Gross domestic expenditure on R&D" and dimension "Zscore: Government", as well as, between the variable "Zscore: Gross domestic expenditure on R&D per capita" and the dimensions "Zscore: Government" and "Zscore: University". The existence of these relations is in agreement with the previous literature review, since the R&D investment by the Government is a central factor in fostering innovation and the economic development of nations (e.g., Wu, et al., 2010; Wang, et al., 2007). In addition to direct R&D policies, central and local governments develop knowledge exploitation strategies through universities and research centres, financing innovation and entrepreneurship projects (Vincett, 2010).

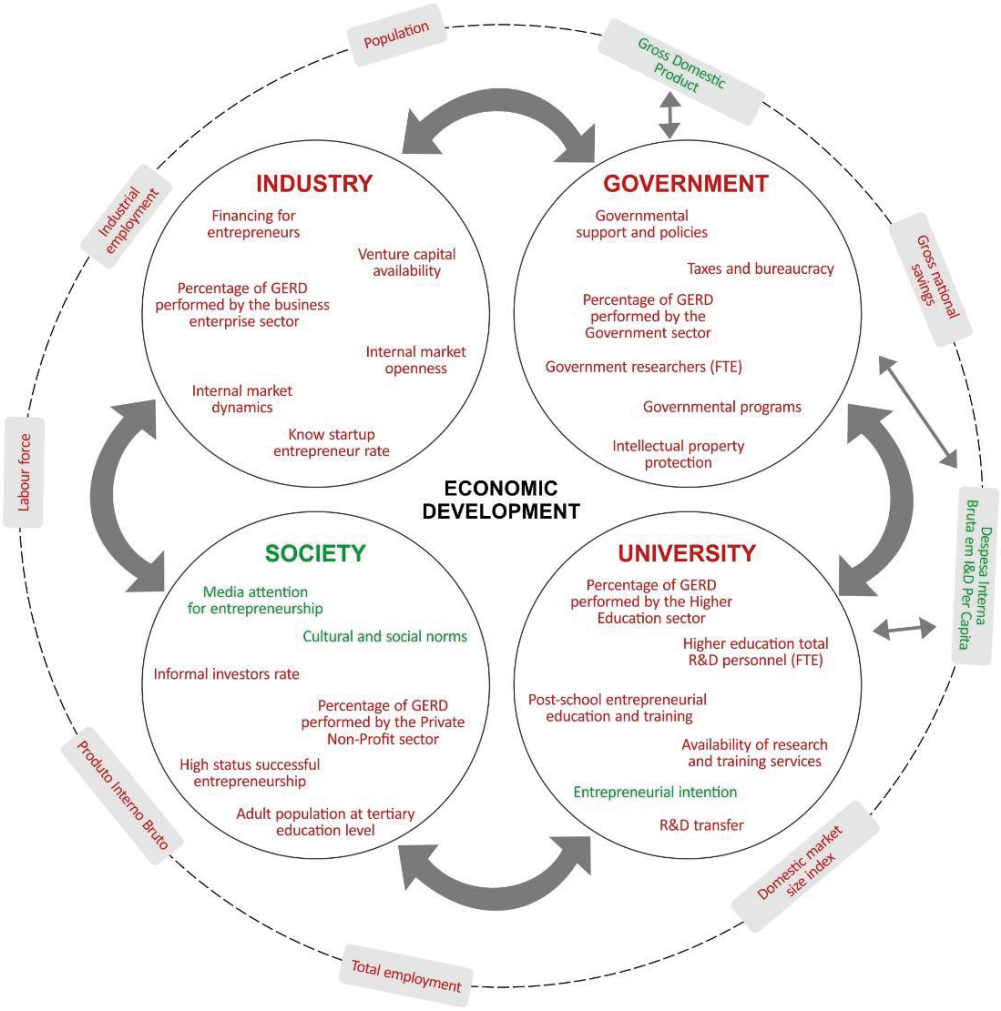

Figure 2: Relationship between variables and dimensions

6. Conclusion

With this study, the quadrupole helix model was constructed, based on variables of innovation and entrepreneurship, to which control variables were added, aiming to determine the existence of differences in the functioning of the helices when comparing different multinational regions. It was considered relevant to understand how the operation of the four propellers contributes to economic development.

The results show that the Society dimension presents statistically significant differences, with a higher average for non-European countries. In this way, it can be concluded that Society plays a more relevant role in non-European countries than in European countries. Considering the constituent variables of this dimension, it is also noted that the "Social and cultural norms" and the "Social media attention for entrepreneurship" show statistically significant differences, also playing a major role in non-European countries. This evidence may be associated with the fact that European culture is more homogeneous, given that, despite regional cultural differences, there are common dynamics, such as geographical proximity, political, historical and economic factors that determine a cultural approximation between the different countries (Liñán and Fernandez-Serrano, 2014).

Regarding Company, Government and University dimensions, there were no significant differences, except for the variable “Zscore: Entrepreneurial intention” which are of greater importance in non-European countries, recalling that GEM considers both formal and informal entrepreneurship.

In this study it was observed that the control variables do not interfere in the model dynamics, noting the existence of a positive relation between the Government dimension and the variables “Zscore: Gross domestic

expenditure on R&D" and "Zscore: Gross domestic expenditure on R&D per capita" and between the second and the University dimension. These relationships could have in their genesis the government's R&D investment policy, which could, on the one hand, directly finance innovation and entrepreneurship (Wu, et al., 2010), or otherwise, transfer funds to the University so that it can carry out research (Vincett, 2010).

It is hoped that this research may contribute to existing scientific literature, helping to clarify the image of entrepreneurship and innovation in economic development. In addition, it is hoped that this work will serve to define policies and strategies that foster innovation and entrepreneurship, with a view to a sustained increase in the level of economic development.

With the development of this research it was possible to identify some limitations that may be of interest to future investigations. The first limitation is the use of multiple databases, the low uniformity of the countries that constitute the same. Thus, only those countries that had data available for all the variables under study were selected, which resulted in the exclusion of several countries from the final sample, most of them non-European. This fact determined that the European countries had a greater preponderance in the sample.

Another limitation is related to subjectivity, since, although all precautions are taken, the choice of the independent variables of innovation and entrepreneurship and their distribution by the propellers, as well as the selection of control variables, entails some discretion.

With regard to future investigations, it would be interesting to repeat the study with new variables or to add variables to the already existing ones regarding the four dimensions of the quadruple helix model, as well as to select other control variables, in order to verify if the obtained results are consistent. Another suggestion is to study the variables and the model used in this study in comparison of countries in order to identify cases of good practices.

This work is also supported by: European Structural and Investment Funds in the FEDER component, through the Operational Competitiveness and Internationalization Programme (COMPETE 2020) [Project No. 006971 (UID/SOC/04011)]; and national funds, through the FCT – Portuguese Foundation for Science and Technology under the project UID/SOC/04011/2013.

Universities Fostering Entrepreneurship Ecosystems: From Teaching Entrepreneurship to Being Entrepreneurial

Viviana Molina-Osorio and Alejandra Molina-Osorio
Universidad Autónoma de Manizales, Colombia
vmolinao@autonoma.edu.co
alejamoli@autonoma.edu.co

Abstract: Entrepreneurship education must be more than the study of a bunch of theories about entrepreneurship. If something has been clear in the last ten years is the importance of action, experimentation and even failure, in order to understand what being entrepreneurial actually means. Change is difficult, and the University in general is an institution that challenges society, but seldom looks inside to challenge itself; it is the role of innovative teachers to begin a transformation from within the institution. Sometimes this transformation is easier when there is a particularly appropriate environment to foster change, if there is an ecosystem that supports the new initiatives and helps the innovative teachers come together, it is manageable to go from theory to Action. This paper presents the case of Universidad Autónoma de Manizales, one of the five Universities that started the Entrepreneurial ecosystem "*Manizales Más"* in Colombia and a good example of what means going from teaching entrepreneurship to being entrepreneurial. After five years fostering the entrepreneurial ecosystem the university has transformed the way entrepreneurship is taught and lived inside the institution, several changes in its strategic planning, policies and pedagogical approach have allowed the formation of an entrepreneurial community. Some of the most tangible changes have been noticed in the entrepreneurship course, now mandatory for all programs in the university, and the construction of the entrepreneurial competence that shows to the community what are the elements and the rubrics to take into consideration when developing the entrepreneurial spirit, not only in their students, but teachers and administrative staff all together. By the end of the paper it will be clear why the city of Manizales is a University campus and how Universidad Autónoma de Manizales has become a leader in developing an entrepreneurial university.

Keywords: Entrepreneurship Ecosystems, Entrepreneurial universities, teacherpreneurs

1. Introduction

When talking about the entrepreneurial University, maybe the characteristic that draws most of the attention is "that entrepreneurial university is a place possessing a capacity for change" (Clark, 2015). Change is difficult, and the University in general is an institution that challenges society, but seldom looks inside to challenge itself; it is the role of innovative teachers to begin a transformation from within the institution and generate a spill over effect that transforms the classes, the curriculum, the community, the city, and why not, the world.

One of the models used to describe the impact of entrepreneurial Universities is the 'bottom-up' model, community-led, catalysed by students, alumni and entrepreneurs in the regional economy. Often responding to economic and societal challenges, E&I development is triggered by a desire to stimulate regional economic growth, and thereby create graduate jobs, research opportunities and broader avenues for university support through the creation of a vibrant localised entrepreneurial ecosystem. (Graham, 2014). One way this can be achieved is by promoting a transformation within the classrooms, bringing more challenges and "real life problems" in to the academic environments. When academics, businessmen, policy makers and citizens work together it is amazing the kind of deep cultural transformations that can be achieved in a shot span of time.

Such is the case of Manizales, a city in the middle of the Colombian Andes that is promoting an entrepreneurial revolution with the help of the local university system.

"Manizales Más" is a public - private - academic alliance that begun with thirteen institutions working together to promote the development of the entrepreneurship ecosystem in the city of Manizales, Colombia. The main goal is to foster the economic development and to allow business ventures of all sizes and ages to grow more rapidly. Within the axis of this ecosystem, there is knowledge and intelligent action to transform the economic conditions of the city. This entrepreneurship ecosystem is based on Daniel Isenberg theory (2010) and has been developed with the help and support of Babson Entrepreneurship Ecosystem Project (BEEP). They presented the six domains necessary to have a self-sustaining entrepreneurship ecosystem: conducive policy, markets, capital, human skills, culture, and support organizations. (Isenberg, 2011). Every domain has a share in the responsibility of promoting growth and the network expansion. In this case, even the use of the

ecosystem metaphor itself explains the importance of symbiotic relations between agents, necessary to have the companies to survive and flourish.

Something interesting about *"Manizales Más"* is that between the first stakeholders were five of universities in the city, one in particular; Universidad Autónoma de Manizales – from now one referred as UAM – has been the host of Manizales Más headquarters and has certainly become a leader in developing an entrepreneurial university. UAM has a multidisciplinary faculty that welcomes students to Arts, Social, health and engineering studies; And it has been recognized for its entrepreneurial legacy. This legacy is part of the foundational pillars of UAM, a place where senior management promotes the entrepreneurship and innovation as the fundamental ingredient to promote regional development and value creation across all disciplines. Every department has a commitment with excellence, the teachers are empowered to collaborate with businessmen and entrepreneurs, so the students can have access to real industry examples and challenges, turning the classes into spaces for experiential learning and setting the foundation for bigger opportunities for graduates and the university community in general. This Kind of approach towards problem-based learning, requires more integration of knowledge within faculties, departments and disciplines. It is a way show the best theory is one that is tested and works in practice. (Gibb and Hannon, 2006)

In 2001 International Management in Higher Education Conference in Paris it was discussed if being an entrepreneurial university was merely a new way to say that education was a business, about it Burton Clark from the University of California said at the opening session:

> *Universities are much more than a business. They have unique genetic features, and they have developmental trajectories projected by their own generic trends and societal commitments. And proactive universities shape their environments as much as they are shaped by them. Using common terms, they are self-initiating, self-steering, self-regulating, self-reliant, progressive. A well-rounded entrepreneurial narrative spells out the defining characteristics, and especially the advantages, of a type of modern university that stands on its own feet in order to adapt, on its own terms, to a highly complex and highly uncertain world*. (Clark, 2001)

This acknowledges the importance of context awareness and flexibility, the students that walk in to our classrooms today are very different from those walking that same path thirty or fifty years ago. Globalization, cultural transformations and a new need for personal growth and freedom have put entrepreneurship on the spotlight as a great alternative to build a career on. This societal change urges the Universities to raise awareness of the importance of entrepreneurship and actively encourage individuals to become entrepreneurs, provide opportunities to experience entrepreneurship and support moving from ideas to action and implementation.

Transforming the university is quite a challenge, it requires that entrepreneurship is embeded into the university mission and objectives, it requires to foster a culture of innovation and problem solving in their particular environments, so the "creation" of an entrepreneurial ecosystem sounds as a great way to start.

Manizales Universities have played an active role in developing and strengthening the ecosystem, demanding for programs that were as impactful for markets as they are for academia. Even with the first program: "High potential ventures" the universities asked for a couple of spots for teachers so they could share the room with the companies, listen to their experiences and understand the needs of the industry in the city. More programs followed focusing on start-up and growing business but everything gain momentum when the Teachers got a program designed for them. At that point universities knew they were more than mere agents participating in the ecosystem and took *"Manizales Más"* as part of their core, as part of their strategy in changing the way they teach, act, and think.

2. The role of university in *Manizales Más* entrepreneurship ecosystem

Since its creation "Manizales Más" has being a melting pot; it has welcomed the inputs of every agent and has promoted practices like empathy, which allows entrepreneurs to understand the market, but it also has allowed the stakeholders to understand each other. Each program in the project has very specific target audience and depending on what results are meant to be accomplished there are different focus and ways the

university can participate in. let's read a little about each program in the ecosystem and the university participation:

High Potential Ventures, is a program aimed at companies that have at least US$200.000 sales. The goal is income growth and job creation; for this kind of company the workshops focus on the idea of expansion and company improvement. Peer to peer and mentorship meetings become moments to rethink and discuss the entire company with people that can see the opportunities, strengths, and weaknesses with fresh eyes. There is a figure called accompanying teacher, that works with the companies and suggest possibilities based on experience and expertise.

Addventure Más, is a six-week business accelerator. In this case, new companies take the time to plan and rethink the business model. For almost two months around fifteen companies work together in a living lab, getting to know what they do, how they do it, and most importantly, what they should try to overcome the obstacles they are facing to earn more, have better employees, and sale better products. The program is completely run by universities, each week one university is in charge of one of the main topics and the entrepreneurial units get to test their abilities to teach and accelerate companies.

Startup Más, is the place for idea exploration and business model construction. It was created with the students and graduates in mind, many of which went to entrepreneurial units asking for help with their ideas. This early stage is the perfect moment to prototype and iterate ideas before launching anything. This program is also fully operated by the entrepreneurial units of the universities, teachers create different level workshops to help participants explore, pursue, launch and grow the business ideas.

The Mentoring Program, takes advantage of the experience senior managers have accumulated; the growing companies get the chance to talk and learn from seasoned businessmen, that advise them based on their own personal experiences. This method has permitted to recognize the expertise and abilities of many CEOs that have a chance to give back to the community and share the lessons hard learned in business life. The accompanying teacher figure also operates here and it has helped teachers to bring the mentors as guest lecturers to their classes.

Affiliates: a program designed for teachers to become visiting scholars at Babson College, an opportunity to immerse in Boston entrepreneurial ecosystem and Babson College entrepreneurial thought and action methodology. After the six-month experience, teacher come back to Manizales to implement new programs and share the best practices learned while in Boston.

High Potential Teachers, was created to promote a new mindset on professors so they can be the catalyst of change in the university. This is one of the most interactive experiences because educators are both learning and teaching in different moments. Sometimes on the learning side, they are with another faculty member, sharing experiences, accompanying mentorships, or attending workshops. And when they are conducting sessions they lead the audience, whether students or companies to use the resources they have to create new things, evolve, and transform the ecosystem. The idea of this program is to spark the interest of the innovative teachers to transform their classes and university curriculum.

Entrepreneurship Route with its six courses has become the space for experiential learning. Students are encouraged to create new companies, propose new products, and the most important part, to build a functioning prototype to test their ideas. The students have learned by doing and have had to face an audience to convince them of the importance of the proposal and explain how they solve a problem or have found a more innovative way to do things. Some of the projects presented by students are now start-ups or have been developed further as graduation projects.

In the end the success of "Manizales Más" entrepreneurship ecosystem lies on the Entrepreneurial community that has been formed, and the University is the catalytic agent to have a bigger and more impactful transformation.

3. Entrepreneurship in UAM vision mission and history

By the end of 1979, a group of businessmen saw that the city of Manizales needed a university where young people could be trained to address the local needs. Back in those days the scarce academic offer generated many young people to migrate to bigger cities like Bogotá and Medellin. This migration became permanent in the medium term, because these young people began to work in other cities and few returned to Manizales.

At that time the companies needed skilled labour that was not easy to find, this is how Universidad Autónoma de Manizales was born. A university with a business focus from its conception, created by entrepreneurs and businessmen to train the local talent into the future managers and employees they needed. The UAM begins with three academic programs that were the pillars of the three academic faculties that UAM has today: economics, dentistry and systems engineering have evolved over the years and now they are the social and business studies, health, and engineering faculty.

From that first moment the university´s mission was to educate people committed with regional development, following this purpose, the subjects were created focusing on promoting student's skills in the administrative and business field, even for the health students it was part of their core competencies development, because even if the graduates could be employed in public and private existing companies, they also had the possibility to create their own business and generate new economic dynamics in the city.

UAM was not the only university be born at that time in the city to, more universities were created or opened offices in Manizales, but this did not interfere with their growth and with their entrepreneurial conviction, that is why they strengthened their ties with the companies and promoted the triple helix model were science, industry and government need to collaborate and work together. All students carry out internships and practices, visits and class work, in different companies. Since all the students have to take some mandatory courses, the university developed a macro-curriculum that reflected their mission, where subjects like ethics, political culture, art or sport, are included. Also, in the macro-curriculum there was the subject entrepreneurial spirit and administration, today these last two subjects have become the entrepreneurship course, which is the beginning of the entrepreneurial route; the elective courses mentioned before.

As the theories and approaches to entrepreneurship were changing, UAM also change the way they talked and teach entrepreneurship, it became clear that it was important not just to generate economic growth in the city, but also to promote a new dynamic in the university were all the members of the community (managers, professors, administrative employees and students) would internalize that entrepreneurship is more than doing business. From every task and project, they do, they can be entrepreneurs and innovate. That is why within the graduate training programs UAM has a master's degree called Creativity and innovation within organizations, fundamental axes of entrepreneurship and growth in companies.

Given the entrepreneurial vision and the need for guidance and support that many students, graduates and workers requested, the entrepreneurship unit was created. Although at the beginning it was dedicated to advising about the idea, business plan and opening of a business, it was maturing more and more until becoming an ally not only for the people who wanted to set up a business but for the academic and administrative part to become entrepreneurial leaders and take innovation to all university's spaces.

To reinforce the university differentiation, UAM has a set of general competences that included the entrepreneurship competence along with quantitative thinking, citizenship, communicational and digital competence. UAM's current mission and vision is committed to entrepreneurship, from entrepreneurial training to the consolidation of entrepreneurial culture to respond in a creative, innovative and relevant way to the environment needs.

4. The transformation of its curriculum

Betting on entrepreneurship and educational innovation implied the challenge of transforming the curriculum, how students are taught and how the community in general, perceived education. It was necessary to break with the paradigm that knowledge was only in the teacher student direction. An integral change was needed, and that is the reason why UAM begun with a curricular adjustment in 2011. The Adjustment is conceived around four proposed moments: i) epistemological moment, ii) pedagogical moment, iii) curricular moment

and iv) didactical moment. For its development, the proposed work strategy implied to start from a general context perspective to reflected about the faculty, each of the programs and subjects that comprise it.

The first moment is the epistemological, there an analysis on the foundation of the professions is made, A reflexion on what allows them to solve problems of the context from the perspective of sciences, disciplines, techniques and technologies. Here is the nature of the knowledge required to contribute to the training of professionals. The problem field, object of study, generating concepts, logics of disciplinary organization and methods are revised and redefined if necessary; the theoretical underpinnings that guide the epistemological construction in the programs are demarcated.

The second moment is the pedagogical one, that particular reflection is centred on the human development, it is the moment to question about the type of human and professional the university wants to educate, it is fundamental to support in an integrating theoretical position, at this moment the specific and general competences of the program are reframed, as well as the professional and occupational profile, the training purposes and program problem.

The curricular moment is the articulation between the epistemological and pedagogical dimension to rethink the curriculum, an analysis of the curricula is carried out taking as reference the guidelines of the two previous moments; traditionally, the structure and reflection of the study plans had been defined based on criteria about types of subjects, such as basic, professional, socio-humanistic and complementary training. From the Adjustment, and as a complement to the established classification, an analysis of the curriculum is carried out by training areas starting from the professional and occupational profiles of the program. A problem-based curriculum shows the relational diagram of concepts and sub-concepts, the levels of problem comprehension (competence), the contribution areas and subjects, as well as the distribution of contents are taken into account for the product that is the curricular design.

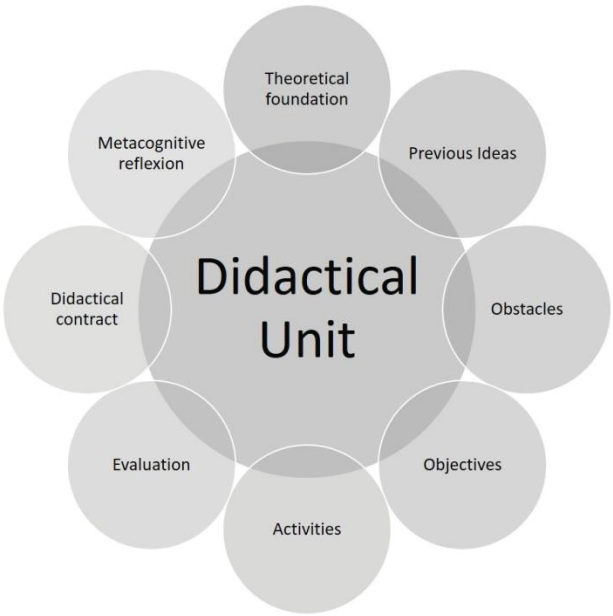
Finally, the didactic moment is where an analysis of the products and clarities reached with the reflections of the previous moments is made and the didactic unit is structured, through which the teaching process is planned and constructed, the definition of the means and resources that facilitate the student's conceptual evolution, and the achievement of the proposed objectives to contribute to the construction of the skills of the future professional.

The didactic unit becomes the integrator of the moments, it is the problem-based planning aiming for the critical thinking development of the student, teacher and context; the unit can be developed by subject or course and it depends on the analysis and / or requirements, the units are composed of eight fundamental factors that are not necessarily linear and become a system (as shown in figure 1). Here a brief description of each:

1. Theoretical foundation, which includes the epistemological and pedagogical moment grounded in the subject or subject.
2. Previous ideas where the preconceptions are explored and the main concepts needed to address the didactic unit are adressed.
3. Obstacles that can be detected in students, which can be of different types such as epistemological, linguistic, affective-emotional, technological, contextual, among others.
4. Objectives, an evaluation of teaching objectives and learning objectives is made from the obstacles identified in the students. The proposed objectives must lead to the development of general competences (communicative competence, quantitative thinking, digital competence, entrepreneurial competence) and the specific ones to each program
5. Activities, It is important to see if the activities planned to be done by the student and the teacher really aim at the proposed objectives.
6. Evaluation, construction of the rubric of qualification of the activities that are going to be evaluated in the course
7. Didactic contract, is the generation of agreements regarding student and teacher commitments, to overcome the initial obstacles and those that may be encountered throughout the course.
8. Meta-cognitive reflection is how the student is aware of what obstacles are faced and how they are going to be addressed and how the concepts, knowledge and objectives are internalized and achieved by the unit.

9. All of the mentioned parts putted together create a didactical unit, a big change in the way classes are planned and executed. The next figure shows all the elements you need to take in consideration to build a didactical unit.

Figure 1: Didactical unit components



Source: UAM teachers work group

As a fundamental part of the didactic unit we have as inputs the socially relevant problems for the development of critical thinking and the solution of problems as a teaching strategy as well as the combination of virtual and face-to-face learning environments under the B-learning modality that contribute to the incorporation of ICT through the use of digital classrooms as a mediator in the relations of the teaching system.

The implementation of the curricular adjustment has been progressive, for this the Institutional Curriculum Committee was created which is formed in a multidisciplinary way with representatives of the faculties and different academic and administrative units. In the committee, the steps to be followed are discussed and reformulated according to the needs of each program and faculty. The process began with the implementation of the adjustment to two academic programs: physiotherapy and economics who later with the help of the committee begin to work with the other programs of their same faculty; Finally, a strategy for the faculty of engineers is built to bring the whole university to adjustment. Currently the adjustment has not ended because the idea is to cover all the programs and that all subjects have built didactic units which are not static, because every semester facing a new student group involves making revisions to the different components of the same.

That is why it is vital to work with teachers, so that they see that the didactic unit is their course in class, it is their integral planning and they leave behind just going to dictate some contents without analysing the reason for the importance of them for the Professional training

For the subject of entrepreneurship, the process of curricular adjustment was something different, as it was said before, the analysis usually starts from the problematic field of the faculty, but entrepreneurship is not a subject that depends on a single faculty, it is more than a subject a stamp that the UAM wants to have in its community. That is why the analysis started from the institutional approach and transcended to its strategic planning where it is contemplated in the UAM entrepreneurship culture, and in the mission, vision and entrepreneurship competence.

Entrepreneurship competition seeks to take into account the entire UAM community, students, employees, graduates and companies, but also seeks ways to take entrepreneurship to the classroom beyond the subject of entrepreneurship. Entrepreneurship competition consists of the following dimensions:

1. Create or Identify opportunities and manage the necessary resources
2. Management of uncertainty and awareness of the work context
3. The ability to define the acceptable loss we call calculated risk
4. The Design Thinking method as a tool to propose solutions to environmental problems.
5. Leadership and ability to plan, manage projects and work teams

Which have performance criteria that students are expected to develop as a result of their training process with respect to each element, which serve as a guide to establish objectives and learning activities. Some of the strategies applied in class that contribute to develop the entrepreneurship competence are: Workshops with specific challenges, Case study for teaching, RPGs, Simulations, Work in subgroups in the classroom, among others.

Entrepreneurship at the UAM has not only permeated the academic sphere in an integral way, it has also permeated the administrative area and the physical plant where today there are spaces designed to encourage collaborative work processes and innovation, with classrooms with technology such as pad board and starboard that promotes interaction in the group, with furniture design that allows work in subgroups and take advantage of the space of the classrooms in its 360° since seeing a problem from different angles can lead to multiple and innovative solutions.

5. Entrepreneurship classes and the Entrepreneurial University

As previously mentioned, all UAM students take a course called entrepreneurship, the course seeks to strengthen the understanding of the entrepreneurial process and business opportunity evaluation that allows entrepreneurs to determine potential feasibility and viability of a new businesses or growth initiatives for an existing company. Part of this process involves different methods and the development of a mindset for adding innovation and the advance of new ideas. This course is mandatory because it helps students from all different programs to understand the impact they can have in any given project they pursue in their careers and it also helps them prove themselves when generating and presenting a business idea and prototype in a pitch event where all the university can participate.

This process of experiential learning and the use of play has allowed students to become much more interested in entrepreneurship and it is not considered as “just another subject” in their curriculum, but an opportunity to find their path as entrepreneurs, regardless of the bachelor’s degree they are pursuing.

Attitudinal changes are seen, students work with more motivation in their projects, present more innovative and ambitious proposals, and form multidisciplinary teams that support integration between different schools.

This work develops tolerance towards uncertainty and the ability to face new situations, search for resources, investors and new markets.

The shift from traditional to experiential classroom management presents multiple challenges for both teacher and student. Each task, reading, video and workshop must fulfil the objective of bringing theoretical knowledge to its practical application in the environment. Each extra class activity should be an opportunity for the student to observe and become aware of the realities that surround them and the world they will have to face once they receive their professional title. Students are now involved with real entrepreneurs, and we are integrating the participants of other “Manizales Más” programs as guest speakers or real industry problems providers for students to work in class.

The course has six moments, an entrepreneurial myths unit to discuss the different approaches and lies that surround an entrepreneurial venture, a self-assessment unit to have a chance to discover each other strengths and passion, a creativity unit to allow students to propose new and unconventional ideas that could be the base for a developable project, a Feasibility unit where students begin to understand the possible customer and need they are targeting with their value proposition, then they move to develop a business model canvas to understand the kind of business they want to create and finally they develop a prototype and a pitch to present in front of an audience of 300 people, usually students and teachers, but occasionally, businessmen and ecosystem representatives.

All of the above description just reaffirms the commitment Universidad Autónoma de Manizales has made to move entrepreneurship from just a subject to a way of teaching and doing things in Manizales. UAM is a young institution that evolves and adapts to the times and context, proving that a university can be entrepreneurial from the core to their everyday actions.

Abstract: The Higher Education Sustainability Initiative (HESI, 2017a) states that higher education institutions (HEIs) are integrating the SDGs into sustainability strategies in the form of research, teaching, pedagogy, and campus practices, and to position HEIs as key drivers for achieving the UN Sustainable Development Goals (SDGs). Concern has been raised (HESI, 2017b) as to the potential impact of HEIs in helping to achieve the SDGs; the challenges faced by HEIs with integrating the SDGs into curriculum and institutional strategies; the role of partnerships for HEIs among students, faculty, government, and various stakeholders; and how the adoption of the 2030 Agenda for Sustainable Development, including the SDGs, will transform the work of HEIs. According to CASE (2017) "… the need of new ways of teaching and learning…includes sustainable entrepreneurial education." This paper reviews progress of a sample of n=307 signatories to the HESI and identifies implications for practice.

Keywords: SDGs, HEIs, UN HESI, Sustainability Pedagogy, HEIs and Governance.

1. Introduction

The Higher Education Sustainability Initiative (HESI) was established in 2012 by a group of UN partners including the Executive Coordinator of Rio+20, UN DESA, UNEP, UNESCO, UN Global Compact, UN GC PRME and UNU. Initially 272 HEIs from 47 countries made voluntary commitments to drive the sustainability agenda.

Progress was evaluated in 2014 (HESI, 2014) finding that 73% of 272 commitments made by HEIs indicated partial progress, either directly or indirectly; 18% hadn't demonstrated any progress, 9% could not be determined.

Research for this paper provides a more recent review of progress and discusses implications for Enterprise & Entrepreneurship Education within HEIs. The focus is on HEIs as they are considered to be a key catalyst for a sustainable society (IARU, 2016); and HEIs serve as institutional moral reinforcers (Hanson *et al*., 2017). And, as Mindt and Rieckmann (2017) contend, the transformation of current economic systems towards sustainable development requires innovative sustainability-driven enterprises with competent managers and staff. This includes HEIs.

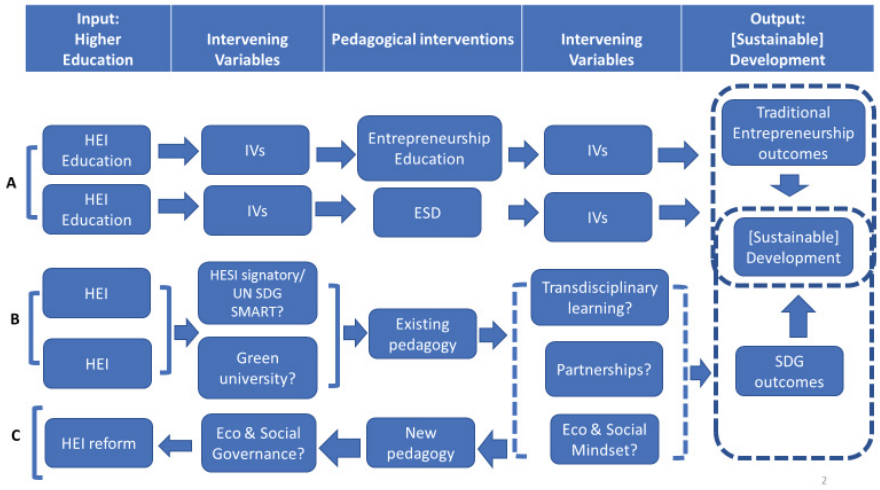

Figure 1: Conceptual framework.

The conceptual framework in Fig.1. is based on academic literature relating higher education to sustainability outcomes (e.g. Wals, 2013). The literatures on the 'need' for both entrepreneurship education (ED) and education for sustainable development (ESD) are both strong. The impact of pedagogical interventions on both EE and ESD outcomes is less clear (conditions A&B) due to numerous intervening variables (c.f. Wals, 2013). In fact, there are tensions between the goals of traditional entrepreneurship and sustainable development i.e. economic growth and the exploitation of resources (self-interest) vs. limiting growth and conserving resources (sustainability). As James & Schmitz (2011) acknowledge, business schools sometimes fail to engage the exploration of sustainability holistically because of the lure to view sustainability as a tool for profitability instead of responsibility.

Aragon-Correa *et al.,* (2017) also draw attention to these tensions. These tensions partly explain the lack of eco and social entrepreneurship courses in HEIs (Moon, 2017); and also creates a potential problem for policy makers in regard to higher education. For example, Snelson-Powell *et al*., (2016) suggest that: rather than institute actual change and include sustainability in organizational activities, business schools may 'merely' indicate that such change is taking place. This paper, therefore, investigates key factors of the above literature e.g. transdisciplinary learning, partnerships and eco & social mindsets (condition C), to see if there are significant pedagogical and governance implications necessary for HEI reform, in order that HEIs can transform from mere catalysts of sustainable development to fully committed enablers. The impact of the research could represent a paradigm shift from conditions A&B to condition C.

2. Prior research

Dawe *et al*., (2005) in a report for the Higher Education Academy (HEA) investigated sustainability 'literacy' of students in different academic disciplines over a six-month period. The authors found an overall patchy picture with sustainable development being marginal or non-existent in some influential disciplines but increasingly higher profile in others; major gaps in curricula; and four major barriers to implementing ESD: (1) overcrowded curriculum; (2) perceived irrelevance by academic staff; (3) limited staff awareness and expertise; (4) limited institutional drive and commitment. The problem over major gaps in curricula and the four barriers cited above all have implications for Enterprise & Entrepreneurship Education.

The Mader and Rammel (2015) study for UNESCO Chair in Higher Education for Sustainable Development, International Association of Universities, Institute for the Advanced Studies of Sustainability (United Nations University) concluded that: to achieve related goals of drafted UN SDGs, HEIs, and higher education policy needs to take action to change not only single curricula, research programs or waste systems within institutions but enable a whole of institution and system-wide transformation in collaboration with practice.

This highlights the importance of taking a more holistic approach to education. 425 higher education stakeholders from 101 countries responded and reported about their achievements and challenges. The study, carried out in collaboration with the International Association of Universities and financed by the Austrian Federal Ministry of Science Research and Economy, was presented in September 2014 at the international Conference on Higher Education for Sustainable Development in Nagoya, Japan. Globally 45% of respondents say that they are inspired by policies to integrate sustainability into their institution. The authors concluded that this transformation would be enhanced by the following actions:

- Establishing transdisciplinary settings for research and education;
- Aiming at capacity building and training to enable individual and collective leadership for sustainability in higher education;
- Initiating the assessment of global, regional and local challenges so to link global challenges to regional context;
- Establishing sustainability as a base line for higher education policies at national, regional and global levels;
- Applying a whole institution approach that reflects people's needs and competences;
- Inspiring transformations at the interface of education, research, policy and practice;
- Supporting a stronger focus on transformative education and new ways of teaching and learning.

Thus, it appears that HEIs might be willing to embrace the sustainability agenda in general but might lack the capacity to support the UN SDGs in their governance strategy and operations. In fact, Wyness *et al* (2015) in a

survey of N=54 entrepreneur educators from Australia, New Zealand, UK and the USA found embedded sustainability practice was typically limited to "add-on" courses to traditional entrepreneurial teaching. Yet, Snelson-Powell *et al*., (2016) conclude that failure to implement sustainability could subject [HEIs] to legitimacy risks, if the lack of operational engagement is later exposed. Thus, the Mader & Rammel (2015) recommendations provide an agenda for change. And this is supported by TEF (2017) in the UK.

3. The need for more 'holistic' approaches

HESI (2017b) have noted that institutional structures and hierarchies within universities often impede interdisciplinary and trans-disciplinary research and studies. A focus on more holistic approaches could, therefore, have a considerable impact on spurring sustainable innovation and applied research. The emphasis could, therefore, shift from 'teaching' students to supporting students, 'enabling' them to learn applied skills of relevance to business and society in general. And if students were more involved in formal or informal institutional governance then perhaps there could be a renewed interest in the SDGs and in developing new and innovative solutions from the perspective of youth or the next generation.

Unfortunately, the European Commission funded project "University Educators for Sustainable Development" (UE4SD) revealed that among 33 European countries there is a big lack of professional training programs in education for sustainable development. An investigation among 33 countries showed that even though 16 countries report about national strategies or action plans on sustainable development or ESD, only 9 strategies call for professional development and only seven countries report about national or regional initiatives for professional ESD training (UE4SD, 2014). Consequently, there is a sizeable gap between what is explained in national or regional strategies and what is done to empower people to act accordingly. Significant to CPD (continuous professional development) is ensuring that teaching-learning approaches are updated; and this can be achieved via good academic-business partnerships.

4. The need to partner with business

The most recent review of progress with the HESI was in July 2017 (HESI, 2017b) in New York, on the occasion of the 2017 session of the High-Level Political Forum on Sustainable Development - United Nations' central platform for follow-up and review of the 2030 Agenda for Sustainable Development and the Sustainable Development Goals (SDGs) - and in conjunction with the 2017 Global Forum for Responsible Management Education. Over 500 participants from governments, the United Nations (UN) system, academia, and other relevant stakeholders including business attended the two-hour event, which presented concrete case studies from a wide range of higher education institutions and initiatives on how they are contributing to implementation of the Sustainable Development Goals. Examples of best practices collaboration between academia and business include:

- ESPAE-ESPOL - five companies presented their experiences and progress in aligning their strategies with the SDGs through use of the SDG Compass.
- ChallengeLab.org of Chalmers University of Technology provides a broad platform for students to engage and take on the planet's biggest challenges in collaboration with industry, governments and academia.
- Stanford University Sustainable Urban Systems (SUS) initiative – an initiative which applies multiple engineering knowledge fields in an integrated approach to shape the future of cities to test SDG localization strategies, collecting relevant actionable data at the city level to achieve the SDGs.

Whilst it is too early to evaluate the impact of these partnerships, it is clear that the overall trend is for companies to work with HEIs to better inform their strategies in support of the SDGs.

5. The need for new approaches to teaching and learning entrepreneurship

Mindt and Rieckmann (2017) conclude that 'To date, there is no comprehensive literature review dealing with teaching-learning approaches and methods of higher education for sustainability-driven entrepreneur-ship'.

These authors distinguish sustainability-driven entrepreneurs as having: (1) systems thinking competence; (2) normative competence (values thinking); (3) action competence; (4) interpersonal competence; and (5) strategic management competence. This builds on the work of Wiek *et al* who more recently identified a meta

competence (6) integrated problem-solving (Wiek *et al*., 2016, 243). And of ENTRECOMP (2016) which identifies ethical and sustainable thinking as a key competence of entrepreneurs.

Active, collaborative, problem-based, experiential, and interdisciplinary approaches can all benefit from academic-business partnerships. Mindt and Rieckmann (Ibid) cite various authors that testify to such benefits (e.g. Barth *et al*., 2014; Lehmann *et al*., 2008; Thomas, 2009). One example is the European project CASE – Competencies for A Sustainable Socio-Economic Development – which is a joint European Master's Programme on Sustainability-driven Entrepreneurship involving 10 universities and business partners from five European countries (CASE, 2017). The pedagogical framework is shown in Fig. 2.

