of individual entrepreneurship (2007). The characteristics whose influence on engaging in entrepreneurial behaviour has not been confirmed in earlier research include independence in making decisions, proactiveness and ambition.

Independence in decision-making is connected with readiness to make decisions in every, even the most extreme, circumstances. Ambition is associated with setting goals that force an individual to develop and push certain boundaries. Finally, proactiveness means a willingness to act and tackle new challenges.

The research also discovered some correlations between the ratings assigned to individual features. The higher the respondents assessed the level of their self-esteem, the higher they rated their propensity for taking risks.

A similar relationship occurred between enthusiasm and dedication to work, and ambition.

5. Conclusions

Entrepreneurship is a complex and ambiguous concept. It is defined as the fourth factor of production, a process, a complex personal competence, an attitude or behaviour. It is often postulated that not only entrepreneurs and enterprises, but also employees or even whole societies could be entrepreneurial. That is why the need to develop entrepreneurship is increasingly emphasised, and this development should occur in different places and at different levels.

One of the most popular approaches to entrepreneurship is that which perceives it as a set of traits, abilities and predispositions of an individual. In the literature, the authors present extensive lists of the qualities and abilities of an effective entrepreneur. However, only in the case of a few of those features has their real impact on individual entrepreneurship been verified. In this article, the author attempted to determine the relationship between the features and predispositions of an effective entrepreneur indicated in the literature and a person's level of individual entrepreneurship. The following conclusions can be drawn from the pilot study conducted:

1. No relationship has been found between the set of features forming the profile of an effective entrepreneur (the average rating for all the features included in the profile) and the level of individual entrepreneurship,
2. Weak relationships were identified between four personal characteristics and a person's level of entrepreneurship. These features were decision readiness (connected with independence in making decisions and the ability to make decisions even in conditions of uncertainty); proactiveness and strong internal motivation to achieve goals; a propensity for taking risks; and ambition. A higher degree of these features was reflected in a respondent's higher level of individual entrepreneurship,
3. Relationships between the assessments of certain features were identified. A higher rating given to the self-esteem trait was accompanied by a higher assessment of the risk propensity level. A similar relationship occurred between the assessment of enthusiasm and dedication of work, and ambition,
4. It would seem desirable and cognitively interesting to conduct in-depth empirical research in this area, the results of which could be applied in managerial practice. The findings of such research could make it possible to construct a hierarchy of the attributes and abilities of an effective entrepreneur. In view

of P. Drucker's assertion that entrepreneurship is a way of behaviour, a discipline that can be practised and learnt [Drucker 1992, pp. 29-30], it can be assumed that such a hierarchy of qualities and predispositions would enable entrepreneurs to focus on developing and enhancing those features that have the greatest impact on individual entrepreneurship.

The Role of Informal Micro-Entrepreneurs in the Development of a Rural Border Region

Abstract: The informal sector plays an important role in developing economies and peripheral rural regions, particularly in areas near borders. Businesses in the informal economy are flexible, adapting quickly to changing market demand and supply situations. This sector also generates employment, helps diversify economic activities, provides raw materials to local producers and helps alleviate poverty. Informal businesses are attractive to workers and companies worldwide because these firms typically require relatively little capital, offer greater independence and flexibility and provide opportunities for economic independence and better wages, as well as the most important advantage of evading regulations and taxation. Many entrepreneurs select the informal sector purely as a result of structural disadvantages arising from these individuals' gender, income, education, class, ethnicity or religion. Self-employed workers are considered by experts more likely to operate in the informal economy when these workers live in peripheral rural regions. The present study thus sought to identify the motivations of informal micro-enterprises and their role in the development of a rural border region in Portugal, analysing the perspective of micro-entrepreneurs, customers and local government. Qualitative data analysis was carried out on in-depth, semi-structured interviews with 9 informal entrepreneurs from 3 different sectors (i.e. agro-food, agriculture and handicrafts) and 8 regular clients in a northern border region of Portugal. The content analysis of interviews was done with QSR International's NVivo Version 11 software. The results suggest that more than 75% of the informal entrepreneurs interviewed are innovative and independent and that they are passionate about their enterprises. They do not want to formalise their business because they do not see any advantage in doing so. In addition, customers and local government officials see these businesses as boosting economic development in their region. The findings contribute to a deeper understanding of entrepreneurs' motivations to avoid legalising their micro-businesses and clients' perception of these enterprises. The results imply that researchers need to examine how national and local government policymakers can create laws that stimulate micro-entrepreneurs' transition from the informal to formal economy, including further dissemination of the benefits of formalising micro-businesses, especially in rural border regions.

Keywords: micro-entrepreneurs, informal economy, economic impact, rural development, border region

1. Introduction

For many years, scholars have struggled to achieve a consensus on why some entrepreneurs avoid making their business ventures entirely legitimate and instead operate informal enterprises. These businesses are either not constituted as a legal entity independent of the owner, do not keep formal accounts and/or are not registered with the authorities, including for tax purposes (International Labour Organisation, 2012). The generally accepted working definition of an entrepreneur is somebody actively involved in starting a business or the owner and/or manager of a firm (Reynolds *et al*., 2002). Therefore, Williams (2015: 5) states that: "[Informal entrepreneurs are] those starting a business or are the owner/manager of a business who engage in monetary transactions not declared to the state for tax, benefit and/or labour law purposes when they should be declared but which are legal in all other respects". The only illicit aspect of their activity consequently is that, when trading licit goods and/or services, some or all of these entrepreneurs' monetary transactions are undeclared.

In recent years, many studies have focused on the informal economy, with the majority concentrating on developing or emerging economies in which this phenomenon is far more common (Babbitt, Brown and Mazaheri, 2015; Adom, 2016; Williams and Shahid, 2016; Eijdenberg and Borner, 2017). In addition, researchers have investigated differences based on gender, reaching the conclusion that women are more likely to engage in informal entrepreneurship activities (Franck, 2012; Babbitt *et al.,* 2015; Quagrainie, 2016; Ratten, 2016; Marques *et al.*, 2017). Thus far, few studies have been conducted in developed economies and

especially in rural border regions. In order to contribute to bridging this research gap, the present study sought to identify the motivations of informal micro-entrepreneurs and their role in the development of a rural border region in Portugal, by analysing the perspectives of these micro-entrepreneurs, their customers and local government officials.

This paper is structured as follows. Section two reviews the literature on informal entrepreneurship and its impact on regional development. Section three outlines the research methodology, after which section four presents the results. Section five offers the study's conclusions, policy implications and limitations.

2. Literature review

Informal entrepreneurship is a globally represented characteristic of entrepreneurial activity, mainly differentiated from other forms of entrepreneurship by occurring outside of official regulations and/or laws while being accepted and tolerated to different degrees by various groups in societies (Welter *et al*., 2015).

The term 'informal economy' was first introduced at the beginning of the 1970s, although much evidence indicates that this type of activity existed prior to that time (Webb *et al*., 2014). Informal economies play a key role in business activities worldwide (Babbitt *et al*., 2015; Al-Mataani *et al*., 2017) but to a different degree in every country (Saunoris and Sajny, 2017). This topic has recently received increasing attention from researchers (Ratten, 2016; Eijdenberg and Borner, 2017).

The growing literature on the informal economy has sought to define informal economic activities in order to differentiate them from formal activities (Al-Mataani *et al.,* 2017). Scholars have argued that this term describes 'an endeavour occurring outside of formal institutional prescriptions but within the norms, values, and beliefs of informal institutions' (Williams *et al*., 2016a: 775). Nonetheless, the distinction between formal and informal economies is still fuzzy (Welter *et al*., 2015), and close connections can exist between the two types of activities (Peberdy, 2000). One persistent belief is that informal entrepreneurship is a survival strategy (Adom, 2016), but this perception has begun to change because emerging research has advanced the notion that many entrepreneurs voluntarily choose to operate entirely or partly within the informal economy to avoid the formal economy (Adom, 2016). Informal entrepreneurship activities carried out on a 'cash-in-hand' basis may be seen as adding to individuals' income from their formal activities or may represent the only income available for a household or family (Welter *et al*., 2015).

2.1 Explanatory theories

The neo-liberal approach to economics treats informal entrepreneurship as a result of rational individuals' voluntary choice to operate in the informal economy because of overly heavy regulations (Williams and Martinez, 2014; Williams *et al*., 2016b). Entrepreneurs have to elect to operate informally or formally, and this decision is influenced by countless factors (Siqueira *et al*., 2014). To run a formal business often requires entrepreneurs to register their firms, and this act is associated with various costs (Siqueira *et al.*, 2014).

Registration contributes to government institutions' awareness of these enterprises and, subsequently, to the need to meet regulatory requirements and pay taxes (Siqueira *et al.*, 2014). In contrast, the political economy perspective argues that informal entrepreneurship is a result of too little government intervention, which excludes entrepreneurs from the formal economy (Williams and Martinez, 2014; Williams *et al*., 2016b).

However, only a few scholars currently view informal entrepreneurship as either a necessity or an exit option (Williams *et al*., 2016b). Instead, most researchers feel 'that a nuanced, context-bound understanding of informal entrepreneurs' rationales is required which recognises how this varies across various socio-demographic, firm-level and regional populations' (Williams and Martinez, 2014: 235).

Micro-entrepreneurship can be defined as businesses with a maximum of 9 employees, which play an important role in Europe's economy (Klöppel and Stummer, 2015). Although micro-entrepreneurs do not have sufficient resources to modernise, they usually have a medium-term strategic vision and developed organisational skills. Their businesses are frequently profitable, and these individuals sometimes make an effort to formalise their activities. This is in contrast to entrepreneurs who engage in survival activities, possess limited planning and organisational capacities and cannot afford to formalise their businesses (Zuin, 2004).

Researchers have demonstrated that economic growth in less developed areas results from micro-entrepreneurs' business activities and industriousness (Gosenpud and Vanevenhoven, 2011). For example, micro-entrepreneurs in India use the informal economy to increase their income, earning nearly twice that of other informal employees (Gurtoo, 2009). A large number of people in these regions fall into this category, especially as poor women use small businesses as a livelihood strategy (Mukherjee, 2016). Nonetheless, women's informal micro-entrepreneurship is not necessarily linked to poverty or exclusion from the labour market. Franck (2012) discovered that women are motivated by their own and their families' future outcomes. Women's competitive behaviour is also a significant variable in the growth of micro activities (Quagraine, 2016). Overall, Williams *et al*. (2016b: 322) found that 'the major determinants of the level of informality of micro-enterprises are the characteristics of the entrepreneur and enterprise, rather than their motives and the wider formal and informal institutional environment'.

2.2 Informal entrepreneurship and regional development

Border regions are normally the most disadvantaged areas given their peripheral geographic and economic position, but they also offer the advantage of exploiting variations in prices and goods between the countries in question (Xheneti *et al.*, 2013). Scholars have failed to reach a consensus about whether informal activities in these regions foster development or inhibit the evolution of dynamic cross-border networks (Xheneti *et al.,* 2013). However, informal entrepreneurship activities along borders clearly offer excellent opportunities to learn how to trade, which can develop into more substantial businesses in the formal economy over time (Xheneti *et al.*, 2013).

Entrepreneurs' transactions can remain in the informal economy to escape excessive transaction costs, but, as a result, these businesses do not contribute to gross domestic products (Saunoris and Sajny, 2017).

Nonetheless, informal entrepreneurship plays a central part in lowering poverty levels and functions as a substitute for the formal sector when entry barriers are excessively high (Babbitt *et al.*, 2015). The informal economy can have both positive and negative impacts on local and regional economies (Llanes and Barbour, 2007), and, in developing economies, this sector has an unfavourable effect on economic development and growth. Thus, many governments have sought to stimulate registration and formalisation (Williams *et al*., 2016a).

Regarding the positive and negative impacts of informal entrepreneurship, academics and policymakers largely agree that negative impacts outweigh positive impacts and, therefore, that interventions are required to reduce informal entrepreneurship (Williams, 2015). Table 1 summarises the main negative and positive impacts of informal entrepreneurship on different stakeholders.

Table 1: Negative and positive impacts of informal entrepreneurship on different stakeholders

Stakeholders	Negative Impacts	Positive Impacts
Informal Entrepreneurs	• Lack of access to credit and financial services partly due to limited credit histories • Difficulty in expanding businesses that cannot be openly advertised • Higher barriers to entry into the formal market due to an inability to provide employment histories that back up their skills	• Source of income to reduce poverty • Flexibility in where, when and how to work, which is especially important to women who remain responsible for childcare • Reduction of barriers to entry into the workforce because the majority of informal activities start with close social relationships
Formal Entrepreneurs	• Unfair competitive advantages for informal versus formal entrepreneurs	• Escape route for entrepreneurs from corrupt public sector officials • Exit strategy in contexts in which the regulatory burden stifles business development
Customers	• Lack of legal resources if poor work is done without insurance coverage • No guarantee that the work conducted has followed health and safety regulations	• More affordable products or services can be offered to or asked for by customers if payment is made in cash and no receipts change hands
Local and National Governments	• Loss of revenue for the central state in terms of non-payment of taxes	• Income from informal entrepreneurship spent in the formal economy boosts demand for formal goods and services and contributes to 'official' local and regional economic growth

2.3 Conceptual research model

Based on the present research's objective and the above literature review, a conceptual research model was proposed (see Figure 1). This study sought to identify the motivations of informal micro-entrepreneurs and their role in the development of a rural border region in Portugal, by analysing the perspective of micro-entrepreneurs, customers and local government officials.