Figure 2: CASE thematic and pedagogical outline.

Evaluations of 9 pilot courses are currently under way. Examples of innovative pedagogical practices involving external partnerships (from a total of 19 partnerships) include:

- Austria 'sustainability challenge' – intra and transdisciplinary course in cooperation between four HEIs - encourages students to develop their own business solution together with business partners. TryOut – six-week internships in start-ups.
- Germany 'Outside the University Box' provides city challenges for students with three external partners: the city administration, a local food entrepreneur (start-up company) and a municipal institution for elderly people and intense nursing. Working with a company partner on corporate sustainability communications. Internship in an institution with disabled persons.

According to CASE (2017): The CASE Knowledge Alliance jointly accepts the need of new ways of teaching and learning as well as a strong cooperation between higher education and business to enhance a sustainable socio-economic development in general and new forms of sustainable driven enterprises in particular.

6. The need for adequate measurement of sustainability in HE

Cortese (2003) highlighted the critical role of higher education in creating a sustainable future. In fact, he acknowledged that it is the people coming out of the world's best colleges and universities that are leading us down the current unhealthy, inequitable, and unsustainable path. Thus, a transformation of higher education is called for. More recently, IARU (2016) have produced a report on 'greening' the university. Whilst the report is written by the International Association of Research Universities, the findings are aimed at all HEIs. Thus, IARU recognise that all aspects of HEI life need to be geared towards achieving sustainability including: sustainable campus organisation, campus-wide operations, buildings, laboratories, green purchasing, transport, communication, employee and student engagement. There are clear implications here for the governance of HEIs. Indeed, without top level support and more holistic approaches there is little to suggest that HEIs can overcome the 'cynical' or 'instrumental' attitudes towards the environment that many students can have (Moon, 2015). Therefore, steps that HEIs take towards 'greening' the university (as identified by IARU) will be used as a default measure of 'holism' for the purposes of this research.

Another measure of HEI commitment to sustainability is 'sustainability literacy'. In fact, there is one test named SULITEST (2017) that has been taken by over 61K students from over 600 HEIs in 57 countries. Results show that students are on average more aware of specific SDGs than of the 2030 Sustainable Agenda and related UN processes. However, this test reveals general awareness of sustainable development knowledge rather than impacts of HEIs tackling SDGs in particular. And Dawe *et al.,* (2005) in their report for the Higher Education Academy (HEA) concluded from 'sustainability literacy' there was an overall patchy picture with sustainable development being marginal or non-existent in some influential disciplines and higher profile in others; major gaps in curricula; and major barriers to implementing ESD. Nevertheless, various statements are included in the accompanying survey for this paper to check for the strength and depth of HEI commitment.

Thus, statements pertaining to pedagogical approaches, transdisciplinary projects, partnerships, give a more thorough indication of the level of commitment provided towards the HESI and concomitant SDGs.

Clearly the best measure of the effectiveness of ESD is actual behavioural change. This can be evidenced by identifying sustainable development projects initiated as a result of ESD programmes in HEIs. However, the actual impact of educational programmes might not be evident for years after students graduate, if at all.

Thus, apart from impact case studies written of projects undertaken by participating students, most educators are again left to try and measure the effectiveness of ESD programmes through various default measures e.g. attitude change, propensity to engage in sustainable development initiatives, etc. One approach to eliciting such propensity is through identifying sustainability mindset, or more specifically eco and social mindset in the case of eco and social entrepreneurs. Moon (2013) used personal construct theory and rep grid technique to show that the mindset of eco and social entrepreneurs does differ from more traditional entrepreneurs. The stage is now set to more precisely measure what this mindset involves; and several scales are explored in this study relating to compassion, empathy and connectedness in relation to the SDGs. The findings will form the basis of a tool that can be used by organisations, educators and students for reflection, appraisal and development purposes. From the above literature the following research questions were formed.

6.1 Research questions

Our survey instrument, educator interviews, and student feedback mechanisms, were designed to get answers to the above challenges:

1. What are the benefits and best practices in adopting the UN SDGs?
2. What are the benefits and best practices of the UN HESI as a tool for adopting the UN SDGs?
3. What are the challenges and obstacles faced by HEIs in adopting the above e.g. governance issues, silo issues, mindset issues?
4. What are the implications for enterprise and entrepreneurship education e.g. mindset of educators, CPD of educators, tools for educators?
5. What added value does enterprise and entrepreneurship education bring to HEI implementation of the SDGs?
6. To what extent is the 'competence' model the primary theoretical underpinning to pedagogical development in this area i.e. sustainable entrepreneurship.
7. How can we effectively measure changes in student attitudes and behaviours as a result of ESD interventions?

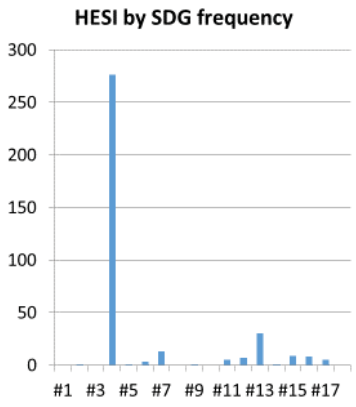
6.2 Methodology

The target sample was the 307 HEI signatories to the UN HESI. Follow-up interviews were also conducted with 80 students of enterprise education and 8 entrepreneur academics. The initial survey instrument included questions on which SDGs each HESI had signed up to, progress with their implementation, challenges faced and how obstacles were overcome. Further, a series of statements from the literature were designed to test the validity of the literature on ESD pedagogy, governance, and partnerships, etc. As our research analysis is not yet concluded, at the time of writing this paper, only related responses from the initial survey are reported below.

6.3 Findings

Fig. 3 shows that 276 of 307 HEIs committed to SDG#4 Education i.e. 89%. 30 HEIs committed to SDG#13 Climate Action i.e. 9.7%. Only 24 HEIs committing to > 1 SDG i.e. 7.8%. Of particular concern is that five SDGs

are not being committed to by any of the HESI signatories. And SDG#17 Partnerships for the Goals is only committed to by N=5 HEIs.



Raw data

SDG#4	**Education**	**N=276**
SDG#13	Climate Action	N=30
SDG#7	Affordable & Clean Energy	N=13
SDG#15	Life on Land	N=9
SDG#16	Peace, Justice & Strong Institutions	N=8
SDG#12	Responsible Consumption & Production	N=7
SDG#17	**Partnerships For The Goals**	**N=5**
SDG#11	Sustainable Cities & Communities	N=5
SDG#6	Clean Water & Sanitation	N=3
SDG#5	Gender Equality	N=1
SDG#9	**Industry, Innovation & Infrastructure**	**N=1**
SDG#14	Life Below Water	N=1

Missing: #1 No Poverty; #2 Zero Hunger; #3 Good Health & Well-Being; #8 Decent Work & Economic Growth; #10 Reduced Inequalities.

Figure 3: Frequency of SDG SMART commitments by HESI signatory.

Table 1 indicates that although over 300 HEIs signed the UN Higher Education Sustainability Initiative, only a small proportion are taking the more holistic approach across the HEI to implementing the SDGs. Our measure based on IARU (2016) provides an indication of the extent to which whole institution approaches are being implemented i.e. board level support with sustainability integrated into operations. For each HEI that means ESD curriculum, transdisciplinary and extra-curricular activities including academic-business partnerships. For the majority of HEIs these are still absent.

Table 1: Implications of the SDGs for HEI reform & enterprise education.

How the SDGs can help HEIs (PRME)	Obstacles for HEIs that can hinder the adoption of SDGs (adapted from Rasche et al, 2016)	How HEIs can overcome the obstacles (adapted from Rasche et al, 2016)	Implications for HEIs (EEUKRP 2017/18 survey findings)	Implications for entrepreneurship education (EEUKRP survey findings 2017/18)
Strengthen and enable future business practitioners, thereby adding value to modern business and society	Groups of actors can obstruct the development and implementation of the SDGs	Base on mission and strategic vision of HEI; integrated through all levels of the HEI and through strategic engagement with staff and students	HEIs are catalysts for a sustainable society. Therefore, HEIs need to develop sustainably: including campus organisation; campus-wide operations; buildings; laboratories; green purchasing; transport; communication; employee and student engagement.	Entrepreneurship education can benefit from being more competency based e.g. CASE competences for a sustainable socio-economic development with real-world orientation, university-business cooperation, and sustainability-driven entrepreneurship.
Give future business leaders the tools to recognise and maximise sustainable opportunities	Aspirational talk, greenwashing, and 'bullshit' can be used to oversell commitment to SDGs	Ensure specific, time-bound and measurable, linked to value creation, financial drivers and future investment	HEIs need to set goals based on achieving all 17 SDGs, with measurement and reporting based on all 17 SDGs.	All enterprise and entrepreneurship students should be tooled in e.g. Circular Economy Design techniques and Life Cycle Analysis (LCA) tools.
Create a paradigm for teaching, learning and understanding sustainability as core to the business model	Individuals can exploit loopholes in the SDGs	Ensure covers all dimensions of sustainable development and implemented on an interdisciplinary scale	There are 17 SDGS. EEUKRP found that most HEIs have only signed up to one SDG #4 Education. Sustainability needs to be integrated across schools and programmes building on the agenda set by Mader& Rammel.	Approaches to solving global risks increasingly need to be based on developing sustainability innovations via transdisciplinary approaches, partnerships and eco & social mindsets. Policy makers for EE should ensure that there is a paradigm shift in this regard.

How the SDGs can help HEIs (PRME)	Obstacles for HEIs that can hinder the adoption of SDGs (adapted from Rasche et al, 2016)	How HEIs can overcome the obstacles (adapted from Rasche et al, 2016)	Implications for HEIs (EEUKRP 2017/18 survey findings)	Implications for entrepreneurship education (EEUKRP survey findings 2017/18)
Connect with a network of stakeholders reaching beyond the business sphere, into signatories and supporting organisations	[Isolation; institutionalisation, bureaucracy, etc.]	Ensure covers entire value chain and all HEI stakeholders	Only N=5 HESI signatories commit to SDG#17 Partnerships for the Goals. HEIs need to more actively consider ecosystems development in this regard e.g. glocal identities; and promote academic-business partnerships across disciplines.	Learning gain by students needs to be curricula and extra curricula. The Erasmus CASE program provides examples of academic-business partnerships.

7. Discussion

This paper has highlighted some of the benefits of adopting the UN SDGs and a sample of best practices.

Benefits include providing a focal point for students to learn about the breadth and depth of sustainability issues and problems within local and global contexts. Best practices are more evident when HEIs have committed to more than one SDG. In fact, this highlights the interdisciplinary nature of problems and potential solutions. The UN HESI has been shown to be a valuable tool for adopting the UN SDGs in HEIs. The framework provides a reminder that there are 17 SDGs and innovative projects can be based on single or combined goals.

By combing goals in different ways students across disciplines can 'disrupt' silo thinking and develop more creative solutions to complex problems.

HEIs are facing numerous challenges and obstacles when implementing the SDGs. Becoming one of the UN HESI signatories does provide an impetus to each HEI tackling the SDGs. However, there can still be important governance issues to face. Thus, HEIs that are adopting the more holistic approach to implementing sustainability have a more effective platform for SDG implementation, overcoming the vagaries of silo thinking. Indicators of this holistic thinking are evident when HEIs adopt more comprehensive measures to become a greener university (IARU measure). The growing emphasis on eco and social entrepreneurship in a small number of HEIs also provides a positive indication that mindsets are changing within HEIs. That is, accepting that traditional entrepreneurship has not always considered eco and social entrepreneurs as having qualitatively different mindsets which are more supportive of achieving the SDGs in general.

The main implication for enterprise and entrepreneurship education is that CPD of educators is an important perquisite for developing the next generation of eco and social entrepreneurs. Thus, there needs to be more CPD tools and training to enable staff development in this regard. This is especially true for enterprise and entrepreneurship education which is designed to enable the entrepreneurs of the future. Education to develop the mindset of entrepreneurs has ideally included an awareness of social, economic and environmental factors (QAA, 2015). However, there is increasing recognition that all graduates need to be prepared to make a strong contribution to a sustainable society (TEF, 2017). There is evidence of a changing emphasis on broader competences (ENTRECOMP, 2017). Thus, the development of sustainability competences is now a feature of a small but growing number of university programmes. However, the efficacy of the competency model in this regard is still relatively untested and should be subject to further research.

8. Conclusions

This paper has reviewed developments in higher education towards achieving the SDGs. The UN Higher Education Sustainability Initiative was used as a default measure of HEI commitment as each HEI has to make SMART commitments towards tackling one or more of the SDGs. Of the 307 HEI signatories surveyed 276 (89%) only committed to SDG#4 Education. Whilst HEIs are clearly part of the education industry and education is critical to sustainable development, there is concern that some HEIs have selected SDG#4 out of mere convenience or marketing.

Other HEIs have committed to a broader range of SDGs and this provides the opportunity to identify best practices in relation to more than one SDG. And several HEIs have identified academic-business partnerships as evidence of such best practices. However, these examples are in the minority which raises concerns that the governance of HEIs is not fully committed to achieving the SDGs. Thus, numerous HEIs are still at the stage of simply providing courses in sustainability but not fully integrating them across disciplines; and not addressing sustainability practices in a holistic way across HEI operations.

This paper recognises that if HEIs are to fully prepare students to work in the green economy, and to be the creators and innovators of more sustainable solutions, then HEIs need to transform their governance systems to fully endorse sustainability principles and practices. This includes signing up to the UN HESI but more so for each HEI to make SMART commitments towards achieving all the SDGS. Ashridge/Hult, in the UK, now report against all the SDGs; and is a leader in this regard globally. Perhaps it is time for other HEIs to transform or reform, in this way, in order to fully realise the transformative potential of the SDGs cited by Stevens & Kanie (2016).

Abstract: This explorative study investigates the early stages of a health-technology startup in the Slovenian context. Although numerous stage models have attempted to clarify management priorities during the early stages of business growth, more focused, context-specific studies are needed. This study bridges this gap by synthesising these studies and answering the following research questions: (1) How do the most recent empirical stages of growth describe the early-stage management priorities in technology-based firms? (2) How do the experiences of managers in a technology-based health startup relate to the assumptions of stages of growth theory in the Slovenian business context? First, a revised synthesis of earlier published stages of growth literature is provided to clarify the central management priorities of early-stage technology-based firms. Second, though a single exploratory case study in a Slovenian context, we test a new research protocol based on a revised four-stage grid-type framework. Meta-analytical methodology is used to revise the framework, and a sequential incident technique and semi-structured interviews are used for case study data collection. For triangulation purposes, multiple managerial perspectives (e.g. company, operations and marketing management) are analysed for each company studied. In this study, the applicability of the revised framework are explored and context-specific viewpoints in Slovenia are analysed. Based on the results, the next steps for data collection and analysis in Slovenia are suggested. This study is limited by the context, the number of cases examined and the study's focus on the first phase of the framework. The applicability of the results to other contexts is, therefore, limited. Context-specific viewpoints and their effects on the early stages of companies have not been widely investigated. This work considers and provides new insights into the growth and management of technology-based health startups in the Slovenian context.

Keywords: stages of growth, growth process, sequential incident technique, entrepreneurship, micro-entrepreneurship

1. Introduction

Enterprise growth can be studied from multiple perspectives, including stochastic models (e.g. Gibrat, 1931) as well as static equilibrium (e.g. Coase, 1937), transaction cost (e.g. Williamson, 1975), economics of growth (e.g. Penrose, 1959), resource-based (e.g. Penrose, 1959), evolutionary (e.g. Nelson and Winter, 1982), organisational ecology (e.g. Hannan and Freeman, 1977), strategic adaptation (e.g. Sandberg and Hofer, 1982), motivational (e.g. McClelland, 1961) and configuration (e.g. Churchill and Lewis, 1983; Greiner, 1972) theories.

This study focuses on the configuration perspective, which deals with the actual growth process, in contrast to perspectives that are concerned with factors that *lead* to growth. According to Davidsson and Wiklund (2006), the configuration perspective focuses on how managerial problems occur and how they can be dealt with during the presumed growth of a firm in typical stages of development.

The configuration models developed during the past few decades vary widely in terms of their focus industry, use of empirical evidence, number of stages and other factors (e.g. Siu and Kirby, 1998). Recent reviews of the literature show that numerous stage models abound (see Levie and Lichtenstein, 2010; Muhos et al., 2010; Phelps et al., 2007). In the management literature, generic analyses of these models have shown neither consensus nor empirical confirmation of the stages theory because many of such models and frameworks are conceptually based. However, focused empirical models have produced consistent findings. Empirical studies have mostly examined technology-based firms. Empirical tests by Hanks et al. (1993) and Kazanjian and Drazin (1990), among others, have provided support for the applicability of technology-based, firm-focused models.

The main findings of 14 recent empirically based stage models that centre on technology-intensive companies were synthesised into a four-stage self-evaluation framework by Muhos (2011) to test the main results of the models. The framework was preliminarily tested in Thailand, Finland, Taiwan and the United States (Muhos et al. 2016; Muhos et al. 2014a; Muhos et al. 2014b). The findings initially supported the applicability of the framework in these contexts, and some context-specific viewpoints were emphasised and further analysed. An

in-depth analysis of the experiences of the managers of case companies will allow an examination of the gaps between reality and stage models, as well as highlight potential paths for the further development of these models.

In this research, the abovementioned reference framework is revised and further developed into a new research protocol that will be preliminarily tested in analysis of a technology-based health startup within the Slovenian business context. By implementing a single-case study to test this research protocol, this study supports the collection and analysis of a broader multiple-case study to be implemented in the Slovenian and, eventually, other contexts.

The startup period is critical for the survival of a new company; decisions made during the early stages of growth greatly influence the lifespan, productivity and success of a company. An empirical and context-specific understanding of the underlying processes of startup growth is urgently needed. This study bridges this gap by answering the following research questions: (1) How do the most recent empirical stages of growth describe the early-stage management priorities in technology-based firms? (2) How do the experiences of managers in a technology-based health startup relate to the assumptions of stages of growth theory in the Slovenian business context?

This retrospective single-case study seeks to clarify which viewpoints the managers of technology-based health startups experience in this critical stage. Through a single-case study strategy, we explore these experiences from conception and development to commercialisation and compare the managerial experiences to literature describing the early stages of technology intensive firms. A preliminary test is conducted of the applicability of the research strategy and framework to technology-based startups within the Slovenian context, and context-specific viewpoints are explored.

2. Early stages of service-based companies: revising the self-evaluation framework

This study devises a reference framework based on a meta-analytical synthesis of recent studies focused on technology businesses and the empirical stages of growth[1]. From an analysis of 14 recent and relatively consistent models (Abetti, 2001; Garengo and Bernardi, 2007; Hanks et al., 1991; Hanks and Chandler, 1992; Hanks et al., 1993; Hanks and Chandler, 1994; Kaulio, 2003; Kazanjian, 1988; Kazanjian and Drazin, 1989; 1990; Mitra and Pingali, 1999; Poutziouris et al., 1999; Smith et al., 1985; Stam, 2007; Swiercz and Lydon, 2002; Van de Ven et al., 1984), the early stages of technology-intensive small and medium-sized enterprises were identified as (1) **conception and development**, (2) **commercialisation**, (3) **expansion** and (4) **stability/renewal**.

The first two stages of the four-stage self-evaluation framework for early-stage technology-based companies are presented as a frame of reference to describe what happens during critical early development of a firm from establishment to commercialisation.

The above-described framework was revised for this study following a meta-analytical research strategy. First, an in-depth analysis of the abovementioned 14 models was conducted. The models that were selected and further analysed in this study are presented in Table 1.

Table 1: A sample of the selected empirical studies included in the meta-analysis

#	Authors, Year	Peer review	Business focus	Stages	Research strategy	Sample size
1	Van de Ven et al., 1984	yes	Technology	5	Case study	12
2	Smith et al., 1985	yes	Technology	3	Survey	27
3	Kazanjian et al., 1988; 1989; 1990	yes	Technology	4	Multi-method	283
4	McCann, 1991	yes	Technology	4	Survey	100
5	Hanks et al., 1991	yes	Technology	4	Survey	166

10	Abetti, 2001	yes	Technology	4	Case study	2
11	Swiercz and Lydon, 2002	yes	Technology	2	Multi-method	27
12	Kaulio, 2003	yes	Technology	4	Case study	8
13	Garengo and Bernardi, 2007	yes	Technology	4	Survey	100
14	Stam, 2007	yes	Technology	5	Survey	174

[1] The main phases of growth were identified earlier in an extensive literature review (see Muhos, 2011).

Second, the models were analysed to describe their characteristics in relation to the stages identified by Muhos (2011) to clarify shared growth management themes. Data were interpreted through explorative meta-analysis, based on which the shared perspectives were classified into the following nine themes:

1. Focus
2. Power
3. Structure
4. Decision-making system
5. Strategic management
6. Product and/or technology development and delivery
7. Marketing
8. Human resources
9. Growth management

Third, the results were described in the form of a revised self-evaluation framework. The revised reference stage framework is presented in Table 2.

This explorative meta-analysis was completed to lay a foundation for developing reliable self-evaluation frameworks and conducting further analysis of the early stages of technology-based businesses. The framework described above is used to analyse and reflect upon the experiences of managers during the early stages of firm growth.

Table 2: Developmental characteristics of technology-based startups: a revised self-evaluation framework

	Stage 1: Conception and development	Stage 2: Commercialisation	Stage 3: Expansion	Stage 4: Stability/renewal
Beginning of the stage	The establishment of the company	Early reference customers	Technical feasibility and market acceptance, which lead to high growth	A slowing growth rate and intense competition in maturing product markets
Focus	A1.1 The main objectives are product and/or technology development and the establishment of an early customer base.	A2.1 The main objectives are the creation of the business and commercialisation of the product; resource generation and survival are key issues.	A3.1 The main objectives are management of the company towards growth and increasing the market share by marketing and manufacturing the product efficiently at a high volume.	A4.1 The main objectives are the second generation of the product and improvement of the effectiveness and efficiency of the first generation.
Power	A1.2 The newly established firm is owner-dependent.	A2.2 The firm is dependent on the owner(s) and/or a small number of partners.	A3.2 The owner and/or partners remain central but delegate responsibilities to a small management team.	A4.2 The owner–manager(s) is/are supported or replaced by a professional executive or a team of executives.
Structure	A1.3 The organisation functions as a product development team.	A2.3 The owner(s) and/or a small number of partners form the nucleus of the administrative system.	A3.3 Specialised functions are considered and added. Efficiency and effectiveness is improved through structures and processes.	A4.3 A formal structure with defined roles is introduced; more specialised functions and processes are added.
Decision-making systems	A1.4 Formal decision-making systems and procedures are almost non-existent.	A2.4 Development of decision-making systems and procedures is started.	A3.4 The firm moves rapidly from basic decision-making systems to scalable systems.	A4.4 Strategies, rules and policies are written and supported by professional management systems.
Strategic management	A1.5 The owner(s) makes the strategic decisions.	A2.5 The owner(s) and/or a small number of partners make the strategic decisions.	A3.5 Strategic planning is gradually formalised by the owner(s) and/or a small number of partners.	A4.5 Strategies, rules, regulations and procedures are standardised and formalised.
Product and/or technology development and delivery	A1.6 The development of a working technology and/or prototype is started.	A2.6 The stage is characterised by early manufacturing and initial technical challenges. The company learns to make the product and produce it.	A3.6 The company needs to produce and distribute the product at an increasing volume.	A4.6 New product generation(s) and profitability improvements help to maintain growth and a reasonable market share.
Marketing	A1.7 The main activities relate to the business idea, identification of a market and resource mobilisation.	A2.7 The stage is characterised by early marketing activities.	A3.7 The company needs to sell the product at an increasing volume. New customers and new market channels require constant attention.	A4.7 The identification of new markets is essential for company renewal.
Human resources	A1.8 Management is informal, flexible and creative. Communication is face-to-face.	A2.8 The management style is participative and coordinative.	A3.8 A sense of hierarchy increases. Personnel problems result from high growth.	A4.8 Employees become specialised non-risk-takers.
Growth management	A1.9 The cash flow falls into the red due to a lack of product at this point.	A2.9 Amount of negative cash flow decreases.	A.3.9 Positive cash flow increases rapidly.	A4.9 The stage is characterised by a decreasing growth of cash flow.

3. Method

This study is a retrospective single-case study with a holistic research strategy (Saunders et al., 2007; Yin, 1989). This case study followed the guidelines established by Yin (1989). The sequential incident technique (SIT), a specific form of the critical incident technique (CIT; Edvardsson and Roos, 2001; Fisher and Oulton, 1999; Flanagan, 1954), is also used. Figure 1 presents the research process.

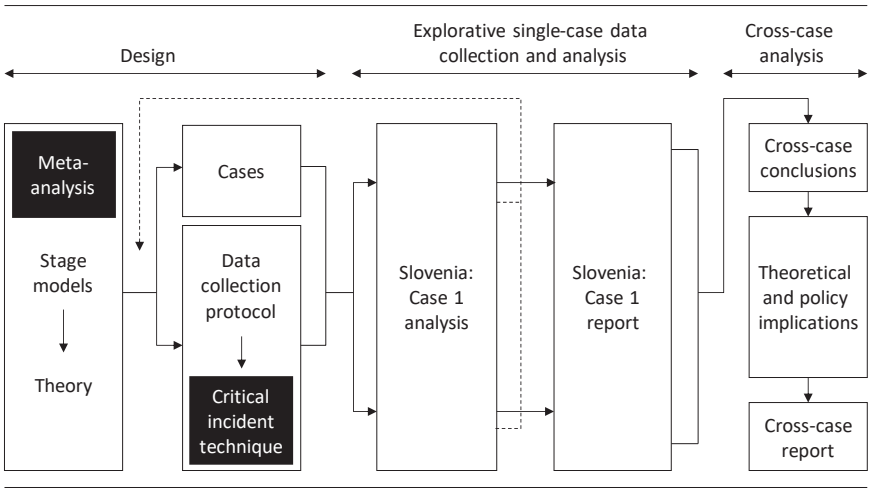

Figure 1: The research process of this study (modified from Yin, 1989)

In an overview of CIT methods, Gremler (2004) recognises SIT, a variant of CIT that considers the sequential characteristics of a process (see Stauss and Weinlich, 1997). Case studies using SIT clarify the main stages of the process under analysis prior to data collection, which is advantageous if the process has already been defined empirically. Critical incidents are reflected in the sequential framework presented in the theoretical section of this study. Here, a critical incident is considered to be an extreme behaviour, which is either outstandingly effective or ineffective with respect to attaining the general aims of the activity (Fisher and Oulton, 1999).

For the case study, a private-owned case company in Slovenia was selected on the basis of its focus on new technology and the 'newness' of the firm. This technology-based startup was analysed from multiple managerial perspectives using CIT and semi-structured interviews, which were conducted in 2016 (Edvardsson and Roos, 2001; Fisher and Oulton, 1999; Flanagan, 1954). For triangulation purposes, three managerial viewpoints were examined from company, operations and marketing management, respectively. The key indicators of growth and the main characteristics of the case company are summarised in the next section.

4. Results

In this section, a test case analysis of the critical incidents related to a technology-based health startup is provided. First, positive and negative incidents are analysed. Aspects that are either parallel or contradictory to the assumptions of the framework are first presented in a quantified form to test the applicability of the framework to each case. Then, the contradictory aspects are analysed further to point out potential context-specific aspects.

4.1 Case A: A Slovenian health-technology startup

Case A is a startup aiming towards a new type of disruptive optoelectronic innovation. The company was established in 2000. By the end of 2016, it had 10 employees and €444,980 of positive cash flow. The company reached stage 2, commercialisation, in 2010. When the interviews were conducted in 2016, it was almost ready to move from stage 2 to stage 3, expansion.

Altogether, 85 critical incidents (59 positive and 26 negative) were recalled by the management team interviewed. Of these critical incidents, 58 were parallel to and 27 were contradictory to the assumptions of the framework. The majority of the incidents were, thus, parallel to the framework and were positive. According to the interviewees' evaluations, the framework fit their experiences very well at this stage.

4.1.1 Stage 1: Conception and development

The distribution of stage 1 critical incidents recalled by the management team of Case A during the interviews is presented in the following table. Although the majority of the incidents were parallel to the framework assumptions, many contradictions were also detected. These contradictions were mostly related to the original contract manufacturing business model, which was later used to fund the supplementary owned product business that soon became the core vision of the management team.

Table 3: Stage 1 – critical incidents experienced by the Case A management team

Stages and assumptions	Case A P*	Case A C**
Stage 1: Conception and development		
A1.1	12	5
A1.2	2	-
A1.3	5	3
A1.4	-	1
A1.5	-	-
A1.6	4	1
A1.7	1	1
A1.8	1	-
A1.9	-	9
Stage 1: Total number of parallel and contradictory critical incidents	25	20

A = assumption, P* = parallel incidents, C** = contradictory incidents

The parallel aspects related to stage 1 are presented in the following table:

Table 4: Key parallel aspects related to the assumptions of stage 1

Assumption	Key parallel aspects
A1.1	Simultaneously with contract manufacturing, the company conducted research and development gradually: *'…We did some research and development in electronics [but] did not have our own product. …So, we did the research [and] development, and we tested the prototypes… The first equipment was just for cosmetic purposes. Then, while we were searching this* [name removed] *database, we found a lot of similar articles, with similar technical parameters to our device. We tested this device in an institute, which confirmed that [it] can be used for medical purposes'.* Development was lengthy because the target market (health-technology) is heavily regulated (medical directives, quality assurance, certification, etc.).
A1.2	In the first stage, the company was owner-dependent. The vision of this health-technology business was driven by the owner–manager's positive passion for technology: '*First, the thing what was interesting is that stuff works – really works. It's maybe the first decision to try something yourself that is really some kind of miracle'.*
A1.3	The group of technology founders functioned as a product development team: *'…We were not afraid to invest in a product, even if it was not our idea. We were searching for solutions. … We didn't think about its cost, but we did find the solution, and [in the end], it was good choice'.* The main driver of the team was technology development: *'We tested … a simple prototype [by ourselves to] see … [how] it works. And it's enough reason to ask yourself how to make it if it is so good'.* Case A was creative in its acquisition of human resources during the conception and development stage: *'Human resources vary, including students, which comprise one quarter of our team, and other kinds of employees. When there are there are new products to make, then you have to hire new employees.'*
A1.4	-
A1.5	-
A1.6	At this stage, the development of a working health-technology prototype was mainly self-financed using the revenue generated by the contract manufacturing business: '*…We tested a prototype, a simple prototype, and we saw that it worked. … [We included] technical folders, risk analysis and a clinical evaluation report to make it medical,… [and] we made a lot of developments and changes'.*
A1.7	After recognising a business opportunity, the owner–managers aimed at establishing a customer base within the challenging health-technology market*: 'So basically, this was our first finished idea…. First, you [need to] get an idea for a product, …but this, I think, was the first product that I was ready to develop all the way from an idea to the market'.* However, they took an outsourcing approach to reaching the final target market: *'…We do not have contracts, and we do not have data. …They [just] sell the product. But still, maybe our problem is that we are not pushy; we are not asking, "Tell us when you will say how much you will sell". We are just thinking about our job – making good developments [and] technical solutions. They will do their part. This is our strategy'.*
A1.8	*'I think that … our cooperation between our team is always very strong, so I think this is very empowering. …I think we always listen to each other's ideas'.*
A1.9	-

The contradictory aspects related to stage 1 are presented in the following table:

Table 5: Key contradictory aspects related to the assumptions of stage 1

Assumption	Key contradictions
A1.1	Case A started as a contract manufacturer in 2000: *'[We were] just in production without our own technology'.* They were highly dependent on the main supplier, a large international player: '*We can't sell their product, only they can. We would like to be more independent'.* Since the management team had limited business capability, the company focused on its strengths in technology development and contract manufacturing; the latter was used to fund the business as it was not yet possible to sell the product in this target market.
A1.2	-
A1.3	The company funded research and development through contract manufacturing, which provided a stable revenue. That part of the business was organised as a typical contract manufacturing unit rather than a product development team: *'Very specific manufacturing – that is our in-house know-how'.*

Assumption	Key contradictions
A1.4	The company had to invest early in formal decision-making systems because of the demanding target market: *'…Generally, it's always a conflict between producers and [individual] certifications. It is one of the most difficult things. We are a small company, and it's sometimes hard to follow all protocols. … The certification … was a positive … in this management system, [which conformed to] ISO [standards] for medical devices…. Big companies maybe have five employees: … one for technical data, one for risk analysis, one for clinical evaluation reports, [etc.]. This is very hard for [both] small companies [and] organisations, and these critical points can show you what you are doing wrong and what you should do [instead]'.*
A1.5	-
A1.6	Although contract manufacturing provided constant income to support health-technology product development, which was considered by the owner–manager as the core business, it sometimes distracted the focus from product development.
A1.7	Due to the market characteristics, actually selling the product is time-consuming: *'I have personally written the clinical evaluation report, … with support from [medical] doctors. Risk analyses [and] technical files … are our [area of expertise], but when it comes to selling the product, we [prefer] to give [this task] to someone else'.* The company has not yet been able to sell the product to an actual customer: *'Okay, so later, … much later, we will ask ourselves again how to sell this, but… it's a little problem* [laughs]*'.*
A1.8	-
A1.9	The company's cash flow has been steady from the beginning due to the original contract manufacturing business model: '*Cash flow. This is everything, let's say, from* [the main contractor]*; this is* [Case A]. *So, the main profit comes from* [the main contractor]. *… This is quite constant business … for you, and [a somewhat] secure source of financing. …We have one core business, and one part of the money goes to the development our products'.* The company was supported by an external investor: *'…he found us, and he wanted to have his own device, so we [worked] together with this … investor, [who] … contributed maybe one quarter or even less of the [funds required] for development. … He is a distributor, and he has the distribution rights. He is not a medical [professional] …He [let us know] that he is very good at marketing [and] selling [products] … [and that] he will almost definitely sell [our product]. The problem just was "Can you make enough of this?" and of course we can'.*

4.1.2 Stage 2: Commercialisation

The distribution of critical incidents in stage 2 recalled by the Case A management team during the interview is presented in the following table. The majority of the incidents were parallel to the assumptions of the framework. Only a few contradictory incidents were reported. The contract manufacturing business model and the characteristics of the heavily regulated health-technology business environment are related to most of the contradictions found in stage 2.

Table 6: Stage 2 – critical incidents experienced by the Case A management team

Stages and assumptions	Case A P*	Case A C**
Stage 2: Commercialisation		
A2.1	11	3
A2.2	2	-
A2.3	1	-
A2.4	-	-
A2.5	-	-
A2.6	12	-
A2.7	5	3
A2.8	2	-
A2.9	-	1
Stage 2: Total number of parallel and contradictory critical incidents	33	7

A = assumption, P* = parallel incidents, C** = contradictory incidents

The parallel aspects related to stage 2 are presented in detail in the following table:

Table 7: Key parallel aspects related to the assumptions of stage 2

Assumption	Key parallel aspects
A2.1	The company aims at commercialising the product to decrease its dependency on the main contractor. The company found an investor to help speed up this process. However, its own product sales had not started yet: *'…We [realised that we] closed the door [and] couldn't sell our own product because he was an investor, and we need investors. …[Because he was more than] just… a partner with rights, … we gave him a chance to … sell our product…. We [would] do the technical changes, [but he would say, for example, "We] cannot sell this if [it is] in grey – it must be white" … [or] "It should not be 17 programs; it should be 5 programs". …This is a medical product, and it must be [made] according to a standard. …He [proposed] a lot of these changes, which made it difficult for us… [and] cost a lot of money'.*
A2.2	The company is still highly dependent on a small group of partners that was recently extended to include an investor: *'…Marketing and selling are [done by] our partner. …[There are] other kinds of development'.* The managers started to delegate responsibilities: *'…People who were previously working in production now can work, let's say, in administration. So, this is a kind of reorganisation [in] a new business – reorganisation with better tasks, better positions and new jobs'.*
A2.3	Case A does not yet have complex structures established. However, its administration is built around the owners and partners: '*A group of owners and partners control the administration – that's true'.*
A2.4	-
A2.5	-
A2.6	*'In 2012, we finally developed our medical product, which was quite a breakthrough for us'.* The company will soon have to respond to the expected demand with serial production: *'We spent almost a year and half [doing this], and now we are at 80 or 90 percent completion. …[Next,] it goes into serial production. For … [one or two years], production was only experimental, testing the best parameters and the best design solutions for the product…'. 'But right now, [the number of] orders [and purchases] is [increasing]…, [so] they need to … automatise – make production cheaper [and] faster. These are the last two percentile points of development that are going through the process right now'.* The company is solving the technical challenges related to serial production: *'We already know how to make the product and how to produce it, but we still have some small difficulties … [which will require minimal] finances until the final production. … [we just need to confirm] the 3D prototype, the electronics, the program – everything – and … in a few months, we can start production'.*
A2.7	The company is focused on ramping up its marketing activities with help from a distributor who invested in the company: *'…We …did find a distributor. We are still waiting; we did give him some contract definitions that he must turn around in a few months. …He must sell a [minimum quantity] of this medical equipment per month and must pay all the certification costs, but from our point of view, this is zero cash flow – nothing for our personal growth. But in the end, we have a device. Now we have a contract [with a buyer from a European country]'.* The owner–manager pointed out that funding for technology development is available but limited *'for implementation in the market, I think. It's always expected that the product should come to the market at the end, but the mentality here of the people is that this is an automatic process'.*
A2.8	Management was found to be participative and coordinative in the company, which has been able to build a loyal core team: *'…That's why …[for] all these years [the employees have basically been the same] in number. [We have always had between] nine [and] eleven full-time employees'.*
A2.9	-

The contradictory aspects related to stage 2 were further analysed in detail; see the following table:

Table 8: Key contradictory aspects related to the assumptions of stage 1

Assumption	Key contradictions
A2.1	The initiation of sales and distribution has begun to worry the owner–managers: *'…You [become so involved] in your research and development that you … forget about the business. You think, "Oh my God, we are still in stage 1 or 2 two, and we should be in the market now! What will we do to get into the market? With whom will we cooperate? What will our conditions be?"'.* The revenue generation model is not clear yet as the company has focused on technology development with the support of contract manufacturing: *'…For the next project, [we might take a slightly] different approach. [We will have] a few more calculations, a few more requirements [in terms of] where the money comes from, where it goes and how much it will cost – especially in medicine. It's very, very important simply because today, it's impossible to start certification somewhere in the middle. First, you have to have plan'.*
A2.2	-
A2.3	-
A2.4	-
A2.5	-
A2.6	-
A2.7	The original group of owners does not participate in marketing activities. The new partner of the company is currently testing different distribution channels, while the original team focuses on technology: '*…First we were talking about… some kind of net-marketing. It was his first idea. Then he [thought it might not be a good idea], so he started to [talk to] doctors. …We don't think about marketing because this distributor now has all-exclusive rights, but we have some internal flow*'.
A2.8	-
A2.9	Just before the commercialisation stage, the company is still funding most of its development activities organically by revenue generated from the contract manufacturing business. The cash flow has been positive for a long time.

5. Discussion and Conclusion

This explorative study aimed to develop and test a new type of research protocol to clarify the early stages of health-technology startups. The functionality of the research protocol was preliminarily tested through a single-case study in the Slovenian context. This study answers the following research questions.

First, *how do the most recent empirical stages of growth describe the early-stage management priorities in technology-based firms*? An earlier-published four-stage self-evaluation framework of early-stage technology-based companies was revised through meta-analytical methodology. Table 2 in the second section details the startup stage from the revised grid-type version of the stages of growth framework. This is a preliminary, experimental attempt to provide a more comprehensive research protocol for in-depth analysis of the management priorities in early-stage technology-based companies.

Second, *how do the experiences of managers in a technology-based health startup relate to the assumptions of stages of growth theory in the Slovenian business context*? The first two stages of the framework were used as a set of assumptions to be tested in a single Slovenian case study. An analysis of context-specific viewpoints was also provided.

Case A was analysed utilising SIT to test how the managers' experiences were related to the key management themes of the framework and answer the first research question. The applicability of stages 1 and 2 of the framework for analysing Case A was tested in the context of Slovenia by analysing the number and content of positive and negative incidents experienced by the management team. First, the positive and negative incidents experienced by the managers were reflected through the key management themes and the related central assumptions:

Table 9: The number of positive and negative management priorities of a Slovenian technology-based startup and the central management themes

	Stage 1	Critical incidents		**Stage 2**	Critical incidents	
Management theme	Assumption	Positive (+)	Negative (-)	Assumption	Positive (+)	Negative (-)
1. Focus	A1.1	14	5	A2.1	5	8
2. Power	A1.2	2		A2.2	2	
3. Structure	A1.3	8		A2.3	1	
4. Decision-making system	A1.4	1		A2.4		
5. Strategic management	A1.5			A2.5		
6. Product and/or technology development and delivery	A1.6	3	2	A2.6	8	4
7. Marketing	A1.7	2		A2.7	5	2
8. Human resources	A1.8	1		A2.8	1	1
9. Growth management	A1.9	6	3	A2.9		1
Number of incidents, + and -		**37**	**10**		**22**	**16**

Second, the central parallel and contradictory aspects in relation to the assumptions of the framework were explored. The condensed distribution of the abovementioned management priorities is provided in the following table:

Table 10: The number of parallel and contradictory critical incidents experienced by the Case A management team

Stage	Case A P*	Case A C**
Stage 1 (conception and development): Total number of parallel and contradictory critical incidents	25	20
Stage 2 (Commercialisation): Total number of parallel and contradictory critical incidents	33	7
Total number of parallel and contradictory critical incidents in stages 1 and 2	58	27
A = assumption, P* = parallel incidents, C** = contradictory incidents	Total	85

The majority of the framework assumptions were preliminarily supported by the experiences of the owner–managers of the Slovenian technology-based startup. However, more cases need to be analysed to make further conclusions.

The research protocol utilised functioned reasonably well for analysis of the positive and negative incidents experienced by the management team of the firm sequentially. Not only did the management team interviewed find it easy to self-evaluate the current stage of development, but they also found it useful to

externalise their experiences. The research protocol prompted the managers to evaluate their prior decisions and clarified the path from the establishment of the company to the current state of the business. They were encouraged to reflect on the past while making strategic decisions concerning the future. The empirically based stage framework seems to be an effective tool for reflecting on and predicting the challenges faced by a company during its early developmental stages.

In this study, the framework and research protocol were tested in Case A, a health-technology company, which revealed context-specific perspectives. By analysing more similar types of cases, it would be possible to develop stages of growth theory towards a more dynamic understanding of the business growth process.

In conclusion, this study formulated and preliminarily tested the startup stage of a four-stage framework and a research protocol for further context-specific analysis of the early stages of technology-based companies. This study revealed a number of viewpoints that were contradictory to the framework: Companies in different contexts face culture- and context-specific issues during their early growth. Growth is a multi-dimensional phenomenon, and every service-based startup is, to some extent, unique.

The preliminarily tested case study research protocol using SIT seems to be effective for an open-ended analysis of early growth; it considers the sequential characteristics of the process. The construct validity of the study is based on a sound research plan, multiple sources of evidence, the synergy between quantitative and qualitative data and an established chain of evidence. Analytic generalisation (generalisation to theorisation) is possible when building frameworks applicable to a specific context. Because the research focus of this study is limited to one test case, the findings cannot be directly generalised to other countries or business contexts; furthermore, the findings are not replicable. However, a case study protocol was followed, and a database was established, which allow for further testing of the findings.

Abstract: Open Innovation offers great chances for the improvement of the success rate of innovations to enterprises and is widely researched among bigger companies and corporations. This case study investigates the knowledge transfer and dissemination of Open Innovation for German small and medium sized enterprises (SMEs) from the very traditional technical textile industry. The study investigates sample of 56 SME, which corresponds to 22% of enterprises of the German textile industry. This study shows that the corporates' cultural framework and the resulting organizational structures have a massive influence on Open Innovation and the willingness to open up innovation processes. Nevertheless, a very interesting result of this examination is that, when it comes to cooperation, a similar culture within the cooperating enterprises is of less relevance for executives compared with other factors. Moreover, many of the surveyed companies still struggle with their experiences after Germany was reunited and complain about a lack of confidence especially when cooperating with companies from former Western Germany. On the other hand, when it comes to international cooperation, the missing skills in speaking English are named as the most important obstacle. A special focus of this examination is on the influence of the employee's mind-set and the company's culture as well as on the mind-set of the executives to develop an assessment tool regarding the cultural readiness for Open Innovation. This paper shows the concept of the culture based Open Innovation approach by a set of success factors, which are defined in cooperation with the technical textile SMEs themselves.

Keywords: Open Innovation, Corporate Culture, SMEs, Germany, Technical Textiles, Readiness Check

1. Introduction

The results presented in this paper are part of a study, which was conducted during the futureTEX project that was funded by the German Federal Ministry of Education and Research. The aim of the futureTEX project was to enable the technical textile industry in Germany, which is characterized by small and medium sized enterprises (SMEs), to prepare themselves for a successful future. One promising way for this preparation is the application of methods from and the dissemination of knowledge about Open Innovation (OI).

Furthermore, one specific research question was to investigate the correlation between the corporate culture and OI.

1.1 Open Innovation capabilities in German SMEs

During the past 15 years, starting with Chesbrough's published monograph "Open Innovation: The new imperative for creating and profiting from technology" in 2003, Open Innovation became more and more popular among researchers as well as companies (West et al., 2014). Open Innovation is defined as a paradigm, which assumes that companies must open up to their environment and culture in terms of ideas, knowledge transfer and different market accesses in order to improve their own technologies (Chesbrough, 2003).

Lately published research results show that it seems like especially SMEs struggle with the implementation of OI and it does not really seem to be accessible to SMEs in particular (Brunswicker, 2014). However, OI is a relevant topic for SMEs because it offers many promising advantages. Being active in networks and cooperating with enterprises to combine and bundle different competencies and knowledge with the help of the OI paradigm is a promising opportunity to increase the efficiency and quantity of innovations and to enable new areas for business opportunities (Chesbrough et al. 2006; Nawroth et al., 2017).

To improve the innovation capability of companies, networking – both internally and externally – is one of the essential elements to make a significant positive contribution (Dhanaraj & Parkhe, 2006; Tsai, 2001).

External openness leads to new cross-industrial impulses (Gassmann et al., 2010) and involvement of innovation-relevant external competencies and knowledge. Besides external cooperation, also internal cooperation can lead to competitive advantage through cross-divisional cooperation and internal competence bundling (Freytag & Young, 2014).

In addition to the organizational and structural based view of opening up innovation processes, there is another very important component of the OI paradigm: the cultural based view of opening up is the foundation to spread Open Innovation across all employees within a company. This means that an open mind-set of employees and executives can dramatically improve the innovation capabilities of enterprises (Lindegaard, 2010).

As this cultural based view has an excessive impact on the innovation capability of a company, this study investigates the influence of the corporate culture on OI among SMEs from the German technical textile industry.

1.2 General challenges in the German technical textile industry

To collect the challenges of SMEs from the technical textile industry they are currently facing, a workshop in Chemnitz, Germany, with 35 participants from the technical textile industry was organized in March 2016.

From an economic point of view, the German technical textile industry is challenged by strong competition and strong competitive pressure especially from Asian low-wage companies. Resulting from this competition there is a high price pressure in the international market, which is particularly challenging for the German non-low-wage SMEs from this industry. Therefore, those companies focus their innovation efforts on high-quality and high-tech products. Hence, the traditional German textile SMEs aim to evolve from a producing to an innovating company.

With regard to this evolvement, technical textile SMEs feel uncomfortable and precarious due to the lack of knowledge about the future workplace and content in the textile environment. Moreover, these enterprises feel like they are lagging behind the technology trends. One of the most impacting global trends - the digitization - is often unknown and/or underestimated within the textile industry.

2. Open Innovation and corporate culture

In the beginning of the following section a common understanding of corporate culture and Open Innovation (from a cultural perspective) was developed. Following this, general success factors for integrating Open Innovation in SMEs were identified. Finally, the specific cultural challenges for the SMEs from the German technical textile industry were collected.

2.1 Definition of corporate culture

For this study, corporate culture was understood and defined, based on one of the first anthropological definitions of culture, as the “complex whole” of “human habits” within an organisation (Tyler, 1871). This simple interpretation of corporate culture makes it clear that, on the one hand, describable, supra-individual habits exist within an organisation; on the other hand, it allows the measurement of the organisational homogeneity (Rathje, 2010). This interpretation enables an access to corporate culture by looking at the habits of an organisation and is in line with the core of established, usually much more detailed corporate culture definitions of the last three decades. Moreover, it stands for the equal inclusion of manifest and cognitive elements (Rathje, 2010).

2.2 The understanding of Open Innovation for this study

To create a common base of understanding regarding Open Innovation, we chose a cultural-based approach of describing Open Innovation and discussed this description with SMEs from the technical textile industry (see Figure 1).

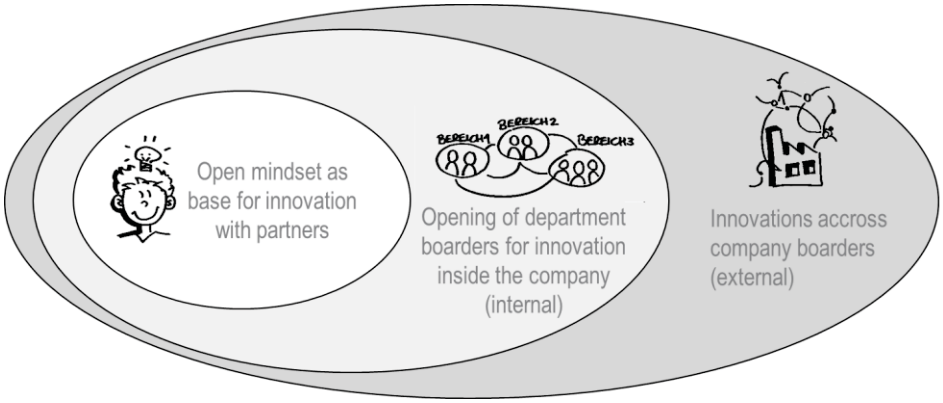

Figure 1: the three openness stages

This model, which was developed during the workshop in Chemnitz, displays the correlation between the three different culture-dependent stages of openness, we differentiated:

- **Stage 1:** individual based openness stage
  The model states that an open mind-set of the employees and especially the executives of an enterprise is the most relevant prerequisite for opening up processes and innovate with both internal and external partners. In particular, it is intended to prevent the old known "Not-Invented-Here-Syndrome" that can occur as one of the major obstacles of cooperation, both internally and externally (Katz & Allen, 1982).

- **Stage 2:** company based openness stage
  Based on the open mind-set of the employees, a corporate culture in which different departments or divisions from the same company cooperate and co-innovate is possible, if the organizational structures are also created for this purpose. This internal opening of processes and the exemplary function of senior officials is the first step towards a successful performance of OI activities between several divisions inside a company to establish inter-divisional and interdisciplinary cooperation.

- **Stage 3:** external openness stage
  Following this behaviour, the opening of innovation processes for and integration of external partners and knowledge, which allows innovations across company boundaries, characterize the third stage of openness.

In the commonly developed understanding of Open Innovation, all of these three culture-dependent stages need to be established in enterprises. Both, the stages concerning the personal attitude of the employees and executives as well as those stages concerning culture-organizational aspects.

2.3 General success factors for the implementation of OI

In the same workshop, we extracted following four fundamental success factors, which were seen as necessary for a success promising preparation for the future by the SMEs:

1. Culture for Open Innovation:
   OI requires a corporate culture that is characterized by a willingness to share knowledge and an inner attitude that learning orientation requires a strategically oriented ability to change.

2. Integration of target groups:
   In the introduction and implementation of OI, the selection of the actors involved and the way in which they are involved is decisive for success.

3. Structure for Open Innovation:
   Open both real and virtual structures are necessary for successful OI in order to effectively shape the flow of knowledge and ideas from outside to inside and from inside to outside.

4. Open Innovation Strategy:
   OI is not an instrument separate from other management systems, but is always closely linked to the strategic challenges of the organization.

Knowing these general success factors, we developed solutions for the successful use and implementation of these factors into the SMEs.

In the present paper, we focus on the first success factor, the corporate culture, This is required for the successful implementation of OI, since the participating companies in this workshop rated this factor as the most relevant one.

2.4 Specific cultural challenges in the technical textile industry

The SMEs that participated in the workshop in Chemnitz said that they are facing mental blockades within their companies when it comes to changes. This is the exact opposite of the most important cultural prerequisite, an open mind-set for new topics. Besides these mental blockades an attitude of "we have always done it this way" is dominating. Coming with this attitude is the denial of change processes. These processes are just not started. Furthermore, the SMEs are missing thinking out of the box. This is another big obstacle to being creative and innovative, e.g. by combining the own knowledge with knowledge from other industries.

The limitation of innovations to product-innovations is also named as a specific cultural challenge by the participating SMEs. The great potential of process-innovations and service-innovations is not used by focussing and limiting the resources on innovations of products.

In addition to these "internal" challenges, there is an external challenge that has to do with the demographic change in Germany: It is getting harder and harder for those SMEs to find qualified apprentices.

In addition to the workshop in Chemnitz, an online questionnaire, consisting of 130 questions, clustered into 18 different topics, was set up and in-depth interviews were derived. The online questionnaire was designed according to a Likert scale consisting of usually five answer options. In addition, some questions had only three answer options or free text answers were possible. Moreover, the questions were designed to lead the participant through the questionnaire only asking these questions that were relevant for him. For example only a participant that responded positively to the question whether Open Innovation methods are in use or not, was lead to questions that ask about Open Innovation methods in more detail. The questionnaire was sent to approx. 300 SMEs. From the returned answer-sets, 56 were complete and could be used for analytics.

The whole survey was performed between November 2016 and February 2017. That means, in total, 20% of the complete technical textile industry could be examined. In the second step, personal in-depth interviews with the participating SMEs, researchers and technical textile experts were conducted. These in-depth interviews were based on the results of the online survey.

The results of the surveys show that the corporate culture of the investigated SMEs from the technical textile industry in Germany is characterized by mistrust and suspiciousness against opening up any processes towards external partners. One of the reasons for this fear might be the experiences that were made after the reunion of former Eastern and Western Germany, when qualified employees from Western Germany took the leading positions in companies from Eastern Germany and skilled workers from Eastern Germany migrated to Western Germany (Bluhm & Jacobs, 2016).

Another sign for the protective behaviour and mind-set is the internal organisational structure of the SMEs: A top-down approach is the dominant way of innovating and deciding. That means, the executives of the SME decide about innovations and bring up new ideas. There are strict responsibilities of separated departments in the innovation process and the executives mostly make the final decisions. That means, in addition to the refusal to open processes to external partners, there is also no opening up of internal processes. Furthermore, a conservative and protectionist behaviour on the part of the managerial staff can be observed.

An interesting result of the survey is the fact that the surveyed SMEs do not consider cooperation with external partners to be very important. However, when it comes to cooperating with external partners, companies of a similar size are the preferred partners. Recent research results support this behaviour, as they

reveal that there is an imbalance in the flow of information when cooperating with large companies. Large companies absorb more external information than it flows from them to smaller partner companies (Chesbrough & Brunswicker, 2013; Nawroth et al., 2017).

Moreover, the investigation revealed that many of the SMEs struggle with the English language and the wording of OI. The results show that many of the SMEs use OI methods like participating in networks and similar methods but do not know that they are part of the OI paradigm because they do not know the English names of these methods. Although the SMEs are willing to cooperate with international partners, they also fear linguistic barriers when it comes to cooperating with such partners.

Nevertheless, as already described, one elementary prerequisite for the successful use of OI is the opening up of internal and external processes and integrating different external knowledge and experience into the innovation process. This opening of processes requires a certain corporate culture.

However, the prevailing corporate culture among SMEs from the German technical textile industry, which is characterized by clear hierarchies and strict responsibilities as well as mistrust and suspiciousness towards external partners, makes it difficult to spread the idea and advantages of Open Innovation across the industry.

All of these identified specific challenges as well as the experience of the SMEs, lead to the assessment that undergoing a cultural change is the greatest challenge.

3. Solution: The Open Innovation Readiness Check

This section describes the development and the evaluation of the OI Readiness Check, which is a self-assessment tool for SMEs to compare themselves with similar companies from the same industry.

3.1 Development of the OI Readiness Check

To help SMEs from the technical textile industry in Germany to overcome this clash between the prevailing corporate culture and an OI supporting corporate culture, the so-called Open Innovation Readiness Check, a semi-standardized questionnaire, for a self-assessment was developed. This readiness check helps SMEs to self-assess their current Open Innovation readiness level. Based on the result, we developed and gave individualized advice on how to get the company to their desired readiness level.

As input for the development of the OI Readiness Check, four different sources were used: the information collected in two previous OI projects, InnoKMU and IMProve, as well as the information gathered at the workshop in Chemnitz. These were supplemented by the scientific results concerning Open Innovation e.g. from Chesbrough, Brunswicker or Piller.

Based on the collected information from the four different sources, the cultural prerequisites for successful OI activities were identified. All together, we identified 20 different cultural prerequisites, e.g. an open and transparent handling of information or cross-division cooperation in multidisciplinary teams. From these 20 different prerequisites, seven detailed culture-related success factors were derived and integrated into the assessment:

1. We deal with information openly and transparently
2. We treat each other with respect and trust
3. The commitment and initiative of our employees are very high
4. We regard mistakes in innovation projects as an opportunity to learn (by systematically learning from them)
5. We are open-minded to new things and willing to change
6. We encourage our employees to network with others
7. The willingness of the management to embrace new ideas is very high

The SMEs could answer these statements with one of four answer options ranging from “yes” via “rather yes” and “rather no” to “no”. However, due to the semi-standard questionnaire, the companies do not only assess their degree of agreement but are also asked to explain the reason for their rating (if possible with an example) as well as the cause for their rating and a suggestion for improvement in a free text field to collect some further qualitative information.

The OI Readiness Check is structured into the four different general success factors that are necessary for Open Innovation and asks with a total of 23 indicators (= specific success factors) in more detail about the fulfilment of each success factor. The 23 indicators were derived from the four general success factors as well as from the identified prerequisites for each success factor. Since the presented study has its focus on the correlation between corporate culture and OI, the following section is about the results concerning the culture-related success factor and its seven specific success factors.

3.2 Evaluation of the OI Readiness Check

Since Germany's economy and especially the SMEs in Germany are very diverse, it is very hard to rate the readiness level and assess a level to an enterprise based on only quantitative data. Moreover, SMEs do not have the same capacities and resources as larger companies and enterprises. That means it is almost impossible to be "very good" in each of the identified indicators. Therefore, we have decided not to assign levels based purely on numbers. Instead, the result from the OI Readiness Check is similar to the result from a benchmark analysis and, due to the semi-standard questionnaire, allows a comparison of the own readiness level with the readiness level of other enterprises from the same industry.

The following figure (see Figure 2) displays, the aggregated answers of the approximately 40 participants of the workshop in Chemnitz (n=35). The results indicate that the systematic learning from mistakes is the rarest occurring indicator whereas the willingness of the management to embrace new ideas is applied the most often. These results already allow a first classification of the own SME (even from different industries) in comparison with the OI readiness level of the German technical textile industry.

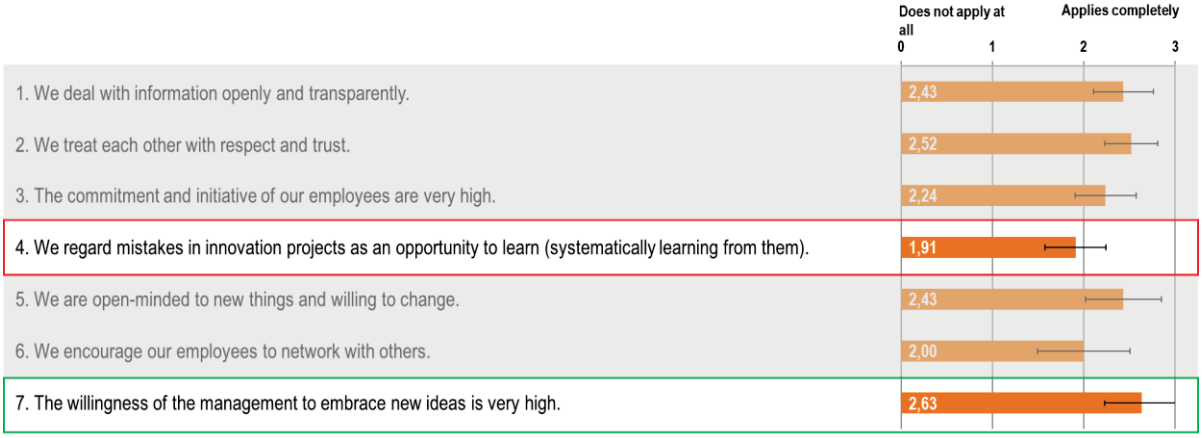

Figure 2: Answers to the corporate culture part of the OI Readiness Check

Subsequently, these indicators were tested on several companies to support an open innovation corporate culture. Therefore, eight different employees from different departments and across the entire hierarchy structure were interviewed to get an enterprise specific value for each indicator. Two extreme use cases are presented below, which show the results of the check on the one hand and the recommendations for action derived from them on the other. The use cases below were selected because they differ greatly in some respects, such as organizational structure and employee development, but can also be easily compared in some respects, such as a similar number of employees. Table 1 shows the most important criteria to get an impression of the companies.

Table 1: Most important criteria of the two use cases

	Use Case 1	Use Case 2
Employees	approx. 200	
Employees development	increasing	stagnating
Organisation	department orientated	process orientated
Enterprise culture	hierarchic culture	grassroots democratic culture
Open mindest	high	low
RnD-Intensity	high	low

Both medium-sized textile companies are comparable in number of employees and innovation activities (employees available for innovation activities (RnD), marketing and customer solutions). Both companies differ drastically in their organisational culture. While use case 1 has a classical hierarchy structure and the

employees are organized in task-related departments, the employees in use case 2 are organized along the company processes, in which a grassroots democratic corporate culture is lived. For example, in use case 2 job interviews are held publicly for all employees and the salary or assignment of work tasks along the company processes is determined together with everyone. In use case 1, on the other hand, the tasks are distributed and monitored by the managers. Outstanding employees may share their ideas with managers and then obtain permission to implement them. In the following, however, due to the comparable boundary conditions and the very different corporate structures and cultures, it is exciting to examine the results of the open innovation check in more detail.

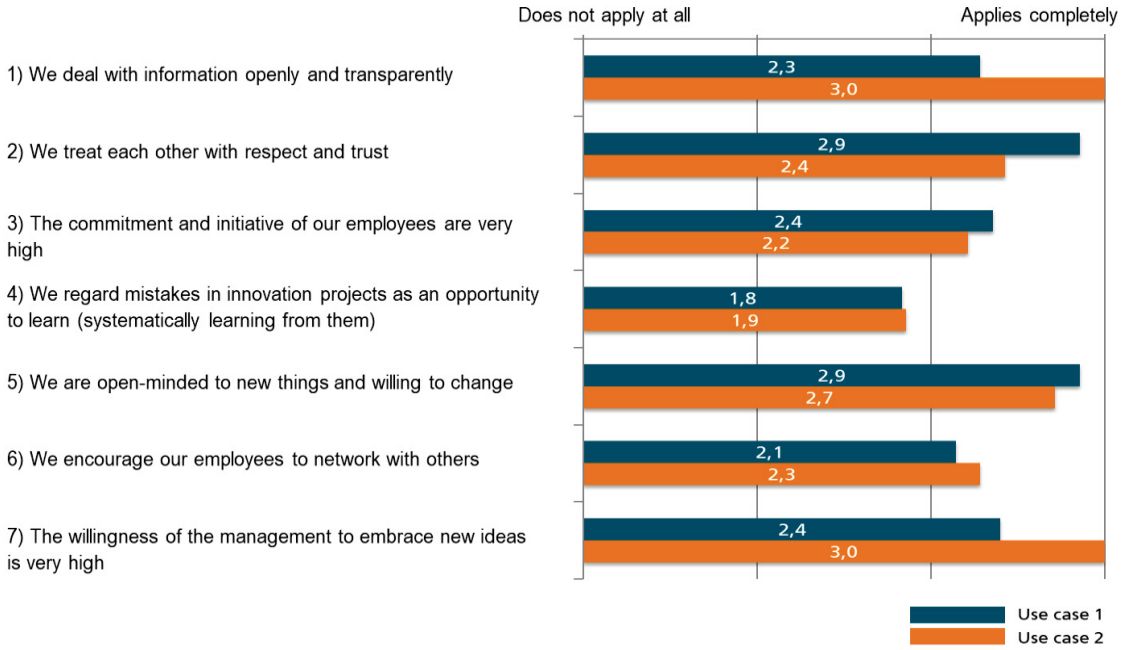

Figure 3: Comparison of the culture indicators for use case 1 and use case 2

There are three main differences shown in Figure 3:

1. While the basic democratic principles of use case 2 reflect the openness and transparent handling of information, the hierarchical structures and the organization in individual departments of use case 1 lead to less transparent exchange of information. In order to improve this indicator for use case 1, the company was given the recommendation to share information before the start of the project and to create shared data servers to which every project employee, regardless of departmental affiliation, has access. In addition, the employees themselves were required to provide training in order to improve cross-departmental cooperation and communication.
2. At the same time, the willingness of CEO to embrace new ideas is significantly higher in use case 2. The basic democratic orientation of use case 2 means that all employees are responsible for solving problems or generating innovation ideas. This means that the CEO is open to new requirements for implementing them. The recommendations for use case 1 were that the transparency of the CEO should be increased, e.g. by regular consultation hours and exchange of information even with the individual employees and not only managers. This contact between CEO and employees should serve above all as motivation to improve the cross-departmental innovation work.
3. It is even interesting to compare how employees treat each other based on respect and trust. Despite the grassroots-democratic orientation in use case 2, trust and respect between the employees are rated significantly worse here. The high individual responsibility of each employee and the lack of individual departments, which also develop a certain identification and affiliation in companies, similar to a sports team, apparently lead to a sometimes innovation-impeding behaviour between the employees. Use case 2 was recommended to increase the trust between the employees through team-building activities and to focus on the interaction between studied and unstudied employees, possibly through joint workshops or joint off-site meetings.

4. Future research directions

As mentioned in the previous section, the diversity among German SMEs is very high. Therefore, future research should focus on matching the most relevant indicators for the success factors with the specific characteristics of the examined SME.

In the case of this study, the general success factors were all rated with the same importance. In future research, it should be investigated if the performance and the accuracy of the self-assessment can be improved by weighting the individual general success factors. For the specific success factors of the Readiness Check as they are described in this paper the same should be investigated.

As our study shows, the biggest challenge for SMEs from the German technical textile industry, is the process of changing the corporate culture. Therefore, new ways, methods or instructions for the successful cultural transformation need to be researched and developed.

Another interesting research gap is the comparison of the corporate culture in SMEs from the technical textile industry with SMEs from different industries. Doing so, might offer the chances of learning from each other and might lead to a sustainable improvement of the economic system.

Creating Entrepreneurial Attitudes among Students of the Faculty of Entrepreneurship and Commodity Science in Gdynia Maritime University

Joanna Newerli-Guz and Agnieszka Palka
Gdynia Maritime University, Poland
j.newerli-guz@wpit.am.gdynia.pl
a.palka@wpit.am.gdynia.pl

Abstract: The recommendations of the European Parliament and of the EU Council of 18 December 2006 on key competences for lifelong learning concern creativity, innovation and risk-taking, as well as the ability to plan projects and lead them to achieve their goals. These are the basic requirements of the competence of initiative and entrepreneurship, which is determined by three basic characteristics of an entrepreneurial person, i.e. knowledge, skills and personal characteristics. There is a difference between learning about entrepreneurship and learning an entrepreneurial attitude. Accepting entrepreneurial attitudes and behaviour by young people is more important than knowing how to run your own business. The goal of educating the students of the Faculty of Entrepreneurship and Commodity Science in Gdynia Maritime University is to shape their entrepreneurial attitudes. The aim of the paper was to assess the possibility of shaping entrepreneurial attitudes among students of the 1st and 5th year of studies at the Faculty of Entrepreneurship and Commodity Science in Gdynia Maritime University with the use of the original questionnaire. The issues contained in the questionnaire concerned the characteristics, skills and knowledge of the creative entrepreneur and how entrepreneurship can be assessed. Students also evaluated the study program in terms of creating entrepreneurship on the example of proposed lectures related to entrepreneurship given during studies. They also indicated the subjects and manner of conducting classes which, in their opinion, support their entrepreneurial attitudes. The answers obtained were compared with the entrepreneurial activities of the surveyed students. Conclusions on whether and how much, through the system of education and other activities, the studies could influence the entrepreneurial attitudes of the academic youth were formulated. The obtained results indicated the necessity of moving away from teaching in a traditional form for teaching into an active way, where the student should be at the centre of the teaching process.

Keywords: entrepreneurship, creating attitudes, entrepreneurial attitudes, entrepreneurial education, academic entrepreneurship

1. Introduction

Joseph Schumpeter's economic thought is indissolubly linked to the study of entrepreneurship. He was probably the first scholar to develop its theories. Since the research and work of Schumpeter (1934), multiple definitions of entrepreneurship were developed and presented. Disregarding all the minor differences, there can be a unified core part identified in most of them. It states that entrepreneurship is a set of actions that combine various resources in order to produce new goods or services. It always includes the risks as the outcomes of the process are uncertain. It needs to be organized, to create the whole process leading to expected results. And lastly it should be innovative in a certain way, that it is not just replicating the existing solutions (Bąk 2016).

Functioning and development of modern organizations are, in the current new economy, directly related to entrepreneurship and innovation. Business environment is the combination of internal and external factors influenced a company's operating situation. It can include factors such as: clients, suppliers, owners, its competition, improvements in technology, laws and government activities, market, social and economic trends. Entrepreneurship development is an important requirement for achieving the goal of smart, sustainable and inclusive growth set out in the Europe 2020 strategy. It is also a means to respond to new economic challenges, to create jobs and to fight social and financial exclusion. The impact of the global financial and economic crisis calls for giving entrepreneurship and self-employment a stronger role in economic and social development policies. This is particularly relevant for youth who face higher unemployment rates than the adult population and face increased difficulties entering the labour market to start their careers (Arzeni 2015). Scepticism exists in academic circles around the idea of 'teaching' entrepreneurship, rather than practicing it hands-on. Practical assignments are mainly utilized in order to teach entrepreneurship, rather than traditional classroom teaching (ASHE Higher Education Report, 2009).

According to Baaken at all. (2015), Polish university managers and academics do not seem to perceive important reasons for undertaking cooperation with business.

1.1 Entrepreneurship education at school level

The primary goal of entrepreneurship education at the school level is to provide young students with an opportunity to learn about entrepreneurship as a labour market activity and develop a positive attitude towards entrepreneurship, which would be expected to increase the desirability and feasibility of entrepreneurship as a career option. Older students should also be given an opportunity to learn some basic technical skills related to business management (e.g. risk management, planning), as well as other important skills such as how to work in a team. It is also important that students have an opportunity to acquire some experience putting these skills into use through project work, business simulations or actual start-up projects.

Currently, entrepreneurship education is not offered systemically in schools in Poland. It is not a compulsory subject and as a result, schools do not receive funding for this activity. International comparisons indicate that the availability and quality of entrepreneurship teaching in primary and secondary schools in Poland are among the lowest in the EU. Despite this, there is a small and growing number of activities to promote entrepreneurship education in schools, including meetings with entrepreneurs, business games, limited entrepreneurship teaching, entrepreneurship workshops and festivals (Arzeni 2015).

1.2 Entrepreneurship as the element of modern oriented university

Entrepreneurship is included in the National Framework of Qualifications for higher education. This requires most students in higher education to receive a minimum level of exposure to entrepreneurship during their studies but entrepreneurship has not yet achieved the same status as other traditional academic disciplines such as science. While there are a number of examples of higher education institutions that actively promote and support entrepreneurship to their students, most public universities only offer a very limited amount of entrepreneurship teaching that covers only the basic elements of business management. Furthermore, entrepreneurship teaching does not generally utilise current research on entrepreneurship and there is often no link between research and teaching. This is largely due to a lack of researchers in the field of entrepreneurship which contributes to the lack of recognition of entrepreneurship as an academic discipline that is on par with the sciences. Those professors and staff who do provide entrepreneurship teaching generally do not receive any training (Arzeni 2015).

Traditional roles of universities: education and scientific research, are still applicable and no one wants to change them. However, the conditions in which the roles are performed are changing. The entrepreneurial university should be interested in building its good position in the academia as well as on the educational and scientific market. At the same time, the university – apart from striving for achievement of the social mission – should build its economic strength by using the resources held and external considerations. An important characteristic of the entrepreneurial university is the proper system of its relations with the socioeconomic environment. The university's environment includes: individuals, groups of people, other universities, social institutions, administrative institutions, and market entities having various relations with the institution of higher education. An important part of the university's environment is its beneficiaries, that is individuals and entities interested in diverse benefits brought to them by good operation of the university. It is necessary to identify individual entities within this environment, to form the desired relations between the institution of higher education and such entities, to maintain and develop the relations – all for the purpose of creating the position of the university as an active and important member of various environments, and as a market entity (Olearnik and Pluta-Olearnik 2015).

Polish institutions of higher education are changing but the scale of the changes towards the entrepreneurial university model is insufficient. The changes need to be intensified in two directions. One is the reform of the centrally codified law, which is an extremely strong determinant in Poland, and at times also a restriction to the activities pursued by institutions of higher education. The other direction is transformations in the consciousness and attitudes of the university's employees and management staff, liberation from the patterns formed over many years, bold exit from the "ivory tower" towards a modern entrepreneurial university that is open to the external environment (Olearnik and Pluta-Olearnik 2015).

It is assumed that an entrepreneurial institution of higher education is one which demonstrates each of the four presented attributes in its determined goals and rules of action as well as in the practice of its operation

and development. The degree (intensity) of a given entrepreneurship attribute may be different, it may change, which provides bases for assessments and conclusions with respect to entrepreneurship of a given university and its distance to the models adopted as standards. The first attribute is the economic orientation, or in the strict sense – the economic and financial orientation. The second entrepreneurship attribute of institutions of higher education is the market orientation. The third attribute is the innovative orientation, as there is no entrepreneurship without innovativeness. The fourth entrepreneurship attribute is the managerial orientation (Olearnik 2013).

The recommendations of the European Parliament and of the EU Council of 18 December 2006 (RECOMMENDATION OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL) on key competences for lifelong learning concern creativity, innovation and risk-taking, as well as the ability to plan projects and lead them to achieve their goals. The Recommendation contributes to the development of quality, future-oriented education and training tailored to the needs of European society, puts forward the key competences for further learning and working life of young people and supports key competences throughout their lives. The Recommendation emphasizes on infrastructure for continuing education and training of adults including teachers and trainers, validation and evaluation procedures. These are basic requirements of the competence of initiative and entrepreneurship. Three basic characteristics determine entrepreneurial person, i.e. knowledge, skills and personal characteristics. There is a difference between learning about entrepreneurship and learning an entrepreneurial attitude.

1.3 Entrepreneurship as an important feature of an entrepreneur

The Oxford English Dictionary (2010) defines entrepreneur as "a person who attempts to profit by risk and initiative". A great number of different studies about the entrepreneur as an individual have been conducted. (Arzeni, 2015, Bąk, 2016, Belás and Ključnikov, 2016, Garlińska-Bielawska, 2015, Kurczewska, 2011, Olearnik, 2013, Olearnik and Pluta-Olearnik, 2015, Omerzel and Kušce, 2013). Also university students are very interested in entrepreneurship. However, the scholarly understanding of the field of entrepreneurship is still limited. Studies have shown that entrepreneurs are not a homogeneous unity and there are different types of entrepreneurs (Westhead et al. 2011). Entrepreneurship has an important role in the creation and growth of businesses and in the growth and success of countries (Hisrich et al. 2013).

Study conducted by (Ahmad 2010) shows that personality characteristics are one of the most general psychological theories used to explain and predict the behaviour of humans, including in entrepreneurship.

According to Westhead et al. (2011) the possession of certain personality characteristics exposes an individual toward entrepreneurial behaviour. According to Beugelsdijk and Noorderhaven (2005), entrepreneurs differ from the general population and from paid employees in a lot of characteristics. They are more individually oriented; they have a greater individual responsibility and effort. Westhead claim that many detailed academic studies have emphasized the characteristics of need for achievement, locus of control, risk-taking propensity, need for autonomy, decisiveness, initiative, creativity, self-confidence and trust. (Westhead et al. 2011). Omerzel and Kušce (2013) indicated that the inclination to take risks, self-efficacy and the need for independence are the most important factors affecting personal performance of the businessman. Belás (2016) found that entrepreneurs consider expertise (54.25%), responsibility (52,94%) and perseverance (51.10%) to be the most important personal characteristics and skills. Propensity to risk (46.36%) and decisiveness (39.18%) are ranked right after them. The same group of three most important attributes is presented by all defined groups of entrepreneurs, except for the case of the youngest entrepreneurs, who reported propensity to risk as the second most important factor. Emotional stability and internal self-control which help to trust in their decisions (Caliendo et al. 2014).

2. Aim and Method of the Research

The aim of the paper was to assess the possibility of shaping entrepreneurial attitudes among students of the 1st and 5th year of studies at the Faculty of Entrepreneurship and Commodity Science in Gdynia Maritime University and quantify the most important attributes of entrepreneurs in this group to compare the opinions of the students in relation to their level of education. For the purpose of this work, personality characteristics and motives of future individual entrepreneurs were investigated. The specially designed for this research author's questionnaire was used.

2.1 Topic Questions

The questionnaire consisted of ten questions. Used questions were alternatives and closed with one or multiple choices and open ended as well. The survey concerned program of studies realized, most useful subjects, modules of classes and methods of entrepreneurship teaching. Statements concerning entrepreneurship and features needed to be a good entrepreneur were also investigated.

2.2 Characteristic of the respondents

Determination of respondents' opinion on education of entrepreneurship was made by a survey conducted in 2017 in Gdynia Maritime Academy. The respondents were chosen in a targeted manner, attention was paid to the year of study - as variability factor influencing his behaviour/opinions. Two hundreds of students from Faculty of Entrepreneurship and Commodity Science, Gdynia Maritime University were investigated. One hundred of respondents came from the first year and one hundred from the fifth.

Table 1: Gender of the respondents [%]

Gender	Year of studies	
	I	*V*
Women	72	65
Men	28	35

Genders of the respondents are shown in table 1. Over 60% of students were female. What is very important, women are a minority among entrepreneurs, both in Poland (34%) and in the entire EU (31%). Women are more burdened with family obligations, which is a significant factor affecting the position of women entrepreneurs in comparison with men. On a positive note, it must be observed that in Poland, the both the share of women among the employers and self-employed (women entrepreneurs) (34%) as well as the rate of women entrepreneurship (14%) are higher that the EU average (31% and 10% respectively) (Garlińska-Bielawska 2015).