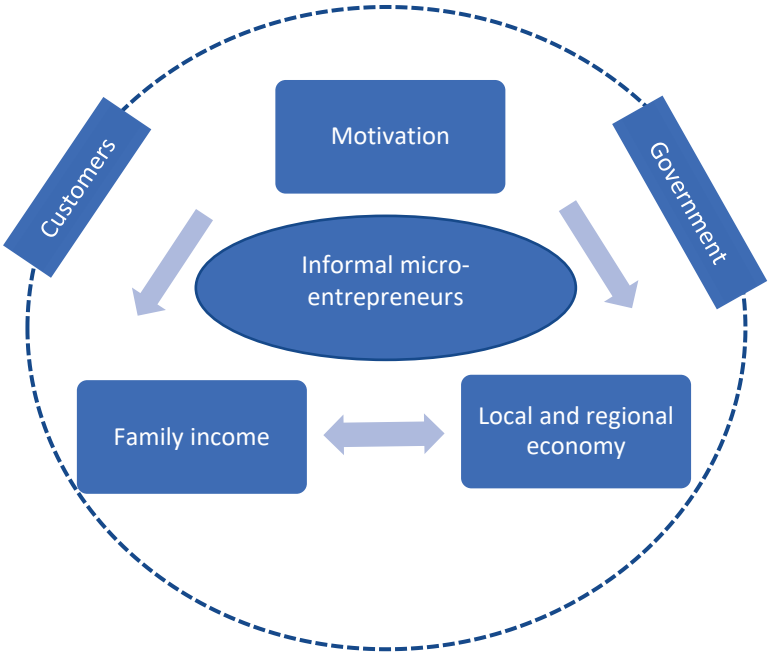

Figure 1: Conceptual model proposed

3. Methodology

The current research, therefore, used qualitative methods to conduct a case study of informal entrepreneurship. Qualitative data analysis was carried out on in-depth semi-structured interviews with 9 informal entrepreneurs in 3 different sectors (i.e. agro-food, agriculture and handicrafts), 8 regular clients and 1 local government official in a northern border region of Portugal. Data were collected on 13 April 2018, during a witch festival held on a Friday the thirteenth.

Qualitative data analysis is a continuous, inductive process that involves immersion into interview transcripts and the application of coding categories. This process is based on data reduction and presentation and the extraction and verification of conclusions (Miles *et al*., 2014). In the present study, the first phase of coding was used to reduce the raw data into generic categories based on the research objectives, existing literature and recurrent themes. The data were then analysed further in order to identify patterns and relationships among the coding categories.

The primary method applied was discourse analysis using QSR International's NVivo Version 11 software to conduct qualitative analysis and build a theoretical framework. This method facilitated a close examination of the transcripts for linguistic patterns, while NVivo provided a means of storing, retrieving, categorising and encoding the transcripts (Wetherell *et al*., 2001; Gibbs *et al*., 2002). The analysis focused on the interviewees' words and actions, as well as documentation about these individuals' activities, to gain an in-depth understanding of the research topic. The relevant literature recommends the use of tools that facilitate computer-assisted analysis of qualitative data because of the benefits in terms of accuracy and validity, which can be difficult to achieve with manual methods (Lindsay, 2004). Excerpts from the data are presented in the results and discussion sections below to allow these human actors to speak for themselves whenever possible (Maykut *et al.*, 1994).

4. Results

4.1 Sample characterisation

The sample included nine informal entrepreneurs, 66.67% of whom are female and 33.33% male. Relative to their age, interviewees were between 30 and 67 years old, with an average age of 42.22 years old and a standard deviation of 10.2 years old. The most representative age groups were those between 30 and 39 years old, and interviewees between 40 and 49 years old, each representing 44.44% of the sample. Regarding educational qualifications, 33.33% of the informal entrepreneurs had econdary education. Two groups – those with a university degree and those who had completed the third cycle of mandatory secondary education – were quite representative of the sample as both were 22.22%. Except for one interviewee, who was single, all were married, and 77.78% had children. All informal entrepreneurs had their main office at home, where they carried out activities in three different sectors (i.e. agro-food, agriculture and handicrafts).

Entrepreneurial passion is defined as a set of intense positive feelings that are consciously accessible and experienced through involvement in entrepreneurial activities associated with roles that are significant to entrepreneurs. This passion also involves a strong inclination to engage in activities that the entrepreneurs like and consider important and in which they invest time and energy. All the informal entrepreneurs interviewed consider their passion the most important dimension of their individual entrepreneurial orientation, followed by innovation and autonomy. More than 80% of these individuals started their informal business out of necessity, and all reported that, after starting their business, they doubled their household income.

4.2 Motivations to legalise their businesses

When asked what motivated them to create an informal business, the interviewees cited financial reasons, with one person mentioning that 'what I earned was not enough to feed a household' (InfEnt1). Others asserted that their business is about providing 'an additional boost to the household income' (InfEnt7).

However, other motivations were also mentioned such as the possibility of 'creating [their] own job' (InfEnt2), being able to manage their 'time and having no boss in [their] business' (InfEnt9), as well as 'promoting the best of Portugal' (InfEnt6).

When the interviewees were asked to assign a degree of importance to a set of motivations considered determining factors in the formalisation of businesses, these individuals emphasised access to social security benefits and the possibility of growing as an entrepreneur. Although these informal entrepreneurs assigned slightly less value to other factors, they also mentioned that formalisation would make it easier for them to sell to public institutions and other organisations that require invoices, to control their accounting more effectively or to hire employees with access to the Institute of Employment and Training and other sources of support. The interviewees attributed the least importance to gaining access to bank financing.

4.3 Effects of business on household income

When asked about the effects of their business on household income, the informal entrepreneurs were almost unanimous in reporting 'a very positive impact of having more money to buy things for [their] home, [and] food and other goods' (InfEnt1). In certain cases, the interviewees contribute to ensuring their spouse is not the only 'that brings money home. ... [They] also contribute with [their] work' (InfEnt9) to guarantee 'higher household income, greater purchasing power and increased equity' (InfEnt2).

Based on an analysis of the socio-demographic data provided, all these entrepreneurs improved their financial situation by creating their business. Almost everyone underlined that they were in a difficult financial situation (i.e. less than 5,000 euros a year) and that their business turned out to be a reasonably good source of revenue, with an annual increase in income in all cases. Most of these entrepreneurs' businesses were started out of necessity, and only one entrepreneur saw it as an opportunity.

4.4 Effects of businesses on local and regional economy

The informal entrepreneurs interviewed started by pointing out that 'informal businesses are very important for this region. ... We have many people in the region working in the agro-food sector' (InfEnt1). Concerning the effects of their businesses on the local and regional economy, three types of effects were highlighted. First, the interviewees emphasised that the region's products are recognised by those outside the area as 'it helps that the potatoes and the county has become famous and attracts a lot of people' (InfEnt8). These

entrepreneurs refer to their businesses as a way to ensure 'work that people of the region can be proud of because there are not many people making handmade linen towels' (InfEnt9).

Second, their activities enable more money to circulate, which in turn has led to 'having more money to buy goods. [We are] helping the local economy with [a greater] flow of money' (InfEnt1). Last, they point out that their businesses promote self-employment. We 'were able to live in Montalegre without having to emigrate' (InfEnt3). One interviewee said, 'people survive from the sales made. Otherwise they would be forced to emigrate' (InfEnt5). Thus, these informal entrepreneurs contribute significantly to keeping people in the region and diminishing the rural exodus to large cities or to other countries.

4.5 Effects of this type of business on region from clients' perspective

An analysis of the interviewed clients' perspectives on the effect of informal businesses on local and regional economy revealed a unanimous agreement on three types of outcomes. First, the financial situation of the entrepreneurs' families has improved. One client stated:

> *It enables people to create better financial conditions for themselves, providing higher household income by selling these products. They end up earning money, and, at the end of the month, it is more money that comes in and that people have available. (Client4)*

Second, the interviewees strongly emphasised that the main, most decisive effect on the region is that informal businesses 'help keep families here in Montalegre' (Client6). Another client added, 'they don't have to emigrate or leave the region' (Client8). Last, customers point to another fundamental effect on the local and regional economy, namely, that 'it also promotes regional products' (Client2). The informal entrepreneurs thus take the local products and brands further, promoting them and drawing customers' attention to the best merchandise, as well as publicising the region's specificities, such as gastronomy, culture, traditions and practices.

The local government supports and promotes all kinds of witch festivals and gastronomic and agro-food fairs throughout the year. The official interviewed reported that:

> *They attract lots of customers to witch festivals and agro-food fairs, who buy, sleep and eat in the region, [and] spend their income … . Many families in the region live year-round on sales revenues from these festivities and fairs. Most of them have informal businesses. (Local Government Official)*

Customers and local government officials, therefore, see these informal businesses as boosters of economic development in this region.

5. Conclusions

This study sought to identify the motivations of informal micro-entrepreneurs and their role in the development of a rural border region in Portugal, by analysing the perspectives of micro-entrepreneurs, customers and local government officials. The findings suggest that more than 75% of the region's informal entrepreneurs are innovative and independent and that they have a passion for their business. They avoid formalising their activities because they see no advantages in doing so. Customers and local government officials perceive these businesses as boosting the region's economic development. These results contribute to a fuller understanding of some entrepreneurs' motivations not to legalise their micro-businesses and their customers and local government officials' perceptions of these businesses and their importance to the local economy.

Despite the significance of informal entrepreneurship in local economies, especially in low-density rural areas and border regions, officials should consider and discuss measures and programmes that can help transform some informal businesses into formal ones. Researchers need to examine how national and local policymakers can create laws that stimulate micro-entrepreneurs' transition from the informal to formal economy, including further disseminating the benefits of formalising micro-businesses, especially in rural border regions. The questions that remain include which policy measures are most effective and which sequences and combinations of measures are currently most successful and thus need to be evaluated.

Clearly, governments need to move away from deterring informal entrepreneurship and towards the use of incentives and indirect controls if formalisation of informal entrepreneurship is to occur. According to Williams (2015), various policy measures are required for different types of informal entrepreneurs. In other words, a tailor-made approach to formalising informal entrepreneurship is required to tackle the specific barriers to formalisation confronted by different sectors, cultures and regions. A variety of stakeholders in each region must be involved in the planning and implementing of policy measures (i.e. informal micro-entrepreneurs, customers, formal entrepreneurs and local government officials).

This research's results present some limitations in that the sample's size and qualitative analysis methods mean the findings cannot be applied to the entire informal sector. Future investigations may want, first, to use questionnaires to test a more empirically robust model. Second, researchers need to verify whether significant differences exist in the informal economy, taking into account sectors, genders, cultures and regions. Third, further studies could apply the same research methods in other border regions. Last, other research may want to examine the programmes and policies that encourage micro-entrepreneurs' transition from the informal to formal economy.

Enlivening HEIs as Creative, Humanised and Innovative Environments

Ana Martins and Isabel Martins
University of KwaZulu- Natal, South Africa
martinsa@ukzn.ac.za
martinsm@ukzn.ac.za

Abstract: The purpose of this research is to focus on the importance of distributed leadership in Universities and Higher Education Institutions (HEIs). The research question is whether there a significant finding in self-reported ratings of leadership styles of those respondents that are studying Management. The study aims to further discover whether students are encouraged to become responsible and proactive citizens, to develop their skills set, specifically shared leadership and higher-level skills to inspire creation knowledge, sharing and distribution thereof. Contemporary organizations need active and responsible individuals who are capable to make decisions swiftly and responsibly. Leadership influences innovative results and education plays a dynamic role in preparing graduates. Critical reflection of extant literature indicates a need for a culture of leadership and innovation to promote organizational sustainability in the globalised world. This study debates the need for HEIs to prepare the graduate for both organizations and society as a whole. This active collaboration should be the very essence of both universities and the industry in order for these to achieve responsible sustainability. Learning and innovation further depend on leadership efficacy. The self-efficacy construct highlights the importance of tacit knowledge because it leads to analysis and reflection on the unique capacity that individuals have to share complex and tacit knowledge. Self-efficacy is considered as the essential component for prepared organizational learning. This study follows the pragmatic paradigm methodology. Primary data collection is currently being gathered via the web-based questionnaire link which was made available on the UKZN notice system. The questionnaire has 35 items with a Likert scale of five response options. The purposeful sample method was used and the population entails the undergraduate and postgraduate students in the College of Law and Business, University of KwaZulu-Natal, South Africa. Limitations include the design of the study and the reliance on the quantitative data as the only method of primary data collection. This study is of added value for scholars and organizations in the innovation economy.

Keywords: Efficacy, Knowledge creation, Learning, Performance, Shared Leadership, Sustainability

1. Introduction

Responsible leadership embraces shared leadership among individuals in teams and distributed leadership in the organization as a whole, especially in the education sector. Currently, it is necessary to demystify the mystery that beholds the present HEI environment. This environment is the place wherein learning, teaching and endorsing the concepts of knowledge management takes place, as well as organization learning, complexity theory and a plethora of new models, concepts and ideas should be transmitted according to a holistic paradigm (Jasimuddin, 2008). The objectives of this study are to analyse the importance of responsible leadership education in universities HEIs to increase organizational sustainability; to ascertain the responsible leadership education effects on the continuous management learning of students in actual organizational business settings; to determine the rich implications to the organizational (re)creation of human bodies in the context of organized labour. The structure of this paper includes an introduction, a reflection of the constructs of responsible leadership, humanisation, self-efficacy, learning and distributed leadership. At the time of article submission, the primary data collection was still ongoing for this study. This relevance of this data is to determine the self-reported findings from the sample of undergraduate and postgraduate students about their leadership style. Conclusions and recommendations are provided based on the extant literature.

2. Responsible leadership education in universities HEIs to increase organizational sustainability

There are several definitions of responsible leadership and here a few are included that it is the “art of motivating, communicating, empowering and convincing people to engage with a new vision of sustainable development and the necessary change that this implies. Leadership is based on moral authority. Moral authority requires convictions, character and talent” (The Globally Responsible Leadership Initiative, GRLI, 2008, p.4). According to Mirvis (2010, p.10), Maak (2007) posits that responsible leadership entails, “building, cultivating and sustaining trustful relationships to different stakeholders both inside and outside the organization, and in coordinating responsible action to achieve a meaningful commonly shared business vision”. Pless (2007) maintains responsible leadership as a set of ethical principles, values-based relationships

between leaders and stakeholders. These are connected a shared sense of meaning and purpose. Inducing higher levels of commitment and motivation so as to achieve value creation and social change.