3. Results

Students were asked if they feel entrepreneurial people. The same amount 60% of investigated students from the first and fifth year of study are considered to be entrepreneurial people. Willingness to run their own business but after graduation declares 54% of younger students. Their older colleagues are less willing to this type of business activity, only 33% indicated this answer. This may be due to the fact that most of them are already working. Many of investigated students now have no plans related to this 28% of younger and 52% of older students. Every second person declaring willingness to conduct their own business provides that it will be related to the course of studies carried out. According to Kautonen, Down, and Minniti (2014) people are interested to have their own business especially until the age of 40. Submitted for respondents' evaluation statements concerning entrepreneurship are presented in Table 2.

Table 2: Statements concerning entrepreneurship in respondents' opinion [%]

Statement	I disagree		I neither agree nor disagree		I agree	
	Year of studies					
	I	*V*	*I*	*V*	*I*	*V*
Entrepreneurship can be learned	26	10	22	20	52	70
The entrepreneur must be ambitious and determined	8	4	4	2	88	94
Entrepreneurship is an individual feature	10	4	37	24	53	72
The entrepreneur must be creative and show initiative	7	0	0	2	93	98
The entrepreneur easily establishes contacts and is able to work in a team	11	4	10	12	79	84
The entrepreneur must have leadership qualities	2	6	6	6	92	88
The entrepreneur must be an open person	7	2	7	8	86	90
The entrepreneur must be honest	10	10	18	16	72	71
Anyone can run a company	70	62	16	10	14	28

In the opinion of the surveyed students, entrepreneurship can be learned, although first year students more often than their older colleagues think that this is not possible. Similar results were obtained for statement Entrepreneurship is an individual feature. This statement is chosen by more than 20% of the 5th year students than their younger colleagues. The culminations of such opinions are the indications of about 65% of all surveyed students who do not agree that "Anyone can run a company". In entrepreneurship it is possible to learn the process of taking advantage of opportunities and creating new value from individual actions, this is

an important factor affecting processes and results in development of both single businesses and whole groups, and thus, contributing to economic development. It is particularly significant for developing countries as well as those transforming their economies, e.g. Poland, where its boom has lasted since 1989 (Garlińska-Bielawska 2015). Many researchers state that decision to take on the business risk is symptomatic of a certain type of people (Kozubíková at all. 2015, Frese & Gielnik 2014, Hvide & Panos, 2014).

Most of the surveyed students think that the entrepreneur must be an ambitious, determined, creative and show initiative, he must also have leadership qualities and be an open person. Slightly fewer respondents thought that the entrepreneurs should be able to work in a team. About 70% of all students believed that the entrepreneur must be honest. Respondents from 15 submitted features (tab. 3) had to point 5 particularly important for a creative entrepreneur. Among them they pointed on characteristics like: organized, ready to risk, can plan and anticipate, self-confident and creative. Differences between students were shown on Figure 1.

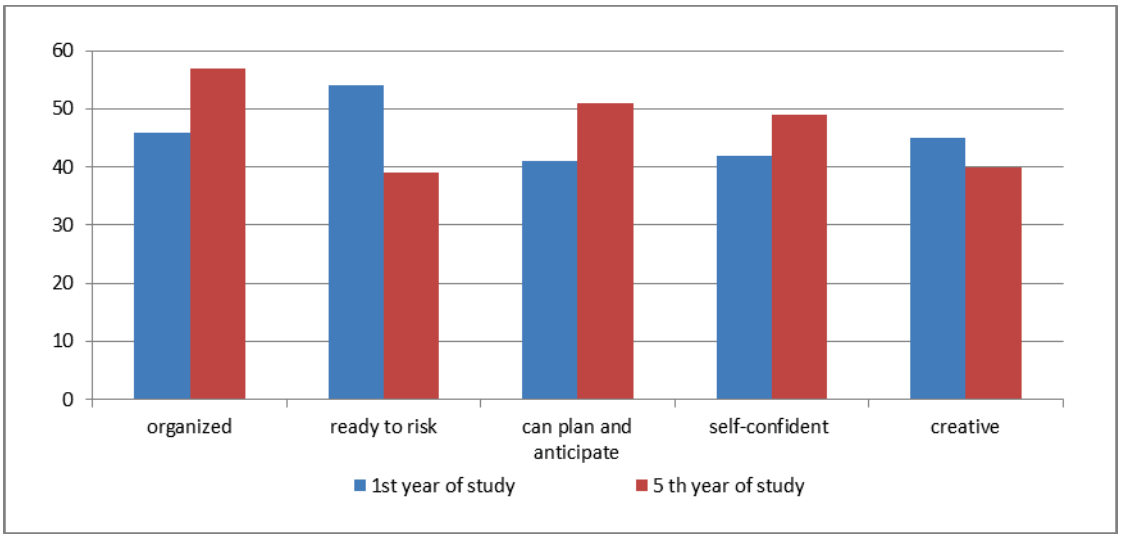

Figure 1: The most important features for creative entrepreneur in respondents opinion [%]

Table 3: Most important characteristics of the entrepreneur in the opinion of the respondents [indications]

Important characteristic of the entrepreneur	Year of studies		Total
	I	*V*	
organized	*46*	*57*	*103*
ready to risk	*54*	*39*	*93*
can plan and anticipate	*41*	*51*	*92*
self-confident	*42*	*49*	*91*
creative	*45*	*40*	*85*
learning all his life	41	32	73
rugged and patient	38	34	72
well-timed management	23	44	67
can work in a team	24	39	63
honest	37	18	55
sociable	27	26	53
enthusiastic	32	20	52
have respect for money	29	12	41
determined	8	25	33
can select the information	13	14	27

Ready to risk, self-confident are two of the five most important characteristics of the entrepreneur in the opinion of the respondents. That is confirmed by earlier indications regarding openness as a significant characteristic of the entrepreneur. The respondents admittedly also pointed out that determination is such a feature, but according to research, it is not one of the most frequently indicated attributes, in contrast to creativity. Two further important characteristics of an entrepreneur is good organization and planning and anticipation skills. The ability to select information is, in the opinion of the respondents, the least important characteristic of an entrepreneur. According to Deáková et al. (2010) the most important personal features for an entrepreneur are: courage, self-reliance, responsibility, determination, perseverance, proactive approach, creativity and scholarship in a particular area, where this entrepreneur intends to do business. Majková and

Ključnikov (2017) divided the features of an entrepreneur into three groups as follows: (1) ability to accept and face the risk, (2) creativity and new ideas, (3) ability to solve a complex task.

The completed study program in terms of usefulness in current/future work in the opinion of the 65% first-year surveyed students is overloaded with theory, but for 18% of them it prepares well to conduct its own activities and for 13% respondents prepares to work in various enterprises. Their older colleagues (45%) also think that the program is overloaded with theory, includes not enough content related to the own enterprise management (59%). For 25% of investigated students study program does not educate interpersonal skills and they (19%) suggested changing the form of classes.

The most useful for conducting activities forms/modules of classes in the opinion of the younger respondents are professional practice (69%) and exercises (38%), laboratories (33%), the least useful are lectures. For last-year students the most useful forms of classes are professional practice - 67% indications and exercises (41%), the least useful also are lectures. Table 4 presents the useful and useless study subjects in opinion of surveyed students.

Table 4: Useful and useless study subjects in opinion of surveyed students [%]

OBJECT / GROUP OF ITEMS	I disagree		I neither agree nor disagree		I agree	
	Year of studies					
	I	*V*	*I*	*V*	*I*	*V*
Basic subjects (mathematics, physics, chemistry, foreign languages)	53	67	21	8	26	25
Major subjects (biochemistry, microbiology, storage, etc.)	71	50	6	17	23	33
Economic subjects - humanities and social (economics, marketing, management, psychology, sociology, etc.)	59	81	20	12	21	7
Specialization subjects (commodities, quality management, consumer behaviour, dietetics, etc.)	87	93	3	0	10	7
Subjects shaping skills in the laboratory	55	44	11	19	34	37

In the opinion of more than half of the students, basic subjects, i.e. mathematics, physics, chemistry, foreign languages, are useful in their own business management, but over 20% of students consider them unnecessary. This may be due to the fact that they are taught in the first year and students nowadays are dealing with them and they are causing them difficulties. Younger respondents, for the same reason, may more often consider that major subjects like biochemistry, microbiology, storage, etc. will be useful. Less than half of the respondents consider shaping skills in the laboratory to be unhelpful. They consider specialization subjects (commodities, quality management, consumer behaviour, dietetics, etc.) to be the most useful in running their own business. Economic subjects: humanities and social (economics, marketing, management, psychology, sociology, etc.) are important for 60% of younger and for 80% older students. The respondents were asked to indicate the subjects that most effect on the creation of entrepreneurial attitudes among students. The most influential subjects in the opinion of the respondents are: finances - in each group over 20% of respondents reported this subject.

Other subjects mentioned by students are economics, entrepreneurship, management and commodity science. At the same time, the economy was twice more often indicated by younger and the entrepreneurship by older students. First-year students also indicated foreign languages -16 indications, and older students HR - 12 indications and quality management - 13 indications. The subject consumer behaviour on the market was indicated by 10 young and 6 older respondents.

Changes that should be introduced in the study plan to encourage students to run their own business in students' opinion are: meetings with entrepreneurs, practical classes, lectures conducted by entrepreneurs, specialization subjects should be earlier in study plan.

According to Case Study of Entrepreneurship Education at Cracow University of Economics (Wach2008) studies curricula should include more practical education, especially based on the cooperation with local entrepreneurs, within which students should prepare real world consulting projects for cooperating enterprises. Such workshops should be offered as optional courses for students of all economic and managerial majors. Academic education in the field of entrepreneurship should also implement training enterprises (similar to the idea of Junior Enterprise Concept JADE). Students should run their own training

companies to gain real experience in entrepreneurship. It should be supported by the idea of university incubators.

There are three actors involved in effective entrepreneurship education: an educator (an academic teacher), a student, and an institutional framework (university or other higher education institution). In a contemporary paradigm, the role of a teacher is to design the most effective learning opportunities for students; while the role of a student is to get involved in the process of learning and profit from that process. Institutional framework should enable a fruitful execution of both roles, that is create the most favourable conditions for entrepreneurship courses development and make the students' learning and educators' teaching possible. The active approach from all three actors is expected. However, the challenging issue remains the problem of types of teaching interventions to be implemented in order to make learning of entrepreneurship most efficient, or in other words – *how to be effective?* (Kurczewska 2011). Ho et al.(2014) found that entrepreneurship education encouraged entrepreneurial behavior in students,and more profoundly, that experiential learning had a significantly higher impact on entrepreneurial engagement than classroom-based programs.Tutaj wycinek behavior (Ho, Low & Wong, 2014,

4. Conclusions

This paper intended to answer the question whether the program of studies in AMG influenced od entrepreneurial attitudes among students. The study showed that there is a growing need for increased contextual knowledge on the aspects of learning, forms, content and methods in the future teaching and training of students.

Human resources should be considered as good educated, motivated and highly skilled workers, should be the essence of innovation processes in enterprises. Good and active cooperation of researchers and academics with entrepreneurs could be very useful and necessary for the quality of entrepreneurial teaching.

Study confirmed, that given by Entrepreneurship Education (2014) Entrepreneurial competences require active methods of engaging students to release their creativity and innovation. Entrepreneurial skills can be taught across all subjects as well as a separate subject (Entrepreneurship Education 2014). Many of top-rated universities in Europe and the UK do not offer Entrepreneurship, but if they do it is usually across faculties, available to all as an elective option. However, at many European and UK universities, various minor and major modules in Entrepreneurship are presented at undergraduate level (i.e., at Erasmus University and Tilburg University) (Nieuwenhuizen et. al. 2016).

Arend et al. (2015) found that effectuation theory satisfies the basic criteria for theory building, but the criteria theorizing about entrepreneurship were not met (Arend at all. 2015). USA university students are free to select their own electives that accompany their majors and are, therefore, not limited by fixed modules within their chosen programs. It is less onerous to introduce alternative modules within such universities. Entrepreneurship-focused programs are offered through centres for professional development or executive education. These are focused on stand-alone, workshop-based programs to train entrepreneurs in creating new ventures and growing these ventures. The targeted audience for such workshops are international and local entrepreneurs, as well as educators and academics (Nieuwenhuizen at all. 2016). Parsley & Weerasinghe determined that 40% of sampled institutions in Canada did not have a strategy for delivering Entrepreneurship as part of their curriculum, while 28% did have a strategy in place. It was determined that Entrepreneurship courses were primarily offered in conjunction with business and engineering courses. It is, however, noteworthy that 98% of surveyed institutions offer a module in Entrepreneurship, while 23% offer full degrees specializing in Entrepreneurship. This could indicate that, while the vast majority of institutions offer an Entrepreneurship module, there exists minimal effort in teaching entrepreneurship comprehensively (Parsley & Weerasinghe, 2010).

According to students' opinions entrepreneurship can be learned but in proper way, using active methods of teaching. Students pointed on meetings with people running their own business, successful. They also suggested changing the form of classes by minimalizing lectures and maximizing workshops. The year of the study influenced on the opinion about most important subjects creating entrepreneurial attitudes.

Use active and innovative teaching methods that will bring closer the reality of the business. Involve the business community in entrepreneurship teaching as lecturers and mentors and in entrepreneurship projects for students.

Regular surveys on the outcomes of entrepreneurship education should be conducted. According to the results of these surveys the program of the studies and way of teaching should be actualized to achieve better teaching results. Teachers must continually improve their education.

A Typology of University Business Incubators: Implications for Research and Practice

Charlene Nicholls-Nixon, Dave Valliere and Zohreh Hassannezhad

zhassannezhad@ryerson.ca

Abstract: The use of incubators and accelerators as institutions to facilitate the development of new business ventures has exploded worldwide in recent years. In particular, there is significant growth in the numbers of university-based business incubators (UBIs), which are incubators housed at and closely integrated with the knowledge development and dissemination activities of universities. In addition to the common incubator objectives of company creation and economic wealth generation, these incubators therefore also have objectives related to student experiential education and the commercialization of university IP. This divergence of stakeholder objectives creates unique challenges for UBIs, which have been addressed through a wide range of structures, processes and management models. This paper is an attempt to bring greater clarity to this situation by proposing a typology of UBIs, based on broad review of the UBI literature and data from incubator management practitioners. The typology examines UBIs from the perspectives of Stakeholders, Objectives, Strategic Focus, Incubation Processes, Resources and Services provided, and the resulting Socioeconomic Effects. Use of a clarifying typology by future researchers should help guide future UBI research by suggesting potential linkages between the context of different universities and the appropriate UBI types. This should lead to more valuable insights than current "one size fits all" isomorphic approaches to UBI management.

Keywords: UBI, incubation, accelerator, stakeholders, incubator performance, typology

1. Introduction

Currently, there are over 10,000 business incubators worldwide and approximately 4000 of these are associated with universities (Bhatli 2016). Business incubators are organizations that support the establishment and growth of new businesses by providing tangible resources (e.g., space, shared equipment and administrative services) and intangible resources (e.g., knowledge, network access) during a flexible period and sustain their operations through self-funding and/or external sponsorship by governments or corporations (Hausberg and Korreck 2018). This definition subsumes 'accelerators' which are defined as organizations that aim to accelerate successful venture creation by providing specific incubation services, focused on education and mentoring during an intensive program of limited duration (Pauwels et al., 2016)

Business incubaors have become a popular vehicle used by different levels of government, the private sector, and universities to reduce risk of business failure and to encourage and support entrepreneurial outcomes, including: innovation, wealth creation, employment, and entrepreneurial skill development (Roig-Tierno et al. 2015; Pauwels et al. 2016; Kolympiris and Klein 2017). The widespread use of business incubators as a public policy instrument has produced a variety of different typologies (see reviews by Barbero et al. 2012; Bakkali et al. 2014; Barbero et al. 2014).

Yet across these typologies, universities are treated as a homogeneous category. This is surprising given that university-based business incubators (UBIs) vary widely in form and function reflecting the diversity in their historical resource and capability endowments (Todorovic and Suntornpithug 2008), institutional logics (Redondo and Camarero 2017), and their unique regional and organizational characteristics, constraints, and stakeholder groups (McAdam et al. 2016).

Our paper addresses this deficit in the literature by (1) developing a parsimonious typology that identifies the sources of systematic variation in UBIs, and (2) drawing implications for incubator management and academic research.

2. Literature Review

2.1 The entrepreneurial university

> *Despite industrial and academic systems at varying stages of development, governments in all parts of the world are focusing on the potential of the university as a resource to enhance innovation environments and create a regime of science-based economic development (Etzkowitz et al. 2000: 314)*

Much of the growth of university business incubators has occurred since the early 1990s as the concept of the entrepreneurial university became a global phenomenon (Kalar and Antoncic 2015) and universities accepted economic development as a third mission, alongside research and teaching (Etzkowitz et al. 2000).

The realities of reduced government spending on higher education and increases in student enrolment, coupled with the need to demonstrate more direct contributions to economic development, pushed universities to extend their mission beyond creating and disseminating new knowledge to commercializing knowledge. Thus, universities began pursuing third stream activities like contract research, technology transfer through patenting and licensing, the creation of science parks and incubators (as mechanisms to generate revenue while facilitating knowledge sharing and diffusion), or taking equity stakes in university spin-offs, spin-outs, and start-ups (Fuller and Pickernell 2018). Interactions across the 'triple helix' of university-industry-government institutional boundaries became a foundation for explaining pathways to innovation and economic development (Etzkowitz 2008).

Against this backdrop, it is not surprising that UBI research has focused on activities associated with the commercialization of science and technology (Mian et al. 2016), rather than exploring the broader role UBIs play in advancing entrepreneurship and innovation. This technology centric perspective is consistent with the view that UBIs support academic entrepreneurship by licensing and commercializing intellectual property developed within the university (Barbero et al. 2012). Shah and Pahnke (2014) assert that this conception of academic entrepreneurship is too narrow: Universities generate start-ups across all departments - including music, social sciences, and the humanities – not just in those associated with science, technology, and engineering. Moreover, a university's entrepreneurial activities may include actors who innovate in the context of universities, regardless of whether they are employed as current faculty, staff and students.

To capture the full range of activities associated with university entrepreneurship, Shah and Pahnke (2014) propose conceptualizing university entrepreneurship along two dimensions: sources of innovative knowledge (academic research or other source) and sources of entrepreneurial knowledge (university provided entrepreneurial education or other source). The resulting 2x2 matrix distinguishes between four different types of new ventures. The implication is that universities create societal and economic benefits by laying the foundation for entrepreneurial activities regardless of where or when that activity occurs.

It is important to recognize that universities are embedded in a broader entrepreneurial ecosystem involving multiple contexts, actors, stakeholders, and processes that influence the nature and quality of entrepreneurial activities (Autio et al. 2014; Wright et al. 2017). Entrepreneurship education is increasingly viewed as a core function of the university and because experiential learning has been associated with improved employment outcomes (Wright et al. 2017), universities are moving to provide an experiential component in their approach to entrepreneurship education. Embedding opportunities for all students to launch start-ups expands the scope of universities third-stream activities and provides impetus to define UBI activities more broadly than as a vehicle for technology commercialization.

The specific approaches universities take to the formation and operation of UBIs depends upon their prevailing institutional logic.

2.2 Institutional logics

Institutional logic refers to the socially constructed, historical set of material practices, assumptions, values, and beliefs that shape individual cognition and action (Thornton et al. 2012). Multiple logics are embodied in most organizations. In some cases, one logic can dominate and in other cases the logics blend to provide a single set of practices, assumptions, values and rules (Besharov and Smith 2014). The diversity of stakeholders influencing a university's mission and objectives (e.g., faculty, students, government policymakers, private

sector sponsors) suggests the potential for multiple institutional logics to evolve and co-exist within a university. Thus, even when entrepreneurial universities share a common strategic goal and certain comparable economic and social conditions, they still differ from each other on account of their traditions, characteristics, and policies (Guerrero and Urban 2012; Kalar and Antoncic 2015).

Entrepreneurial universities must balance their roles as knowledge creators, disseminators, and exploiters. Their unique institutional logic(s) guides choices about how resources are allocated toward: basic or applied research; STEM disciplines (science, technology, engineering mathematics) versus social sciences, humanities, and liberal arts; building faculty competence in research versus teaching; educating students with broad capacities for scepticism and learning versus developing marketable job-related skills and offering experiential learning opportunities; use of various mechanisms to facilitate and capture value from activities related to innovation and entrepreneurship (e.g., establishing technology transfer/licensing offices, building science parks, creating incubators/accelerators to support new venture creation and/or taking equity positions in spin-offs and start-ups associated with academic entrepreneurship), etc.

2.3 Prior literature on Business Incubation

There is a growing body of academic literature on business incubation (see comprehensive reviews by Theodorakopoulos et al. 2014; Albort-Morant and Ribeiro-Soriano 2016; Mian et al. 2016; Hausberg and Korreck 2018). Barbero et al. (2012) identify seven different business incubator typologies. Six of these typologies include UBIs as a category in their classification scheme. Following from our previous discussion about institutional logics, and the diversity they can encompass, we assert that researchers interested in the study of business incubation need to recognize that universities are not homogeneous. Thus, there is a need for a more nuanced approach to examining and explaining how these differences are reflected in UBI form, function, and performance.

We take a first step in this direction by offering a typology of UBIs.

3. Method

We conducted our search for literature on university business incubators and incubation using the largest scholarly abstract and citation databases - Scopus and the ABI/Inform collection of ProQuest. We restricted the search to peer-reviewed journal articles, as they are considered to be validated knowledge. We searched for journal articles containing both “Incub*”, and “Business” in their abstracts, without any date restrictions. This search initially yielded 927 papers; 442 of them from Scopus and 485 from ABI/Inform. In the first step, we excluded papers that were not published in scholarly peer-reviewed journals, were in languages other than English, or were on unrelated topics. From this stage remained 63 articles from Scopus and 89 articles from ABI/Inform. Then we read the abstracts and titles and retained 26 articles from Scopus and 13 papers from ABI/Inform. The criteria for retention were papers that were conceptual or empirical studies focusing on UBIs or review papers related to the functions, typologies and performance of UBIs. After reading these papers and carefully reviewing the references they cited, five more papers (not found in the original searches) were added to the set. The resulting set of 44 articles reflect the current state of scholarly knowledge about university-based incubators and became the foundation for development of our typology.

4. Analysis

4.1 Stakeholders

Stakeholders matter to UBI operations; they set objectives, provide resources and legitimacy. Institutional support matters (Dahms and Kingkaew 2016). Different UBIs can have very different institutional contexts.

They also have a lifecycle within this context: Starting up operations, getting embedded with the institutions, ongoing operations. UBI lifecycle stage affects level of autonomy and ability to access resources.

Different classes and levels of stakeholders have different interests. University is the overall administrative institution, but stakeholders also include the various different faculties (especially STEM vs non-STEM), the faculty members (innovator-entrepreneurs, advisors), UBI management staff, and students (launching new ventures, working as employees for new ventures or for the incubator itself). The new venture is an entity itself, with founders and employees. Investors are providers of funding or corporate partners (seeking

innovation). Governments at the national, regional, or municipal levels may also exert influence on the UBI. Society can be general, the local community, and the specific entrepreneurial ecosystem members.
Different types of stakeholders have different institutional logics, such as the public/private distinction made by Hausberg (2018) or the academic/industry distinction by Theodorakopoulos (2014). Even those of the same class but of different levels may have different logics. These could be market logic (pursue competitive advantage to make profits), education logic (discover knowledge, disseminate to students), social development logic (poverty reduction, employment), or political logic (negotiate competing community demands). For example, government may have the objective to empower a marginal community (women, immigrants) (Dahlstrand and Politis 2013).

If a UBI is supported by a range of different stakeholder classes (or different levels of the same class) there can be competing institutional logics. Investors want to make financial returns, while faculty members want to teach students, and university administrators want to enhance institutional reputation. A biomedical UBI operated in partnership between a university, a research hospital, and a venture capital fund will have many such competing institutional logics. Somehow in the governance and management of the UBI, these differences must be resolved to a single dominant logic that guides strategy and defines reporting structures.

4.2 Objectives

Generally, objectives and performance measures of incubators have been poorly defined and reported (Dee et al. 2011). Performance definition is implicit in the dominant logic, and so it should reflect that choice (Hausberg and Korreck 2018). The details may be different between one-time (during start-up) and operational (operations) (Wann et al. 2017). Some identified success factors (Gozali et al. 2015), but we don't really know which are best (Lumpkin and Ireland 1988; Dee et al. 2011). Further, objectives can focus on output efficacy (measures of quantity of desired outputs created), on output efficiency (measures of the inputs required to create the desired output), or as simple inputs (activity/effort measures of utilization or consumption of inputs, regardless of their effect on creation of outputs).

4.3 Strategic focus

The UBI's strategy reflects its objectives and the chosen dominant logic. Within a single set of objectives and logic, different strategic choices are possible for different UBIs, including: sectoral focus (especially STEM vs non-STEM), lifecycle stage (ideation, launch, growth, maturity), and desired impact over time (short-term vs long-term) and across space (specific geographic, or community focus). These strategic choices drive the adoption of specific performance measures, which may be a mix of stock (amount) and stream (rate of change), hard (quantitative) and soft (qualitative) measures (Voisey et al. 2006).

These strategic choices are operationalized through the design of a business model, including the choice of revenue streams (rent, fees, royalties/equity, or sponsor grants) and the choice of cost structure. Even within a single strategy, multiple business models are possible for different UBIs (Dee et al. 2011). For example, the market-logic imperative to make money can be interpreted as a strategy to increase prices, decrease costs, or increase volumes. Research has not provided a theoretical basis for selecting/designing strategies or business models. So, there is still a lot of practitioner uncertainty about which business models work best for UBIs. This is hard to know because we don't know which stakeholders are best, which institutional logics are best, and which measures are best (Dee et al. 2011).

The choice of strategic focus also necessitates control structure, such as the governance of the UBI, or the degree of proactive intervention the UBI management makes in incubated new ventures (laissez-faire, monitored, picking winners, survival of the fittest (Dee et al. 2011; Hausberg and Korreck 2018)) (Lewis et al. 2011).

4.4 Incubation process

The incubation process will exhibit a particular structure of intake, value-adding interventions, and graduation (Wann et al. 2017; Hausberg and Korreck 2018). Intake may be open or closed to entrepreneurs outside of the university community, may be continuous or in cohorts, and may use selection criteria that may emphasize the market potential, the founder management team, or the quality of the business idea. And graduation may be based on elapsed time or on achievement of new venture milestones (valuation points).

Through this process, the UBI may provide various value-adding interventions (see Resources and Services below). In many UBIs, this value-creation process may follow a pre-determined causal development logic. But in others it may follow an ad hoc effectuation logic. And, in both cases, UBIs may differ on the degree to which they customize this process – matching it both to the specific demands of the type of new ventures (e.g., industry dynamism), and to the changing needs of new ventures as they progress through the start-up lifecycle (Dee et al. 2011).

4.5 Resources and services

A key capability decision for a UBI to make is how to translate the chosen strategic focus into the suite of resources and services provided. In this choice, they may decide to provide what is "typical" of similar UBI institutions of the same generation (Theodorakopoulos et al. 2014), or what is specifically wanted/needed by the new ventures. There is an unfortunate dearth of research to rigorously establish what actually works.

Many therefore opt for the typical offerings (Hausberg and Korreck 2018): infrastructure (space, tools, business services) (Dahms and Kingkaew 2016), training (mentoring and coaching, formal education, peer learning), networking (inbound connection to customer opportunities, resource providers or partner capabilities, or outbound connection for marketing or PR), and capital (funding provided by the incubator or external investors).

Recent research suggests the important role played by less-objective resources and services, such as culture, legitimacy, and social capital (Redondo and Camarero 2018). Culture provides new ventures with community support, identity, and the negotiation of boundaries with stakeholders and other institutional or market participants (Theodorakopoulos et al. 2014).

4.6 Socioeconomic effects

Effects of UBI operations on stakeholders can be quite varied, and a mix of positive and negative.

For the university, these include entrepreneurial skills development, fostering entrepreneurship on campus (Stal et al. 2016), encouraging innovation (Wonglimpiyarat 2014; Wonglimpiyarat 2016; Kolympiris and Klein 2017), and enhancing reputation among university stakeholders. Commercialization of university IP leads to regional economic development, employment, and increased tax base (Jamil et al. 2015; Lasrado et al. 2016).

The successful operation of incubated new ventures involves the creation of valuable new products and services in the marketplace. For founders of new ventures (students or faculty members) the support of the UBI means increased human and social capital, higher sales and higher growth rates, and longer survival, (Hausberg and Korreck 2018). Most of these are immediately beneficial to the new venture. And some are of benefit to all future ventures involving the same individuals (i.e., acting as serial entrepreneurs) (Westhead et al. 2005).

In addition, the effects of a UBI on third parties should also be considered. A UBI is an employment and income multiplier (Markley and McNamara 1995; Sherman and Chappell 1998). And a targeted UBI can act as a powerful tool for social development among disadvantaged groups. Furthermore, the entrepreneurship supported by the UBI may act as an inspiration to others or make the locale of the UBI a more-desirable home for immigrants and creative-class residents. It may also initiate relationships that lead to other, unrelated transactions or benefits. For example, the UBI activities of DMZ at Ryerson University initially attracted the attention of Google, which led to increased Google interest in the Toronto area for a variety of other non-incubation business operations.

5. Discussion

The existing literature has relatively little to say about the varieties of UBI that may exist. Clarysse et al. (2005) provided one of the first attempts to bring structure to the types of UBI, classifying by what is done, what is used, and how. Todorovic and Suntornpithug (2008) implied a typology that focussed on the unique role of the university as supporter and beneficiary of the UBI activities, and drawing an interesting distinction between static and dynamic factors. Barbero et al. (2014) recently drew together various incubator archetypes in the literature and related these to innovation (as a key UBI output). Table 1 summarizes the key typological features of these previous attempts.

Table 1: Summary of extant typologies

Study	Typological Features
Clarysse et al. (2005)	Activities (opportunity search, IP protection, strategy, business planning, funding, spin-out). Resources employed (organization, human resources, technology, physical resources, finance, network). Reference models (strategies, outcomes).
Todorovic & Suntornpithug (2008)	University involvement. Nurturing. Community networking. Teaching (static, dynamic). Commercial networking. Emphasis: differing capability/resources, proprietary, capital, production, entrepreneurial culture.
Barbero et al. (2014)	Archetypes: basic research (conducting fundamental research), university (promotion of academic entrepreneurship), economic development (creation of profit and jobs), private (corporate R&D).
Wonglimpyarat (2016)	Source of budget (university, government). Policies (intake, graduation, IP management, resources). Area of focus (STEM sector). Operational functions (services, governance, partnerships).

5.1 Proposed Typology

By drawing upon the features of these previous typological attempts and incorporating the attributes of UBIs that are fundamental to the literature reviewed above, but overlooked in the previous typologies, we are able to propose a more comprehensive and unified typology of UBIs. This new typology is presented in Table 2. It features six major dimensions of UBI classification, as well as 17 sub-dimensions that prescribe the scope of each dimension. We also provided illustration of the possible values each sub-dimension may take. For example, the Stakeholder dimension comprises which classes of stakeholder have an interest in the particular UBI, the range of institutional logics that these stakeholders will strive to implement, and the resulting dominant logic that emerges and therefore guides the Objectives and Strategic Focus of that UBI.

Table 2: Proposed typology

Dimension	Sub-dimension	Values
Stakeholders	Classes	University, faculty, new venture, founders, investors, governments, community
	Logics	Market, education, social development, political
	Dominant logic	Resolution of stakeholder competition
Objectives	Performance definition	Market, education, social development, political
	Outputs	Efficacy, efficiency, effort (utilization of inputs)
Strategic Focus	Target scope	Sector, stage, time horizon, geography, social or political group
	Measures	Hard/soft, stock (amount) vs stream (rate)
	Business model	Revenue streams, cost structure
	Control	Governance, intervention
Incubation Process	Structure	Intake, cohorts, proactivity, graduation
	Value creation	Development, customization
Resources and Services	Infrastructure	Space, tools, business services
	Training	Mentoring, education, peer consultation
	Networking	Inbound (customer, supplier, investor, capability), outbound (marketing, PR)
	Capital	Own funds, partner funds, referral
	Culture	Legitimacy, community
Socioeconomic Effects	Classes	University, faculty, new venture, founders, investors, governments, community

We pilot tested the application of this typology by encoding three UBIs at our home institution, Ryerson University. In particular, we confirmed that the typology is comprehensive enough to capture the differences between the *Digital Media Zone* (one of the world's top-ranked UBIs, focused on STEM commercialization through company creation, with strong partnerships with investment funds and local governments, and with multiple revenue streams), the *Design Fabrication Zone* (focused on student experiential learning through one-off project installations, with strong faculty member involvement, but with a more limited range of support services, and supported in-kind by the university), and the *Social Innovation Zone* (focused on community development through creation of social ventures, with strong student leadership, and supported largely by grants).

5.2 Implications

Our proposed typology allows researchers to capture variation across UBIs while comparing their features systematically along a common set of dimensions. It reveals the heterogeneity of UBIs as reflected in their key stakeholders, dominant institutional logic, objectives, strategic focus, incubation process, resources and services, and their socioeconomic effects. Several compelling insights emerge from this classification scheme.

First, not all stakeholders want the same things from a UBI. Stakeholders can create competing institutional logics that need to be reconciled in establishing the objectives and strategic focus of the UBI. While it is possible to have multiple institutional logics, it also is important to ensure that they are reconciled so that the UBI can move forward with a clear set of values and beliefs that can guide resource allocation decisions. Failure to resolve tensions between competing institutional logics risks leaving the UBI manager to steer a rudderless ship.

Second, UBIs may not be focused solely on commercialization for economic gains. While the initial concept of UBIs focused on their role in commercializing intellectual property originating in academic labs, it is clear that they also serve other functions. Most notably, as a mechanism for bringing together sources of innovation and sources of entrepreneurial knowledge developed both inside the university and externally, through the support of new ventures that have direct as well and indirect university affiliations.

Third, UBIs can support start-ups that do not have a focus on science, technology or engineering. The concept of the entrepreneurial university embraces and supports innovations across all university departments, including social sciences, humanities, and liberal arts.

Fourth, UBIs are not concerned only with new venture creation. In an effort to provide students with experiential learning in entrepreneurship, UBIs may also admit students/teams in the early stages of opportunity creation and validation, before a viable market opportunity has been demonstrated.

Fifth, there is no 'one size fits all' approach to performance measurement for UBIs. The measures used to assess UBI performance (at the venture-level and at the incubator-level) should be consistent with the UBIs institutional logic, objectives and strategic focus.

We acknowledge that the dimensions and values in our typology may be Canadian/North American-centric. Thus, the typology may not be collectively exhaustive in capturing the sources of variation in UBIs across all international contexts. We offer the typology as a 'straw man' and invite researchers in other geographic locations to further explore and articulate the dimensions, subdimensions, and values needed to fully reflect the diversity in the form and function of UBIs on a global scale.

Determinant Factors and the Impact of ICT on Organizational Creativity Support

Celina M. Olszak
University of Economics in Katowice, Poland
celinaolszak@gmail.com

Abstract: The issue of organizational creativity is an important aspect of contemporary management that offers a better understanding of organizational innovation, effectiveness, efficiency, and ultimately organizational survival. Several arguments can be found in the pertinent literature that Information and Communication Technology (ICT) provides organizations with faster and easier access to information, improving creativity in business processes, and better communication between employees and all stakeholders. While the subject of creative problem solving, creative processes, and support for individual or group creativity has been broadly discussed in the literature, studies of organizational creativity support are still fragmentary and scattered. Little guidance has been given to mangers how to develop ICT-based organizational creativity support. The main objective of this paper is to provide organizations a theoretical, conceptual, and applied grounded discussion of ICT-based organizational creativity support. This study identifies the main determinants and factors of the ICT-based support to organizational creativity. The so-formulated objective involves performing a critical analysis of the literature on the subject of the relation between organizational creativity and ICT, as well as conducting an empirical research on factors, determinants and barriers in the field of the ICT-based organizational creativity support. The empirical survey was conducted in the form of in-depth interviews with 24 experts.

Keywords: organizations, creativity, organizational creativity support, ICT, determinant factors, experts

1. Introduction

Organizational creativity is considered one of the most actively developing research areas. It is asserted that it is a main vehicle of organizational development, the basis for staying on the market and innovative success (Amabile, 1988; Elsbach and Hargadon, 2006; McLean, 2009; Mitchell et al., 2003; Shin and Zhou, 2007).

Organizations face the need to constantly generate new and useful ideas that concern products, services, processes, managerial practices as well as competitive strategies. They are required to have a strategic organization's capability, meaning adapting to changing environmental conditions through continuous acquisition of new information resources and the creation of new configurations from them (Sirmon, et al., 2011; Arora and Nandkumar, 2012; Zahra, Sapienza and Davidsson, 2006; Klijn and Tomic, 2010).

Several arguments can be found in the pertinent literature that Information and Communication Technology (ICT) enables organizations faster and easier access to information, improving creativity in business processes, and better communication between employees and all stakeholders (Cooper, 2000; Olszak, Bartuś and Lorek, 2018). ICT enables an organization to search and absorb new knowledge that is needed in organizational creativity and solving business problems. On the other hand, the practice shows that success from ICT-based organizational creativity support is still questionable. Organizations do not achieve the appropriate benefits from ICT usage. Many organizations are not able to make ICT an effective tool for creativity support. The reasons for this failure are not clear and still not well investigated. So, the need for a more systematic and deliberate study of ICT to organizational creativity is crucial.

The main goal of this paper is to identify the main determinants and factors of the ICT-based support to organizational creativity. The so-formulated objective involves performing a critical analysis of the literature on the subject of the relation between organizational creativity and ICT, as well as conducting an empirical research on development determinants and barriers in the field of the ICT-based support to organizational creativity. The empirical survey in the form of in-depth interviews with 24 experts, was conducted at the turn of November and December 2015. The experts represented science (12 respondents), business (7 respondents) and ICT (5 respondents).

In order to achieve the research goal, the logic of the discourse is as follows. At the start, a critical review of the relevant literature is conducted to identify an essence of organizational creativity. Next, a link between organizational creativity and ICT is investigated as well as the role of ICT in supporting organizational creativity

is described. Then, the assumption of a qualitative survey in the form of in-depth interviews with experts is presented. Finally, determinants and barriers to the ICT-based organizational creativity support in the light of conducted study are discussed. In conclusion, theoretical contributions and practical implications of the study are presented.

2. The essence of organizational creativity

The term "creativity" is rooted in psychology. It concerns mainly individual and group creativity (Amabile, 1983). However, today creativity is increasingly used in different organisational contexts – business strategies, business processes, strategic management, competitive advantage, organisational development, leadership and innovation. According to many researchers (Gong, Huang and Farh, 2009; Klijn and Tomic, 2010; Choi, Madjar and Yun, 2010; Zhou and Ren, 2012), organizational creativity is the organisation's capability to generate ideas that can contribute to development of new products, services, business practices, as well as competitive strategies. Woodman et al. (1993) define organizational creativity as new ideas that drive the creation of a valuable, useful new product, service, idea, procedure, or process by individuals working together in a complex social system. These "new ideas" are a response to the demand from the organization, e.g. its various departments or customers (Parjanen, 2012). Amabile (1988), on the other hand, stresses that creativity is an important source of organizational innovation, as well as competitive advantage. Creativity means a collaborative, intellectual, psychological and social process that takes place in an organization and is affected by contextual and organizational factors (Blomber, 2014). According to Brennan and Dooley (2005), creativity within an organizational context can be regarded as the sum of the following functions: the creative person, creative task and the organizational context (culture). A similar approach is presented by Amabile et al. (2004) and by Sundgren and Styhre (2007), who emphasize that organizational creativity is more than merely a collection (sum) of creative individuals. The mere presence of creative individuals in an organization does not guarantee organizational creativity. Development of organizational creativity is largely determined by the organizational environment. The authors referred to above claim, that a crucial role in supporting organizational creativity is played by managers and leaders. Evidence is given to prove, that managerial styles based on agility, perceptiveness and rapid decision making are conducive to organizational creativity.