Furthermore, Mirvis (2010) postulates that Nike, Body Shop and Novo Nordisk are two examples of companies that exercise best practice in responsible leadership, a paradigm that should be nestled in a global context and across all sectors. Responsible leadership entails the development of a culture with beliefs and practices, from individual mindsets to collective paradigm changes that support responsible leadership. Universities are, in essence, institutions that generate and share knowledge. Likewise, a knowledge facilitator is the quintessence of the knowledge worker. In addition to sharing and generating knowledge, as a knowledge worker, the teaching faculty member also has the role to encourage the creation of new knowledge among students. The educator, in addition to transmitting specific content, performs the role of teaching individuals to 'think critically'. Several scholars support the argument that education is the centre of social strategic investment (Freire, 1978; Jasimuddin, 2005). Therefore, HEIs should achieve fundamental objectives to prepare the graduate by developing the person to be in tune with various contexts. There is a need for knowledge sharing and creation, networking and leadership as being the relevant criteria in an educational establishment and in any other organizations (Senge, 1990; Soliman and Spooner, 2000; Schonstrom, 2005). Additionally, any educational institution obliges those who teach the minds of tomorrow be champions of knowledge themselves (Schonstrom, 2005). This study argues that HEIs can prosper if they are able to apply the rhetoric they are keen to promote in the wider community (Schonstrom, 2005). Hence, universities should become a knowing organization instead of a knowledge sharer (Rowley, 2000).

Many Universities still currently follow hierarchical processes and systems in accordance with the mind-set of the scientific management paradigm (Martins, et al., 2013). Thus, a contradiction seems to be evident between the fact that some universities teach and encourage new mind-sets and management paradigms while still displaying a tendency to follow the Newtonian paradigm in their own managerial practices, organizational structure and culture. This juxtaposing situation can be discouraging towards the intended vision and mission that universities are supposed to adhere to as being institutions that encourage students to apply the knowledge gained in the organizations they are working with (Beijerse, 1999). If the role of university faculty is to share and provide knowledge, students should transform this knowledge into tacit knowledge. Nevertheless, the hurdle lies in whether universities practice this or not. Morrison (2010) further corroborates that complexity theory facilitates school leaders and managers to initiate conditions for organizational learning to occur and which is based on developing self-organization to deal with change. This self-organising replaces commanding particular actions and behaviours. In this way, command and control mechanisms can be substituted with budding, self-organization.

The conduit of sustainability necessarily encompasses the notions of responsible leadership, responsible education and ensuring that there is a commitment to humanising organizations. Morrison (2010, p. 384) and Fullan (2001, 2005) posit that '[educational] leadership and management are, at heart, deontological, valuative, humanistic and moral enterprises'. The notion of responsible education urges a reflection on humanisation. In this regard, according to Freire (1972b), praxis is essential to humanisation. Freire postulates praxis which is the notion of the dialogical reflection and action for social transformation. According to Freire, transcendental praxis is conscientization, or critical consciousness. Just as Freire viewed transformative leadership should create bonds with school, home, work, family and the community, the same should occur with responsible education in our current new age society of innovation. As a way of opposing the dominant and authoritarian approach to pedagogy, Freire critiqued the notion of banking. This type of education dissuades questioning because only the teacher knows and students have to passively listen and receive the content of the teacher's narration. Freire espoused a form of liberating education. This type of education was built on the idea of presenting problems instead of merely providing answers.

Dialogue is the foundation for educational communication and the fundamental goal is to develop critical consciousness. It is this dialogue and interaction with others in a world of constant change (Roberts, 2015, 2000), this intersubjective exchange that occurs between the self, nature (through its material aspect) as well as organizations (the social, structural, policies, practices and procedures) that enable individuals to actively partake in their pursuit of gaining knowledge and understanding. Freire further posits that the individual's active involvement is a practical illustration of becoming a subject instead of an object of history: "the individuals becomes a being who can, with others, play a part in transforming the social world" (Roberts, 2005, p. 383).

Freire's (1998a) philosophy of education is inexorably linked with the notion that individuals are imbued with autonomy and freedom to live as disciplined beings with power, with an ethical and responsible commitment towards the development of the self which is in a constant work in progress, characteristics which arise from the individuals' ability to develop a critical consciousness. Freire (1998a, p. 53) further depicts this competence as the aptitude to "spiritualize" the world in progress that individuals live in. Through knowledge and power, transformative leadership achieves its goals and strategies. Critical education, according to Freire, denotes the relationship between learning and teaching as '(w)hoever teaches learns in the act of teaching, and whoever learns teaches in the act of learning' (Freire, 1998a, p. 31). Therefore, transformative leaders lead by and through the leadership of those that they lead. Moreover, Freire appreciates that, in the individual's development as a knower, reason and emotions influence individuals (Freire, 1997a, 1998b; Roberts, 2010; Weiner, 2003). Freire also opined that, in view of the fact that education is constantly an ethical and political process (Freire, 1972a, 1972b, 1976, 1985; Roberts, 2000), policy development at the tertiary level education, is based on this premise. Indeed, this gives rise to limitations both in the view individuals have of themselves as well as their view of both the nature and purpose of education, which is frequently diminished to merely skills and method.

"Without hope there is no way we can even start thinking about education" (Freire, 2007a, p. 87). Freire (1994) maintains that the root of both hope and education are ontologically identical revealing a close bond between the two. Webb (2010) further posits that Freire maintains hope is an "essential component" (Freire, 1998a, p. 69) for human existence. Furthermore, Weber (2010) sustains that education evokes and guides hope. Hope and knowledge enthuse the individual with the capability to delight in desires, dreams, emotions (Freire, 1993; 2007a; 2007b). Furthermore, Freire (2007b, pp. 82–83) corroborates that hope instils individuals with values of humility, trust, courage, perseverance and serenity.

In this regard, the United Nations Principles for Responsible Management Education (PRME) include six principles:

1. Purpose (We will develop the capabilities of students to be future generators of sustainable value for business and society at large and to work for an inclusive and sustainable global economy)
2. Values (We will incorporate into our academic activities and curricula the values of global social responsibility as portrayed in international initiatives such as the United Nations Global Compact)
3. Method (We will create educational frameworks, materials, processes and environments that enable effective learning experiences for responsible leadership)
4. Research (We will engage in conceptual and empirical research that advances our understanding about the role, dynamics, and impact of corporations in the creation of sustainable social, environmental and economic value)
5. Partnership (We will interact with managers of business corporations to extend our knowledge of their challenges in meeting social and environmental responsibilities and to explore jointly effective approaches to meeting these challenges)
6. Dialogue (We will facilitate and support dialogue and debate among educators, students, business, government, consumers, media, civil society organizations and other interested groups and stakeholders on critical issues related to global responsibility and sustainability)

Source: www.unprme.org

Based on the abovementioned principles, Universities and HEIs should provide their students with a balance between technical and soft skills that will empower these individuals to achieve positive organizational outcomes in the leadership process, spreading from the organization in particular to society at large.

Therefore, it is perceived that leadership behaviours have a noteworthy effect on innovation outcomes.

Contemporary organizations, being flatter than the traditional hierarchy, need autonomous knowledge workers to enhance their relational capital by engaging their whole new skills set with and through individuals.

Herein arises the potential for distributed leadership. Innovation and creativity arise in an environment where contemporary work and tasks are less repetitive. Human, emotional and spiritual capitals and competencies, new age in nature, enable organizations to develop cognitive thinking models and their collective, interactive

and participative learning capabilities. Leadership programmes at HEIS are defied to change direction in order to encourage partnership and network building; these programmes need to incorporate innovation and entrepreneurial principles. Continuous effort is necessary in revamping HEI leadership programmes to prepare graduates for industry.

Responsible leadership embraces shared leadership among individuals in teams and distributed leadership in the organization as a whole, especially in the education sector. According to Mirvis (2010, p.14), their holistic view of responsible leadership entails 'me, we and us', the individual leader, the responsible organization and the larger environment of stakeholders. Responsible leaders look both inside-out of the organization in order to channel its capabilities (according to the RBV of the firm that Penrose and Barney postulate) as well as outside-in in order to appropriately gauge the external environment. The stakeholder theory as Freeman (1984) proposed is relevant here as opposed to Milton Friedman's profit theory.

The constructs of responsible business leadership entail three perspectives namely, traditional (modernist), contemporary (relational) and horizon (holistic) which depict different approaches, Mirvis (2010). The horizon or holistic approach is indeed the most apt in creating a mind-set to achieving responsible leadership education. This approach equips individuals with social skills which nurture organizational sustainability through partnering with local environments. Ethical values are focused on as wealth creation is indeed achieved holistically and equitably.

In analysis of the report on HEIs from the twelve OECD member countries, Johnston (2007, p. 48) highlights "(t)he study showed that there is a need to institutionally integrate sustainable development into all the different functions of an HEI and to make an institutional commitment through a sustainability agenda". The report further emphasises that the various vision statements featured a concern with staff as an employer in HEIs and not explicitly concerned with the role of teaching. Responsible leadership education in universities will lead to an increase in organizational sustainability because HEIs can establish and promote strong ties with surrounding communities. This partnering can occur in several ways, i) skilled graduates become employable in the region thus HEIs are engendering human capital as well as promoting opportunities for further learning and development education opportunities which enable sustainable development of this region; ii) HEIs supply expertise which arises from research and consultancy; iii) activities to promote good-practice management and development activities and other good citizen programmes held on-campus; iv) local economic community development (Johnston, 2007).

Pearce et al. (2013, p. 247) corroborate with Gitsham et al. (2009) that "(r)ecent scandals involving executive leadership have significantly contributed to the topic of sustainability becoming one of the most important concerns of the management literature in the twenty-first century. The antithesis of sustainability is embodied in executive exploitation for short-term gains at the expense of other stakeholders, i.e. unsustainability".

These anti-social activities are unethical and damage sustainability. Leaders play a fundamental role in upholding ethical principles in the organization. Leadership styles can be a predictor of anti-citizenship behaviours in teams (Pearce and Sims, 2002; Giacalone and Greenberg, 1997). Shared leadership promotes health and responsible behaviour in teams which, therefore lessens anti-social behaviour (Pearce, 1997).

Martins et al. (2017, p. 226) concluded that "different learning loops (feedback and feedforward) are in action because they connect and capitalize on learning (…) leading to exploitation and exploration, thereby opening the way for ambidextrous learning. (…) This implies a mind, both at the individual and group level which is freer from preconceptions, more enthusiastic and (…) committed to furnish organizations with various capitals, namely, intellectual, personal, relational and social. In this way, HEIs in general and universities in specific should be more aware of this malleability in order to contribute to the shift in both organizational and social paradigms. These paradigms can be nurtured through learning, specifically which is future facing (feedforward) and based on efficiency as well as on that learning which is more effective in nature (feedback).

3. The effects of responsible leadership education on the continuous management learning of students in actual organizational business settings.

PRME principles have positive effects in providing skilled graduates instilled with a mind-set focused on ethics, social innovation and corporate responsibility. In view of the fact that individuals perform an array of roles in

the current information society, education entails acquiring knowledge and also developing individual, social and professional skills and competencies in order to galvanise, become attune to and embrace the knowledge that students hold. Furthermore, Blanco et al. (2012) support the idea that students should be intelligent and creative in applying their competencies to boost performance. Indeed, leadership can be associated with varies spheres, the educational system, the work environment, the social networking system. Furthermore, since competencies transcend knowledge and know-how, leadership is also concomitant to competency and skills building.

The self-efficacy construct highlights the importance of tacit knowledge because it leads to analysis and reflection on the unique capacity that individuals have to share complex and tacit knowledge. Self-efficacy is considered as the essential component for prepared organizational learning. Bandura (1977) postulates that environmental and individual factors influence individual performance. An individual's past performance has an effect on self-efficacy as a result of observing how others carry out similar actions and through the individual's independent cognitive processing. Hence, self-efficacy is a fundamental strategic factor in accomplishing high performance levels (Bandura, 1986). Additionally, self-efficacy theory provides a conceptual framework applied in various schools of thought to perceive the relationship between organizational performance and the behaviour of individuals'.

Anderson et al. (2008) substantiate that learning and innovation depend on leadership efficacy, whereas Mumford et al. (2002) emphasise the leader's characteristics. Moreover, Anderson et al. (2008) explain that leadership efficacy result from behaviours that are unconventional and challenging in nature. Accordingly, Mumford et al. (2002) agree that innovation arises from creative thinking skills as well as from the capabilities and experience that are technical and organizational in nature. Furthermore, a nexus arises between learning, creativity, innovation, leadership and the cycles of knowledge creation. Indeed, explicit knowledge is the outcome of the collaborative efforts between explicit and tacit knowledge. Moreover, "the contemporary world does not adhere to fortuitous situations and innovation does not result from isolated geniuses but instead from activists inherent in organizations" (Martins, et al. 2016, pp. 159).

Continuous training, learning and development of employees is essential to ensure that individuals are competent in actual organizational business settings. Furthermore, Hecker and Birla (2008) corroborate that developing a culture of leadership development enables sustainable innovation for organizations arising from an increase in its knowledge base as well as developing individuals as leaders at all levels. This development arises from empowering individuals through autonomy, responsibility and power. Simultaneously, new age leadership behaviours give rise to innovative results.

The leadership self-efficacy construct and its association with learning are eminent in promoting high levels of employee engagement and satisfaction thus raising levels of individual and organizational performance. This is due to the fundamental assumption that opposing leadership behaviours encourage distinct aspects of organizational learning. In an attempt to analyse the importance of responsible leadership education in universities (HEIs) in order to increase organizational sustainability, the literature informs us that business leaders are confronted with social woes, Mirvis (2010). This concern arises from various domains ranging from changes affecting basic standard of living, health, education, climate which impact all stakeholders of the organization, private and public, individual, group and community.

Our current society and economy call for the responsible leadership paradigm that is imbued with values. This paradigm appeals to a shift in mind-set. Therefore, individuals and organizations should move away from traditional ways of thinking to the interpersonal mind-set which nurtures relations and enhances social capital.

Furthermore, in this regard, social innovation and responsibility embrace a holistic approach which enables the organization to make responsible profit while harmonising all stakeholders, internal and external. Martins et al. (2017, p. 140) concur that "(i)n order for organizational learning to occur it is imperative that a culture of creativity and innovation prevail in the organization (…) [a]culture of innovation and creativity is the cornerstone for unlearning those obsolete organizational practices. Internalization of knowledge is the essence of learning because that is where the abundance of information flows and where group and/or teamwork can flourish. In view of it being tacit knowledge, its integration and institutionalization is dependent on preliminary work which lies at the level of Internalization (…). The level of Internalization should be supported by a specific

leadership which is associated with humanizing organizational values (…). The link is accentuated between the constructs of leadership self-efficacy and learning through Internalization".

The context of HEIs entails creativity and innovation; this can only be possible within the context of the complexity theory if the organization fosters its employees with elements of freedom, creativity, risk-taking, communication, feedback and self-organization. In this way, notwithstanding the fact that complexity theory does not take into accommodate emotions, Morrison (2010); Goldstein (2000); Houchin and MacLean (2005), HEIs will allow for humanistic principles to prosper on the 'edge of chaos' Morrison (2010, p. 384).

4. The rich implications to the organizational (re)creation of human bodies in the context of organized labour

Innovation and technology spark the constant need to develop skills in the workforce in order to ensure productivity and sustainability. "(T)he need to upgrade skills applies not only to young people in schools, universities and training institutions, but also to the current generation of workers" (International Labour Office Geneva (2011, p.12). Europe 2020 is the target for skills development; similarly the BRICS countries have development challenges.

Renesch (2006, p. 26) concurs with Gray (2002) on the notion that we are currently "working and living in a deformed Western modernity which has been gradually de-humanizing capitalism". Furthermore, in contemporary organizations, dialogue, discourse and debate are substituted by a digital culture. Hence the need to embark on the journey to individual humaneness and also to humanise organizations at large.

According to the International Labour Office Geneva (2011) report, key elements such as social dialogue as well as collective bargaining prompt a wider allegiance to a learning culture through education and training at various levels, organization, sector and national. These elements are important to encourage investing in the development of skills and knowledge. In 2008, the International Labour Conference appealed for a "holistic approach to skills development" (International Labour Office Geneva, 2011, p. 18). This approach embraces a range of skills, namely,

1. continuous and seamless pathways of learning which are inclusive of age, gender as well as education levels;
2. development of core skills that include literacy, numeracy, communication skills, teamwork, problem-solving skills and learning ability;
3. development of higher-level skills that include professional, technical and human resource skills which ensure individuals are aware of, receptive to and competent for (with the portability of skills) high-quality jobs;
4. portability of skills which are based on core skills so that individuals can apply knowledge and experience to new occupations and industries; and
5. employability based on core skills, motivation, access to training opportunity, ability to take on continuous learning opportunities and support for doing so as well as recognition of acquired skills.

These abovementioned elements further intensify renewal of training programmes. Furthermore, these key elements are actively involved to guarantee productivity gains are equitably and resourcefully disseminated.

Moreover, "countries use a variety of coordination mechanisms: national inter-ministerial bodies; sector-based bodies bringing together training institutions and providers with employers' and workers' representatives; and decentralized local bodies" (International Labour Office Geneva, 2011, p. 20) and above all organizations need to (re)create human bodies in the context of organized labour. The "effective utilization of skills in the workplace both depends on and contributes to conditions conducive to innovation and enterprise development; effective labour market orientation and mediation services; and well-informed decisions about education and training policies".

The current business and economic agenda reveals dysfunctions between labour market demands and the position that HEIs have adopted. In reality, the challenge lies in bridging the gap between what industry is looking for in the graduate. This is translated into a harmonious blend of hard and soft skills, namely, subject specific knowledge and skills on the one hand and, on the other hand, personal, social, relational, spiritual and

emotional skills. For this reason, there is a need for HEIs to prepare the graduate for organizations and for society as a whole. This effective collaboration should be the very essence of both universities and the industry in order for these to achieve responsible sustainability.

Nemanich and Vera (2009) corroborate that transformational leadership behaviours fosters a learning culture and exploratory innovation that enthuse individuals in organizations to challenge that learning which is institutionalized. Indeed, individuals should embrace thinking processes that are generative and exploratory (Sosik et al., 1997). In contrast, transactional leadership behaviours are concurrent with exploitative innovation. These depend on the *status quo* of competencies, products and services (Jansen et al., 2004).

Spillane (2005) maintains that distributed leadership is about leadership practice. In addition, MacBeath (2005) corroborates that distributed leadership is dependent on trust and embodies the mutual response arising from the leadership potential of other individuals. Therefore, distributed leadership fosters consultation and consensus as opposed to command and control. These characteristics oppose and challenge traditional models of organizations.

Currie and Lockett (2011) support that Gibb (1954) postulated the distributed leadership construct which remained latent awaiting Brown and Hosking (1986) to revive it again. Distributed leadership, according to Harris and Chapman (2002) is a traditional organizational theory framework that entails a sequence of tasks.

On the other hand, Spillane et al. (2001, p. 25) advocate a juxtaposing approach and view distributed leadership as 'the execution of leadership tasks is often distributed among multiple leaders'.

Distributed leadership encompasses three main principles, namely, (i) leadership as a flourishing group/network feature of interacting individuals; (ii) approachability to the boundaries of leadership defining who has a role both within and beyond the organization; and (iii) multiplicities of expertise are distributed across the many, as opposed to the few. As a result, distributed leadership is characterised as collaborative, dynamic, inclusive, relational as well as context specific. In view of this nature, distributed leadership entails a system perspective that surpasses organizational levels, roles and boundaries.

Spillane et al. (2001) further argue that distributed leadership is a thinking and acting process that occurs in a specific context, centred on a process which entails individual practitioners' perceptions and their theories in use (Argyris and Schon, 1978). Consequently, in education institutions, leadership is regarded as thinking and acting in a particular situation to support facilitation and learning in order to foster graduates that will be future employees instilled with capabilities to put into practice the harmonious articulation of the hard and soft skillset.

5. Method

This study follows the ontological subjectivist view and an epistemology of the interpretive and radical humanist paradigms, Saunders et al. (2009). The link of the web-based questionnaire was made available on 18 July 2017, via the University of KwaZulu-Natal (UKZN) notice system after obtaining the Ethical Clearance and the Consent Letter for this study as well as the Gatekeeper's Letter. The primary data collection is still ongoing given the delay in obtaining the Ethical Clearance.

The questionnaire is based on the managerial grid concept developed by Blake and Mouton (1964), has 35 items with a Likert scale of five response options and aims to ascertain the self-reported leadership style of respondents. The purposeful sample method is used and the population entails the undergraduate and postgraduate students in the College of Law and Business, UKZN, South Africa. The primary research data will be managed and analysed according to the statistical processing method - SPSS version 25. Analyses will include means, standard deviations and correlations for the variables measured in this study.

6. Discussion and Conclusion

The research aims to determine whether there a significant finding in self-reported ratings of leadership styles of those respondents that are studying Management. Objective one of this study was to analyse the importance of responsible leadership education in universities HEIs to increase organizational sustainability.

The literature shows that just as Freire viewed transformative leadership should create bonds with school, home, work, family and the community, the same should occur with responsible education in our current new age society of innovation. Mirvis (2010) postulates that responsible leadership is a business paradigm that should be nestled in a global context and across all sectors.

Objective two was to ascertain the responsible leadership education effects on the continuous management learning of students in actual organizational business settings. A culture of new age leadership development enables sustainable innovation for organizations develops from an increase in its knowledge base as well as developing individuals as leaders at all levels, Hecker and Birla (2008). Responsible leadership education in universities will lead to an increase in organizational sustainability because HEIs can establish and promote strong ties with surrounding communities (Johnston, 2007).

Objective three was to determine the rich implications to the organizational (re)creation of human bodies in the context of organized labour. The current digital culture urges the need to encourage the journey to individual humaneness and also to humanisation of organizations at large, Renesch (2006).

Methodology of Innovation Generation as an Instrument for Effective Management of Technological Innovations

Adam Mazurkiewicz and Beata Poteralska
Institute for Sustainable Technologies – National Research Institute, Poland
Adam.Mazurkiewicz@itee.radom.pl
Beata.Poteralska@itee.radom.pl

Abstract: The source of many innovations is research activity carried out at specialised R&D organisations. Innovations are developed there with a focus on implementation in business practice. The first stage of the innovation process at an R&D organisation comprises generation of a set of possible innovative ideas and projects. The extreme importance of this stage results from the need to select for development only innovative ideas with chances for scientific and commercial success. Their proper selection strongly determines quality and usefulness of developed innovative solutions, possibilities of their practical implementation, and effective use of available resources. The literature review indicates some tools, including IT applications supporting the project ideas generation. The paper's authors, on the basis of their experience in generating, developing, and implementing innovations, while taking into account approaches applied by scholars and practitioners, propose a methodology of innovation generation that would enable determination and choice of innovations that have potential for the highest effectiveness for development in an R&D organisation. A key element of the methodology is an original project generator. The initial project ideas, coming mainly from results of scientific investigations, orders from industry, and results of foresight research, are gathered in the project generator. Its application assumes use of methods, co-developed by the paper's authors, enabling proper analysis of project ideas, including technology assessment, in respect of implementation maturity, commercial and innovation potential, and executive potential assessment including human, financial, organisational, and infrastructural potential necessary for project execution. Application of the methodology of innovation generation, including the designed IT tool, enables identification of new potential research projects and selection of those with the highest chances of success. The selected projects concern innovations, considered as significant due to their scientific and technological values, and possible economic and social benefits. The paper presents an original methodology of innovation generation and an example of its practical application at the Institute for Sustainable Technologies – National Research Institute, Radom, Poland, which is an R&D organisation involved in technology development and implementation in the field of machine construction and maintenance.

Keywords: technological innovations, project generator, R&D organisation, foresight, technology assessment, executive potential assessment.

1. Introduction

Innovations are regarded as key factors contributing to economic development at both the macro level of a country or region and the micro level of businesses. An effective innovation process is necessary for innovations to have impact on operation of enterprises.

Experience of the authors, involved in processes of innovation generation, realisation, and implementation (Mazurkiewicz, 2009; Mazurkiewicz and Poteralska, 2015), implies an appropriate choice of potential projects so as to ensure successful development of innovations characterised by application potential is a considerable difficulty. Ideas for potential innovations may come from a variety of sources including continued development of innovations prepared in a research organisation, progress of science, needs of an economy, cooperation proposals submitted by research organisations or direct industrial orders. An ordered and effective analysis of ideas for potential innovations and selection of those whose development and implementation stand chances of being successful is of the essence. Such an approach allows for significant savings as only undertakings of substantial chances of success are realised. Thorough-going and comprehensive analysis of innovations to be developed, even time and expense-consuming, always costs distinctly less than the realisation of a project that will end with a failure or will have to be discontinued.

The importance of the stage of innovation generation points to the need to apply tools supporting its effective realisation. An analysis of existing tools to support generation of innovations (Bąk, et al., 2012) shows tools developed to aid development of solutions as part of research projects constitute a majority. These are predominantly tool solutions which provide operational, chiefly IT support for management of research and development processes. The authors, while acknowledging the weight of operational support for processes of innovation generation, propose to aid them by employing systemic methodological tools. Since innovations commonly spring from efforts by specialised research organisations and the authors, working for a research

institute, have extensive experience in this area, a proposal suited to conditions prevailing at research organisations is advanced in this paper.

Based on a literature review and our own practical experience, a methodology of innovation generation is developed for the purposes of supporting the stage of innovation generation at a research organisation and aiding collaboration of such an organisation with its scientific and industrial partners. The methodology is applied to support the process of generating topics for future-oriented research projects concerning technological innovations defined as new or substantially modified products and processes, characterised by innovativeness and market demand on one hand and the executive potential required to develop them being available at an organisation on the other hand. The methodology is dedicated for use in the process of generating forward-looking research projects. Application of the methodology assumes the use of methods, co-developed by the paper's authors, supporting generation of project ideas, including foresight; methods enabling proper analysis of project ideas in the course of their development, including technology assessment, in respect of implementation maturity, commercial and innovation potential, and executive potential assessment comprising human, financial, organisational, and infrastructural potential necessary for project execution.

An original tool – the "Innovative project generator" (Mazurkiewicz and Poteralska 2017) including an IT application as its operational element – has been developed and implemented as part of the methodology in order to effectively support the stage of innovation generation. The project generator is a new methodological idea based on the assumption of a close cooperation of an R&D organisation with potential industrial partners consisting in gathering information about research needs of an economic milieu and suggested innovative undertakings. It serves to monitor the process of generating and conduct of research undertakings. The monitoring process is enabled by use of systematically collected information about innovative research undertakings being prepared or showing potential.

2. Methodology of innovation generation

The methodology of innovation generation is part of a broader methodology of supporting generation and realisation of technological innovations at a research organisation developed with a view to aiding the process of technological innovation development that encompasses the following stages: generation of research problems that results in selection of topics for innovative undertakings, development of innovations from the conception to the stage of technical documentation, prototype, and finished product, where practical employment of results is possible, and the final stage of innovation development, that is, implementation to economic practice (Fig. 1).

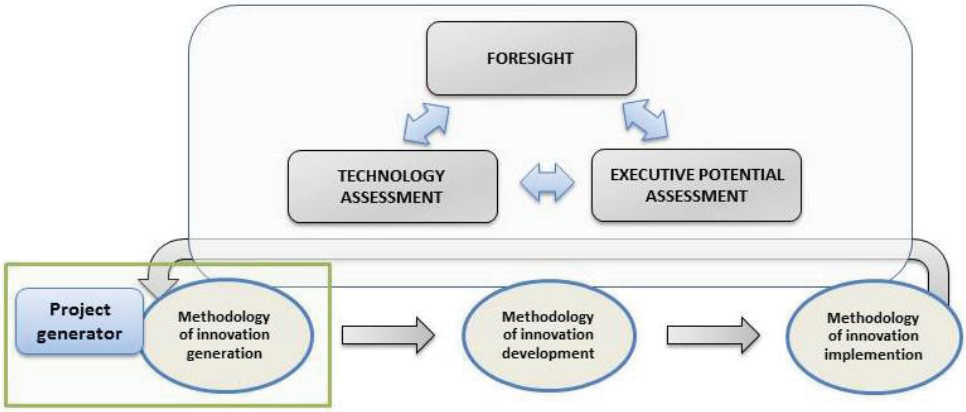

Figure 1: Overall diagram of the methodology of supporting processes of generation and realisation of technological innovations at a research organisation

This article presents the methodology of innovation generation (Fig. 2). Its idea assumes application of methods of foresight, technology assessment, and executive potential assessment in order to compile a set of proposals for future-oriented technological innovations as the starting point for decision-making related to realisation of research and implementation undertakings at a research organisation.