Stenmark (2005) argues that the most important factors enhancing organizational creativity include: motivation, autonomy, work setting, organizational climate and various additional elements, such as time to experiment, for example.

An interesting view on the problem of organizational creativity is demonstrated within the strategic resource-based approach and dynamic capabilities of organisations, where the success of organization's strategy is determined by the configuration of its resources and skills, as well as the by capability to continually acquire new resources and create new configurations of these (Zahra, Sapienza and Davidsson, 2006). Acquiring, reconfiguring and developing an organization's resources is critical to winning competitive advantage and creating value. It is hardly surprising, therefore, that organizational creativity is also likened to the system of knowledge and to the capability to create new knowledge from the existing stock of information (Baron, 2012; Basadur, Basadur and Licina, 2012) When following the line of thinking about the essence of organizational creativity referred to above, it is hard not to take notice of the role of the organisation's infrastructure that drives new ideas and makes it easier to bring them to life (Birkinshaw, 2010; Ford, 2002). Nowadays, ICT tools can be an important contributor to development of such an infrastructure.

3. The role of ICT in supporting organizational creativity

According to the report published by the US National Academy of Science (Mitchell et al., 2003), ICT unquestionably influence our economic, social and private life. They not only improve business processes, products and services, but also facilitate transformations and the new value creation for organizations and society at large (Nunamaker et al., 1996; Olszak, 2016). The authors of the report emphasize that ICT support creative practices in art, design, science, engineering, education and business through enabling development of original creative production types. ICT play a key role in developing new markets, products and services, as well as in competition and in the emerging of new creative sectors (art, computer games, music, publishing). It is worth stressing that ICT have an immense impact on other sectors and on the creation of new jobs, occupations and specializations. ICT are considered to have become a binder for different fields of study, science, business and culture, that triggers creative practices in these domains.

Studies conducted by different authors (Dewett, 2003; Olszak and Kisielnicki, 2018; Shneiderman, 2007; Woodman et al., 1993) indicate certain relationships between ICT and organizational creativity (Table 1).

Table 1: Links between ICT and creativity

ICT and creativity	Authors
Improvement of information and communication flow	Dewett (2003), Woodman, Sawyer and Griffin (1993)
Collecting information, information analysis, problem classification	Greene (2002), Indurkhya (2013), Klijn and Tomic (2010), Lubart (2005), Nakakoji (2006), Proctor (2010)
Discovering new knowledge, discovering associations, learning, searching new ideas	Greene (2002), Indurkhya (2013), Klijn and Tomic (2010), Saldanha (2012)
Information visualization	Lubart (2005), Greene (2002), Proctor (2012), Shneiderman (2007)
Knowledge coding	Dewett (2003), Shneiderman (2007), Saldanha (2012)
Group cooperation	Dewett (2003), Greene (2002), Shneiderman (2007), Saldanha (2012)
Conducting brain-storming sessions, stimulating imagination, modelling creative processes, problem-solving	Dewett (2003), Hewett et. al. (2005), Lubart (2005), Mitchell, Inouye and Blumenthal (2003), Nakakoji (2006), Proctor (2010), Saldanha (2012)
Creating knowledge maps, thesauruses, libraries	Proctor (2010), Shneiderman (2007)
Human-computer interaction	Ulrich and Mengiste (2014), Lubart (2005)
Dissemination of creative effects	Indurkhya (2013), Klijn and Tomic (2010), Mitchell, Inouye and Blumenthal (2003), Lubart (2005)

Source: (Olszak and Kisielnicki, 2018).

The following issues deserve special attention (Olszak and Kisielnicki, 2018):

- improved information flow and communication between employees,
- enhanced codification of organizational knowledge,
- expanded limits to employees' knowledge and abilities.

Electronic media are claimed to intensify and improve communication between employees in organizations. Databases, workflow systems, intranet portals, electronic mail and videoconferences enable employees to exchange opinions and suggestions, to work together on documents, as well as to contact different experts, while also facilitating communication within virtual teams, thereby improving their productivity and creativity.

Many a time, ICT have been proved (Hayen et al., 2007; Kim, 2006; Pissarra and Jesuino, 2005) to be suitable for supporting such activities as brainstorming, categorization of ideas, analysing alterative solutions, sharing knowledge, evaluating ideas, making decisions, as well as planning and group decision support. Today, communication and collaborative group work can be effectively supported using a variety of web technologies.

These include: WebDemo, Sametime, eRoom, Microsoft NetMeeting, Interwise, Groove, PlaceWare, WebEx, GroupSystems, Google Groups, MSN, Yahoo and others. These technologies enable development of (Saldanha, 2012): (1) www platforms (open innovations, integrated team support platforms), (2) e-learning platforms for teaching foreign languages at schools, (3) web 2.0, social software that facilitates access to specialist knowledge, exchange and dissemination of knowledge, as well as new knowledge generation.

To be able to understand the weightiness of ICT in knowledge coding, it is worth remembering the imperfections of human memory, that manifest themselves through the limited ability of memorizing large volumes of information. ICT enable the storage of an immense stock of information in different databases, data warehouses and knowledge bases that are referred to as organizational memory. In particular, much attention is given to data warehouses that integrate historical data and knowledge, both internal and sourced from the organization's environment. Here, many authors emphasize the role of OLAP (On-line Analytical Processing) and data mining techniques that are used to analyse information and discover new knowledge, as well as data visualization techniques that make learning and understanding newly discovered knowledge easier. The tools used for this purpose include conceptual graphs, diagrams, visual metaphors and knowledge maps (Eppler and Burkhard, 2008), as well as image processing systems (Cooper, 2000).

Studies confirm (Shneiderman, 2007) that access to a variety of knowledge repositories and knowledge discovery techniques facilitates the process of overcoming mental barriers and contributes to knowledge expansion. Greene (2002) stresses that organizational creativity support software tools enable exploration and

better understanding of problem domains, learning, discovering new ideas (classifying and storing them), collaboration and visualizing interdependencies between processes (phenomena). Heweet et al. (2005), Indurkhya (2013) and Nakakoji (2006) argue that ICT facilitate brainstorming, merging ideas and ranking them.

Proctor (2010), on the other hand, claims that ICT accelerate the process of moving through the creative process stages and problem solving. Furthermore, they stimulate thinking and creating mind maps. ICT enable employees to reach new sources of knowledge (both within the organization and outside it). Such external repositories as databases, Open Access bases and social media provide extremely valuable knowledge. Exploring them using ICT enables one to break barriers to knowledge.

Arif et al. (2010) argue that ICT may not only support operationalization of different business activities (through providing guidelines, prompts and suggestion methods) but also enable language translations and enhance user's confidence in the system through offering a friendly human-computer dialogue. Similarly, Ulrich and Mengiste (2014) emphasize the role of ICT in human-computer interaction, as well as in supporting business plans and in development of personalised services for users. Lubart (2005) and Klijn and Tomic (2010), on the other hand, appreciate the role of ICT in supporting "what-if" analyses, visualization processes, dissemination of creative effects and visualization of ideas. Shneiderman (2007) adds, that ICT may offer work progress measurement and alert generation tools, support development of libraries of ideas, thesauri, maps of ideas and mind maps. Finally, Saldanha (2012), whose focus is on innovation, describes a wide range of areas that can be supported by ICT. These include in particular: knowledge management, group collaboration, information processing including process coordination and uncertainty reduction, as well as supporting creativity, which includes creative thinking.

4. Research method

The main objective of this study is to identify the most important elements and factors that determine ICT-based organizational creativity support. A qualitative approach is used to address this objective. A qualitative approached is suggested when: (1) there is little known in a particular research area; (2) existing research is confusing, contradictory, or not moving forward; and (3) the topic is highly complex (Yin, 1994).

The qualitative survey in the form of in-depth interviews with 24 experts was conducted at the turn of November and December 2015. The experts represented science (12 respondents), business (7 respondents) and ICT (5 respondents) – all of them being recognized authorities from Polish economic and technical academic institutions, managers representing successfully growing enterprises, and valued ICT professionals. The in-depth interviews were mainly focused on the following eight topics:

- experts' interpretation of the organizational creativity term,
- organizational creativity development (activation) factors,
- opportunities for and threats to organizational creativity development,
- main determinants of computer-based support to organizational creativity,
- development barriers to computer-based support to organizational creativity,
- functionalities of the organizational creativity support systems,
- types of organizational creativity support systems,
- the future of organizational creativity development and computer-based creativity support systems.

Each in-depth interview was transcribed with a word processor, with the interview date, time, and codes relating to organizational creativity support as well as reflective remarks. These notes were then combined with similarly coded notes including written documents, and formed a case database. The analysis presented in the next section is formulated from this database. This study is a part of bigger research project concerning the issue of a methodology for computer-supported organizational creativity.

5. Determinants and barriers to the ICT-based organizational creativity support – findings from the survey

Presenting the research results, it is worth to stress that experts differed in their definitions of the term "organizational creativity". Those who represented academic institutions, most often described it as the organization's ability to change or to learn. Business practitioners viewed creativity as nothing else than organization's competences in generating different ideas that could provide a basis for enhancing the

attractiveness of products and services, or even that of management procedures. ICT specialists, similarly as other respondents, emphasized the strong link between organizational creativity and innovation. When asked about the organizational creativity drivers, the experts indicated four key elements. These included: organizational climate and culture, motivation, support from the management and employees' competences (Table 2).

Table 2: Creativity drivers in the light of the survey

Creativity drivers	
Organizational climate and culture	– climate conducive to knowledge sharing, collaboration, acceptance of new ideas, even those where high risk is involved, – atmosphere of self-realization, – maximum flexibility of the organization, freedom of action, good communication, – willingness to implement changes, – long-term thinking, – high level of independence in action.
Motivation	– adequate employee rewarding mechanisms, – workplace arranged in a manner that promotes organizational creativity (relaxation rooms, libraries, access to repositories, databases, magazines).
Support from the management	– management support to employee initiatives, – supporting high-risk projects.
Competences	– capability of building information resources (e.g. customer data), – capability to make use of new technologies (BI, BD, social media), – organization's analytical skills (understanding and analysing the factors that determine internal and external resources), – organization's ability to make use of its human resources, – organization's ability to attract talented employees and to support their further development.

Source: Own elaboration

According to the experts, organizational climate and culture are the most important organizational creativity drivers. Organizational culture should encourage knowledge sharing, collaboration on different levels (within different employee groups), communication and sharing new ideas (even those that seem risky). The experts agree that organizations need to sent a clear message to their employees, that they are not afraid of changes and that, on the contrary, they are open to them. Employees should perceive themselves as enjoying a high level of independence in their actions and believe that their unconventional thinking is not a waste of time.

Many respondents stressed that organizational creativity should be built on a reward and promotion oriented motivation system. The system should promote individuals who are willing to generate ideas and share ideas. To be innovative, organizations need to provide their employees with access to a variety of libraries, bases of journals and magazines, patent bases, as well as to brainstorming rooms. Attention was given to the increasing requirements and competences expected of employees, particularly as regards being creative in collecting, analysing, processing and interpreting data. In addition, the respondents stressed that employees should be confident that their ideas would be supported by the management.

The interviews with the experts confirm that their opinions on the most important opportunities and threats to the ICT-supported organizational creativity development are consistent with the studies referred to in the literature of the subject (Table 3). First of all, the respondents indicated the role of efficient communication and group work, as well as development of adequate and user-friendly ICT tools. The experts emphasized that information technologies cannot be used solely for the automation and acceleration of routine tasks.

Organizations should be looking for such tools that will enable them to create unique value for the organization and for its customers. Yet, the experts also pointed to numerous threats that accompany the organizational creativity development. These include: the lack of adequate ICT tools that would provide comprehensive support to organizational creativity, the employees' reluctance to accept changes and to share ideas, too much focus on short-term tasks, as well as financial problems experienced by many companies.

Table 3: Opportunities and threats to organizational creativity development support systems

Opportunities for development of the organizational creativity support systems	Threats to development of the organizational creativity support systems
– communication and group work, – development of new technologies (young generations growing together with ICT), – automation of routine processes and focus on more ambitious activities, – improving quality and speed of decision-making processes, and business process mapping and monitoring, – competitive advantage, – innovation, – integration of knowledge resources, improved access to information, better use of silent knowledge.	– ICT tools and ICT infrastructure inadequate to the needs and operation of the organization, – employees' resistance to changes, – fear that ideas can be stolen, – low level of information culture and insufficient professionalism of ICT developers, – ICT tools impose schematic thinking, – schematic, formalised procedures/processes, – financial barriers and time barriers, – employees' low awareness of how ICT can be used in development of organizational creativity, – focus on short-term problems; no long-term thinking; focus on operational activities; "chasing quick money".

Source: Own elaboration

When asked about determinants of computer-supported development of organizational creativity, the respondents mentioned: high quality of the ICT infrastructure (high speed data transfer, high-performance computers, intuitive solutions, data security), openness to innovation and new ideas, Open Access promotion, and development of analytical tools (including in particular Big Data analytics).

The experts believe that the future of organizational creativity and its ICT-based development will greatly depend on the organizations' ability to integrate different ICT tools with the creative thinking and acting techniques, to work effectively in large, interdisciplinary teams and to recognize that human resources are organization's best investments. The respondents emphasize that the future belongs to Business Intelligence Competitive Intelligence and Big Data software, to group work and communication systems, web analytics software and Cloud Computing technologies. According to the experts, the applications referred to above may provide fast access to a wide range of databases and knowledge repositories (20 responses), group work and exchange of ideas (18), computer simulations (18 responses), analysing and discovering new knowledge (15 responses) and visualization of information (13 responses). The experts are most sceptical about the current usefulness of ITC in: knowledge mapping (11 responses), knowledge prioritization and decomposition (10 responses), generalization of new knowledge (6 responses) and identification of creative needs (4 responses).

Eventually, the experts voiced their opinions about barriers to ICT-based development of organizational creativity. Those most commonly referred to included mental (cultural) barriers, organizational barriers, poor quality of data and insufficient development of data repositories, as well as technical barriers (Table 4).

All experts agree that the organizational creativity support needs to be developed on a continual basis and adapted so as to meet new challenges and organizations' expectations. The failure to develop the organizational creativity support may result in depreciation of the latter and, consequently, in withdrawal from use. Furthermore, the respondents highlighted that in terms of expenses, building such ICT-based support involves not only the cost of technology, but also the funds needed to appoint a project team, to provide expert support, change management and staff training. These are also the challenges faced by the organizations that see their future in developing ICT-supported creativity.

Table 4: Barriers to development of organizational creativity support systems – findings from the survey

Barrier type	Specification of barriers
Organizational/ economic	– little motivation to be creative, – scarce budgets for innovation development in organizations, – low level of support from the top management, – hierarchical management styles, low autonomy level at work, – fear of risk.
Mental	– reluctance to use ICT in collaboration, exchange of ideas and information, – lack of confidence in effectiveness of ICT tools, – insufficient knowledge of ICT tools and how they can be used to support organizational creativity, – lack of knowledge about access to patent bases, libraries, knowledge portals.
Technological	– high cost of purchasing software and of ICT infrastructure maintenance, – difficulties with integrating different applications, poor quality of Internet connections.
Quality of data and access to data repositories	– poor quality of data (incomplete, obsolete, inconsistent data), – insufficient access to commonly accessible databases, government platforms and patent bases.

Source: Own elaboration

6. Conclusion

The literature of the subject proves that ICT may play an important role in supporting organizational creativity. Yet, practice shows that organizations and managers do not fully use all the benefits that ICT tools offer as regards supporting organizational creativity. This study shows that the main constraints to development of ICT-based support to organizational creativity include mental and organizational barriers, poor quality of data, as well as insufficient development of data repositories. The study also illustrates that an appropriate organizational climate and culture are the most vital organizational creativity drivers. No less important is a reward and promotion oriented motivation system, as well as employees' competence in creatively collecting, analysing, processing and interpreting data.

This study makes both theoretical and practical contributions to the field. The current study contributes theoretically to the emerging literature on organizational creativity by investigating the issue of ICT to support organizational creativity. Practical aspect of this study is manifested in discovering various elements and factors that can have an influence on ICT-based organizational creativity.

This study suffers from some limitations. Firstly, generalization is not justified because the findings are based only on 24 experts from Poland. Secondly, the study was based on the semi-structured interview conducted by the author. Using multiple informants might be recommended for further research.

Future research might take some of the following directions: (1) it would be valuable to examine more experts in Poland and compare them with other experts in different countries; (2) further research might explore the detailed paths of building the organizational creativity support through ICT; (3) in exploring the phenomenon of organizational creativity and its ICT-based support should be quantitative tests that would cover a much greater number of organizations.

NGOs Perception of Social Entrepreneurship in Kazakhstan

Bakhtnur Otarbayeva
Almaty Management University, Kazakhstan
bakhytnur.otarbayeva@gmail.com

Abstract: In Kazakhstan, social entrepreneurship activity begins its first steps. There are some initiatives and growth points in the non-governmental sector and small business. The purpose of this paper is to identify NGOs understanding of this new phenomenon and their readiness to launch such activity. In our study, we used online survey methods such as Survey monkey and via e-mail. In addition, interviews were conducted with ten social entrepreneurs in Shymkent and Almaty cities. International organizations, business associations, and academic institutions became the drivers of SE development in the country, considering it as an effective solution to the local social problems. The research shows that in the non-governmental sector, there is an awareness of SE, of its dual nature, its commercial and social components. Nevertheless, the wide range of the answers underlines the complexity of this phenomenon and the lack of experience. An experience in providing paid services by the interviewed representatives of NGOs indicates their entrepreneurial potential since commercial activities require the ability to plan revenues and expenditures, calculate the cost, maintain records, and ensure competitive quality of services, i.e. skills, which are peculiar to business. However, respondents found it difficult to identify themselves as social entrepreneurs, which reveals the novelty of this term in the NGO sector, in contrast, to the academic community. Lack of contacts with existing social entrepreneurs shows undeveloped horizontal links and the lack of media coverage of the social entrepreneur's activity. According to expert's opinion, there is a misunderstanding of the nature of SE by the state structures and inadequate support from local administrations, as well as, the difficulties of legislative and administrative promotion of the idea. Summarizing all above, we can say that NGOs are new actors in SE activity in Kazakhstan. NGOs leaders understand the promise of SE as a type of activity that can ensure sustainability and effectiveness when they move to a new commercial approaches dealing with social problems.

Keywords: social entrepreneurship, non-governmental sector, NGO, new phenomenon, commercial approach.

1. Introduction

The theory and practice of social entrepreneurship (SE) has been attracting close attention of practitioners and researchers, as evidenced by the fact that the search engine Google in 0.42 seconds shows 3 160 000 results.

In only the English-language academic literature, there are more than 300 definitions of the SE, where the key words, most often, are: the organization's social mission, business approach, innovation, social problem, sustainability. Interest in this problem is connected with the increase in the importance and presence in the social sphere of non-profit organizations that are becoming an important component of service economy in developed countries.

One of the popular trends in the focus of analysis is the study of blurring of the boundaries between classically separated sectors (state, market and public). This is due to the change of social management models and promotion of activities of organizations of the third sector in addressing social issues through social innovation (Evers, Laville, 2004). The concept of "hybrid organizations "is intended to describe the emergence of such organizational forms, which have characteristics of more than one sector, for example, SE. However, they are not a simple mixture of the characteristics of several spheres, but differ in other principles of management and functioning (Billis, 2010, p. 3). As research shows, "hybrid organization "is not only an Anglo-Saxon phenomenon, they are common in Europe, and in other parts of the world (Billis, 2010, p.3). Changing paradigms for sector roles, increased blurring of traditional roles, emerging of hybrid organizations, where business with social purpose and civil society as market actors has become a favorite topic for discussion at the World Economic Forum (World Economic Forum, 2013, p.10).

2. Literature review

The idea of SE has generated wide interest and academic inquiry. A wide used definition of SE in literature is as «a business solution to a social problem", which, however, does not disclose all its characteristic features.

Gregory Dees, former director of the Center for Social Entrepreneurship at Duke University, believed that the popularity of the idea of SE was because "many of the results of public and charitable organizations were far from our expectations, and most public-sector institutions are increasingly seen as ineffective and irresponsible. Social entrepreneurs are necessary in order to create new models of social activity for the new

century (Dees 2001). He gave the following definition: "Social entrepreneurs play the role of agents of change in the social sphere, by:

- The adoption of a mission to create and maintain social values,
- Recognizing and creating new opportunities for serving this mission,
- Participation in the process of continuous innovation, adaptation and training,
- Acting boldly, not limited by resources available in hands,
- Manifestations of high responsibility for services and for results of activities (Dees, 2001)

Roger L. Martin and Sally Osberg in the article "Social Entrepreneurship: The Case for definition" show SE as a process determined by the following three characteristics:

1. stable, and inherently inequitable balance that causes alienation, marginalization, or suffering of a particular group of people who lack the financial means or political influence to achieve any transformative benefits for themselves;
2. extracting opportunities from this unfair balance, developing social values, inspiration, creativity, active action, courage and strength of mind, thereby challenging the hegemony of a stable state;
3. by creating a new, stable equilibrium that frees up the accumulated potential or alleviates the suffering of the target group, and by simulating and creating a sustainable ecosystem around the new equilibrium, providing a better future for the target group and even for society as a whole (Martin, Osberg, 2007,13).

They believe that it is necessary to narrow the scope of the SE and to define its distinctive features, not confusing them with the notions of social activity and social services, believing that it will help “to better understanding and more informed decision making among those committed to advancing positive social change”(Martin, Osberg, 2007,17).

Georgia Levenson Keohane, an adjunct associate professor of the SE program at Columbia University Business School, defines SE as systems and ecosystems that allow social entrepreneurs of the non-profit, private and public sectors to flourish (Keohane, 2013, p.1).

Pamela Hartigan, former director of the Skoll Centre for Social Entrepreneurship at Said Business School at the University of Oxford, claimed that there must be a change in the understanding of the SE terminology. She believed that “Social Entrepreneurship is not a field – it's an approach, a mindset, a way, how you approach the problem of solving a problem. This way of thinking and approach can be defined as the ability to combine innovation, opportunity and ingenuity to form and evolve a solution to a very specific problem” (Hartigan, 2005). She also believed that “the way of thinking does not belong to any of one sector and can be found both in the private and public sectors, in the mass media and academia” (Hartigan,2006). According to Hartigan, the terms “social entrepreneurship” and “social enterprise” continue to be divided into commercial and social spheres, “when the reality is that” all commercial enterprises should be responsible for the social and environmental impact that they exert and all social enterprises must be in some sort financially stable (Elkington, J. and Hartigan, P., 2008)

Despite the similarity of the overall trends and ultimate goals of the SE in different regions of the world, the driving forces and organizational forms of the SE are largely different due to political, legal, socio-economic and cultural factors. According to Curlin J.A., in the USA, the SE is focused mainly on the commercial activities of non-profit organizations (Curlin, 2006, p.3). In Europe, with the exception of Great Britain, the term “social enterprise” is generally used in relation to a cooperative or association created to open new workplaces or provide certain types of services to its participants (Curlin, 2006, p.6). Despite the lack of a clear definition, SE developed in last decades as a new phenomenon.

A review of the literature on the issues of the research problem makes it possible to identify the primary evidences of SE, to which researchers include:

- Aiming to the solution of a specific social problem.
- The predominance of social mission over commercial profit.

- Commercial activities, the profit from which is used to a social problem solving and the stability of the organization.
- Innovative approach to the solving of a social problem.

In addition, in the most countries where social enterprises are growing, representatives of small business and the nonprofit sector are involved. There is a debate among authors about who is playing a main role in this activity, non-profits or for-profits? Some of them (Mair and Marti, 2006; Perrini, 2007) consider that it is activity of social oriented business. Many well-known western researchers consider SE as a new stage in the development of the non-profit sector, which seeks to reach efficiency applying business approach, business skills in their activity (Taylor et al. 2000; Elkington and Hartigan, 2008; Keohane, 2013). We think, this is not accidental opinion and there are many evidences to prove it.

As it well known, the non-profit sector is a source of important social innovations and development. The sector introduces new mechanisms for ensuring public participation in decision-making processes, provides social services, protects human rights, deals with environmental issues and youth policy, monitors the activities of public authorities and commercial companies, and is generally actively involved in public and political processes in the country. Thus, the non-profit sector gives social stability and sustainable development to the society.

Despite the fact that there are many researches on the SE, the issues of its real content, forms of organization, main actors are not sufficiently studied, especially in the countries with developing economies, where this is a new phenomenon that has not yet been widely disseminated and theoretically comprehended.

In Kazakhstan, the SE begins its first steps. There are some initiatives and growth points in the non-profit sector and among small businesses that are not particularly stable. First, which organizations are considered as non-profits, non-commercial one? According to Kazakhstani legislation, «Non-commercial organization is a legal entity that does not have the goal of deriving profit and not distributing received net income among members». [Law of the Republic of Kazakhstan of 16 January 2001 No. 142-II. About non-profit organizations. (With amendments and additions as of February 27, 2017. Article 2]. Moreover, there is more wide used term as "non-governmental organizations" (NGOs) which according to the legislation means "non-profit organization (with the exception of political parties, trade unions and religious associations), created by citizens and (or) non-governmental legal entities on a voluntary basis to achieve their common goals in accordance with the legislation of the Republic of Kazakhstan."[Law of the Republic of Kazakhstan On the state social order, grants and bonuses for non-governmental organizations in the Republic of Kazakhstan (with amendments and additions as of April 18, 2017), Article 1.]

3. Methodology

The theoretical basis for this research are drawn from existent literature on SE. A mixed approach for data collection has been used. A survey with 15 open-ended and close-ended questions was prepared to reveal existing cases of SE. In our study, we used online survey methods such as through Survey Monkey and via e-mail. In addition, interviews were conducted with ten social entrepreneurs during visit to Shymkent city and in Almaty city. The evaluation of data began with the data collected from secondary sources, such as websites and official documents, followed by analysis of data collected from the primary sources, which are the interviews of NGO representatives. The secondary information offered insights into contemporary activities, thus providing a basis for developing the primary survey questionnaires.

A goal of this research was to understand the perception of Kazakhstani NGOs about SE and to define their capacity to become the social entrepreneurs. Do NGOs of Kazakhstan know about SE? How much do they understand the essence of this phenomenon? Is there any interest and desire of Kazakhstani NGOs to change their grant-dependent status and move on to new entrepreneurial approaches in solving the problems of their target groups? Can non-governmental non-profit organizations that operate in a modern environment, characterized by a high degree of competition, political and economic risks, changes in the legislation, governing the activities of the non-profit sector, change the traditional methods of their activities, and become social entrepreneurs?

3.1 Limitations and Constraints

The sample of respondents and the percentage of return of completed questionnaires is due to the methodological limitations of Internet research and the nature of the object of research. Since increasingly cautious email systems block many emails, recipients are routinely unaware of them. Moreover, the fact that NGOs in Kazakhstan are objects for research from many various government agencies does not increase their enthusiasm to respond for another questionnaire from academic institutions. This circumstance resulted in the small number of participants in the questionnaire-based survey. The number of organizations to which questionnaires randomly have been sent was 300. Responses have been received from representatives of 82 non-governmental organizations. A telephone interviews also were have been organized later with some NGOs for clarifications to the online survey questions and three interviews conducted with experts from SE promoting institutions provided the detailed information required for this research.

4. Results

According to official statistics in Kazakhstan, there are more than 18,000 NGOs of various formats and activities, nevertheless, this figure is not confirmed by the published database of these organizations and is always questioned by both the expert community and NGOs themselves. The "Overview report on the state of the non-governmental sector in Kazakhstan: problems and prospects" [2016, p.17] states, that the conducted research reveal that the number of registered organizations and the number of operating organizations do not coincide. The number of actually operating organizations is no more than 30% of the registered one.

The organizations that participated in the survey work in different sphere of social activity: educational (54%), human rights (37%), social protection (32%), charity (30%), gender, and other. Some of them pointed out two or three types of activity, which is typical to many NGOs who are multifunctional.

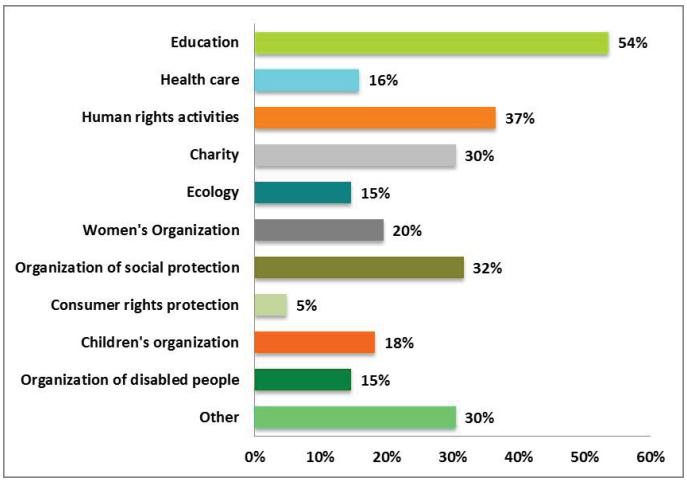

Figure 1: Sphere of social activity of respondents.

Answers to the question about familiarity of NGOs about SE show the following results: 98% of respondents give a positive response, and only a tiny proportion of respondents (2%) never heard about it, which indicates that the SE issues were the subject of discussion among NGOs network.

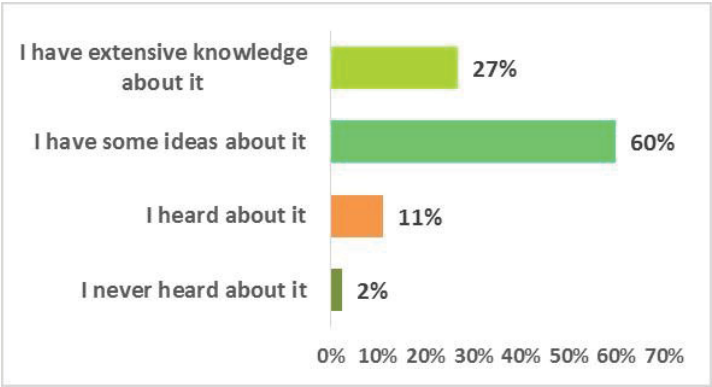

Figure 2: NGO's familiarity with the social entrepreneurship.

Moreover, only 16% of respondents refused to give own definitions of the SE, 18% of them find this task difficult but 66% shared with their understanding of SE.

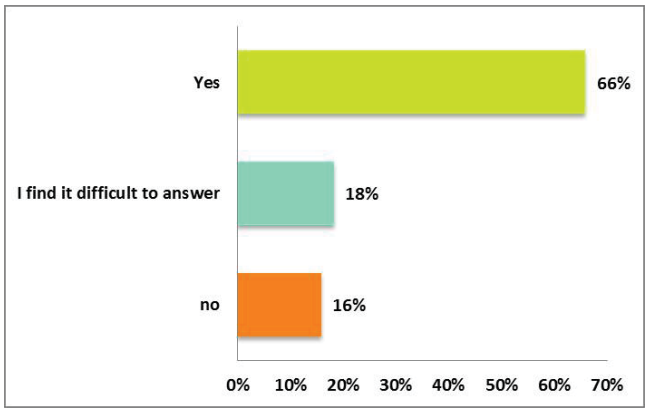

Figure 3: Capability to give a definition of the social entrepreneurship.

In most of the presented definitions, respondents emphasize the dual nature of the SE, underlying the commercial and social components of this phenomenon:

- This is a business solution to the social problem.
- Entrepreneurial initiatives aimed at solving social problems.
- Business with a social component, focused on solving specific social problems of society, the state.
- SE is the solution of some social problems of society by investing without profit.
- When profit from SE activity of NGOs will be directed to solve social problems of the region.
- SE, entrepreneurial activity, aimed at mitigating or solving social problems.
- NGO earns profit for the realization of social activities.
- SE is a way of carrying out social and economic activities that connect the social mission with achieving economic efficiency and entrepreneurial innovation.
- This activity makes profit, but at the same time is aimed at solving social issues (this is a priority).
- Provide social services on a fee basis, but not for profit, but for expanding the services provided.

Separate answers show that respondents distinguish the SE from charity: "Activities that differ from charity, related to entrepreneurship. It is aimed at solving social problems".

At the same time, some respondents do not see the specifics of the SE, giving the following definition: *Under entrepreneurship, I understand the initiative, independent activity of citizens aimed at obtaining profit or personal income, which carried out on their own behalf, under their property responsibility or on behalf of and legal liability of a legal entity.*

Some answers show that the SE is understood as a social partnership: *NGO-State partnership on improving the social status of certain organizations or individuals, while the NGO earns money.*

- Social partnership - a system of institutions and mechanisms for coordinating the interests of participants in the production process: employees and employers, based on equal cooperation.

Despite the fact that only 66% of respondents answered affirmatively about their ability to give a definition to the SE, even those who replied that it is difficult to answer, sent their own definitions. Many respondents underline the complexity of SE phenomenon and the lack of familiarity with it in the practical activities of the non-profit sector.

At the same time, the majority of organizations participating in the survey (60%) have experience in providing paid services to the state structures, businesses and public, which in principle does not contradict to the legislation of the Republic of Kazakhstan, which not prohibits NGOs from carrying out income-generating activities, but under certain conditions and restrictions. Providing support to NGOs in connection with the implementation of their socially oriented activities, the state simultaneously imposes restrictions on

permissible activities. NGOs can only carry out activities stipulated by legislation and by the organization's charter. A received income from commercial activity should be spent to achieve the statutory goals of the organization. The experience in providing paid services by the NGOs indicates the demand for their services, the professional level of employees, since the commercial activities require the ability to plan revenues and expenditures, to calculate the cost of services, maintain records, and provide a competitive quality of services, i.e. to have those specific skills that are peculiar to business.

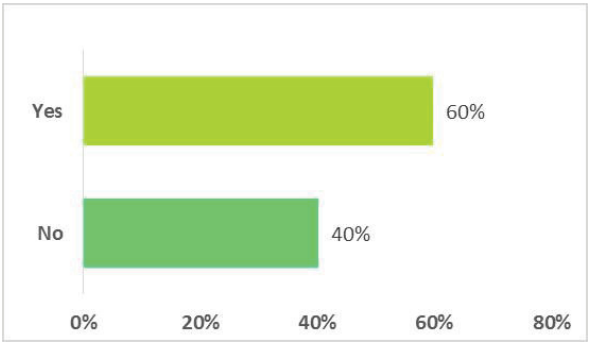

Figure 4: NGOs experience in providing paid services.

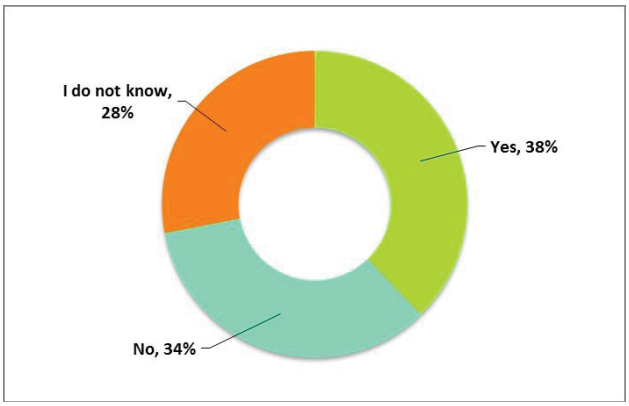

Figure 5: Respondent's self-perception as the social entrepreneurs.

However, to the question whether respondents consider themselves as the social entrepreneurs, only 38% people perceived themselves as social entrepreneurs, 34% respondents do not perceived themselves to be in this category, and 28% do not know the answer to this question.

For Question 9, where respondents asked were they familiar with the social entrepreneurs of their city, district or region, only 26% gave a positive answer.

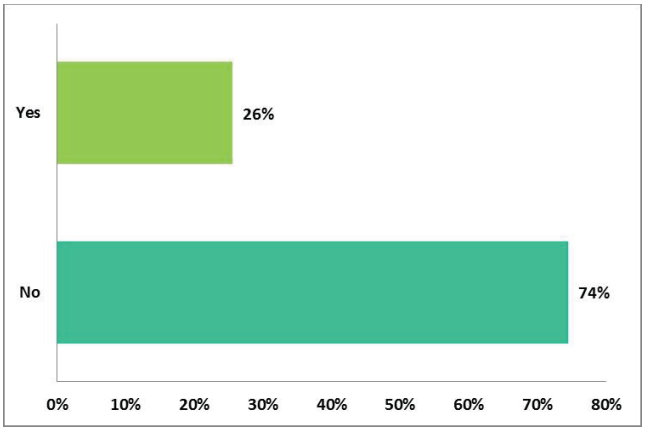

Figure 6: An acquaintanceship with the social entrepreneurs of their city, district, and region.

On the other hand, for the question, do they have an interest to become a social entrepreneur, 89 % gave a positive answer, only 2 % do not want to be engaged in SE, and 9 % are not sure about this.

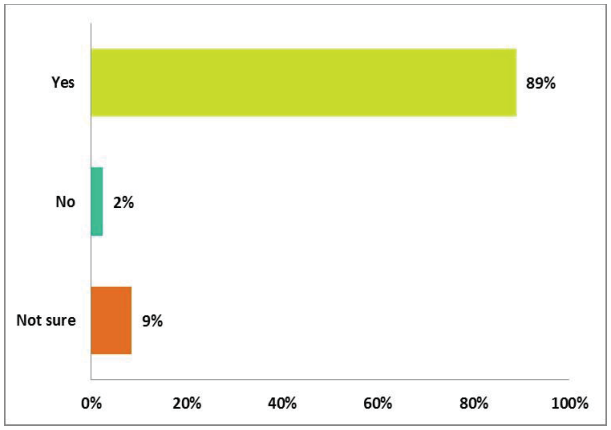

Figure 7: Expression of the interest to become a social entrepreneur.

The answers to the question to which organizations will you apply for consultations if you are engaged in SE shows that respondents chose business structures. The majority of the respondents (54) indicated the Damu Fund (Damu Entrepreneurship Development Fund JSC was established based on the Decree of the Government of the Republic of Kazakhstan of 26.04.1997 № 665 "On the establishment of small business development fund"). 49% pointed out the Entrepreneurs Service Centers, which once again confirms the understanding of respondents of the commercial nature of the SE, well awareness about the activities of these organizations, and, possibly, previous experience with them.

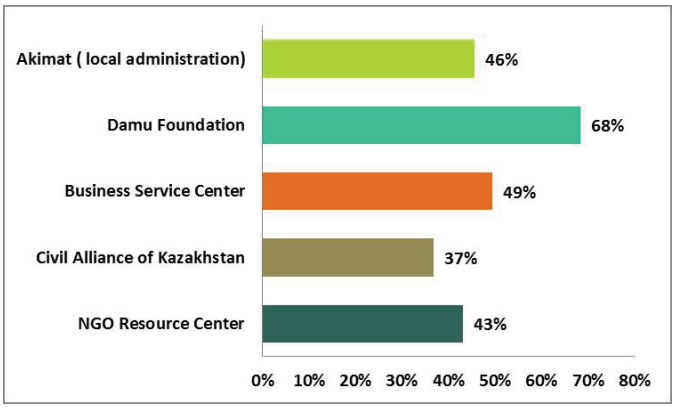

Figure 8: The NGOs preference of the organizations where they could apply for assistance if they will be engaged in social entrepreneurship.

To the question: Do you think that SE is a matter of business, not an NGO, almost 72 % of respondents do not agree with this statement, only 13% agree with it and about 15 % do not know an answer for this question.