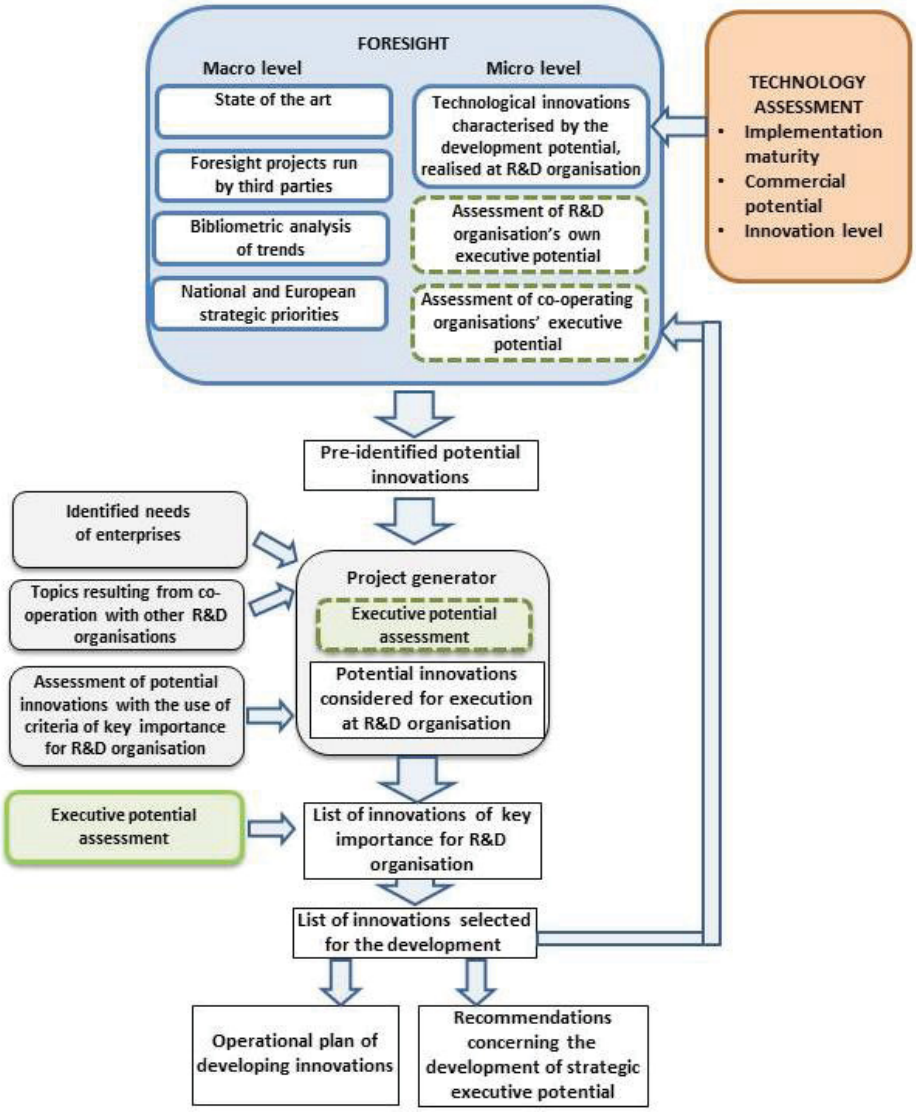

Figure 2: Methodology of innovation generation of a research organisation using the project generator

Source: Poteralska 2018.

The first stage of the innovation process involves looking for ideas or concepts. This generation of innovative solutions can be successfully aided with foresight (with both plentiful descriptions in the literature and universal applications in practice) which is utilised in the process of generating forward-looking research directions and technologies (Cuhls, 2003; Giesecke S., 2007; Cadiou, 2003) and helps to identify emergent development trends and weak signals as well as explore potential for their continued development and future significance (Saer et al, 2017). Foresight is a tool generating future-oriented topics for research and technological innovations, out of which priority tasks are selected that can be developed by an organisation with a given potential. Researchers and practitioners point out foresight is an acknowledged tool for decision-makers and managers to systematically explore, create, and test both possible and desirable visions of the future for the purpose of supporting decision-making processes at level of both institutions, regions, countries and supranationally, with particular focus on decisions concerning innovations (Georghiou, 2003; Hines, 2002; van der Duin, 2006; Masini and Samset,1975). Utilisation of foresight methods (Georghiou et al., 2008; Miles and Keenan 2003; UNIDO, 2005; Porter, 2010; Popper and Korte, 2004) aids decision-making processes as it somehow enforces anticipation of possible threats and opportunities and addressing ways of taking advantage of emerging opportunities or dealing with expected difficulties (Giaoutzi and Sapio, 2013; Georghiou, 2003).

As part of the methodology, foresight serves initial identification of innovations potentially capable of being developed by a research organisation. In connection with foresight undertakings at a research organisation, macro analyses are conducted including reviews of state of the art and analysis of foresight projects realised

by national and international entities, as well as micro analyses of technological innovations already developed by a research organisation. An authorial set is applied of quantitative and qualitative methods of research organisations' corporate foresight (Sacio-Szymańska et al., 2015; Poteralska, 2012; Poteralska and Łabędzka, 2015, Poteralska, 2017).

Micro analyses are aided with technology assessment. Technological solutions that have been developed and addressed as part of foresight by a research organisation are evaluated for the possibility of creating future innovative solutions. To this end, solutions developed at the organisation are assessed for implementation maturity, commercial potential, and innovativeness. Modules of a complex system of technology assessment, prepared under leadership of these authors (Mazurkiewicz et al., 2015; Mazurkiewicz and Poteralska, 2012), are employed in the process of evaluating technological solutions. The system is part of an area of technology assessment for business requirements indicated in the literature and focussing on technical and economic aspects that coexists side by side with the mainstream technology assessment, where technology assessment addressing the social perspective (impact of technology on society) is preponderant (Tran and Daim, 2008; Mazurkiewicz and Poteralska, 2014). The complex technology assessment may be used to carry out the so-called laboratory technology assessment (Van Den Ende et al, 1998), one of four forms of technology assessment distinguished considering the criterion of institutional perspective and consisting in technology assessments by researchers themselves and utilisation of the results as a guide in the process of technology development. Technological solutions evaluated by means of the complex technology assessment system, characterised by both innovativeness and market demand, are seen as potential sources of more technological innovations to be analysed with the aid of foresight methods.

Commencement of innovative undertakings generated is conditioned by existence of necessary executive potential, own or of cooperating institutions (Teece et al., 1994; Stabryła 2004; Pacholski, 2012; Schoemaker, 1993). Executive potential is understood as a state of an organisation's strategic and operational resources and competences that enables realisation of actions and supports the organisation's development in future (Poteralska, 2018). A preliminary assessment of executive potential of a research organisation where innovations are developed and of its collaborating entities is also conducted as part of foresight.

Foresight results in a list of pre-identified innovations that can be developed by a research organisation. The foresight results are but one of the sources of innovation, however. Another source of technological innovations and topics for potential projects lies in innovations developed at a research organisation before, proposals stemming from industry requirements, and cooperation with research organisations. They are addressed in the project generator together with innovation proposals generated by foresight. Potential innovation proposals gathered in the generator are reassessed for executive potential available at the research organisation as far as executive and application capabilities of a project and selection of partners for project realisation and of parties interested in its results are concerned considering knowledge in a given field, experience with realisation of research projects, high standing in a sector and standards of innovation and competences supplementing an organisation's resources, financial credibility, etc. The method of key technologies is then applied as part of pre-identification of technological innovations for the purposes of a research organisation from among potential innovations generated in a given area. Key criteria are selected for an organisation to this end that may encompass, for instance, scientific and technological significance, compliance with strategic directions of a research organisation's activities, as well as economic and social benefits from applying innovations. The key criteria are addressed to select potential innovations considered for realisation by a research organisation. In respect of individual technological innovations selected by means of the key criteria, a detailed assessment is conducted of executive potential available to a research organisation. This is designed to verify whether a research organisation has the material, financial, human and organisational executive potential required to realise the pre-identified technological innovations and to implement them to the economy. The material executive potential, especially the research infrastructure and human potential, is of key importance to a research organisation's executive potential since it determines the possibility of realising work at a research organisation. Material and human executive potentials are prerequisite to decisions to realise specific innovations. Financial and organisational potential are added aspects. With reference to the particular innovations, potential sources of financing their development are indicated that include: international projects, national projects, commercial contracts, research organisation's own financial resources, and an enterprise's financial commitment. In addition, availability of organisational executive potential necessary to realise identified innovations is analysed. The analyses enable a diagnosis if a research organisation has the potential needed to develop innovations, to what extent the organisation's

executive potential must be expanded or modernised to allow for work in a given area to be conducted, and to indicate directions for expansion of the strategic executive potential required to ensure the research organisation's competitive standing in future. Results of this stage help to compile a final list of technological innovations. Innovative solutions which are effective in application and commercial terms are recommended for realisation, for which executive potential for effective realisation and implementation is available at a research organisation or, if necessary, where an organisation's own potential can be supplemented with expert knowledge or research apparatus from external entities.

The final results of the methodology comprise: recommendations to management structures of a research organisation including a list of technological innovations, an operational plan for realisation of selected technological innovations, and proposed areas of expansion of executive potential.

A generated list of technological innovations accepted for realisation encompasses proposals for research and implementation undertakings for which executive potential for effective realisation is available at a research organisation or, if necessary, where an organisation's own potential can be supplemented with expert knowledge or research apparatus from external entities.

Application of this methodology also supports making of strategic decisions to select research directions for an organisation and develop its executive potential within a specified time-frame as well as operational decisions related to work on a selected group of technological innovations.

3. Algorithm of applying the innovative project generator

The project generator is the operational module of the authorial methodology of innovation generation. (Fig. 3).

Initiatives carry different status dependent on progress of work to start a research undertaking. The project proposals and various types of research and innovation undertakings, aimed at economic applications, generated, among others, as a result of using foresight methods, business meetings with industry representatives, study visits, scientific conferences and specialist publications, research as well as development and application needs observed or discussed in the scientific and industrial environment, are collected in a specialised database of proprietary computer applications in the folder "New projects." At short-term intervals, the proposals collected are analysed in terms of executive and application capabilities, including, among others, confirming willingness of an interested research group, industrial entity or a group of industrial entities to cooperate on a given project. A letter of intent constitutes grounds for future activities and determines subsequent tasks to be performed, i.e. recognition of performance capabilities, staff, equipment, infrastructure, time, and financial capabilities (the project gets the status: "Important"). In case of failure to meet one of the above-mentioned factors at a satisfactory level, the possibility is considered of supplementing identified deficiencies in the structure of external substantive and organisational connections.

Instruments of financing viable in a given undertaking are then analysed. These include above all: direct financing of the task from funds of an industrial beneficiary or financing through available regional and national research funding programmes, as well as a research organisation's own means. Continued interest of a third party in a joint undertaking and matching of potential financial instruments to its unique nature are prerequisite to changing a project's status to "Priority." Tasks that did not meet the requirements but can still be fulfiled in future are sent to the folder "Reserve." On the other hand, those projects that do not show prospects for implementation in a foreseeable period of time are collected in the folder "Archive of projects".

Priority projects for which an implementation formula was chosen are prepared on formally and substantively in accordance with the requirements of the procedure for their implementation. For projects with direct industrial financing, or joint funding by an R&D organisation and economic entity, and those that have been finalised as a result of competitive tendering for national or international funds, a feasibility study, and required contracts that include matters of confidentiality, intellectual property, a schedule of financing and implementation, as well as partial and final acceptance conditions are prepared. Obtaining co-financing makes it possible to start an innovative project's execution.