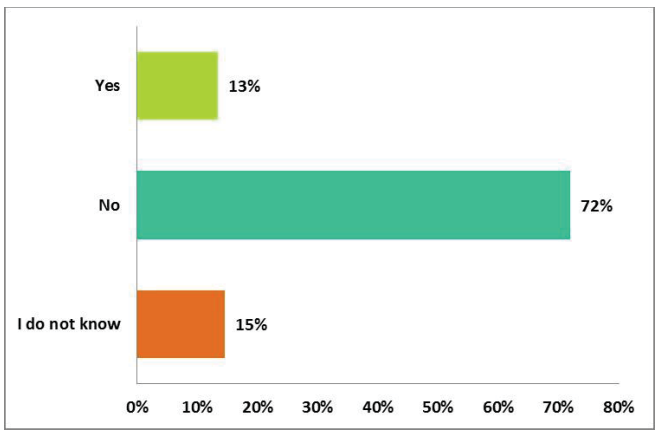

Figure 9: NGOs opinion about whose social entrepreneurship is a matter, of business or NGOs.

At the same time, respondents recognize the existence of following serious barriers and challenges in the transition to the social entrepreneurship activities:

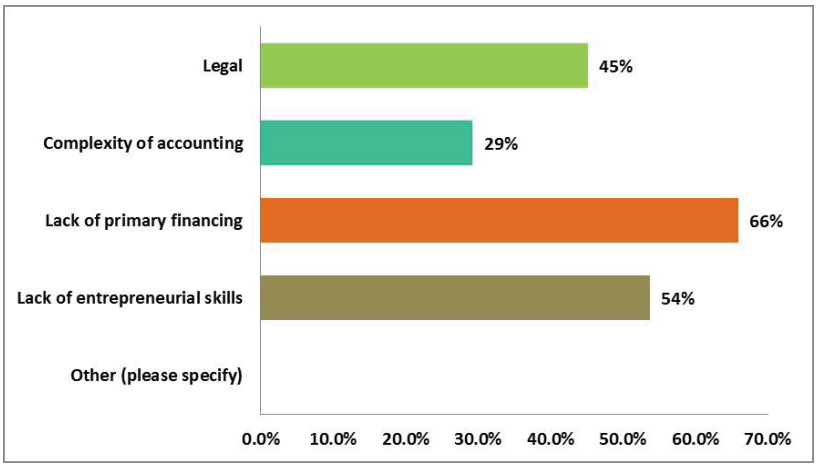

Figure 10: The barriers, which NGOs consider as essential for engaging in social entrepreneurship

The most significant barrier, considered by 66% of NGOs is a lack of primary funding for start-up the entrepreneurial activity; the second most important barrier is a lack of entrepreneurial skills among NGOs - 54% , and the third most important one, legal issues, as 45% respondents consider. About 30% note as the barrier a complexity with accounting, because when doing commercial activity, NGOs should pay an income tax as the business entities.

How NGO consider overcoming these challenges?

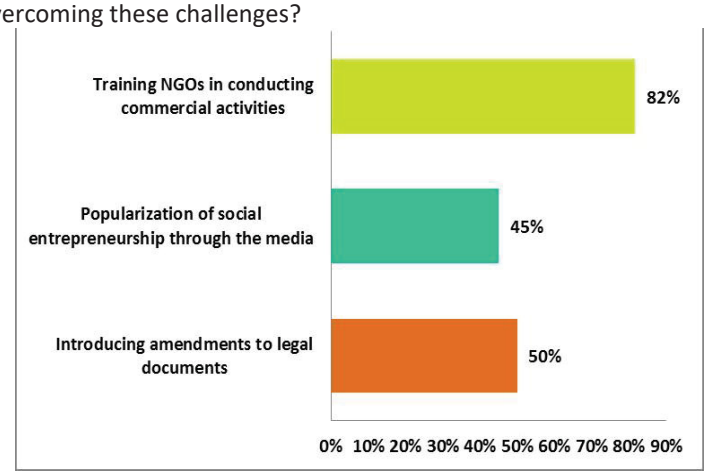

Figure 11: The ways to overcome barriers.

The solution for overcoming the above-mentioned problems is seen primarily in the necessity to train NGOs in conducting business activity 81.7%, to introduce some amendments to relevant laws- 50% and popularize the SE through the mass media 45.12%. These results show the expectations of NGOs from other stakeholders of the SE as a state, business, media, and academic institutions.

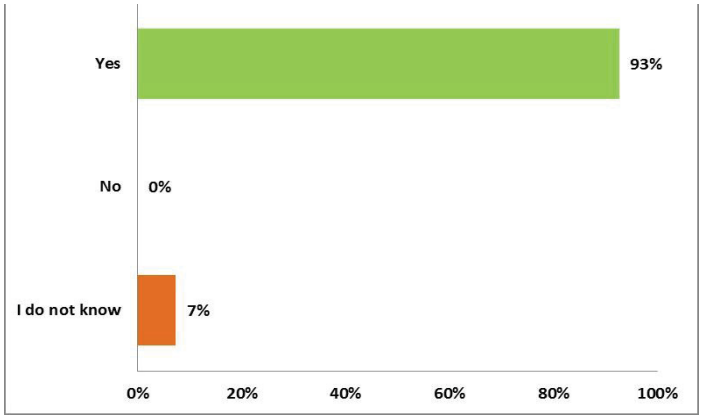

Figure 12: NGO's perception about necessity of state assistance.

Majority of respondents (93%) answered positively for the question about necessity of assistance from the state and only 7% deny the necessity of it.

What kind of assistance from state NGOs are expecting?

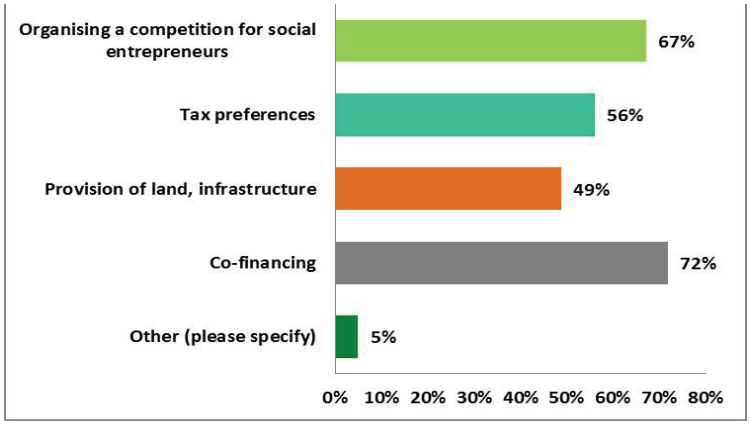

Figure 13: The forms of the state assistance.

Almost 72 % expected that the state could co-finance social activity of entrepreneurs. 67% of respondents consider that the state could organize the competition for social entrepreneurs, 56% of respondents consider that state could provide a tax preferences, 49% of them want provision of land or infrastructure.

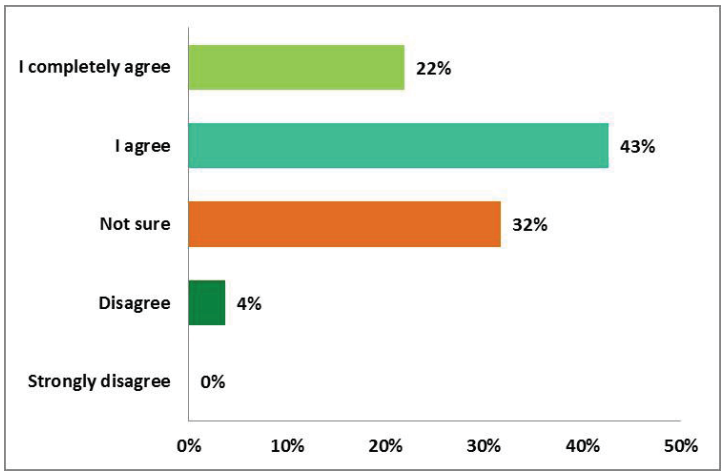

Figure 14: Awareness about NGOs sufficient potential for engaging in social entrepreneurship

65% of respondents gave a positive answer for the question about potential of NGOs from their area to be engaged in SE.

5. Discussion

The findings indicate that there is an awareness about SE in the non-profit sector. The respondents perceive the intended meaning of dual nature of SE, and its commercial and social components. However, SE definitions given by NGOs, see it as an efficient approach to solving and mitigating of social problems, but not consider it as an opportunity to increase institutional sustainability, to provide a transition from a grant-dependent status to a social enterprise. Nevertheless, the wide range of the answers underlines the complexity of this phenomenon and the lack of practical experience.

An experience in providing paid services by the interviewed representatives of NGOs indicates their entrepreneurial potential since commercial activities require the ability to plan revenues and expenditures, calculate the cost, maintain records, and ensure competitive quality of services, i.e. skills that are peculiar to business. However, respondents found it difficult to identify themselves as social entrepreneurs, which reveals the novelty of this term in the non-profit sector. Law number of contacts with existing social entrepreneurs shows undeveloped horizontal links and the lack of media coverage of the social entrepreneur's activity. As reflected in the Figure 8 NGOs understand that to be social entrepreneur they need to acquire business skills that is why they prefer business structures in the case if they plan to be social entrepreneurs. Figure 12 illustrates how much NGOs people rely on a state assistance, which is so typical for organizations, whose institutional stability depends mostly from state grants. There is a negative wide spread NGO image among society as "feeding on grants", which shows NGOs activity where a grant hunting is their main purpose. Leasers of NGOs should change their attitudes, their mentality, should take more initiatives and risks to find innovative solutions. Acquainting with SE ideas and approaches will enhance NGO leaders to work at a high professional level, having in addition to motivation, developed business models, using modern social and business technologies.

Moreover, there are international organizations, business companies and associations, academic institutions, who are contributing in forming SE culture among NGOs. Especially important the role of British Council, which includes Kazakhstan in its Global Social Enterprise programme among 29 countries over the world and providing social entrepreneurs with access to training, mentoring and funding opportunities.

According to the opinion of ex-chair of "Atameken", National Chamber of Entrepreneurs, Nurzhan Altayev, "there is a misunderstanding of the nature of SE by the state structures and inadequate support from local administrations, the difficulties of legislative and administrative promotion of the idea"(Altayev,2016). Moreover, a president of the Association of Social Entrepreneurs, Gulzira Amanturlina, considers that "there is no infrastructure to support SE, credit resources are expensive, and there are no legislative bases for such activities" (Amanturlina, 2016). "Atameken" organizing dialogue platforms with government structures to introduce distinct criteria for SE activity, to discuss adoption of the amendments to relevant laws.

Eurasia Foundation of Central Asia conducing trainings among NGOs to empower the capacity of social entrepreneurs and to provide them with revenue-generating skills. Academic institutions like Almaty Management and Suleyman Demirel universities introducing new curriculum on SE for graduate students. Therefore, various dialogue platforms - conferences, round tables, and trainings have been organized to promote SE ideas among businesses, government agencies and the non-profit sector, considering the SE as an effective approach to social problems.

Summarizing the study, we can say, that results lead us to believe, that the SE is a new activity in the non-profit sector of Kazakhstan, which could bring effectiveness to NGOs to address social problems and help foster a sustainability of non-profit sector.

Abstract: Entrepreneurship plays an important role in the development of economies. In Latin America, specifically, public and private incentives for innovation are fundamental to enhance competitiveness and to strengthen new businesses. In this context, the paper aims to show the scenario of innovation and entrepreneurship in Brazil and Peru from the perspective of development programs, as well as to highlight the policies aimed at improving the quality and impact of the enterprises. In this context, we analyse the government, private and non-profit sector initiatives that deal with programs, projects, and actions to stimulate entrepreneurship and innovation, along with public policies that have an impact on the creation of positive environments for business development, and innovation networks. The focus of the study will be on the policies that are developed throughout the national territory in the studied countries, especially the exchange of experiences in Latin America. Preliminary results point out the importance of public power in the process of encouraging and consolidating innovation and entrepreneurship in these territories. It should be noted that institutions with business activities are essential in the ecosystem of innovation and corporate structure, especially in the smaller ones. Therefore, research in this field is fundamental for guiding development policies and stimulating business competitiveness. In summary, this paper proposes a relevant research on innovation and entrepreneurship, which is very useful to the public and private sectors and to the academic field since it aims to encourage the development of more effective research on the subject.

Keywords: Innovation, entrepreneurship, public policy, programs, competitiveness, development.

1. Introduction

Local development is linked to a number of sociocultural, political, economic, and institutional factors. In this scenario, incentives to foster entrepreneurship are a fundamental attitude in emerging and / or developing economies. In this sense, this paper contextualizes the scenario of innovation and entrepreneurship in Latin America, with an emphasis on Brazil and Peru, in order to guide development policies and stimulate the competitiveness of companies.

Peru and Brazil share records of exports of raw materials, which makes the economy dependent on the price of commodities in the international market. For the Economic Commission for Latin America and the Caribbean (CEPAL), the region's greatest structural challenge is to diversify the export pattern and reduce dependence on raw materials (CEPAL, 2015). In recent years, the industry has not been able to add value to its products and services, nor to improve its productivity through technology and innovation.

Currently, Latin America continues to have a few technological exports. The “high technology” category in Peru represents 0.5% of its total shipments, secondly, the Exporters Association (ADEX). Peruvian shipments in this category are below those of Brazil with 4.5% and Argentina with 2.6% (PERU21, 2017). Peruvian high-tech exports reached US$ 165 million, while in Brazil they reached US$ 9.775 billion (World Bank, 2016).

David Kupfer, professor at the Federal University of Rio de Janeiro (UFRJ), who pointed out that important segments—such as extractive or food production—require investments in R&D at relatively modest levels, while innovation-intensive sectors—such as pharmaceuticals and electronics—have a strong presence of multinationals that produce little R&D in Brazil, opting to import them from the matrices (Marques, 2017).

According to Clamanovici (2011), it is fundamental to analyze the profile of products and services that are offered by a country to measure the technological level of the economy. It is important to note that, according to the “Science and Engineering Indicators 2018”, Brazil achieved a 29% share of the technology-intensive and

knowledge-intensive industries (KTI) in relation to the GDP in 2016. During the same period, the United States reached 39%; the gross domestic product was based on these industries (NSF, 2018).

Olavarrieta and Villena (2014) indicated that Latin American countries and companies seek to increase innovation and entrepreneurship but face challenges and barriers, and that policies and practices in the public and private sectors need to be improved to increase innovation. Alternatively, the authors suggested increasing business research and university-business partnerships. Similarly, Aydogan (2009) recommended that government innovation and entrepreneurship policies should be adequate to meet the specific needs of different groups of countries.

Then the paper aims to present the scenario of innovation and entrepreneurship in Brazil and Peru from the perspective of development programs, in addition to highlighting policies aimed at improving the quality and impact of entrepreneurship. To achieve these objectives, the manuscript is organized as follows: Section 2 presents the concepts and reflections on entrepreneurship and innovation. Section 3 presents an assessment of innovation policies. Section 4 provides the conclusions of the manuscript, the suggestions for its continuity, followed by the used bibliographical references.

2. Entrepreneurship and Innovation: Concepts and Reflections

Entrepreneurship and innovation are related terms and the latter is a fundamental attribute of entrepreneurship (Schumpeter, 1934; Drucker, 1993). In this context, it is mentioned that "...entrepreneurship is not only about small companies and new ventures. It does not only address the creation of new products or services, but rather innovations in all areas of the business" (Chiavenato, 2007).

Innovation can occur in any sector of the economy and it is essential for a country's productivity growth (OECD, 2005). This may be related to processes, products, services, organizational or marketing, and it can be categorized into: (i) disruptive / radical innovation (generates creative destruction of existing products, causing profound changes in the market and society), and (ii) incremental innovation (improvements that increase the good / service, whether through adaptation; an open network that connects several stakeholders in an incremental and / or radical innovation process) (Arbix, 2007; Tidd & Bessant, 2015).

When thinking about entrepreneurship and innovation, it is important to think about competitiveness. In this sense, we emphasize Porter's (1999) statement: "National prosperity is not something inherited, but the product of human creative effort. It is not something that emanates from the natural endowments of a country, from its labor force, from interest rates, or from the value of money as the classical economists insisted. The competitiveness of a country depends on the ability of its industry to innovate and improve". For Zahra and George (2002), innovations increase competitive advantages by stimulating the learning processes.

In Brazil and Peru, studies and reflections on innovation and entrepreneurship are increasingly important (Ketelhöhn and Ogliastri, 2013). Guzmán-Alfonso and Guzmán-Cuevas (2012) confirmed that the entrepreneurial intentions are antecedents of the entrepreneurial behavior related to the creation of ventures in Latin America. For Chaston and Scott (2012), Peruvian companies involved in open innovation reported higher sales growth and indicated greater confidence in the use of double-loop learning. The same authors noted that engaging in open innovation can improve business performance.

Another line of study indicates the importance of the instruments and agents of public policies as inducers of conditions that can facilitate innovation in micro and small enterprises in Brazil (Barboza et al., 2017).

However, affiliation of business groups can be an interesting solution that facilitates the development of entrepreneurial ventures in emerging markets (Mingo, 2013).

Brenes et al. (2016) identified the effects of organizational and marketing innovations on market performance, using data from companies in fast-growing emerging economies in South America (Colombia, Peru, and Chile). The study stated that innovation is a very important capacity for companies that generates rare, valuable, inimitable and non-replaceable goods and services and leads to superior performance. For Pino et al. (2016), organizational innovations have more influence on market performance than marketing innovations and

confirm the importance of innovative performance as an intermediary between organizational innovation and market performance.

It is important to highlight the value of university incubators (Silva et al., 2017) and incubators in Minas Gerais, Brazil (Iacono and Nagano, 2014). This study discusses the critical behavioral pattern in management in the areas of innovation processes, learning and interaction with other actors, and the divergence in the focus and disconnected actions among the incubator, government, companies and university. Some of the roles and tasks of each of these important actors partially meet the needs of companies.

For Rauch et al. (2013), innovation can be effective in each country. The owners' cultural orientations and the national culture explain the variation in innovation-growth relationships. In this way, the authors stated that interactions in different levels of culture have theoretical and practical implications for cross-cultural entrepreneurship research.

In this sense, it is justified to know and exchange experiences on innovation and entrepreneurship between Brazil and Peru in order to guide development policies and stimulate the business competitiveness.

2.1 Global Entrepreneurship Monitor (GEM)

According to the latest GEM study (2017/2018), and based on a World Economic Forum classification, countries are categorized into three major groups: "factor driven countries" predominantly dependent on labor factors and natural resources; "efficiency-driven countries" that are characterized by the advance of industrialization and gains in scale, predominantly capital-intensive organizations; "Innovation-driven countries" that are characterized by knowledge-intensive enterprises and the expansion and modernization of the service sector (GERA, 2018). According to these studies, Brazil and Peru are in the second group: "countries driven by efficiency" (GERA, 2018, p.20).

Also according to the study "... entrepreneurship in countries driven by efficiency or factors occurs more markedly because they have few job opportunities and low GDP per capita, leading the population to venture into entrepreneurship." The main indicator in this study is the Initial Entrepreneurship Rate (TEA), with Brazil reaching 19.1 in 2016 and Peru in the same period, 25.1. In Brazil, the Rate of Established Entrepreneurs (TEE) and the sum of the two rates, the Total Entrepreneur Rate (TTE = TEA + TEE), are also relevant in the analysis due to the impact in terms of employment and income (SEBRAE, 2017). It is worth noting that, in 2016, there were 36% of the adult population involved in the entrepreneurial activity in Brazil and 31% in Peru. It is also important to point out that Brazil has a higher rate of established entrepreneurs, namely 16.9, while in Peru, in the same period of analysis, 6.1.

The analysis of the GEM stated that, "in relation to TEA and TEE, Brazil is ahead of countries like Argentina, Mexico and the other BRICS components (Russia, India, China and South Africa). In terms of entrepreneurship rates it is also ahead of countries such as United States, France, Spain, Germany and Italy. This shows that, comparatively, in Brazil, there is a relatively large portion of adult individuals involved in entrepreneurship. The quality of this, however, still lags behind that of many of these countries" (SEBRAE, 2017).

In Brazil, small business deals are made up of micro and small enterprises (SMEs) and individual micro entrepreneurs (MEI). "Micro and small companies account for 98.5% of the total number of companies in Brazil, account for 27% of GDP and generate more than half of the country's jobs" (Carta Campinas, 2017).

Innovation is fundamental to ensuring greater participation of micro and small enterprises in GDP. In Peru, informality is also a problem that affects the performance of companies, since 88.02% of microenterprises are in the informal sector. According to data from the Foreign Trade Society of Peru (ComexPerú), "the productivity of the formal sector is eleven times that of the informal sector" (Gestión, 2017).

2.2 Brief History of Entrepreneurship and Innovation in Brazil

The term entrepreneurship has been used in Brazil in the last decades, especially in the late 1990s and early 2000s. The importance of this concept in the country is closely related to the need to create lasting companies, as well as to the decrease of high mortality rates of ventures (Dornelas, 2014).

The Brazilian Government has acted more effectively on this agenda since 1999, the year the Brazil Entrepreneur Program was created. This Program involves three sectors, in addition to the government sector (first sector) - represented by the Ministry of Labor and Employment and Banco do Brasil; the private sector (second sector) - represented by the Micro and Small Business Support Service (SEBRAE); and the corporate social responsibility sector (third sector) represented by the Cape Center - Entrepreneurship Training and Support Center, a non-governmental institution (Elache, 2003). The Brazil Entrepreneur Program is aimed to foster micro and small businesses through lower interest financing, as well as to train entrepreneurs.

In 2007, the Entrepreneurial Friend Institution (IAE) Program was launched, as an initiative of the federal government and it aimed to promote the qualification and professionalization of entrepreneurs for entrepreneurship, with the support of public and private educational institutions. Another initiative to formalize the labor market was the launch of the Individual Entrepreneur Program in 2008 that aims to formalize entrepreneurs who kept their business in the informal sector.

As far as innovation is concerned, it started early in the country. In 1951, the National Council for Scientific and Technological Development (CNPq) was created, which carries out a series of programs and actions to promote innovation and the development of science in the country, mainly in the training of researchers. In 1972, the Brazilian Agricultural Research Corporation (Embrapa) was created to encourage innovation in the agribusiness sector; in 1996, Finep was consolidated in the public promotion of Science, Technology and Innovation in companies, universities, technological institutes and other public or private institutions, providing repayable, non-refundable financing to companies of all sizes.

In 2004, one of the first public policies to promote innovation was drawn up, namely Law No. 10,973, which establishes measures to encourage innovation and scientific and technological research in the productive environment, with a view to technological autonomy and the development of the national and regional productive system of the country.

"Over the last 15 to 20 years, Brazil has greatly improved the policies that are intended to foster innovation. Indeed, the country has implemented a series of measures and policies to reinforce its innovation capacity.

Among the new policies are research and development (R&D) tax incentives and subsidized credit for innovation, as well as some regulatory measures that ease the university-enterprise relationship" (The Global Innovation Index, 2017, p.121).

In 1998, the sectorial funds were created to increase funding to foster innovation in the country and, together with the National Fund for Scientific and Technological Development (FNDCT), helped finance priority scientific and technological development programs and projects. For instance, a fund for the oil sector—which is financed by a share of oil and gas royalties—and the Energy Fund—which is particularly concerned with improving energy efficiency and fostering renewable energy, such as biofuels. From the 16 sectoral funds, 14 are linked to economic segments such as oil, energy, health, biotechnology. Each of them is fueled by specific recipes. The energy, for example, receives between 0.3% and 0.4% on the revenues of electric utilities (Marques, 2017).

From the regulatory point of view, several improvements have been made in Brazilian legislation in the last decades. Important laws were approved in the 90's which contribute to enhance the investments in R&D.

Several new technological institutes of Brazilian National Service for Industrial Training (SENAI) and SEBRAETEC Program (SEBRAE) give small businesses access to technological and innovation support, as well as programs to support innovation, such as the Brazilian Company of Research and Industrial Innovation (Embrapii) in 2013.

Finally, another governmental initiative to foster innovation is the National Technological Entrepreneurship Plan, which has been under development since the beginning of 2017 by the Ministry of Science, Technology, Innovation and Communications (MCTIC).

2.3 Brief History of Entrepreneurship and Innovation in Peru

In 1999, the Ministry of Agriculture initiated a reform in the country's agricultural science, technology and innovation system through the creation of the Program for the Innovation and Competitiveness for Agriculture

in Peru (INCAGRO). But it was not until 2001 that, in collaboration with the World Bank, the project began in three phases (Huamán, 2014). A long-term (12 years) vision: establishing a system of science, technology and innovation for the agricultural sector that is demand-based, pluralistic, decentralized, led by the private sector, and made up by a network of producers, firms, academia, government entities, and NGOs. According to the World Bank, the main results included 610 projects, many innovation success stories, over US$60 million mobilized, 1200 institutions, 23 types of products covered (export and subsistence crops), 388 extension projects of which 43% with indigenous peoples / women groups, High rates of economic impact, environmental sustainability, etc. (World Bank, 2011).

When the Science and Technology Program of Peru was funded in July 19, 2006, the Government of Peru and the Inter-American Development Bank (IDB) signed a Loan Agreement to create the Fund for Innovation, Science and Technology (FINCyT) in order to improve the country's competitiveness (FOMITEC, 2018).

The National Science and Technology Council (CONCYTEC) is the governing body of the National System of Science and Technology and Technological Innovation (SINACYT), which consists of the Academy, the State Research Institutes, business organizations, communities and society civil. It is the leading public institution for science, technology and innovation responsible for formulating policies and promoting and managing actions to generate and transfer scientific knowledge and technologies in favor of social development and economic of the country. For this, one of the first tasks is to articulate all the organisms and resources of the sector in function of the objectives and national development policies established in compliance with the laws and policies regulated by the current Government, particularly within the framework of the "National Plan for Science and Technology and Innovation for Competitiveness and Human Development 2006-2021" (CONCYTEC, 2018). An important instrument to promote innovation in the country is Law N ° 30309 - Law of Tax Benefits. This law regulates companies that invest on Research, Technological Development and Technological Innovation (SUNAT, 2018).

In 2014, the National Innovation Program for Competitiveness and Productivity (Innóvate Peru) of the Ministry of Production was created with economic, administrative, financial and technical autonomy. The program aims to increase business productivity by strengthening the actors of the innovation ecosystem and by facilitating the interrelation between them.

In 2015, the MIPYME Fund was created in order to strengthen the productive development of micro, small and medium-sized enterprises. In 2016, the IDB makes a loan of 40 million dollars and the government loans 60 million dollars from the Treasury to improve the levels of productive innovation nationwide.

The resources managed by Innóvate Perú are awarded through national tenders for the non-reimbursable co-financing of projects of Research, Development and Innovation, in all productive sectors. Innóvate Peru covers several areas such as financing offers, business innovation, technological absorption, entrepreneurship, and services to innovation. Up to now, 60 projects have already been financed by FIDECOM, 60 projects by FINCyT, and 14 by other institutions (FOMITEC, 2018).

In 2018, CENTRUM Católica Graduate Business School's Center for Innovation and Sustainability of was launched in Peru in order to stimulate applied research and promote innovation and the development of sustainable businesses. It is also intended with this initiative to increase the exchange of experiences in the Latin American sphere and strengthen the ecosystem of innovation and structuring of companies.

3. Evaluation of innovation policies

According to the study conducted by FINEP (2018), both Brazil and Peru have provided economic subsidies for innovation in companies since 2006, following the rules of the World Trade Organization. Even so, the invested resources are still insufficient, and the effectiveness of the incentive policies is still restricted due to the applicants' lack of knowledge or lack of positive results.

The scarcity of resources invested in innovation is a reality in Latin America. In recent years (2005-15), Peru has invested 0.12% of GDP in innovation, science and technology (CTI). In the same period, 1.17% of GDP was invested in R & D activities in Brazil. Nevertheless, the average of the countries of the Organization for Economic Cooperation and Development (OECD) was 2.4% of GDP in 2015 (World Bank, 2017).

Another problem is the limited effectiveness of instruments to stimulate innovation, such as laws and incentive policies. According to the National Association of Research and Development of Innovative Companies (Anpei) of Brazil: "These instruments did not have the force to encourage innovation in companies and sectors traditionally refractory to this type of effort. Nor were they able to leverage innovation in companies that were already innovative - to a large extent, the stimulus granted by the government replaced the investments that these companies might already have made, rather than multiplying them. The challenge is not exactly to increase companies' R & D spending, but to mobilize segments that invest little" (Marques, 2017).

Finally, another barrier that is founded is the low participation of firms in innovation investments. In Brazil, the participation of companies in the national R & D effort reached 47.1% of investments in 2014, below that of the United States (64.1%), Germany (65.8%) and Japan (77.9%). São Paulo is an exception in the Brazilian scenario, with 60% of state investments in R & D made by companies (Marques, 2017). This can be related to the lack of knowledge of policies to encourage innovation. In Brazil, even though the "Law of Good" is already almost fifteen years old, the demand for tax reductions granted to companies that invest in Research, Development and Innovation (P & ID) is still low. According to the most recent survey by the Ministry of Science and Technology (MCTI), only 991 companies benefited from the tax incentives granted by the federal government, a number included in the national universe (600,000, an amount that refers only to industry and services, to investment in R & D, according to data provided by IBGE) that represents a profit for less than 1% of companies (Macedo, 2018).

According to the Global Innovation Index (GII), Brazil is ranked 69th in the GII 2017, the same position as 2016, has 33.10 as index of innovation, but shows a retraction of 0.27% from last year. According to the study, Brazil's strongest pillar ranking is in Business sophistication (43rd), where it sees one of its highest rankings in IP payments (8th). Peru is ranked 70th in the GII2017; it has improved one position since last year, and obtained an index of innovation of 32.90, 1.2% more than last year. But, its best result was in 2013 when it was ranked 69th and obtained an index of innovation of 35.96 (The Global Innovation Index, 2017).

4. Conclusions

This paper presented the scenario of innovation and entrepreneurship in Brazil and Peru from the perspective of development programs and policies aimed at improving the quality and impact of entrepreneurship. The following are the main conclusions of this work:

First, it is pointed out that countries and companies seek to increase innovation and entrepreneurship but face challenges and barriers, and that policies and practices of the public and private sectors need to be improved.

Second, concepts and reflections on entrepreneurship and innovation are introduced. Through a brief history on the subject in Brazil and Peru, it is indicated that the implementation of several policies aims to stimulate innovation and entrepreneurship, and that entrepreneurship occurs more markedly in countries with fewer work opportunities and with a low GDP per capita.

Third, when evaluating innovation policies, it is perceived that the invested resources are still insufficient, and the effectiveness of the incentive policies is still restricted due to the lack of applicants' knowledge or to the lack of positive results.

Finally, this paper warns about the importance of public power in the process of encouraging and consolidating innovation and entrepreneurship in these territories. It is also recommended to increase business research and university-business partnerships. It should be noted that the institutions that act to stimulate entrepreneurship and sustainable business development are essential in the ecosystem of innovation and structuring of companies.

Therefore, research in this area is fundamental to guide development policies and stimulate business competitiveness. It is considered that this paper will be very useful to the public and private sectors and to academia since it aims to stimulate future research on the subject.

The Institutional Analysis of Development of Social Entrepreneurship in the USA, UK and Germany

Ruslan Pavlov
Russian Academy of Sciences, Moscow, Russia
pavlovru@mail.ru

Abstract: Since the beginning of the world economic crisis the level of unemployment across different countries increased significantly and so did social and welfare polarization of people. Under these conditions the emergence of social entrepreneurship could be viewed as an additional opportunity for the disadvantaged people to enhance their welfare and improve their living quality. As all the phenomena of such kind its activity should be coordinated by some special institutions in order to develop successfully, thus enhancing its aggregate performance. According to the rating of the Global Entrepreneurial Monitor (GEM), the United States have the highest rank in the growth rate of social enterprises for a short-time perspective, which can be determined by the effect of such factors as Community Development Financial Institutions (CDFI), which provide some incentives for the business as well as for the communities to take part in the social projects. The paper reviews different kinds of economic systems inherent to certain types of integration between financial and industrial resources. So, the system of industrial development of the USA relies in most part on the stock market, while that of several European countries, such as the United Kingdom and Germany prefer to use credit resources, or the loan capital, though the United Kingdom is known as a country that has a highly developed stock market system. In contrast to that, the financial systems of the developing economies, such as the Russian one, present to use both types of the financial systems aforementioned and combine the microcredit institutions with those of stock market. The paper contains some implications for such countries suggesting them to consider some opportunities of evolving their market-based institutions and bank sector to create a more suitable institutional system to support the development of social entrepreneurship.

Keywords: social entrepreneurship, institutions, market-based systems, ethical markets.

1. Introduction

Social entrepreneurship has become a very popular phenomenon among different scholars nowadays. It presents a great interest not only because of its extraordinary nature, but also due to the paradigm crisis of the neo-liberal economic model, whose features are becoming increasingly evident for the recent times. The events which happened on 17 September 2011, when the protest movement 'Occupy Wall Street' began in Zuccotti Park, were impressionable by their scale and impact. The wave of protest movements all over the world that followed this action showed that the social discontent with economic inequality of people has been growing. According to the U.S. Census Bureau data, the proportion of overall wealth — a measure that includes home equity, stocks and bonds and the value of jewelry, furniture and other possessions — held by the top 10% of the population increased from 49% in 2005 to 56% in 2009 (Morin, 2012). At the same time the share of economically excluded people is growing steadily, which is evidenced by the recent data on the high rates of unemployment in Portugal and Spain. It is interesting to note that the left movement ideology has attracted lots of new followers which reflects, in particular, in the Marxism revival. 'Why Marx was right?' by T.

Eagleton proved to be a bestseller since lots of problems, connected with the system peculiarities of the paradigm being criticized by the contemporary scholars, were efficiently elaborated in the Marxist' terms and some disturbances in the social and economic system resulted from the current trends of the mainstream policy were emphasized against the same disturbances the world economy faced more than a century ago (Eagleton, 2011). Such analogies have become of a great importance allowing for the crisis of methodological tools in the modern economics. Besides, the legitimacy of the left political movement in Europe is increasing, which is evidenced by the victory of the social-democrats at the last parliamentary elections in several European countries. These are, in turn, the signs of poverty growth, labor migration, social exclusion and the failure to solve such problems by means of traditional ways of applying market mechanisms. Such challenge suggests to think about social entrepreneurship as a possible way to mitigate the distortions stated above. It can be viewed not only as an economic or social phenomenon, but also as a political movement, as it challenges the dominating paradigm at all the levels of its pervasion, forcing the governments to introduce some important radical measures aimed at supporting its development.

2. The classification of institutions fostering the development of social entrepreneurship

The available literature on social entrepreneurship allows us to argue that there were several attempts to classify this phenomenon, though they were based upon a certain criterion, regardless of the fact that it might have different scales of development. In this context the classification provided by A. Nicholls (2007) seems to be successful, as it challenges the dominant paradigm at different dimensions. According to it, social enterprises challenge the dominant paradigm at three levels, micro (the enterprises), meso (new markets; intermediaries) and macro (socio-economic impact; policy implications). These refer to social enterprises that (1) respond to market failure and/or "institutional void" by developing new products and services, (2) contribute to the reconfiguration of markets to generate new or increased social value and (3) challenge institutional arrangements through political action. From Nicholls' point of view, the third level of institutions should be presented by social enterprises. Though it is rather an excessive assumption, as in addition to social enterprises they should also involve the ways of mitigating social problems at the micro-level, which become embedded into an original institutional form. Thus, in order to enable an adequate reflection at micro-level, different ways of eliminating social cataclysms within a given micro-environment should be included into this concept, which don't necessarily have the form of social enterprises. Thus, if we imagine the hierarchy of social entrepreneurship institutions, we'll get the picture as that presented in Figure 1. It's an improved version of Nicholls' classification as a pyramid with three levels, the first of which should present the macro-level institutions, the second deals with the activities of intermediaries and markets, e.g. social capital markets, and the third one presents the myriad of the local country- and region-specific institutions which are inherent to the particular place shaping its origins and nature, while contributing in some way to forming the relative institutions at the meso-level. The intermediaries presenting a nexus of some financial institutions designed to support social enterprises can be viewed as meso-level structures coordinating the activities of those from the bottom level. So, Community Development Financial Institutions (CDFIs) in the United States can exemplify this kind of institutions, as they present a network of special innovative financial mechanisms embedded in the current institutional structure surrounding communities. The macro-level institutions are those which influence much the dynamics of social entrepreneurship as a socio-economic phenomenon in the given country or worldwide. They can be embedded in certain regulations, laws, policies or some original institutions, which are capable to change the existing status quo at the level of a given country, not within certain communities or districts.

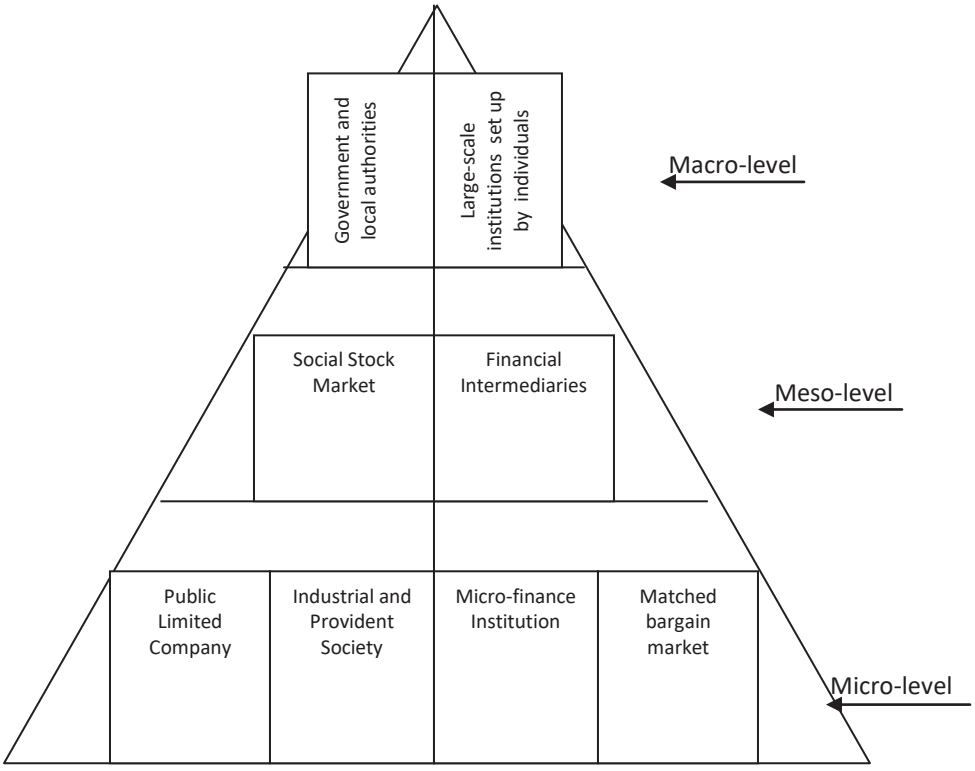

Figure 1: Three levels of social entrepreneurship institutions

2.1 Social reforms as macro-level institutions

The macro-level institutions of social entrepreneurship can be presented as the result of the impact executed by a politician or a public figure. It can be formalized into the system of certain institutions, as well as be realized within a certain political strategy. The first case can be exemplified by a famous public figure Elena Panaritis, who initiated the property rights reform in Peru, which improved significantly the life quality not only of the residents, but of the immigrants as well. Allowing for that the system of regulating property rights was rather disorderly and hazardous in this country, as the houses of people were not secured properly against any fraud, she undertook a special reform designed to improve the situation in this area and to fill the institutional gap with a special agency called "Registro Predial". It was a special registry designed to refine the system of securing and enforcing the property rights. In 1996 Peru's government agreed to extend the property rights reform nationwide, with funding from the World Bank. The government created a new commission, Cofopri, which would work in tandem with "Registro Predial", sharing the process of transforming Peru's property market, which Panaritis called transforming the "Unreal" to Real. The reform did more than change perceptions, however. The security created by the new property rights system generated tangible social and economic benefits for formal property owners that were not available to informal owners and the formal property rights led to the increasing of entrepreneurial activity in those communities as the formal documentation enabled significant increasing in private-sector loans (Panaritis, 2007). It is not surprisingly that due to such action Panaritis is called "a social entrepreneur" (Panaritis, 2018).

Another case of social entrepreneurship at the macro-level is connected with some political measures introduced by the former US president Bill Clinton. Like Panaritis, Clinton managed to improve the live-being of the poorest people through a political initiative. He managed to force the financial institutions to provide loans for the low-income communities, while most of them refused to do that before. According to the amendment of 1995 to the Community Reinvestment Act of 1933, they might be closed in the case of refusal. Such measure can be treated not only as social, but also as entrepreneurial, as it had the same effect as that implemented by Panaritis. As a result, the early-stage social entrepreneurial activity (SEA) increased greatly and achieved the level of 4,2 % by 2009 in the United States, being the highest rate among different countries (see Figure 2). SEA is the social equivalent of the total early-stage entrepreneurial activity index (TEA) which is measured as the percentage of a country's working-age population who are actively trying to start a new business (nascent entrepreneurs) and those who at least partially own and manage a business less than 3.5 years old (a baby business). The highest rate of early stage social entrepreneurial activity can be explained in part by the environment encouraging people to engage in business of such kind. That environment for the most part was formed under the period of Clinton's presidency.

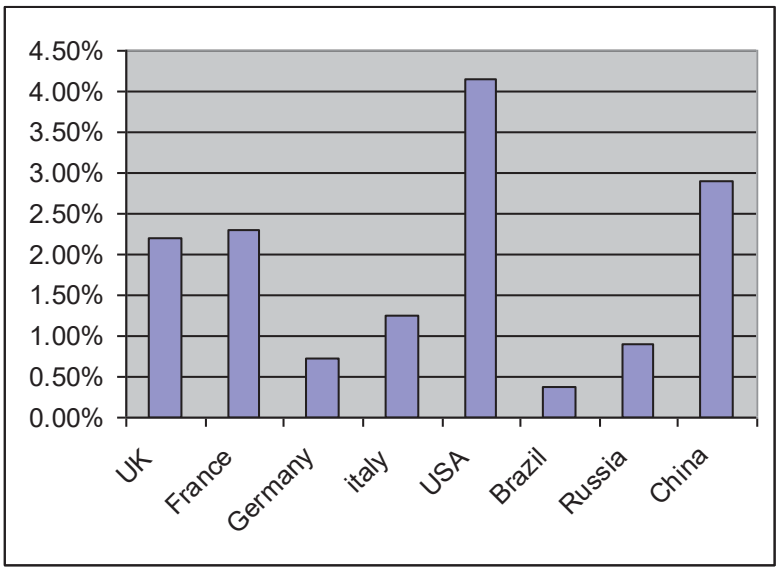

Figure 2: Early-stage social entrepreneurial activity (SEA) rate in different countries, 2009

Source: GEM (2009)

2.2 Social stock market and loan stock institutions at the meso-level

The meso-level institutions present the intermediary level in this structure. Marking this group of institutions as a specific category is of great importance because it is not only a superstucture over that beneath, but is also a factor which shapes and determines the behavior and performance of the micro-level institutions. So, for instance, the social capital market which is coordinated by a network of international financial organizations, such as the International Association of Investors in the Social Economy which was thoroughly investigated by Mendell and Nogales (2009), can be viewed as a cluster which originated from the bottom of this pyramid, but it can influence significantly the subsequent trends of development of micro-institutions worldwide. In this context the emergence of a social stock market should be mentioned. For the recent decade there were several attempts in the world aimed at constructing some mechanisms to enable social enterprises to act as conventional business enterprises – that is to provide them with the opportunity to issue shares, but allowing for the high-level risk connected with their trading at an ordinary stock exchange, it should be advisable to let them trade at a special stock exchange designed for that. So, the United Kingdom and Germany can play a pivotal role in installation and deployment of such mechanisms. Whereas the former belongs to the market-based countries range, the latter belongs to another group, consisting of bank-based countries, but it didn't miss the chance of adopting such mechanisms which seem to be effective. A special meso-institution, such as the Social Stock Exchange Association (SSEA), has been operating in Germany for the recent 5 years. It is designed not only to ensure forming the social stock market within this country, but also expands its influence abroad to help other countries which are engaging in such difficult and controversial process. Though this institution is implementing a pilot project in Germany, it is also engaged in similar activities in Portugal, where the processes of launching a social stock exchange are well underway. Moreover, it organizes different events for similar initiatives to get involved, collaborate and learn from each other's experience (SSEA, 2013). The initiators of such project are deemed to be aware of the financial risk connected with the assets of social enterprises, implying the low return rate on the capital invested. The main task of SSEA project in Germany is to create a platform that will offer investors some clear comparability on the social and technological impact on their investments, which will yield a slightly lower (single digit) financial return. Though this platform is not launched yet, it has a preliminary stage which expressed in the meeting which was held on 25 March 2011. At this meeting five social ventures were pitching to a dozen investors for a financing volume of roughly € 20 million (Kuhlemann, 2011). We should think that taken such event as the first indicator characterizing the activity of social stock market in Germany nowadays, we can make a conclusion that in any case Germany leaves behind the UK where the total sum raised from the ethical issue shares amounted £ 50.1 million by 2005 (Hartzell, 2007) that equals € 58.6 million which is about three times as many as this value.

Table 1: Number of Ethical Share Issues and Total Raised in the UK

Period	Number of issues	Total raised (£ million)
1984-1990	6	3.35
1991-1995	8	4.17
1996-2000	13	10.55
2001-2005	16	32.03
Total	43	50.1

Source: Hartzell (2007)

The process of launching the social stock exchange in the United Kingdom is also still ongoing, as well as in Germany. Nevertheless there are several ways of executing such operations beyond such exchange. Such operations are possible due to a three-step system of ethical share investment in the UK which presents a way for social enterprises to adopt their abilities within a less stringent environment than that for the existing business enterprises. So, these steps are: the Off-Exchange (OFEX), the Alternative Investment Market (AIM) and the London Stock Exchange (LSE). All of them can be considered as a hierarchical tree, in which companies graduate from one level to the next as they grow in size. Indeed, AIM was established by the LSE for companies being at their earlier stages of development. The markets which are higher up the tree offer greater liquidity, but are more expensive to list on and the listing requirements are more stringent in terms of disclosure of the price sensitive information. Thus a company might first choose to list on OFEX, where the cost of listing is only around £ 10,000 a year or less, but trading there can be deceptive, as some OFEX shares are not traded at all for long periods. The share price then remains static and may not reflect the value that a share might achieve in a more liquid market. The lack of competition and the absence of due confidence among investors cause the fall in the share price. Although many companies go straight to AIM, a listing on OFEX is often a first step towards an AIM listing. But AIM is a very important step for social enterprises, as it is a chance for them to attract some major institutional investors. However, fees for listing on AIM are likely to

be between £ 300,000 and £ 500,000 even excluding marketing costs (Hartzell, 2007). For a social enterprise, where a high profit level is not to be expected, share issues therefore need to be in the range between £ 10 to £ 20 million to stand a chance of covering the costs of fees. Raising this level of investment is often unrealistic, allowing for the financial condition of social enterprises. The larger of the AIM companies move to the London Stock Exchange. Some of them have a balance sheet as small as £ 10 million, but most are much larger. However there is a threat of a hostile takeover for the enterprises seeking to attract large amounts from the institutional investors or venture capitalists. That is also the reason which prevents social businesses from being the actors on the mainstream market.

While the UK demonstrates an example of enhanced activity in the field of social stock operations, Germany appears to be one of the leaders on the development rate of microfinance institutions (see Table 2) and in this sense matches its position as a bank-based country absolutely. In most part Germany's successes in the development of microcredit system can be explained by the effective performance of such meso-institution as the German Microfinance Institute, as it provides a wide range of different services, in particular, counseling and training for MFIs (e.g. their loan officers), designing electronic loan processing tools and accrediting MFIs for the risk capital fund which is called "Microfinanzfonds Deutschland" (El-Zoghby, Gähwiler, Lauer, 2011).

Table 2: Main microfinance indicators in selected European countries in 2007

	Microfinance Indicators			
Country	**Number of loans disbursed**	**Total value of loans disbursed (EUR M)**	**Average Loan Size (EUR)**	**Average Interest Rate (%)**
Germany	4,625	52,276,375	11,303	6.92
Italy	3,223	22,451,418	6,966	5.80
Spain	8,773	97,800,000	9,943	5.00
UK	1,252	13,420,000	10,718	13.40
Romania	2,496	18,847,296	7,551	-
Bulgaria	68,348	432,890	6,334	-
Czech Republic	-	-	4,500	-

2.3 Matched bargain market in the UK as an example of micro-level institutions

As in the United States and Germany the social capital market is only at the stage of installation, while in the United Kingdom it is at the stage of deployment yet, we'll focus only on the English institutions as having settled fundamentally and providing a very valuable experience on this point. In this country a company not listed on the mainstream markets can usually only trade its shares through a matched bargain market. This is usually run by a broker or a recognized financial institution, and involves holding a list of buyers and sellers of the shares and matching them at the price they both wish to pay. So the matched bargain market for a certain enterprise can be viewed as a micro-level institution. Matched bargain markets usually operate for one company in isolation rather than for several companies. Moreover, the Financial Services and Markets Act limits the extent to which the investment can be marketed. Price-setting on a matched bargain market is usually a haphazard affair. Quite often it is left to buyer and seller to agree, but if any price at all is recommended, it is usually the broker running the market who would recommend a price, based on information provided by the company. Thus in a matched bargain market, the company itself has much more control over the share price. This is usually regarded as an unsatisfactory situation open to abuse, as two conditions necessary for an efficient stock market are not met. The first one is that the market is sufficiently liquid for expectation of value to be quickly reflected in the current price. The second is that investors have all and equal information available to them surrounding the situation of a company. When these conditions are not met, anomalies occur and some individuals can benefit over others due to the drop in the share price as stated in the previous subsection.

Speaking about matched bargain markets, it's interesting to note that those companies which didn't list on OFEX and AIM have achieved wonderful results. To approve our suggestion derived in the previous section that the division of countries according to the criteria, whether it is a market- or a bank-based system, coincides with the development of the same kind institutions for social enterprises in these countries, we'll

provide some data concerning the growth of capital amount raised as a result of share issues by three most successful social enterprises of the United Kingdom: Ttaidcraft, Shared Interest and Wind Fund.

Table 3: Three leading social enterprises in the amount of shares issued

Company	Year	Legal form	Type of investment	Amount raised (£M)
Traidcraft	1984	PLC	Share	0.3
	1986	PLC	Share	1
	1991	PLC	Share	0.4
	2002	PLC	Share	3.25
Shared Interest	1995	IPS	5 Year Loan stock	0.65
	1996	IPS	5 Year Loan stock	0.85
	1997	IPS	5 Year Loan stock	1.2
Wind Fund	1995	PLC	Share	1
	1998	PLC	Share	1.3
	2005	PLC	Share	4.75

Source: Hartzell (2007)

Thus, according to these indicators, we can conclude that all the three companies achieved such great results, having issued their shares beyond the mainstream market, but whereas Traidcraft and Wind Fund are public limited companies (PLCs), Shared Interest is an industrial and provident society (IPS) which has a limited ability to attract funds. Moreover, the redemption period for the bonds issued by IPSs is rather short. So, the investors usually have less opportunities to buy and sell such bonds, as they would have dealing with bonds issued by a conventional business enterprise. Wind Fund happened to be the most successful among these companies, as it managed to raise its capital from £ 1 million in 1995 to £ 4.75 million в 2005, which is comparable with AIM in its scale. Though Traidcraft managed to have even 2,400 shareholders, while the average number of the AIM company' shareholders is around 800 (Hartzell, 2007). This fact suggests that a matched bargain system presents something like an economic miracle, which is developing intensively, according to its immanent laws, and has an ability to surpass the existing formal markets.

3. The system of microcredit institutions and social stock exchange in the USA, Germany and the United Kingdom

The model of institutions presented here is a sophisticated version of Nicholls' classification, which enables us to make it clear, what kind of financial institutions are best developed in the particular country at the particular level. So we can compare the respective institutions of social entrepreneurship in these countries with their profiles – whether it is a market-based or a bank-based system, according to the classification presented by Demirguc-Kunt and Levine (2003). In bank-based financial systems, such as Germany and Japan, banks play a leading role in mobilizing savings, allocating capital, overseeing the investment decisions of corporate managers, and in providing risk-management vehicles. In market-based financial systems, such as England and the United States, securities markets share center stage with banks in terms of getting society's savings to firms, exerting corporate control, and easing risk-management. Table 3 presents three countries, two of which are market-based (the United States and the United Kingdom) and the third is bank-based (Germany). The distribution of the respective institutions for social entrepreneurship looks like that for the commercial sector in these countries.

Table 4: The loan capital and social stock institutions in the USA, Germany and the United Kingdom

	USA		Germany		United Kingdom	
	Loan Capital Institutions	Social Stock Institutions	Loan Capital Institutions	Social Stock Institutions	Loan Capital Institutions	Social Stock Institutions
Macro-institutions	Community Reinvest-ment Act of 1977 as amended further	The United States Securities Act of 1933	The Act amending the German Investment Act of 2003 (the Amendment Act, 2007)	The Stock Exchange Act of 1896 as amended further	Community Investment Tax Relief, Credit Unions Act	Financial Services and Markets Act; AIM Rules for Companies
Meso-institutions	Community Develop-ment Financial Institutions	Green Stock Exchange (launched in 2014)	The German Microfinance Institute (Deutsches Microfinanz Institut); The Microfinance Fund Germany	Social Stock Exchange (launched in 2013)	Community Development Loan Funds	OFEX, AIM, LSE, Social Stock Exchange (launched in 2013)

			(Microfinanzfonds Deutchland)			
Micro-institutions	Web-resource 'www.kiva.org'	Impact investing organiza-tions	GLS Bank	NExT SSE	FINCA UK	Triodos mathed bargain market

Different laws, regulations and standards coordinating the activity of the respective fields of social investment systems presented here are treated as macro-institutions. Community Reinvestment Act of 1977 with the amendment of 1995, which resulted in increasing the opportunity window for the low-income households, is worth mentioning first. The Act amending the German Investment Act of 2003 (also known as the Amendment Act of 2007 played a major role in forming an environment for the development of microfinance institutions in Germany. It enabled the emergence of two meso-institutions in microfinance area: the German Microfinance Institute and the Microfinance Fund "Germany". As for the system of regulating social stock exchange, it should be stressed once more that the most successful pattern of it is represented by the UK financial system which is, in turn, a market-based country. Maybe that is the reason of its leadership among all the other European countries. In addition, the system of regulating transactions in AIM is simplified so that AIM companies are supervised by a nominated adviser (referred to as a "nomad") rather than by a securities regulator (in the UK, this is the Financial Services Authority (FSA). All the transactions of AIM companies are subject to the AIM Rules for Companies (AIM Rules). AIM's simplified admission procedures generally result in savings in time and cost for an AIM admission as compared to a main market or other listing. In most part the creation of such institution was predetermined by the increased activity of matched bargains, which was, in turn, caused by the traditions of using stock exchange as a leading mechanism to support industrial development in this country.

4. In conclusion

So, in conclusion we can say that the results of the paper suggest that we shouldn't draw any compelling conclusions in such way that in the market-based countries only social stock institutions can evolve or in the bank-based environment only microfinance institutions can emerge. The situation is much more complicated than it seems to be. The results of the study in some way are surprising. We see that despite the fact that the United Kingdom belongs to the category of market-based countries, the amount of its microcredit market is impressive and in Germany we see the active attempts to create the social stock market, though it is considered to be a bank-based country. So, the environment is not so strict that it should foster only those institutions that are typical for its kind, but at the same time the mainstream trend in the respective financial system belongs to that kind of institutions, which are more suited for that environment. So, the level of development of the social stock market institutions in the United Kingdom is higher than those in Germany, and the institutions of the social stock market operate more efficiently in the United Kingdom than in Germany.

Besides, one should say some words about the way of attributing these implications to the analysis of the situation in developing countries. For instance, Russia might be subsumed under the group of bank-based, rather that market-based countries because of its path dependence connected with long traditions of bank monitoring system, which originated in the Soviet Union and was performed by the State Bank. To speak about Russia as a market-based country presents a great difficulty, because it lacks the established class of social investors which is well represented in such countries as USA and UK thereby contributing to their image as market-based countries. Moreover, Russia has one of the lowest positions in the ranking of social responsibility of business across different countries, occupying the 37th place (Belova, 2011). Only Turkey has a worse position being at the bottom of the list. The implications derived in the paper could be valuable when planning the strategy of development for different countries. The link between the kind of economic system and the respective institutions of supporting social entrepreneurship should be taken into account when projecting the strategy of development of financial mechanisms for social enterprises in the respective countries. As the amount of the paper is rather limited we hadn't the opportunity to reinforce our implications by an empirical research. This task faces a problem of collecting data on the development rates of bank and market institutions in the respective countries, but it seems rather realistic to perform. So, maybe further it would be possible to construct a regression model showing the link between the level of development of market- and bank-based economies and the respective rates of social entrepreneurship' institutions in those countries.

Abstract: Subjects concerning entrepreneurship are at the heart of European Union concerns. With growing international student mobility for decades now, many higher education institutions (HEIs) face a more diverse student body. The change of mobility patterns means that students' professional future is not necessarily anymore in their home country. At the same time higher education institutions are under increasing pressure to 'guarantee' the employability and a successful access to labor markets of their graduates. One of the challenges for HEIs, is to deliver a comprehensive education, to develop their graduates' employability relevant skills and support them with structures that ease either their integration in the national and the international labor markets. Entrepreneurship is as an engine for economic growth for young and senior people to create new business opportunities and corresponding jobs while increasing markets' competitiveness and innovation. Some higher education institutions provide with comprehensive trainings and courses, as well as guidance for those who want to become an entrepreneur. Therefore, the purpose of this paper is to show a case study about building entrepreneurial practices and knowledge together with a community of international partner universities, in order to enhance student's competences in relation to labor market, mainly focusing on entrepreneurship skills. Higher education institutions can foster entrepreneurship and, consequently, be entrepreneurs incubators by delivering a comprehensive and interactive education, developing their students' entrepreneurial relevant skills, as well as supporting them with infrastructures and guidance. In particular, HEIs can educate tomorrow' entrepreneurs by offering entrepreneurial summer schools. Summer schools have been key in this ongoing process of teaching students how to be entrepreneurs. We highlight the essence of the research as an innovative scenario for students to innovate and enhance the development of their business skills beyond our borders within educational atmospheres.

Keywords: entrepreneurship, entrepreneurship in business, higher education, summer school, innovation

1. Introduction

Providing optimal support for students and graduates when entering the labor market has become an integral part of the role of HEIs. The Bologna process led to an increase in the implementation of career services at European HEIs in order to strengthen the employability of their institution's graduates. In fact, in the 2014-2016 period, traineeship has showed an upward trend (European Commission, 2018a). Universities have developed strategies to internationalize their structures and to favor international mobility (study and placement). The number of students abroad doing an internship has grown a 14%, from 73,338 students (and recent graduates) in the first year of the Program implementation to 84,190 students in 2016 (European Commission, 2015; European Commission, 2018a).

The provision of student services, including career services, has become a key topic among academics and different stakeholders due to the growing numbers of mobile students (Perez-Encinas, 2017). A good provision of support services can attract and retain international students and meet their expectation as to provide with better structures and opportunities locally and internationally can enhance their general experience (ACE, 2016). To this respect, this paper explores how placement mobility as well as career services operate in an international and national level, where they normally focus on local. Two central questions are addressed, how fit are HEIs to facilitate international work mobility and how could international career service consortia support HEIs global ambitions?

2. Literature review

The increasing number of internationally mobile students reflected the expansion of tertiary education systems worldwide (OECD, 2013). Consequently, it is claimed that a more comprehensive approach to internationalization of higher education (Hudzik, 2014) will increase the awareness that internationalization has to become more inclusive and less elitist by not focusing predominantly on mobility but more on the

curriculum and learning outcomes (European Parliament, 2015). One indicator of the inclusiveness and the change of focus is the recent definition of internationalization by the Internationalization of HE study requested and published by the European Parliament (2015, p. 33):

> *"the intentional process of integrating an international, intercultural or global dimension into the purpose, functions and delivery of post-secondary education, in order to enhance the quality of education and research for all students and staff, and to make a meaningful contribution to society".*

In 2014 the ERASMUS + program was launched as the successor of the ERASMUS program, integrating other mobility schemes that were previously separate. The EU's program with a budget of €14.7 billion provides opportunities for more than 4 million Europeans to study, train, gain experience and volunteer abroad. It contributed to the achievement of strong, sustainable and balanced region's growth. In particular, it aims to tackle high levels of (young) unemployment and reduce poverty by promoting education system modernization and encourages cooperation and partnership of higher education providers, aside from serving as a vehicle for social inclusion, intercultural comprehension, and networking (European Commission, 2018a).

3. Benefits for students to work abroad

By moving abroad to work, participants face up to new challenges and unfamiliar situations related to live in a new environment that requires them to act with creativity, at the same time that enables them to develop autonomy and self-confidence. Moreover, students are more eager to work abroad once their traineeship experience was finished. Erasmus+ beneficiaries can be seen as more employable by promoting the acquisition of knowledge and competences that may not be taught at home and are demanded by employers to satisfy today's business needs (European Commission, 2015; European Commission, 2018b). In this sense, working abroad is a valuable opportunity for students to improve their CVs (European Commission, 2014), for instance by stressing newly developed skills, understandings and personal attributes (Yorke 2006, p. 8).

The *Erasmus for traineeship* has gradually grown in importance since Erasmus+ was launched. In the three years of implementation, around 235,000 students went abroad on traineeship, 20,500 of them being recent graduates (Erasmus+ annual report 2018b).

During this period, in the European context, the international dimension of higher education came to be managed less by incidental and individual initiatives and began to be structured into organized activities, projects and programs based on political rationale and driven more by national governments than by higher education itself (De Wit & Merkx, 2012). It was also at that time that internationalization started to be seen as a process that affected the institutional strategies of universities and a time to rethink support service structures. In particular, career services play a key role in supporting students in their school-to-work transition and in the acquisition or improvement of crucial skills and competences to gain an initial employment. A way career services may do so is by providing them with seminars, workshops, career counseling and information (Do Céu and de Nazaré, 2014). Moreover, career services help students to be aware about the existence of mobility programs to study or train abroad that allows them to enhance employability. Knight and Yorke (2003) suggested that employability improvement might be achieved through work experience, entrepreneurship modules, portfolio of achievement, and (good quality of) career advisers.

Yet, the delivery of support services varies significantly across European HEIs, having students getting information and support from different sources instead of a central and unified structure. For instance, international students may have to ask for information, advice or support on offices which originally where create to support only exchange students or on their enrollment department (Kelo & Roger, 2010).

Additionally, especially for European institutions there seems to be a lack in research literature around the internationalization of career services, which is not written from an Anglo-American perspective and that provides more in-depth knowledge about the heterogenic developments (cf. for American universities e.g. Kenyon & Rowar-Kenyon, 2014). How beneficial a broader view would be shows Kelo and Roger's (2010) innovative work, which analyzes student support provision in six European countries (Denmark, France, Germany, Italy, Poland, and UK) and found out that while Denmark has a well-established provision of international students support and advise - a task entrusted to each Danish HEI -, in Poland student services

provision has more room to improve. When it comes to international students' needs, still many European HEIs *find it difficult* to satisfy them.

4. Method

This paper is exploratory in nature and does not aim to generalize or to evaluate with statistical certainty. Instead it is as a first step based on desk research combining and interpreting already known statistics and surveys about careers services mainly in Europe under a new research interest – hence outlining main issues and challenges in the European careers service landscape with regard to global student work mobility facilitation. Based on the presentation of the current state of career services – we followed a case study approach to explore the benefits of a careers service consortium model for addressing some of the issues of part one. Part two follows generally Yin's guidelines for case study design. We applied an exploratory holistic single case analysis (Yin 2017, p. 26-32; see also Ridder, 2016). The case was chosen because the authors are involved with the career consortium implementation, which allowed us in-depth insights and produced intimate knowledge regarding the unit of analysis but it leads to the danger of bias. Yet, the danger of bias is rather limited since the purpose of the study is to develop propositions for further research and not to judge or assess overall impact or quality of the work conducted. The data was gathered mainly during evaluation sessions, where project participants discussed the stage and progress made during the project and through evaluation surveys for the different activities of the consortium. Additionally we had access to funding proposals, internal documentation and project outputs. We worked through the material "ground up" (Yin, 2017, p. 168-169) and analyzed it using a hermeneutical approach close to Yin's "logic models" (Yin, 2017, p. 194-195).

5. Context: How fit are HEI structures to facilitate global student work mobility?

As the literature review has shown, there are still many white spots if one wants to assess and compare career service work internationally, especially when it comes to something as specific as the internationalization of careers services. Relatively well documented is the structural situation of career services in Germany and their internationalization efforts. In the following section, we will examine the case of Germany in detail and contextualize it with findings from other countries (Netherlands, Sweden, Canada, Romania, Spain, Italy, France, UK, USA). Whilst this proceeding does not offer sufficient knowledge to give a quantitative global answer to the question, it helps to outline where further research is needed, what it should focus on and support the initial argument, that more intra- and inter-institutional cooperation is needed.

5.1 The German Case

In 2014 conducted the German rector's conference a survey amongst German career services and international offices, asking about their internationalization attempts (Böhm & Brandl, 2014). The same stakeholders published in 2015 a general report on the structural situation of career services in Germany (CSND, 2015). Additional valuable data to compare the German case internationally can be derived from the Expert Council of German Foundations on Integration and Migration's (ECGFIM) study "Train and Retain. Career Support for International Students in Canada, Germany, the Netherlands and Sweden" (2015) and data published by the Qareer-project (2017), which conducted a cross-national study with special focus on Italy, Romania, Spain and Poland. The main findings serve as a good indication for the current state of affairs but show as well that there is a dire need for more reliable academic research:

The HRK-survey (Böhm & Brandl, 2014) results show that German HEIs have started to internationalize their career services. More than 78 % of the answering institutions state that they already provide activities aiming to internationalize their services (e.g. trainings, projects, specific classes), which shows that these institutions recognize to a certain extend that facilitating support for the international dimension of careers is part of their responsibilities.

When asked about their main target group, about 61 % of the institutions identified international students trying to integrate into the German labor market, whilst 39 % stated that the focus of their internationalization activities aims at local graduates.

The responsibility for the integration of international students into the German labor market is largely assigned to career services (57 %), which are in Germany usually central departments (78,9 %). This is also reflected in the budget shares (without personnel). There is no target group specific activity receiving larger budget shares

than career service activities aimed at international students compared to activities specifically for i.e. men, women, doctoral students, disabled students, drop outs (cf. CSND, 2015).
The main challenge is a student body that might not be accustomed to the specifics of the German labor market, that might face prejudices and that might struggle with language barriers – so most career service's offers somehow aim to minimize the effects of these "disadvantages". The usual formats are application trainings, individual coaching for international students, language trainings and intercultural trainings (Böhm & Brandl, 2014). This is true for most countries according to the "Train and retain"-report (ECGFIM, 2015, p. 24-25). German HEIs, similar to Swedish universities, focus rather on students which are about to graduate with their services, whilst Canadian and Dutch HEIs tend to start early after enrolment and offer support throughout the study circle (ECGFIM, 2015, p. 22-23). Even though German institutions score high in targeting their services on international graduates compared to Canada, Sweden and the Netherlands, it is only in the Netherlands that using international alumni strategically in job market integration is a popular activity of career service work (ECGFIM 2015).

Unfortunately, there is not enough data to directly assess the extent of these measures and their impact. A problem which is quite common, when addressing the impact of career service work (Eimer, 2014). Whilst offering these services surely is a useful undertaking – we simply don't know – if for example supply and demand matches. In Germany we find for example the situation that on the one side one report states that only 31 % of international students were satisfied with the support received at German universities when looking for an internship (Esser & Gillessen 2014, p. 105; also ECGFIM, 2015 refers to the same report) and on the other side that career services in Germany more often than not are for data protection reasons not able to promote their offerings directly to the relevant target group (ECGFIM, 2015, p. 23).

So from an organizational perspective – communication is an issue. But even more severe is the resource question that makes a continuous need focused, ready-when-demanded service delivery rather unlikely. Thanks to the 'Train to retain'-report (ECGFIM, 2015) and the HRK-survey (CSND, 2015) one has a rough idea of the student-to-staff ratios in career services (Canada: 2,922:1; Germany: 7,283:1; The Netherlands 8,765:1; Sweden: 4,999:1). Though these numbers differ quite a bit from institution to institution, it is fair to say that it is close to impossible to imagine that all students could benefit from individual attention and counseling.

Considering that the student-to-staff ratios at international offices (Canada: 2,770:1; Germany: 2,082:1; The Netherlands 2,445:1; Sweden: 1,941:1) are much lower, it seems that organizational priorities (expressed in funding and resource allocation) do not favor career departments. The answers to the survey questions clearly refer to a lack of resources when asked about sustainability of internationalized services (Böhm & Brandl, 2014).

As the authors of the "Train and Retain" study wrote: "Despite international students' need for more systematic and coordinated job entry support at the local level, most of them encounter a poorly coordinated patchwork of occasional career fairs, job application training and chance acquaintances with service staff or company representatives who may or may not be able to help them" (ECGFIM, 2015, p. 4).

The countries in the above mentioned study belong to the rather well off countries and while in Germany for example the establishment of most career services is about 10 years ago, countries like for example Romania only started in 2014 with the establishment of university career services on a larger scale. The uneven development of careers services in Europe is also a reason that there are no commonly shared international standards of careers service work (Qareer, 2017), which leads also to the question of professional careers qualifications. Whilst the UK within the European context is leading in offering careers qualifications as fully recognized study programs on a university level, such high degree of professionalization is the exception not the rule in Europe (cf. Qareer, 2017).

When we shift our focus towards the outbound perspective, similar aspects way in:

There is a lot of financial support in the EU for students to support mobility. Students can apply for ERASMUS+ internship funds and/or government funding (e.g. BAFöG) in order to get some financial help when they go abroad (in 2013/2014 the National Agency managing ERASMUS funds in Germany alone allocated about 10.000.000 € for 6.500 students to do internships abroad and additional funding schemes are available).

According to the HRK's survey (Böhm & Brandl, 2014) around 39 % of the career services identified home students as their main target group for their internationalization activities. Organizing workshops that aim to enable students to find work abroad and/or intercultural trainings aiming to prepare graduates for a global work environment are the most popular services offered (ibid.). The survey answers suggest however that institutions quite often do not possess the necessary knowledge internally but must rely on external coaches providing these workshops (ibid.). About 29 % provide job boards, where also international job ads are published. Unclear remains how many students can benefit from such workshops and how well-connected career services are internationally. European universities rarely provide structured schemes that aim to place students with companies abroad, contraire to many north-American universities (cf. Kenyon & Rowan-Kenyon, 2014).

All outlined aspects considered, the patch work impression prevails. Though one finds admirable efforts at institutions and surely there was never a time when more has been done to support international work mobility, there still is a great deal of work to be done to improve services to support global work mobility.

5.2 Case study: Benefitting from inner- and intra-institutional cooperation

As shown, the main challenge for institutions to support their students are scarce resources. To build knowledge of foreign labor markets, to produce target group specific activities and resources for international students to integrate into the local economy and to build worldwide company collaborations is a very costly endeavor. Seldom are the necessary institutional resources in place to put a systematic strategy and aligned effective operations into practice.

One answer to limit the expense for individual institutions could be the participation in career service consortia. Considering the amount of HEIs worldwide there is enormous potential to connect and collaborate in order to improve student career mobility. Rooted in the context provided so far, we present in this part learnings of a ERASMUS+ strategic partnership project, that aimed to address many of the outlined challenges and to improve the service offer of the involved institutions – a transnational career service consortium operating under the name "European Centre for Career Development and Entrepreneurship" (ECCE).

The ECCE-consortium was established between Universidad Autónoma de Madrid, Universíta Cattolica del Sacro Cuore, Regent's University London, Paris School of Business and EBC Hochschule. The preparation phase started in 2014, in 2015 the initiative got funding through the ERASMUS+ Key Action 2-strategic partnerships.

The project partners aimed to create a small, operatively minded consortium, which should in its core work like a second-level-support for career officers. Meaning, the goal was not that now all German students would contact directly a Spanish career officer but rather that the colleagues collectively develop and share materials and job offers, train each other on labor market standards in their respective country, regularly liaise with each other, and are open for specific questions from their student-facing colleagues. This approach aimed to improve the availability of international know-how at all times and not only when external coaches where present, the institutional reach (meaning rather share company networks than trying to develop your own) and push inner- and intra institutional cooperation through the involvement of a diverse set of stakeholders.

Besides the classical career service responsibilities, the partners decided to add 'Entrepreneurship'-education to their consortium-portfolio to enhance cooperation within their own institutions and between institutions. The later decision allowed through project based summer schools on Entrepreneurship in Europe to train students. The basic assumption is that the core of entrepreneurship education is to foster problem-solving skills and initiative – both traits beneficial also for students aiming for a corporate career, hence here was a clear link to career service work (ECCE, 2015). The summer school curriculum was developed commonly involving academics and project managers from all institutions – also the summer school delivery is involving all institutions. Doing so allowed career service officers to expand their workshop offer, reach out and collaborate with colleagues from international offices and most importantly involved academics and entrepreneurs, which again brought their entrepreneurship knowledge and networks to the table and gained international teaching experience and the possibility to cooperate with like-minded academics from the partner institutions (ECCE, 2017a).

The heart of this network is a platform where the partners share resources like job-boards, application guides etc. and offer the possibility to match academics, students and other stakeholders who have an interest in

entrepreneurship in terms of research or actual start-up cooperation. This has been accompanied by staff training weeks for career service members, summer schools and the like in order to develop internationally-aware staff and students. The aim remains to keep the network small and foster deep relations between the involved career officers so that they truly benefit from their enlarged network in their day-to-day operations. At the same time, ECCE promotes the model and its experiences, since it wants other institutions to copy the model.

The long-term impact remains yet to be seen but several results indicate that pursuing such models could be worthwhile:

- *Career service.* Officers participating in the training expressed their high satisfaction with the training, and felt better prepared to advise their students and appreciated the exchange with their international colleagues. They also indicated that the work led to increased overall work satisfaction, as they have better target specific materials at hand to advice both inbound and outbound students. The overall international job offer has increased, though language remains a major obstacle for easy mobility.
- *Summer Schools.* Participants in the summer schools expressed very high satisfaction with learning outcomes and execution of the trainings; appreciated the enlargement of their international networks and oftentimes stayed in contact with their peers; several participants went on to put the learned into practice by funding their own business and led to spin-off projects
- *Collaboration.* The collaboration led to increased academic cooperation and to a larger network of entrepreneurs, academics, administrators and students supporting each other with advice and contacts. From initially 5 project managers there have been until now more that 50 people (without students) contributing to the success of the project from across institutions and institutional levels and external stakeholders
- *Institutions.* By now each institution has named fixed liaison career officers, which transform the initiative from project phase into institutionalization. Other institutions outside the network can benefit from the ECCE-experiences in utilizing several outputs which have been produced by the project team, such as a European career advisor curriculum, which synthesizes the learnings of the staff weeks, the ECCE-concept paper, which documents the project and key learnings, parts of the platform in order to enlarge the entrepreneurship community or a career guide for the involved partner countries, specifically written with international students in mind. (ECCE, 2017a)

In the above-mentioned concept paper the ECCE-team stresses the following learnings as most essential, if one wants to implement a similar structure:

"The main challenge for a consortium is not so much the creation of technical resources and tools to share but to foster a team spirit across universities and countries and to keep this spirit alive over time and personnel turnover. The advantage of small consortia compared to larger associations is that the colleagues know each other faster and better" (ECCE, 2017b).

6. Conclusions

Given the challenges of very heterogenic economies and careers service landscapes internationally, smooth global work mobility facilitated by HEI will remain a long-term goal.

The ECCE results indicate that a lot of small actively cooperating networks could have a larger impact and offer truly helpful student-centered support than large associations would have, though they would not necessarily need to compete but could complement each other. Personal relations will be key if we want career officers to not only broaden their perspectives, but also obtain the tools necessary to assist students on a larger scale.

These transnational models have a lot of potential to add a new dimension to already existing EU university networks. The challenge will remain to find sustainable funding models and to scale the operations for a larger input.

Relational Social Capital Dimension and Entrepreneurial Intentions in Online Environments

Noemí Pérez-Macías, José Luis Fernández-Fernández and Antonio Rua Vieites

Abstract: Entrepreneurial intention (EI) is perceived as a key element for understanding the process of entrepreneurship because it is considered a prerequisite of the entrepreneurial action. Once the models that explain the development of this intention are established, the results add new variables that could help deepen the knowledge about this important element of our economies. Among these variables, social capital (SC) gains relevance as an influencer of entrepreneurship because transactions produced with this process depend on social interactions between individuals: their proper development will largely depend on the nature of these social relationships. Thus, our main goal is to explore the way in which relational SC dimension is integrated in the explanatory model of the development of the EI. To analyze the relationship among the model constructs, we use Structural Equation Modelling (SEM) applying Partial Least Squares (PLS). Data is obtained from an online sample of 307 students. The results obtained from this sample show that the three main components of the relational SC dimension exert a different influence on the antecedents of Theory of Planned Behavior (TPB) but indirectly influence EI. The proposed structural model explains 75.8% of the variance of EI and its capacity to predict EI is 63.7%, which is considered highly predictable. One of our principal limitations is that our study is comprised only of students enrolled in online university. This paper contributes to the literature on entrepreneurship because it analyzes the impact of the main constructs of the TPB and the effect of relational SC dimension on the EI of students enrolled in an online environment where lack of physical contact requires higher trust, norms of reciprocity and identification; three of the main components of the relational SC.

Keywords: Entrepreneurship, Entrepreneurial Intentions, Online universities, Social capital, Relational dimension

1. Introduction

Due to its impact on employment, economic growth, productivity, innovation and social cohesion, there is widespread attention in entrepreneurship (Audretsch & Keilbach, 2004). Studies on the birth of entrepreneurs focus on university students because these students tend to show a higher propensity towards entrepreneurship. The university environment plays a key role in motivation and provides opportunities for individuals to create a business based on knowledge and technology (Turker & Selçuk 2009).

An entrepreneur does not emerge simply because of an opportunity in the market but also because of the individual's capacity and intention to exploit it (Fayolle & Liñán, 2014). Hence, our analysis is focused on the study of the factors which influence an individual's intention as intention is considered the best single predictor of entrepreneurship (Kautonen et al., 2015). Despite extensive studies on EI, we have not found any studies analyzing the impact of SC and TPB model in online university students, an aspect supported by Fayolle and Liñán (2014). Lately, studies associate SC with the formation of EI (De Carolis et al., 2009). This justifies why our study focuses on the effect of SC on EI as a facilitator of the entrepreneurship process: we cover the gap.

The main aim of this research is to analyze the link between SC and EI (Davidsson & Honig, 2003; Liñán & Santos, 2007) in the online environment. In 2019, 50% of higher education will be completed through 100% online methodology (Santamans, 2014). Our study develops and integrates intention-based framework and analyzes the impact of the main constructs of the TPB and SC on EI of the online students.

The paper is structured as follows: Section 2 is a literature review presenting the theoretical framework exposed to underpin the model and hypothesis included in Section 3. Section 4 details the methodology, summarizing the sample and the measures employed. Results are presented in Section 5 and discussed in Section 6. Conclusions are presented in Section 7, highlighting the main contributions, implications and paths for future research.

2. Theoretical Background

2.1 Entrepreneurship, Entrepreneurial Intention and the Theory of Planned Behavior

Entrepreneurship represents a planned behavior that is influenced by the individual's intentions, attitudes and beliefs. Those attitudes and intentions are learned and necessarily vary across individuals and situations (Krueger & Brazeal, 1994). Thus, individuals will be more or less enterprising depending on the external and internal influences effect on the EI. This is why higher education plays a role in nurturing and shaping EI and can effectively equip graduates with necessary entrepreneurial skills and capabilities (Nabi et al., 2010).

EI, defined as a "*self-acknowledged conviction by a person that they intend to set up a new business venture and consciously plan to do so at some point in the future"* (Thompson, 2009: 687), is considered the most powerful predictor of entrepreneurial behavior (Krueger et al., 2000). The TPB (Ajzen, 1991), the most widely used model when studying EI (Nabi & Liñán, 2013), is considered one of the most robust models for its study (Krueger et al., 2000; Schlaegel & Koenig, 2014). TPB states that three are the attitudes that predict intentions: attitude towards the behavior (ATB), perceived behavior control (PBC) and subjective norms (SN). Despite the robustness of the TPB to predict intentions (Kautonen et al., 2015), the inclusion of other constructs representing the social relationships of the individual will enrich the explanatory capacity of the intentions models (Liñán & Santos, 2007). Thus, we include SC as an antecedent to the cognitive factors; given that intention models assume that external variables do not directly affect the EI of an individual (Boyd & Vozikis, 1994).

2.2 Social Capital and entrepreneur´s environment

SC is a part of an entrepreneur´s environment and entrepreneurial activities are the results of social interaction and the interplay among environments (De Carolis & Saparito, 2006). SC facilitates entrepreneurship and the formation of start-up companies. Scholars have extensively examined the importance of social networks, embeddedness and SC in the creating and formulating EI (De Carolis et al., 2009).

The tenet of Social Capital Theory is that social relationships among people can be productive resources (Coleman, 1988). The concept of SC varies depending on the focus. In our work, we follow the neutral definition where SC is defined as *"the sum of the actual or potential resources embedded within, available through, and derived from network of relationships possessed by an individual or social unit". SC thus comprises both the network and the assets that may be mobilised through that network*" (Nahapiet & Ghoshal, 1998: 243). According to Nahapiet and Ghoshal (1998), relationships are an important element of SC and, more specifically, the strength or the weakness of the linkages in these relationships (Granovetter, 1973).

Nahapiet and Ghosal (1998) established three dimensions to analyze SC: *structural, relational and cognitive*. In our proposal model we use the relational dimension which describes the nature of relationships that people have developed with each other through a history of interactions as manifested in strong versus weak ties (Granovetter, 1973; Nahapiet & Ghoshal, 1998).

3. Model and Hypothesis

3.1 Social Capital Dimensions

There are three dimensions of SC: structural, involving the pattern of relationships between the network actors (Inkpen & Tsang, 2005); cognitive, representing common goals, shared culture, language and codes (Inkpen & Tsang, 2005); and relational (See 2.2).

Although the structural position of an entrepreneur may be necessary, it is not enough to have an impact on the venture creation process (Liao & Welsch, 2005); that´s why relational SC is necessary to capture the extent that an entrepreneur is actually able to receive informational, physical and emotional support in the venture creation process (Chiu et al., 2006; Nahapiet & Ghosal, 1998). That is why we focus our work on the main components of this dimension.

3.1.1 Relational Dimension

Following Chiu et al. (2006), the key elements of the relational dimension are *trust (TRU), norms of reciprocity (NR) and identification (IDE)* as described below:

TRU, plays a key role in the willingness of networks' actors to share knowledge (Coleman, 1988; Inkpen & Tsang, 2005). TRU is essential in the entrepreneurial context because most of the entrepreneurial activities require some level of TRU (Caliendo et al., 2012). Individuals who are unwilling to rely on others will be less able to run a business while people with a higher level of TRU will develop a more favorable attitude towards entrepreneurship and a higher PBC which will translate into higher EI. Given that trusting relations will make individuals more confident when making an entrepreneurial decision, as they think the environment around them is trustworthy, the perception of what the individual´s close circle thinks about the idea of setting up a business will be greater with higher levels of TRU. Though trusting someone can be risky, individuals who are willing to accept risks have a more favorable attitude towards running a business and a higher PBC (Lüthje & Franke, 2003; Nabi & Liñán, 2013). Relationships based on TRU allow better communication, transfer of knowledge and resources and a greater sense of belonging between the individuals which might encourage them to have a favorable attitude towards an entrepreneurial career and feel more secure on one's capacities based on the TRU and support. Based on this argument, we proposed:

H_{1a}: TRU is directly related to ATB
H_{1b}: TRU is directly related PBC
H_{1c}: TRU is directly related to SN
H_{1d}: TRU is indirectly related to EI
H_{1e}: TRU is directly related to IDE

NR refers to knowledge exchanges that are mutual and perceived by the parties as fair. The operative norm in TRU is what Putnam calls *generalized reciprocity* which is "*…I´ll do this for you now, knowing that somewhere down the road you´ll do something for me"* (1993: 182-183).

For entrepreneurs whose activities are based on exchange of factors and knowledge, NR is one of the key prerequisites to develop networks and social interactions (Caliendo et al., 2012). But when entrepreneurs fail to reciprocate, this could lead to reduced trustworthiness (Stewart, 2003). NR generates increased pressure in individuals to reciprocate the favorable behaviour that would lead individuals to be more committed to a common interest and display a higher ATB. In the same way, if it is perceived that this NR exists, individuals would generate a greater PBC as they will feel more secure that someone will provide assistance if they need help. Strong ties contain an implicit principle of reciprocal obligation, so when these reciprocity obligations are stronger it is more likely that family and business logic are at odds and the planned venture's future performance is more likely to be compromised (Sieger & Minola, 2017). Based on literature we proposed:

H_{2a}: NR are directly related to ATB
H_{2b}: NR are directly related to PBC
$H_{2c:}$ NR are directly related to SN
H_{2d}: NR are indirectly related to EI.
H_{2e}: NR are directly related to TRU

IDE is defined as *"the process whereby individuals see themselves as one with another person or group of people*" (Nahapiet & Ghoshal, 1998: 256). IDE refers to an individual´s sense of belonging and positive feeling toward a virtual community. Firm creation is considered a social activity and entrepreneurs shape their behavior in relation to how they perceive themselves in relation to others (Fauchart & Gruber, 2011). IDE is a potential mediator of an entrepreneur's decisions and action (Hoang & Gimeno, 2010) but few studies address social identity in the entrepreneurship context (Sieger & Minola, 2017).

Virtual entrepreneurial context often lacks clear structural mechanism that promotes cohesion or identification with a group or organization (Schenkel & Garrison, 2009: 527); therefore, in online universities where there is a lack of physical contact, the sense of belonging is particularly desirable because it acts to provide a source of "glue" that promotes group cohesion (Fiol & O'Connor, 2005: 19). Thus, those individuals that identify themselves as part of a virtual community with a strong sense of belonging to it, will develop greater PBC and ATB and subsequently, a higher EI. Based on the above we propose:

H_{3a}: IDE is directly related to ATB.
H_{3b}: IDE is directly related to PBC
H_{3c}: IDE is indirectly related to EI.

3.1.2 Main constructs of the TPB

ATB refers to the expectations and beliefs about the consequences of developing a certain behavior, *PBC* reflects the perception of an individual´s self-perceived capacity to undertake an entrepreneurial venture and *SN* represents the perceived pressure of what important people think about adopting this type of behavior (Ajzen, 1991). The individual´s intention to perform a certain behavior is the central construct of the TPB. The PBC is considered one of the most influential constructs of this theory on EI (Krueger et al., 2000) with the ATB (Liñán, Nabi, & Krueger, 2013; Lüthje & Franke, 2003). Regarding SN, several studies have tested its influence over EI (Kautonen et al., 2015; Schlaegel & Koenig, 2014) but other stated that its effect is may be indirect via ATB and PBC (Liñán & Chen, 2009; Liñán et al., 2011). Therefore, entrepreneurial activity can be predicted from the influence of these three factors on EI (Krueger et al., 2000). Based on the above, we propose:

H_{4a}: PBC is directly related to EI
H_{4b}: ATB is directly related to EI
H_{4c}: SN is directly related to EI
H_{4d}: SN is directly related to PBC
H_{4e}: SN is directly related to ATB

The conceptual model is shown in Figure 1.

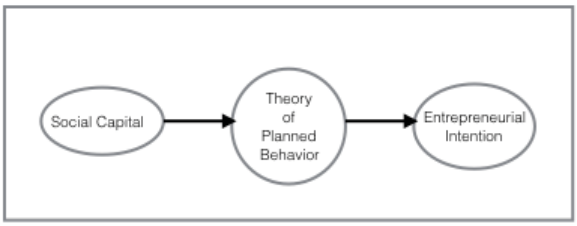

Figure 1: Conceptual Model

4. Method

4.1 Measures

The key-constructs were captured through a seven-point Likert scale ranging from strongly disagree (1) to strongly agree (7). This research uses the measures employed in Liñán and Chen (2009) to assess ATB, PBC, SN and EI and the measures of Chiu et al. (2006 to measure the relational dimension of SC. A range of control variables are used (demographic and socioeconomic characteristics) as background factors. These variables have been coded as follows: age (years), gender (1=Male; 2=female; 3=neuter) and self-employment experience (1=Yes; 2=No).

4.2 Sample

The survey was carried out through an online questionnaire given to the students enrolled in an online university from the 15th to the 26th of January 2018. Student samples have been widely used examining EI (Krueger et al., 2000; Liñán et al., 2011). The EI model was tested using SEM-PLS (SmartPLS 3.2.7). The sample comprised 307 respondents engaging in different degrees and masters: 80% university degrees and 20% masters, with a sample error of 5.37% at a confidence level of 95% (Z=1.96 p=q=0.5) and it was determined toward a finite formula. Regarding the students enrolled in university degrees, 18.67% were in their 1st year, 10% in the 2nd, 15.33% in the 3rd and 36% in the last year. Of these respondents, 60.59% were female and 39.41% were male, with an average age of 35 years (*SD=8.314*). Likewise, 95.10% of the respondents have previous working experience and of those 31.25% have previous self-employment experience. Almost 13.36% of their fathers are self-employed while 8.14% of their mothers are and around 41% of their parents are pensioners or retirees which is consistent with the medium age of the sample.

5. Results

5.1 Analysis of the Measurement Model

The results analysis is based on SEM-PLS because the study objective is to predict the key constructs or its antecedents. Our investigation is an extension of an existing theory and the structural model is complex and

the sample size is relatively small (Hair et al., 2011). Also, SEM-PLS has been widely used in entrepreneurship research (Liñán & Santos, 2007; Liñán et al., 2013).

The analysis was developed in two stages: assessment of the measurement model (reliability and validity analysis) and study of the structural relationships among the constructs (once the first stage is accomplished). Reliability analysis was carried out using items loading. To assess the internal consistency of the constructs Composite Reliability (CR) scores and Average Variance Extracted (AVE) have been used. Both achieved (See Table 1).

Table 1: Composite reliability and convergent validity

Construct	*Item*	*Loading*	*AVE*	*CR*
ATB	ATB1	0.858**	0.835	0.962
	ATB2	0.913**

	TRU2	0.921**		
	TRU3	0.944**		
	TRU4	0.946**		
	TRU5	0.942**		

Note *p<0.05; **p<0.01; ***p<0.001 based on a one-tailed t-student (499) distribution; t (0.05; 499) = 1.6479; t (0.01;499) =2.3338; t (0.001;499) =3.1066

Discriminant validity has been tested by two criterias: Fornell and Larcker (1981) and heterotrait-monotrait ratio (HTMT) of correlations (Henseler et al., 2015). Both accomplished (see Table 2).

Table 2: Discriminant Validity criteria's

Construct	*ATB*	*EI*	*IDE*	*NR*	*SN*	*PBC*	*TRU*
ATB	*0.914*	0.898	0.285	0.248	0.455	0.622	0.262
EI	0.864	*0.936*	0.277	0.244	0.435	0.618	0.261
IDE	0.274	0.269	*0.960*	0.884	0.255	0.292	0.855

TRU	0.251	0.253	0.826	0.847	0.248	0.323	*0.924*

Diagonal (italicized values) represent the square root of the AVE
Upper triangle: Ratio HTMT
Lower triangle: correlations between latent variables

5.2 Structural Model Analysis

The second stage, focuses on the structural model. To assess its adequacy two criteria´s are used, the coefficient of determination (R^2), and the Stone-Geisser´s Q^2. Both show that the model explains a high percentage of the variance in EI and its high level of prediction (see Figure 2).

Bootstrapping (5000 samples) has been used to generate standard errors and t-statistics that allow us to verify our hypothesis. Figure 2 presents the results for the sample.

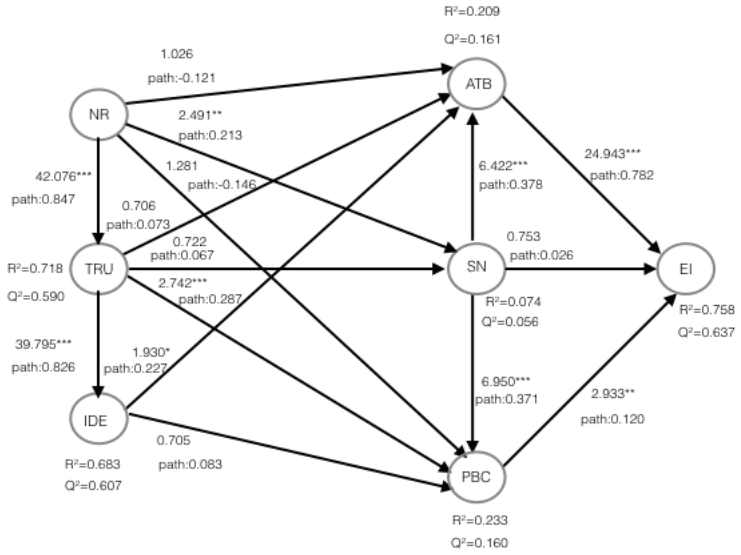

Figure 2: Final structural model results

Figure 2 shows the significant influence of IDE on ATB but not significant on PBC. NR have no significant effect neither on ATB nor PBC but significant influence on TRU and SN. The effect of TRU is significant over IDE and PBC but not over ATB and SN. Concerning TPB constructs we corroborate that ATB and PBC exert a significant influence over EI; however, the direct effect of SN over EI is not significant but it is significant on ATB and PBC. Indirect influences are on Table 3.

Table 3: Structural Model: Total indirect effects

Relationships	***Original Sample***	***Standar error***	***T-statistics***
IDE->EI	0.187	0.101	1.861*
NR->ATB	0.323	0.094	3.438***
NR->EI	0.195	0.054	3.594***
NR->IDE	0.700	0.031	22.431***
NR->SN	0.057	0.079	0.720
NR->PBC	0.401	0.089	4.479***
SN->EI	0.340	0.052	6.513***
TRU->ATB	0.213	0.106	2.013*

Relationships	*Original Sample*	*Standar error*	*T-statistics*
TRU->EI	0.271	0.100	2.709**
TRU->PBC	0.093	0.102	0.912

Through the indirect effects (Table 3) are appreciable, there is significant effect of IDE on EI and high significant effect of NR over ATB, EI, IDE and PBC but not significant on SN. Concerning SN, the study reveals its high effect over EI. Finally, TRU exerts a significant effect on ATB and EI but not significant over PBC.

6. Discussion

Explored the influence of relational SC on the TPB model, we concluded that all of its components exert influence over the antecedents of TPB model but not over the same ones (Table 4).

Table 4: Summary of hypotheses testing

Hypothesis /Description	*Decision*
H_{1a}:TRU->ATB	Rejected
H_{1b}:TRU->PBC	Supported
H_{1c}:TRU->SN	Rejected
H_{1d}:TRU->EI	Supported
H_{1e}:TRU->IDE	Supported
H_{2a}:NR->ATB	Rejected
H_{2b}:NR->PBC	Rejected
H_{2c}:NR->SN	Supported
H_{2d}:NR->EI.	Supported
H_{2e}:NR->TRU	Supported
H_{3a}:IDE ->ATB	Supported
H_{3b}:IDE->PBC	Rejected
H_{3c}:IDE->EI	Supported
H_{4a}:PBC->EI	Supported
H_{4b}:ATB->EI	Supported
H_{4c}:SN->EI	Rejected
H_{4d}:SN->PBC	Supported
H_{4e}:SN->ATB	Supported

The TRU results show its influence in the conformation of an EI through the reinforcement of the PBC. TRU is essential to pursue an entrepreneurial career because entrepreneurial activities require high level of TRU (Caliendo et al., 2012). The higher the TRU the greater the PBC because individuals will perceive more security on the resources and knowledge obtained because TRU enhance the quality of resource flows. Despite the difficulty developing IDE in the virtual communities (Fiol & O'Connor, 2005), the generation of TRU will enhance the approachment between individuals, creating share norms that will act as a mediator in the conformation of attitudes and EI.

Regarding NR, the results show that close relations are characterized by high reciprocity (Malebana, 2016), generating a higher pressure to reciprocate (Sieger & Minola, 2017) which might explain why NR exert an indirect effect on EI through SN and it affect ATB and PBC through SN. Also, the existence of NR generates trustworthiness in what will make individuals feel more secure, reducing the uncertainty which will lead to improve the exchange of resources and knowledge (Malebana, 2016).

Despite that, entrepreneurs have been seen traditionally as individuals who are less likely to identify themselves with conventional practices, norms and values and usually do not follow the same stream as the rest (Liao & Welsch, 2005), IDE has influence on ATB because individuals developed their behavior towards a certain action based on the perception they have of others (Fauchart & Gruber, 2011). However, it does not exert influence on PBC because the sense of belonging does not enhance the perception of the individual of their capacities just for belonging to a community but it does have an indirect effect on EI. So, relational SC exerts a direct influence on the antecedents of the TPB and indirectly on EI (Malebana, 2016).

The results for the main constructs of the TPB model are on line with other studies where ATB and PBC have a high, direct and positive effect over EI and SN exerts a positive influence on EI (Liñán et al., 2011; Liñán et al., 2013; Liñán & Chen, 2009; Lüthje & Franke, 2003) but indirectly through ATB and PBC (Liñán & Chen, 2009; Liñán et al., 2011).

7. Conclusion, Limitation and future lines of research

SC and EI are vital for the development of entrepreneurship. Entrepreneurs can be seen as the engine of economic and social development. Due to the importance of the entrepreneurial figure, it is reasonable that researchers focus their attention on the antecedents of EI; that´s why we have incorporated the influence of the relational SC dimension on the antecedents of the three main components of TPB. The analysis results show that the proposed structural model explains 75.8% of the variance in EI and its capacity to predict EI is 63.7% considered high predictable power.

Our analysis enriches the studying of EI, validating the importance of relational SC in the formation of EI in an online environment where lack of physical contact requires higher TRU, NR and IDE. These variables are important for the development of entrepreneurial activities because starting a business assume that: IDE will enhance the degree of knowledge and sharing contribution easing the discovery of market opportunities, TRU will make individuals engage in social exchange and cooperative interaction increasing their PBC and finally, assuming that people give expecting to receive something in exchange will increase the pressure to correspond the share of knowledge, resources, ideas and so on, enhancing the possibilities of generating EI.

Institutions involved in the system should be aware of the importance of building TRU through the community system. Institutions shape beliefs so if they enhance the communication oriented in the legitimation of entrepreneurs with real changes (improvements on the regulatory and educational system and, for example, enhancing the access to financial and network support), future entrepreneurs will feel that everything said is not just air but real and this TRU will be translated in more EI. Also, as TRU derives from moral values which have been shaped in the early ages by parents or schools, it is essential to build an educational system that considers the elements of relational SC as key. This can be obtained by using a horizontal teaching based on work in groups, doing projects together and asking teachers questions because all these things will improve the social skills and the principal components of relational SC.

It would be interesting to incorporate the other two SC dimensions (relational and cognitive) into the model.

Likewise, it would be interesting to study if SC is a moderator instead of an antecedent between the EI and its antecedents.

National Ruralities as the Blockchain for Global Agriinnovation System

Sergei Polbitsyn
Ural Federal University, Yekaterinburg, Russia
s.n.polbitsyn@urfu.ru

Abstract: The paper presents the research results that specify current institutional and economic hurdles to local agriinnovation systems development in rural areas in Russia inhibited by indigenous people. To surmount the obstacles to rural area development, mandatory would be to consider the role of indigenous people in innovative development of the global agrifood system. The research design is based on the survey that was conducted among Bashkir people living in rural areas in Russia. The survey was designed as a combination of Likert Scale. One sample mean comparison test was applied to test the proposed model, which was found satisfied. Results suggest that the lack of information and support from local authorities are named as the most significant hurdles to development of rural areas inhibited by indigeneos people in Russia. The reported research relied on self-reports and on a sample from the one region of Russia. Future research should be multiregional and multinational to test the assumptions of the present study. The paper reveals that local agrifood systems in rural areas in Russia inhibited by indigeneos people could play more significant role in fastening the innovative development of global agrifood system. The research indicated that to develop global agrifood system is possible only supporting innovative activities of rural entrepreneurers. The basis for stimulating of innovative development of global agrifood system should be shaped as a set of divergent national agrifood systems. Enclaves of rural areas inhabited by indigenous people create better opportunity for innovative development of national and regional agrifood systems. Standartization in local agrifood systems organization leads to the decrease of innovative development of the global agrifood system and to the decrease of its efficiency. The present study provides evidence about the hurdles to innovative development of rural areas in rural areas in Russia inhibited by indigeneos people. Results could be of value to policy makers focusing on the development of small businesses and entrepreneurship and the promotion of entrepreneurial and innovative capabilities in rural contexts.

Keywords: agrifood system, innovative development, indigeneous people, Russia

1. Introduction

Food is the basic condition for the existence of mankind as biological species and a factor linking the expanding network of intellectual production, agricultural technologies and technologies for processing agricultural products, consumption, and a system for regulating production and consumption. At the same time, food, more precisely, guaranteed provision of food for the population, is the main goal of the functioning of any socio-economic system, therefore, the production and distribution of food should be viewed as a systemic problem to be solved within the agrifood system (Global food security : challenges for the food and agricultural system, 2013).

The essence of the agrifood systems is that the provision of food is the primary basis for the existence of mankind, civilization and any national socio-economic systems, therefore the agriculture should be built on the institutional principles of a system organization (Science, policy and politics of modern agricultural system, 2014). It can be argued that the national systems of food production and distribution, through their capacities of development, determine capacities of development for any national economic system, hence the main objective of national agri-food policy, on one hand, must be aimed to ensure the national food security, but, on the other hand, to provide the population with the food of the required quality, quantity and variety (Lawrence, Lyons, & Wallington, 2010). This explains the extension of the concept of "agro-food system" for analyzing the system of food production, distribution and consumption (Carolan, 2012).

According to the Organization for Economic Cooperation and Development (Global food security : challenges for the food and agricultural system, 2013), the agrifood system is the set of relationships and activities establishing methods of food production and distribution. In our opinion, this definition does not fully reflect the essence and the main goal of agrifood systems and doesn't clarify the uniqueness of evolving processes in agrifood systems comparative to other economic systems.

The essence of the agrifood system determines its unlikeness to other economic systems. Its social and humanitarian orientation and non-alternativeness should be called as the most important specific feature of the agrifood system. From the first distinctive feature of the agrifood system the second feature is originated:

any national and indegenous socio-economic system can develop only being based on an effectively functioning national or indegenous agrifood system. An efficiently functioning national agrifood system should be considered as the necessary condition for the development of the national economic system (Polbitsyn, 1928).

The main target of this paper is to analyze the agri-innovation system formation in indigenous ruralities to give policymakers the opportunity to carry out the most appropriate actions. The author argues that the more prominent national agriinnovation policy should be based on the development of the rural national identity as the basis for the national agri-innovative development. This approach should be rested on the support of indigenous rural areas. The difference in national identities plays significant role as the basis for rural innocative development because it serves as one of most important sources of innovation. Different nationally based approaches to agrifood system organization create the information basis for the development of the global agrifood system.

For this purpose, an overview is provided on the theoretical foundations outlined in economic literature. Specific emphasis is laid on the survey conducted among indigenous entrpreneurs in rural areas in Russia. The paper finishes with some conclusions and recommendations for agri-innovation system players.

2. Methodology

A comprehensive literature review, different factors and entrepreneurship intentions serves as the basis for the development of conceptual framework for this study. The purpose is to identify the most dominant factors effecting intention of indigenes towards entrepreneurship. The focus of the study is on Bashkirs, gauging their intention towards entrepreneurship.

Recoginzing the high dependence of the very existence of a national economic system, as an organization of society, on the uninterrupted food supply, there is an urgent need for any national government to play a direct role in providing the develpment of the national agrifood system and the unacceptability of the concept of non-interference of the state in the activities of economic entities (Marsden).

After the essence and specific qualities of the agrifood system were determined, elements of the agrifood system can be specified. The list of essential elements should include the population as a consumer of food and agrifood organizations that produce and distribute food. Given different types of agri-food organizations, all agrifood organizations are commercial, so they can be considered as a single element of the agrifood system, named agribusiness. The similar approach can be applied to self-regulating organizations and associations of agricultural producers. Despite the fact that, as a rule, the activities of such associations and associations are non-commercial, they are aimed to increase the commercial efficiency of the agribusnesses.

Lawrence, G., Lyons, K., & Wallington, T. (2010) presented the agrifood system as a relationship of four elements: the agro-technology sector, agricultural production, processing of agricultural products and food consumption. These four components link knowledge, production and consumption. Busch, L. (2007) proposed to consider the technologies of agricultural production, processing, organization and food consumption as agrifood chain.

The above described specific feature of the agrifood system is based on the dominant social orientation of the system and adds public administration to the number of mandatory elements of the agrifood system to observe the balance of social and economic priorities.

Based on revealed essence, specific qualities and elements of the agro-food system the problems of the functioning of the agro-food system a wide range of issues must be examined within the conceptual framework developed by the Organization for Economic Co-operation and Development (OECD).

Since the agrifood industries have specific properties and characteristics that distinguish them from the extractive and manufacturing industries, the form of organization of agrifood systems differs significantly from the forms of organization of other industries (Allen, P., 2008).

It can be argued that the formation and development of global and local civilizations took place on the basis of the prevailing mode of production and distribution of food. In the socio-economic systems that emerged within the framework of European civilization, the goal of an effective system for the production and distribution of food was achieved within the framework of several basic concepts of the organization of production and distribution of food. All the realized concepts can be divided into two groups: systems aimed at providing the physiological needs of the entire population living in the state and systems aimed to satisfy the consumers' demand for food.

Initially, the emerged national food security systems were aimed at preventing famine and, accordingly, the excesses caused by the hunger, so the main purpose of these systems was to ensure the provision of basic food to the population within physiological norms of consumption.

Historically national food supply systems consist of three main elements:

1. Agricultural producers;
2. National and local authorities;
3. The population.

Initially, until about the 19th century, when the majority of the population lived in rural areas and was engaged in agricultural production, the food supply systems were primarily directed to protect the population in crisis situations caused by both negative natural conditions and negative social events (wars, riots, etc.). In the state of predominantly local markets, agricultural producers carried out direct trade operations with end users, i.e. local population (Colbourne, 2017). The role of national authorities was limited to the collection of natural taxes, which allowed to form national reserves, and regulate prices and quality of the main types of agricultural products.

The most vivid indicator of the demonstration of the desire of any state to limit itself to satisfying the basic, physiological needs of the population in food and the inability of the state to provide the population with even basic foodstuffs was the implemention of food cards giving the right to residents of the country to receive a certain extremely limited diet.

To solve the problem of food security by creating national reserves and distributing food in accordance with physiological needs, the national authorities resorted to two main methods: compelling agricultural producers to transfer the ownership to the government, or compulsory selling at unprofitable prices for the agricultural producer of all or part of the grown produce.

For the Soviet Union, the task of providing basic foodstuffs to the population due to historical circumstances remained the most important national problem. Commitment to the command and administrative methods of its solution can be explained by their practical applicability within the framework of the Soviet state management mechanism and by the conformity with the general conceptual approach in the development of the national economy.

Summarizing the argument on the development of the national agrifood systems, it should be noted that the key issues in their development in the second half of the twentieth century was the industrialization of agrifood production and the creation of global trade networks, which led to the standardization of food on a global scale. The genesis of the transnational fast food industry, aggressively implanted by international trade and food chains, can be considered as a neoliberal theory of economic reform, boosted by an extremely aggressive business strategy, which became generally accepted in the second half of the twentieth century (Ritzer, 1996).

The agrarian revolution was the path to implement the civilizational, rational process of industrialization in the agrifood system. The active use of emerged technologies of land reclamation, irrigation and chemical improvement of land and chemical treatment and genetic variation of seed introduced industrial, streamlined new forms of agricultural production aiming to increase the yield.

The industrialization of agricultural production has revealed deep biological differences in products produced by the traditional "artisanal" method and products produced with the help of modern technologies. The consumer qualities of food prepared by traditional and industrialized methods are diametrically opposed.

Agriultural production based on crafted for centuries natural and biological processes can not be standardized and organized as a flow, conveyor production. As a result, capitalist investors are trying to replace natural food production with artificial methods, which, in their opinion, allow them to reduce risks and increase the profitability of investments. This led to a wide use of substitute food, food with a sharply limited set of useful properties.

The industrialization and capitalization of agricultural production can be considered as the consequence to the development of bank lending. The availability of bank loans to agricultural producers, on the one hand, led to the increase of potential investors attractiveness to agricultural production and processing, on the other hand, led investors to adjust the agrarian technologies to the bank requirements of lending, and first of all, the requirements of mandatory and urgent loan payments. Agricultural production, being dependent on natural and climatic conditions, can not be unconditionally inscribed in the system of bank lending, which led potential investors to the need to transform agricultural production and agricultural technologies to the conditions for providing banking services, namely standardization of finished products. The greatest "progress" in the process of industrialization of agricultural production was achieved in poultry farming and processing of agricultural products.

The development of globalization processes in the agrifood system made evident that global, national and local trade networks claiming to develop standards and norms for the food production and designed to ensure the technological effectiveness can not adequately reflect the current processes of the agrifood systems development, production and processing of agricultural products required by popultaion. Even poultry farming, considered to be a highly integrated industry, practically breaks down into poultry farming, focused on the production of deep-frozen products and the production of chilled “home-made” poultry, which can be attributed to quality goods.

A distinctive feature of any national agrifood system is the use of protectionism as the part of the national policy, to a greater or lesser extent, in one form or another, in order to improve the country's food security. The task of ensuring the national food security, as a rule, is solved by methods of economic protection of local producers, which leads to extremely complicated forms of support for national agricultural producers and protection of national food markets. Among local producers, who needs protection from the national government indigenous entrepreneurs must be named. Entrepreneurship is seen as a “major resource ofr the economic development of indigenous people (Croce, 2017).

At the same time, many important issues related to public health, food safety, environmental safety remain under the responsibility of private enterprises, which operate on their own rules with the goal of making a profit. The introduction of private standards leads to a decrease in public efficiency and, ultimately, to a decrease in the level of food security of the country.

Traditional agrifood policy is focused on ensuring the country's food security. Rural entrepreneurs tend to follow the tradional police and “rely mainly on the internal market” (Pato & Teixeira, 2018). The principle of food security, which is treated too narrowly as satisfaction of the physiological needs of the population for food, determines the functioning of the agrifood system. Agriinnovation policy implies a more holistic approach to providing the population with food, based on the priority to ensure the changing and increasing individual needs of the population for food. Agroinnovational policy should be considered as an evolutionary development of agri-food policy that meets the requirements of innovative development of the national economy.

The active participation of the national government in the formation of institutional conditions for the development of an agrifood system based on knowledge is the basic condition for achieving national food security. Thus, a higher degree of organization of food provision for the population is achieved. One of the most striking manifestations of such an organization is the creation of regional and local agriinnovation systems, formed within the framework of a new network model of knowledge development (Dana & Anderson, 2011).

In the modern world, rural entreprenurship is becoming important for increasing the competitiveness and sustainable growth of national economies (Newbery, Siwale, & Henley, 2017). Countries that implement their agrifood policy towards the development of the knowledge economy demonstrate their effectiveness and high level of food security (Brouwer, 1999).

The emergence of a state agriinnovation policy capable of blooming an innovative approach to providing the population with food and rural development is one of the most difficult but important challenges for Russia today. If the traditional agrifood policy for Russia is oriented towards the introduction of new agro-technologies, and to a lesser extent to the creation of new organizational forms for their implementation, then the agriinnovation policy assumes a more holistic approach and focuses both on the creation and practical use of knowledge both of technologies and organization.

The complexity of elaborating and implementing agroinnovational policies is explained not only by the need for qualitative changes in the public consciousness, but also by the need to involve a large number of social, economic and spatial institutions and resources in order to integrate the capabilities of science, business and education (Muller & Korsgaard, 2018).

Although there is a growing interest among researchers in rural entrepreneurship (Gretzinger, Fietze, Brem, & Ogbonna, 2018), only few authors raise the problem of indigenous entrepreneurship (Burnett & Danson, 2017). One of the sounded significant problems is the problem of competition between established business systems and indigenous entrepreneurs (Cahn, 2008).

Rural entrepreneurship is constrained by a number of factors that can not only reduce the innovation activity of enterprises, but also negatively affect the rural social and economic development as a whole (Harpa, 2017). Our research presents a framework for the influence of the rural area indigenes on regional agrifood system innovative development and is based on socioeconomic and structural forces engaged in developing innovations in agrifood organizations (Peredo & Anderson, 2006).

Typologically factors were divided into two groups: external and inner factors. For our research, the following factors were chosen:

F1. Support of indigenes from local administration. Local and regional administrations are awaited to clearly pronounce their position on support of indegenous rural areas (Castelnovo, 2009);

F2. Necessity of marketing information on indigenous production. Rural indigenous entrepreneurs often do not have access to reliable market information on national food. Imperfections of existing rural information infrastructure restrain the flow of information, extremely necessary for entrepreneurs (Morrison, Murray, & Ngidang, 2006);

F3. Neccesity for dissemination of information on specific features of indigenous rural areas development (Maguirre, Portales, & Bellido, 2018);

F4. Necessity for the special education programs on indigenous entrepreneurship (Torri & Herrmann, 2011);

F5. Difficulties in international interaction of indegenes (Muller & Korsgaard, 2018).

The questionnaire for the survey was designed as a combination of Likert Scale directing from “strongly disagree” – 1, to “strongly agree” – 5, and one sample mean comparison test was found as the most useful method in this kind of research in literature. The questionnaires were distributed in different entrepreneurial companies working in rural indigenous areas of the Urals region in Russia. A simple random sample of 30 respondents was generated. The study was conducted according to the principles of the Oslo Manual.

Individual ratings were treated as continuous data (Harpe, 2015). The observed data was analyzed by applying Stata 11 classical tests of hypotheses. One-sample mean comparison test for the 2017 data gave the following results (Table 1). The confidence intervals are sufficiently narrow to take the sample means for the population means.

3. Research results and discussion

Based on the conducted surveys, several conclusions were made, explaining the problems of innovative development of entrepreneurial entities in rural areas. The survey results are presented graphically on Figure 1.

Table 1: One-sample mean comparison test results

Variable	Obs	Mean	Std. Err.	Std. Dev.	[95% Conf. Interval]	
Support of indigenes from local administration	30	3.5	.1841414	1.008584	3.123389	3.876611
Necessity of marketing information on indigenous production	30	3.566667	.189878	1.040004	3.178323	3.955011
Neccesity for dissemination	30	3.233333	.1329016	.727932	2.961519	3.505148
Necessity for the special education programs	30	2.766667	.1491997	.8172002	2.461519	3.071814
Difficulties in international interaction of indegenes	30	2.533333	.1244143	.6814454	2.278877	2.787789

The research was conducted during special session for representatives of Bashkir people in the Ural Federal University, Russia. The Bashkirs are one of small indigeneos Turkic people of Ural region in Russia. According to the official Russian census office Goskomstat they count less then 1% of the regional population. They stand on the strong position of preserving their national culture.

The dynamics of the factor “Difficulties in international interaction” is the most interesting. It was supposed to be one of the main hurdles, but interviewers marked as inessential. In oral conversations, the respondents determined the reason for the downgrading this factor by saying that the idea of innovative development of indegenous rural areas is recognisible and supported by many Bashkirs and in persuit of national identity there is no need to take into account achievements of other nations.

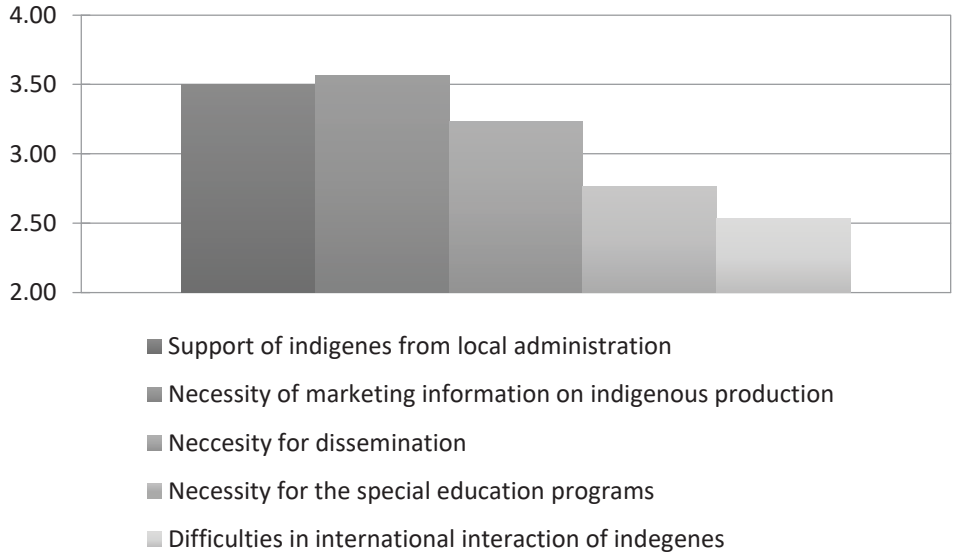

Figure 1: Factors restraining the innovative development of Bashkir rural areas in Russia

The factor “Necessity of marketing information” is valued by respondents as a significant factor. However, its content has undergone significant changes from the statements “hard to find the right information in our

backwoods" to an understanding of the necessity to create an information service. The urgency of the lack of information is determined by rural entrepreneurs as the lack of an information system to request and search for the necessary information. As a result, a number of respondents identified the actual problem as the lack of accessible qualified specialists in the information databases, rather than in information technologies. Cooperation with research organizations having experience in information management was suggested as an alternative solution, but the majority of respondents rejected this possibility, appealing to the need to preserve the confidentiality of information.

When respondents were questioned on "special education progrms" in their indigenous rural areas, they demonstrated a lack of understanding of the need to teach them not only national customs and traditions but also basic entrepreneurial skills.

The information dissemination factor, which should be seen as internal, intersects with the lack of marketing information about potential demand. The increase in value of this factor was supplemented with verbal comments from respondents about the dissatisfaction with the capacity of accessible information chanels. Until now, the inability to conduct high-quality market research, to determine the clear picture of the existing demand for produced goods and also the demand trends on target markets, remains a weakness of Russian marketing specialists. This leads to their incompetence to accurately focus the target audience, and, consequently, this increases advertising costs for enterprises.

Almost all respondents pointed out the lack of support from local and regional administrations, but respondents were requesting this support mainly in the form of subsidies. Most of repondents had no information and were not seeking information on federal and regional programs for national rural areas and entrepreneurship support.

4. Conclusions, proposals, recommendations

The research indicated that indegenous entrepreneurs in Russia view entrepreneruial activity not only as one of many methods for breadwinning but also the way to state their national identity, and therefore their