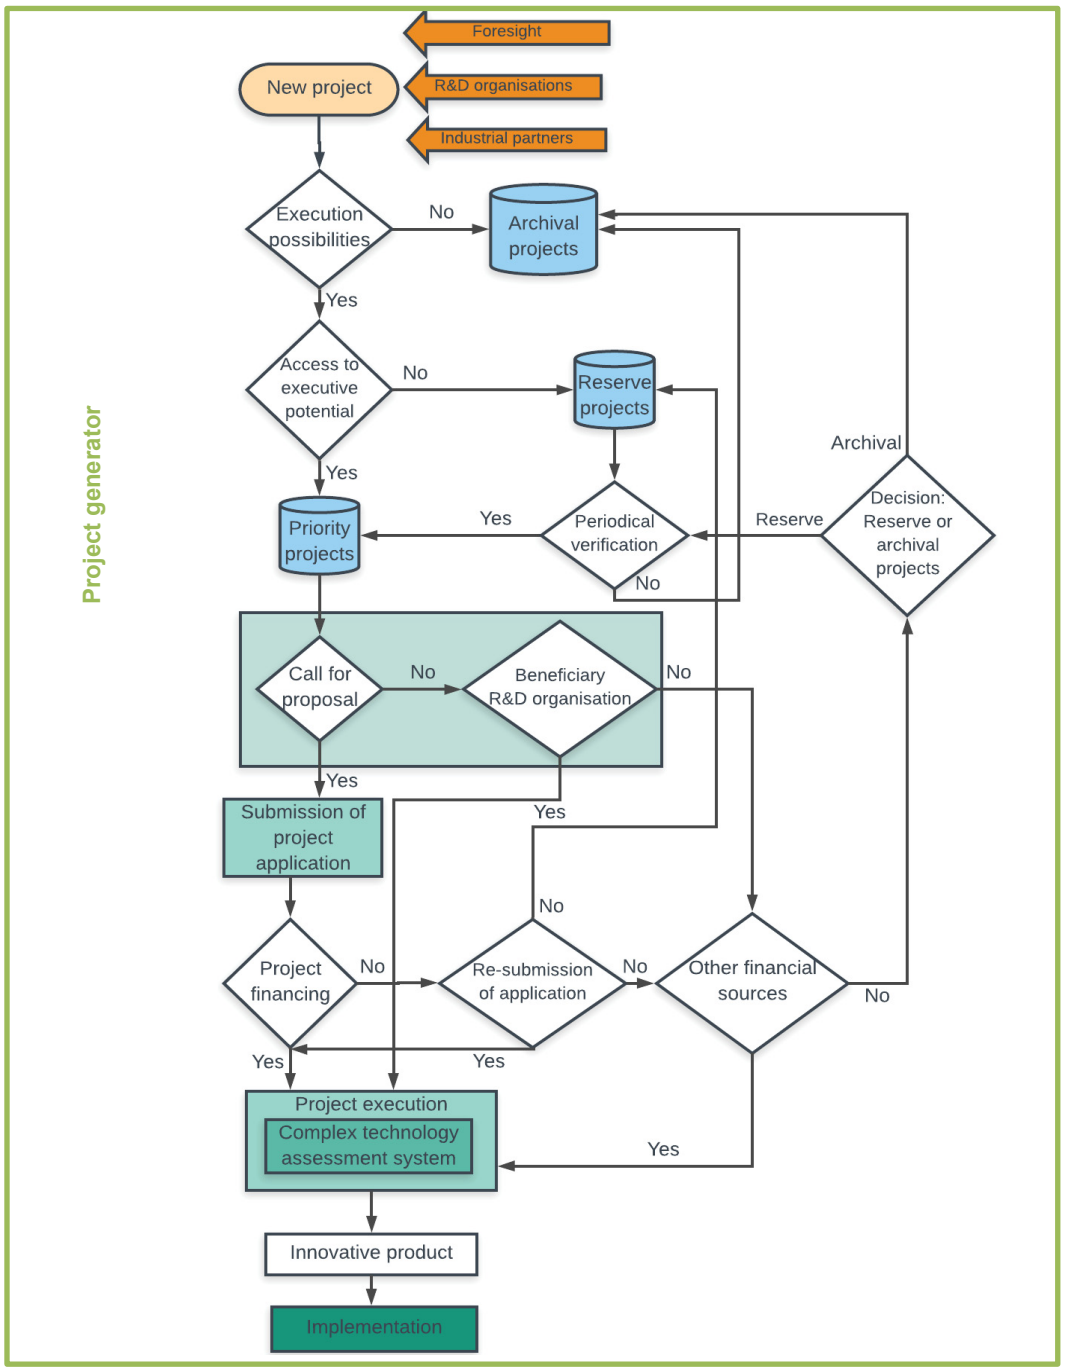

Figure 3: Algorithm for use of the project generation

4. An instance of application of the innovation generation methodology

The methodology has been verified in the practice of supporting generation of technological innovations at the Institute for Sustainable Technologies – National Research Institute, Radom, Poland, in the field of machine construction and maintenance including: surface engineering, mechatronics, and optomechatronics, control systems, environment-friendly technologies, technical and environment safety technologies, and special production. An implementation of the methodology to solutions in the field of mechatronics, chiefly including optomechatronics, is presented in this paper.

The technological solutions developed as part of the Strategic Programme “Innovative Systems of Technical Support for Sustainable Development of Economy” coordinated by the authors provided the source for proposals of subsequent innovations and research undertakings collected in the project generator. Demand and orders of enterprises and project proposals generated by collaboration with science organisations, as well

as results of successive foresight iterations by the research organisation at regular three years' intervals, which involved generation and monitoring of priority research directions in order to support ongoing operational efforts, constituted some more sources of innovation. In effect of the undertaking, research and development priorities for 2015–2018 were updated. The updated priorities were taken into account as potential future research and implementation undertakings in the project generator, which is illustrated for the example of the research area of mechatronics (Fig. 4).

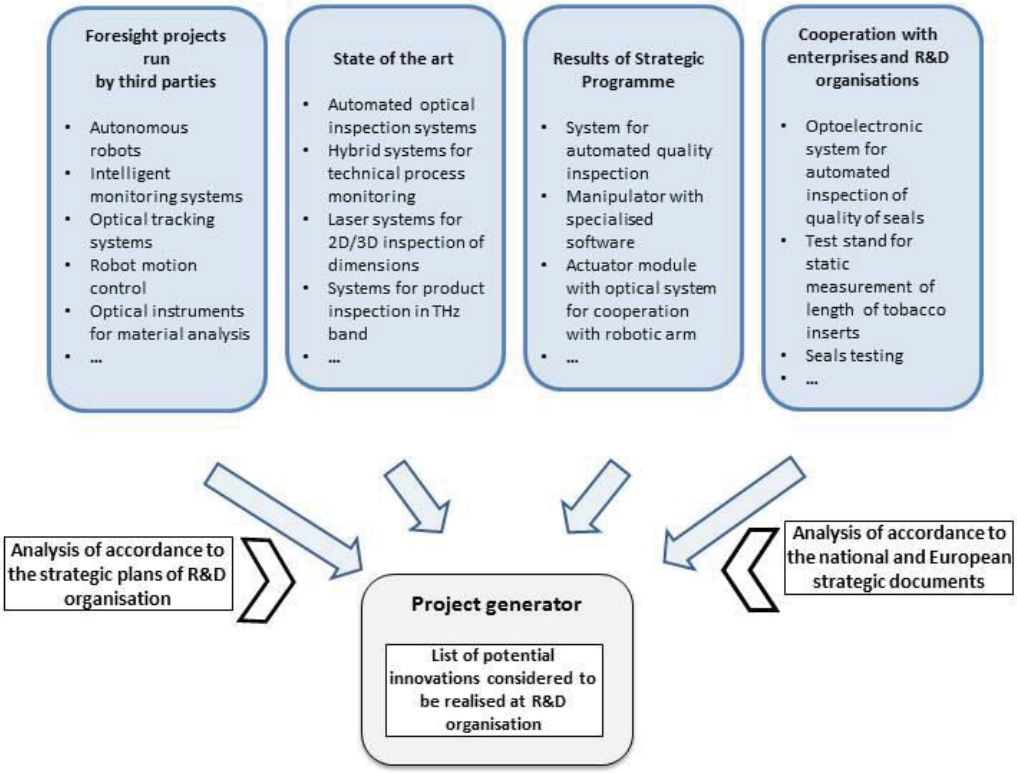

Figure 4: Sources of topics for potential technological innovations in the instance of optomechatronics

The project proposals gathered in the generator were subject to initial evaluation for executive potential required for their realisation. Projects aligned with strategic directions of the research organisation's activities, with the necessary executive potential and interest of external entities in place, were considered as future-oriented undertakings aimed at developing technological innovations. In order to support processes of innovation identification, development, and implementation, an authorial methodology of supporting generation and realisation of technological innovations was submitted. It integrates application of the following tools: foresight, technology assessment, and executive potential assessment, whose individual utility in supporting realisation of innovation processes has been demonstrated as part of undertakings at the research organisation.

The proposed topics of research and implementation undertakings generated in this way were collected in the project generator. They were assessed by means of the criteria of key importance for the Institute for Sustainable Technologies – National Research Institute: scientific and technological significance and accordance with strategic directions of the research organisation's activities. In addition, an analysis was undertaken which of them could bring commercial, economic, and social benefits. Topics of interest to industrial partners and with chances of working on innovations jointly with or ordered by such partners were addressed first of all.

Available executive potential is a major aspect influencing selection of technological innovations scheduled for development at the organisation. Material executive potential, especially the research infrastructure in place, and human potential are of key importance as part of the executive potential, since they determine feasibility of efforts in such a specialist area of science and practice as optomechatronics. The analysis proved the material executive potential necessary for realisation of the generated optomechatronics innovations is available at the research organisation. It was also found, however, realisation of work in these areas of

research that would enhance their standard in line with development trends in science and technology would require additional equipment with infrastructure of parameters adequate to world-class standards. This signals the need to expand the strategic executive potential.

Presence of material and human executive potential was a prerequisite to decisions to realise specific innovations. Additional aspects related to financial and organisational potential. Potential sources of financing development of individual innovations were indicated, including: international projects, national projects, commercial contracts, research organisation's own financial resources, and financial commitment of enterprises. The analysis also showed organisational executive potential necessary to realise identified innovations was in place at the research organisation. It is insufficient, though, for all the undertakings considered. It needs to be developed.

The generated list of technological innovations accepted for the development includes proposals for research and implementation projects for which an executive potential is available in the research organisation to carry them out effectively, or if necessary, there is the possibility to supplement their own expertise by using expert knowledge or using external research equipment. An example of such an innovation is a device for quality control of shaft sealers. The process of its development is presented in Fig. 5.

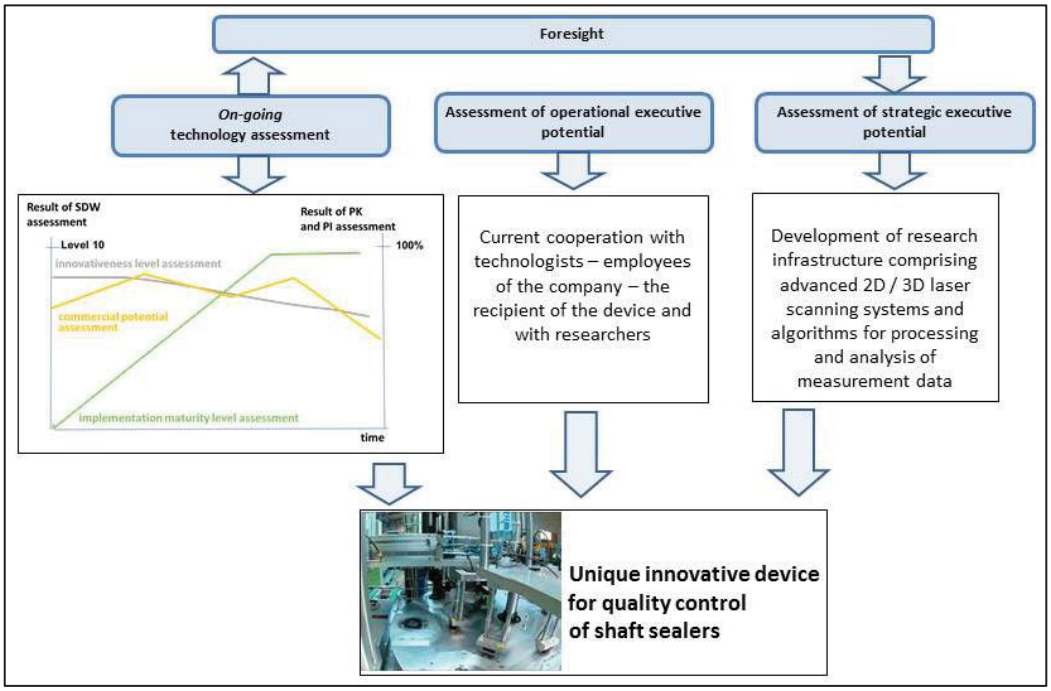

Figure 5: Process of the innovation development

The process of innovation development is monitored through a systematic technology assessment comprising implementation maturity, commercial potential, and innovativeness. *On-going* technology assessment is carried out in parallel with the assessment of operational executive potential. It enables on-going support for the process of innovation development and making operational decisions regarding, for example, strengthening a specific type of potential. Furthermore, in case of significant problems with the development of the innovation, for instance, the lack of a possibility to supplement the executive potential, it enables making a decision to stop further work on the innovation. Apart from the assessment of the executive operational potential, the strategic executive potential is also assessed, which is aimed at indicating the areas where it needs to be expanded to make it possible to undertake the generated research projects. On the other hand, results of *on-going* technology assessment are used for the needs of generating new project ideas, as technologies characterised by innovativeness and market demand are treated as one of sources for future projects.

The number of potential innovative projects in the field of optomechatronics generated with the use of a project generator shows a dynamic upward trend. Among them, a limited number of the most promising ideas are selected. 32 out of 120 proposals for potential technological innovations collected in the project generator

in the period from 2015 to 2018 were qualified for the stage of realisation. Relatively many, even cognitively interesting topics for innovative undertakings were abandoned as necessary executive potential was absent from the research organisation and its cooperating entities or because the proposed solutions exhibited insufficiently low levels of innovative or commercial potential, among other reasons that could be identified due to the application of the proposed project generator and the algorithm of its application.

5. Conclusion

The proposed methodology of innovation generation is a tool supporting the decision-making process concerning generation of undertakings aimed at development and implementation of innovative technological solutions including those in cooperation with industry. Application of the methodology aids management of the innovation generation process by means of foresight, technology assessment and executive potential assessment and by including the project generator, a tool solution that supports innovation generation operationally. The methodology is a major part of a complex system of technological innovation generation and realisation support at a research organisation, developed with leading contributions of the paper's authors, including stages of innovation generation as well as development and implementation.

The proposed methodology, in comparison to the existing tools supporting generation of innovations, provides, not only operational, mainly IT support for management of research and development processes as other currently applied systems, but also provides a comprehensive system support enabling the selection of the best innovative ideas analysed while taking into account numerous aspects, e.g., implementation maturity, commercial potential, and innovativeness. One of the main advantages of the methodology consists in taking into account a wide spectrum of sources of innovations, including, among others, the needs of enterprises, ideas resulting from cooperation with research organisations and universities, and innovations currently under development. The process of generating innovations while taking into account innovation ideas from various sources is carried out with the use of foresight methodology. Another important advantage of the methodology consists in applying in the process of generating project ideas, apart from foresight and other future research methods, also technology assessment and executive potential assessment, which increases the chance to select for the development only ideas with considerable chances for success. Application of the methodology enables a multidimensional approach to the issue of generating project ideas and aids operational decision-making processes by supporting the process of selecting innovative technological solutions that can be developed successfully at a research organisation and stand chances of being utilised in the economy. Application of the methodology additionally supports the generation of a research organisation's directions of development in the most promising and forward-looking areas of research, thus aiding strategic management of an organisation.

The instance of a model implementation of the methodology to optomechatronics solutions introduced in this article reaffirms utility and effectiveness of its application for the purposes of supporting innovation generation processes and initiation of new undertakings at a research organisation.

carlam@utad.pt

Abstract: With secondary data obtained from the Global Entrepreneurship Monitor, Global Competitiveness Index and Organisation for Economic Co-operation and Development databases for 27 European countries and 13 non-European countries, this study aims to understand which factors of entrepreneurship and innovation, through the quadruple helix model, influence economic development. For the data treatment, SPSS software was used to perform a set of tests that led to the results obtained. The results show that the Society dimension presents statistically significant differences, with a higher average for non-European countries, and the other dimensions did not present statistically significant differences. It is hoped that this research may contribute to existing scientific literature, helping to clarify the image of entrepreneurship and innovation in economic development, as well as a mean to help define policies and strategies that foster innovation and entrepreneurship, with a view to a sustained increase in the level of economic development.

Keywords: Innovation, Entrepreneurship, Economic Development, Quadruple Helix

1. Introduction

Political agendas have been dominated in recent years by macroeconomic reasoning, which clearly favoured austerity. As economies recover from the severe recession they plunge into, there is widespread recognition that long-term growth depends on decidedly microeconomic concerns such as innovation and entrepreneurship (Feldman, et al., 2016). According Dang e Pheng (2015), economic development is considered a multifaceted and complex process that includes interactions between different long-term objectives and policies. The literature (e.g., Galvão, et al., 2017) argues that both innovation and entrepreneurship have a central contribution to the economic development of nations.

According to some authors (e.g., Ramadani, et al., 2013; Feldman, 2004) innovation is at the heart of the economy of the 21st century. It brings new technologies and products that enable global challenges to be met, generating allowing a sustained increase in productivity, as well as the creation of new jobs, with the ultimate aim of improving the quality of life of citizens.

In the latest years, innovation and entrepreneurship have gained great evidence (Amorós et al., 2012; Audretsch & Peña-Legazkue, 2012; Sánchez, 2013; Casadella & Uzunidis, 2017; Lee, 2017; Acs, et. al., 2016; Liñán and Fernandez-Serrano, 2014; Audretsch, et al., 2008; Acs and Varga, 2005), being perceived as true drivers of economic development, so it is considered pertinent to investigate the relations between these three concepts. For this, the model Quadruple Helix (QH) (Industry, Government, University and Society) will be applied to two samples from countries (European countries and non-European countries). To the traditional QH model it was considered appropriate to add control variables, of a macroeconomic nature, with a view to measuring the endogenous characteristics of the economies.

In the literature it is noted that the large part of the authors (e.g., Carayannis & Campbell, 2009; Cavallini et al., 2016; Flour, Ferreira, & Gouveia, 2016) uses the model Triple Helix (TH) (Industry, Government, university) neglecting the influence of society (QH) in the process of economic development. At the same time, it is noted that investigations are scarce in the literature that use control variables, representative of the endogenous characteristics of the countries, in order to gauge their motivation on the operation of the model. It should also be noted that this study has a supranational character, covering a considerable sample of countries, coming to fill a gap in the literature since much of the investigations have as an object of study an economy or region (e.g., Brem, & Radziwon, 2017; Pugh, 2017; Yi, & Jun, 2018; Lew, Khan, & Cozzio, 2018). In order to contribute to bridging these identified gaps, the aim of this work is to understand the importance of innovation and entrepreneurship in economic development, by comparing European and non-European countries, checking whether there is one or more dimensions of the QH model that stand out significantly

against the rest. Moreover, it will also be looked at whether the control variables have an influence on the functioning of the QH model.

This model will be built using secondary data for innovation and entrepreneurship, collected on international reference platforms (GEM, GCI and OECD). For data processing, the SPSS 22.0 software was used and several multivariate statistical tests were applied.

2. Literature review

2.1 The Role of Entrepreneurship and Innovation in Economic Development

Many authors have been studying, in different perspectives, the contribution of entrepreneurship to the economic growth and development of countries (e.g., Lee, 2017; Liñán and Fernandez-Serrano, 2014; Audretsch, et al., 2008; Acs and Varga, 2005), there is a significant increase in the literature that recognizes its important contribution (e.g., Acs, et. al., 2016). In fact, high levels of entrepreneurship translate directly into high levels of economic development, as entrepreneurs create new businesses, generate jobs, intensify competition and introduce technological innovations increase productivity (Acs, 2006). According to Dang and Pheng (2015), although theories of economic development are plentiful, many have so far neglected the role of entrepreneurship.

Entrepreneurship is a global phenomenon that has attracted the interest of governments and the most diverse institutions, both private and public, with the aim of promoting a culture and an entrepreneurial society.

For Schumpeter (1934), the entrepreneur is seen as an agent of imbalances in the market, fostering the process of "creative destruction", by which new companies introduce new products or methods of production, destroying existing ones. This same author, in1942, also argues that companies are resistant to change and therefore individuals with innovative ideas found new companies to continue their ideas. This was one of the first authors to relate entrepreneurship and innovation to economic development.

In the last two decades, and especially in recent years, with the onset of the economic and financial crisis that devastated most of the world's economies, associating a great availability of information and an authentic revolution in knowledge, theoretical thinking revived the concept of entrepreneurship, linking it with the concepts of innovation and economic development (Rüdiger et al., 2014; Libecap & Hoskinson, 2011; Audretsch, 1995).

Crecente-Romero, Giménez-Baldazo e Rivera-Galicia (2016) argues that entrepreneurship contributes positively to the economic development of countries, through the creation of new companies (startups), which in turn leads to the creation of new jobs and investment.

The literature shows the role of the entrepreneur as an actor capable of identifying and exploiting new business opportunities created endogenously by the deliberate accumulation of knowledge (e.g., Van Stel, et al., 2014; Braunerhjelm, et al., 2010; Audretsch and Keilbach 2008). For authors like Audretsch and Fritsch (2003) or Landström and Johannisson (2001) the innovation is generated and implemented by entrepreneurs with specific personalities who wish to achieve power and independence with the will to conquer and the joy of creating.

For Amorós e Bosma (2014) entrepreneurship has a significant impact on economic development and social welfare if there is concerted action by a wide range of actors in society, including policy makers, academics, entrepreneurs and the general population.

In addition to entrepreneurship, innovation is being studied for several years as one of the promoters of territorial development (Schumpeter, 2000; Acs& Audretsch, 2005).

Schumpeter (1934) extols the "entrepreneur as innovator," being a key figure in the conduct of the economic development process. Thus innovative entrepreneurship, which is based on the development of new products, sold on the market until another innovation makes them obsolete, fuels a process of "creative destruction" (Schumpeter, 1942), causing disturbances in a balanced economic system, which determines new business opportunities (Feldman, Hadjimichael, Lanahan, & Kemeny, 2016).

Innovation is far from being a recent phenomenon, and is inherent to human development. In fact, starting from Schumpeter's theory of "creative destruction" (1942), many empirical studies have argued that innovation is one of the most significant economic development factors (Fang & Chiu, 2017; Pradhan, Arvin, Hall & Nair, 2016; Romanenko & Chaplay, 2016; Kebebe, Duncan, Klerkx, Boer & Oosting, 2015; Kireeva, 2015; Ramadani, Gërguri, Rexhepi & Abduli, 2013; Bradford & Wolfe, 2013; Prystrom, 2012; Guellec & van Pottelsberghe de la Potterie, 2001; Engelbrecht, 1997; Coe & Helpman, 1995; Lichtenberg, 1993).

According to González-Pernía, et al., (2012), in recent years, there has been a greater concern with territorial competitiveness and development. Developmental theory has altered its focus, giving greater emphasis to endogenous developmental factors, to the detriment of exogenous developmental factors (e.g., Audretsch and Belitski, 2013; Álvarez, et al., 2014). Thus, the prosperity of an economy results from its ability to compete in the global marketplace (Murphy and Stajano, 2006). Schwab (2013) argues that a country's competitiveness is globally accepted as the main driver for sustaining prosperity and increasing the well-being of its citizens.

As stated by Veeraraghavan (2009): “Innovation and entrepreneurship are two sides of a coin. While there is a need for the innovations to occur which should be facilitated and even encouraged deliberately by entrepreneurs, it is equally important for them to create opportunities and environment to realize those innovations. There is no single, but a combination of factors such as market opportunity, family background in entrepreneurship, a new idea with business potential, the prospect of challenge offered by Entrepreneurship, as well as long cherished dreams and desire, that lead to successful entrepreneurship.”

2.2 The Quadruple Helix Model

The Society, a differentiating dimension of the quadruple helix model, arises since the triple helix model is not sensitive enough to express democracy. This perspective allows the territories to follow non-traditional innovation paths, namely non-technological improvements, service creation and exploration of creativity.

Most quadruple helix approaches focus on citizen-generated innovation and entrepreneurship. Social inclusion, user centrality and creativity are central concepts in the process of knowledge production. Economic development occurs through the innovation of products and services, provided by companies and the government, oriented to the satisfaction of citizens' needs (Park, 2014).

Both the triple helix and quadruple helix concept are based on the idea that innovation is the result of an interactive process, involving the different spheres of actors, each contributing to economic development, with its institutional functionl (Cavallini et al., 2016). The contribution to innovation is through the sharing of knowledge and the transfer of know-how. As society becomes more interactive, knowledge acquires a central role and there is an increase in the number and scope of the spheres, which participate in the creation of innovation (Cavallini et al., 2016).

The quadruple helix model is an evolution of the triple helix model, according to which the interaction between the three helices originates new knowledge, technology, products and services, in accordance with the needs of society (Etzkowitz and Klofsten 2005; Etzkowitz and Leydesdorff 2000).

This model argues that government provides the regulatory framework and financial support for the definition of innovation strategies and policies; universities and industry provide the necessary conditions for an integrated ecosystem of innovation; civil society, on the one hand, uses knowledge and innovation in the form of goods and services, on the other hand, it becomes an active part of the innovation system, that is, innovation co-producers, with information and communication technologies (ICT) are a facilitator of this same participation (Cavallini et al., 2016). Civil society still participates in the innovation process, constantly demanding a better quality of the goods and services it acquires (Afonso et al., 2012).

For Khan and Al-Ansari (2005) the long-term growth of innovation must integrate the citizens' perspective based on the media and culture. Batzordea (2010), argues that the development of modern economies requires cooperation between all economic actors, in particular the social partners and civil society.

2.3 Conceptual Model

According to the literature review developed throughout this chapter, the conceptual research model was constructed, which will serve as a basis for the pursuit of empirical research, being mirrored in Figure 1.

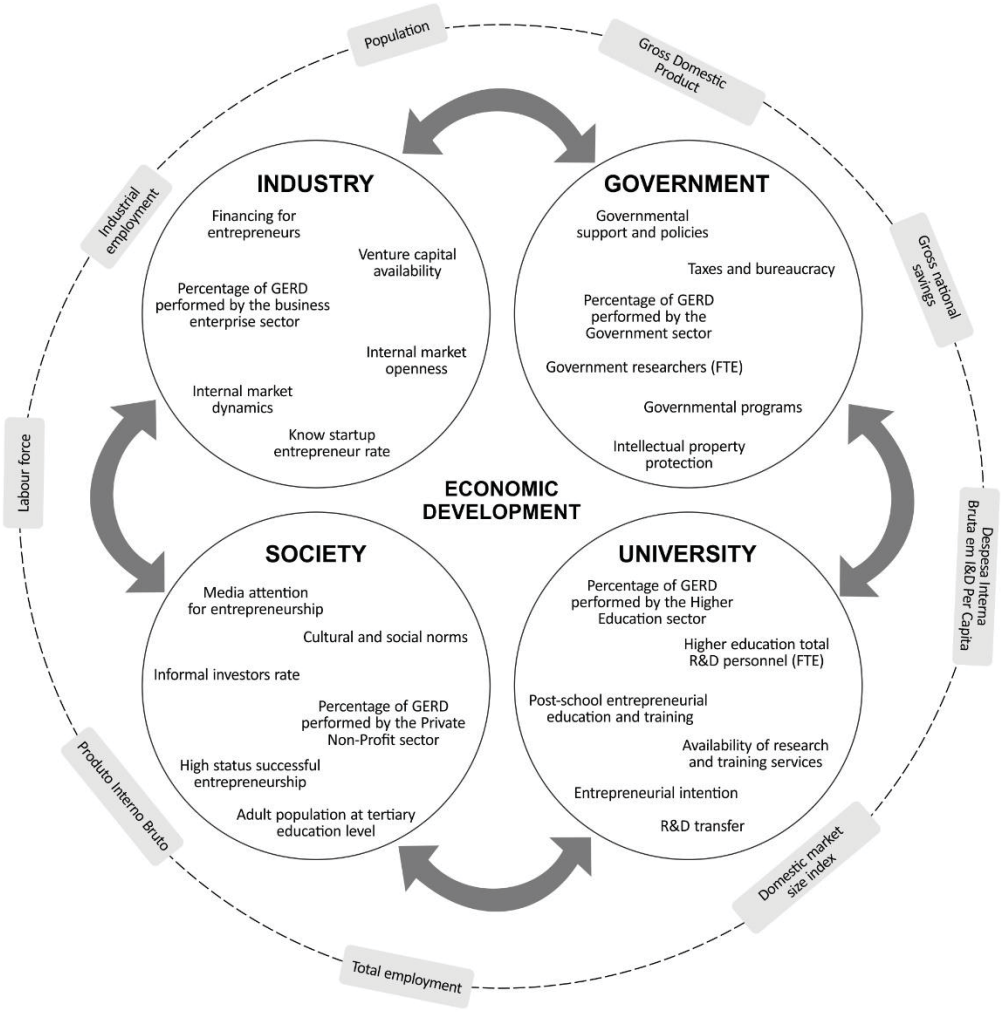

Figure 1: Conceptual Model

3. Methodology

The empirical aspect of this research is based on the use of the quantitative method, since a broad set of quantitative variables, innovation and entrepreneurship will be surveyed for the period 2007-2015. In addition to quantitative, this study will be prepared using secondary data, since the variables will be collected on several international reference platforms, namely in the GEM, OECD and ICG. After the quantitative data were compiled, the countries whose data were available for the largest number of variables were selected, and those that did not have sufficient data were eliminated from the sample. This gave rise to a sample of 40 countries, 27 of which are European and 13 are distributed across the rest of the world (Table 1).

Table 1: List of European and non-European countries under study

European	Germany, Austria, Belgium, Denmark, Slovakia, Slovenia, Spain, Estonia, France, Finland, Greece, Holland, Hungary, Ireland, Iceland, Italy, Latvia, Luxembourg, Norway, Poland, Portugal, United Kingdom, Czech Republic, Romania, Russia, Sweden, Switzerland.
Non-European	South Africa, Australia, Argentina, Canada, Chile, China, South Korea, United States of America, Israel, Japan, Mexico, Singapore, Turkey,

As can be seen in Table 2, for this investigation, six variables were selected to measure each of the dimensions of the quadruple helix model (Industry, Government, University and Civil Society). In addition to these variables, nine control variables were selected. The present variables were collected from the GEM, GCI and

OECD databases for the period 2007-2015, given that this year alone there was uniformity in the data available.

Table 2: Variables to use

Industry	**Government**
GEM: Internal market dynamics; Internal market openness; Financing for entrepreneurs; Entrepreneurial knowledge rate. **OECD**: Percentage of gross domestic expenditure on R&D by the business sector. **GCI**: Capital risk available	**GEM:** Government support and policies; Taxes and bureaucracy; Government programs. **OCDE:** Percentage of gross domestic expenditure on R&D by the government sector; Governmental researchers. **GCI:** Intellectual property
University	**Society**
GEM: Education and higher education for entrepreneurship; R&D transfer; Entrepreneurial Intention. **OECD:** Percentage of gross domestic expenditure in R&D, carried out by the Higher Education sector; Total R&D staff, full-time equivalent, in tertiary education **GCI:** Research and training services available	**GEM:** Cultural and social norms; Media attention to entrepreneurship; Informal investor rate; Status of successful entrepreneurship. **OECD:** Adult population with higher education; Percentage of gross domestic expenditure on R&D carried out by the non-profit private sector
Control Variables	
OECD: Gross domestic expenditure on R & D; Gross domestic expenditure on R&D per capita; Gross Domestic Product; Population; Total Employment; Industrial employment; Workforce. **GCI:** Gross national savings; Index of the size of the internal market.	

For the development of this research, in order to perform the analysis and interpretation of the data, SPSS 22.0 software was used, which allowed the application of different statistical tests.

4. Results

4.1 Internal Consistency Analysis of dimensions

Given that the variables being studied are measured at different scales, it is necessary to standardize the measurement scales, by standardizing the variables.

According to Table 3, the value of Cronbach's alpha is higher than the value of 0.80 for the Government dimension, for which we can consider the appropriate data as one-dimensional, is higher than the value of 0.70 for the University dimension, for which we can consider the data acceptable as one-dimensional, and for the other two dimensions is higher or is close to the value of 0.60, so they can also be considered minimally acceptable as one-dimensional. Therefore, we can concept variables to measure all dimensions under study.

Table 3: Internal consistency statistics

	Cronbach Alfa	N of Items
Industry a)	0,677	5
Government b)	0,902	4
University c)	0,730	3
Society	0,532	6

1. without the item “Zscore: Know Startup Entrepreneur Rate”;
2. without the items “Zscore: Percentage of Gross domestic expenditure on R&D (GERD) performed by the Government Sector” e “Zscore: Government researchers (FTE)”
3. without the items “Zscore: Entrepreneurial Intention”, “Zscore: Percentage of Gross domestic expenditure on R&D (GERD) performed by the Higher Education sector” e “Zscore: Higher Education Total R&D personnel (FTE)”

4.2 Comparison between European and non-European countries

4.2.1 Dimensions Analises

After having verified the normality assumption for all dimensions, we will use the parametric test t (Table 4).

Table 4: Descriptive statistics and Tests t: Relationships between European and non-European dimensions and countries

	Countries	N	Mean	Standard deviation	t38	p
Zscore: Industry	European	27	-,048	,6055	-0,652	0,519
	Non-European	13	,099	,7799		
Zscore: Government	European	27	,029	,9305	0,293	0,771
	Non-European	13	-,059	,7920		
Zscore: Univesity	European	27	-,013	,8917	-0,147	0,884
	Non-European	13	,027	,6222		
Zscore: Society	European	27	-,164	,4462	-3,168	** 0,003
	Non-European	13	,343	,5291		

** $p < 0{,}01$

As can be seen in table 6, the only dimension that presents significant differences between European and non-European countries is civil society.

The average value of the Civil Society dimension is higher for non-European countries, with the differences observed to be statistically significant (t38=-3,168; p=0,003).

Therefore, we can conclude that the Civil Society dimension is more common for non-European countries. Regarding the dimensions Industry, Government and University, there are no significant differences between European and non-European countries.

4.2.2 Individual item analysis

- Industry

After having verified the normality assumption for the industrial dimension items in European and non-European countries, we used the parametric test t (Table 5).

Table 5: Descriptive Statistics and t Tests: Relationships between items of the Industry dimension and European and non-European countries

	Countries	N	Mean	Standard deviation	t38	p
Zscore: Internal market dynamics	European	27	-,196	,8171	-1,842	0,073
	Non-European	13	,407	1,2397		
Zscore: Internal market openess	European	27	,091	1,0573	0,828	0,413
	Non-European	13	-,189	,8778		
Zscore: Financing for entrepreneurs	European	27	-,061	,9693	-0,554	0,582
	Non-European	13	,127	1,0901		
Zscore: Entrepreneurial knowledge rate	European	27	,010	,8680	0,091	0,928
	Non-European	13	-,021	1,2716		
Zscore: Percentage of gross domestic expenditure on R&D by the business sector	European	27	-,008	,8610	-0,070	0,945
	Non-European	13	,016	1,2820		
Zscore: Capital risk available	European	27	-,064	,9568	-0,576	0,568
	Non-European	13	,132	1,1127		

The value of evidence is more than 5% for all items of the Industry dimension, there are no significant differences between European and non-European countries.

- Government

After having verified the normality assumption for the government dimension items in European and non-European countries, we used the parametric test t (Table 8).

Table 8: Descriptive Statistics and Tests t: Relationships between items of the Government dimension and European and non-European countries

	Countries	N	Mean	Standard deviation	t38	p
Zscore: Government support and policies	European	27	-,084	1,0377	-0,763	0,450
	Non-European	13	,175	,9315		
Zscore: Taxes and bureaucracy	European	27	,037	1,0102	0,331	0,742
	Non-European	13	-,076	1,0146		
Zscore: Government programs	European	27	,066	1,0992	0,600	0,552
	Non-European	13	-,138	,7757		
Zscore: Percentage of gross domestic expenditure on R&D by the government sector	European	27	,009	,9659	0,084	0,934
	Non-European	13	-,019	1,1081		
Zscore: Governmental researchers	European	27	-,119	,6218	-1,119	0,270
	Non-European	12	,268	1,5581		
Zscore: Intellectual Property	European	27	,095	,9701	0,866	0,392
	Non-European	13	-,198	1,0715		

The value of evidence is more than 5% for all items of the Government dimension, there are no significant differences between European and non-European countries.

- University

After having verified the normality assumption for the government dimension items in European and non-European countries, we used the parametric test t (Table 6).

Table 6: Descriptive Statistics and Tests t: Relationships between items of the University dimension and European and non-European countries

	Countries	N	Mean	Standard deviation	t38	p
Zscore: Education and higher education for entrepreneurship	European	27	-,122	1,0617	-1,118	0,271
	Non-European	13	,254	,8391		
Zscore: R&D transference	European	27	,006	1,1126	0,055	0,957
	Non-European	13	-,013	,7533		
Zscore: Entrepreneurial intention	European	27	-,292	,6408	-2,908	** 0,006
	Non-European	13	,607	1,3299		
Zscore: Percentage of gross domestic expenditure in R&D, carried out by the Higher Education sector	European	27	,073	,8959	0,659	0,514
	Non-European	13	-,151	1,2142		
Zscore: Total R&D staff, full-time equivalent, in tertiary education	European	27	-,162	,7133	-1,540	0,132
	Non-European	12	,363	1,4296		
Zscore: Research and training services available	European	27	,077	1,0816	0,695	0,492
	Non-European	13	-,159	,8214		

** $p < 0,01$

According to table 9, we can conclude that the intention of entrepreneurship is more for non-European countries than the European countries and that the remaining items of the University dimension do not show significant differences.

- Society

After having verified the normality assumption for the government dimension items in European and non-European countries, the parametric t test was used (Table 10).

Table 10: Descriptive Statistics and Tests t: Relations between Civil Society items and European and non-European countries

	Countries	N	Mean	Standard deviation	t38	p
Zscore: Cultural and social norms	European	27	-,306	,8578	-3,074	** 0,004
	Non-European	13	,635	1,0041		
Zscore: Status of successful entrepreneurship	European	27	,017	1,0568	0,151	0,881
	Non-European	13	-,035	,9102		

Zscore: Media attention to entrepreneurship	European	26	-,337	,9278	-3,358	** 0,002
	Non-European	13	,675	,7960		
Zscore: Informal investor rate	European	27	-,160	,7674	-1,479	0,147
	Non-European	13	,332	1,3405		
Zscore: Adult population with higher education	European	26	,004	,8299	0,032	0,974
	Non-European	11	-,008	1,3704		
Zscore: Percentage of gross domestic expenditure on R&D carried out by the non-profit private sector	European	20	-,237	,3951	-1,918	0,065
	Non-European	10	,474	1,5869		

** $p < 0,01$

With table 10, we can conclude that cultural and social norms and media attention for entrepreneurship is more evident for non-European countries and that the remaining items of the Society dimension do not show significant differences between European and non-European countries.

4.2.3 Multivariate regression model to study the effect of control variables on the relationships between the four dimensions under analysis and European and non-European countries

When applying the multivariate tests (Pillai's Trace, Wilks' Lambda, Hotelling's Trace and Roy's Largest Root) it was found that all tests indicate that "Countries (European vs. non-European)" and "Zscore: Gross domestic expenditure on R&D per capita" are the statistically significant variables to explain the dependent variables (p<0,05).

The significant relationships that are statistically stronger are therefore observed, (Eta2=0,631), followed by Industry (Eta2=0,583), University (Eta2=0,546) and finally Civil Society (Eta2=0,52). It should be noted that the values of Eta2 are the values of the coefficient of determination R2, representing the proportion of the variation of the RVs that is explained by the VIs included in the model.

Table 7 shows the mean RV values for the study factor categories.

Table 7: Descriptive statistics: Relations between dimensions and types of economies

	Countries	N	Mean	Standard deviation	p
Zscore: Industry	European	27	-,048	,6055	0,319
	Non-European	11	,159	,7174	
Zscore: Government	European	27	,029	,9305	0,436
	Non-European	11	,073	,7000	
Zscore: University	European	27	-,013	,8917	0,485
	Non-European	11	,065	,6740	
Zscore: Society	European	27	-,164	,4462	** 0,000
	Non-European	11	,348	,5731	

** $p < 0,01$

The results are not exactly the same as those that had already been obtained using the t-test, due to the existence of missing values for some of the variables in the model, which mean that only 11 non-European countries are used in the overall model. The test values (p) change, but the conclusions remain, with the Civil Society dimension continuing to be the only one that presents significantly different values between the two groups of countries, and this dimension continues to be significantly higher for non-European countries.

Regarding the dimensions Industry, Government and University, there are no significant differences between European and non-European countries.

Overall, therefore, we can conclude that control variables do not affect the previously studied relationship between the four dimensions and European and non-European countries. Regarding the relationship between the control variables and the RVs, there were differences between the bivariate analyzes, in which there were positive relationships between:

- "Zscore: Gross domestic expenditure on R&D" and the domensions "Zscore: Industry, "Zscore: Government" e "Zscore: University.
- "Zscore: Gross domestic expenditure on R&D per capita" and the dimensions "Zscore: Industry", "Zscore: Government" e "Zscore: University".

- "Zscore: Gross National Savings" and the dimensions "Zscore: Industry" e "Zscore: Government".

While in the global model of multivariate regression some of these relations are no longer verified by the moderating effect of some control variables on the others, with positive relationships only occurring between:

- "Zscore: Gross domestic expenditure on R&D" and the dimension "Zscore: Government" (p=0,006).
- "Zscore: Gross domestic expenditure on R&D per capita" and the dimensions "Zscore: Government" (p<0,001) e "Zscore: University" (p=0,002).

5. Discussion

In the comparison between European and non-European countries, the results reveal only statistically significant differences in the Society dimension, with a greater weight being found in non-European countries. Using the individual analysis of this dimension it is verified that the items "Zscore: Cultural and social norms" and "Zscore: Media attention for entrepreneurship" have statistically significant differences, the average of these two variables being higher for non-European countries vis-à-vis European countries. These results are in line with the GEM report 2016/2017, according to which, European countries, when compared to other world regions, had the lowest belief in entrepreneurship as a good professional career and the lowest media attention for entrepreneurship (Herrington & Kew, 2017). In European countries, although there are regional cultural differences, there are common dynamics that bring different countries closer to a common European culture, supranational in nature (Liñán and Fernandez-Serrano, 2014). According to Schwartz (2008), the geographical, political, historical and economic proximity plays a central role in the configuration of cultural values. In this way, since European culture is more homogeneous, it is plausible that there are significant differences when compared to cultures of several world geographies, which are characteristically heterogeneous, taking into account their dispersion.

Regarding the constituent items of the Company and Government dimensions, it is verified that none presents significant differences between European and non-European countries. However, in the University dimension, it was found that the variable "Zscore: Entrepreneurial Intention" shows statistically significant differences, with the mean value being higher for non-European countries. Thus, GEM does not distinguish between formal and informal entrepreneurship, so that in the constituent sample of non-European countries we have economies such as Chile or Argentina, which have a very high level of informal entrepreneurship. On the other hand, in European countries entrepreneurial intent essentially measures formal entrepreneurship and, as such, it is plausible that they have a lower level of entrepreneurial intent (Galvão et al., 2017). In this regard, the GEM report 2015/16 points out that entrepreneurial intent tends to be higher in factor driven economies and lower in economies driven by innovation, so that in the sample of European countries it is found that almost all economies are innovation oriented (Herrington & Kew, 2017).

With the introduction of the control variables, it can be seen that they do not affect the relationship between European and non-European dimensions and countries, with the Society being the only one with significantly different statistical values. It is also verified the existence of positive relations between the variable "Zscore:
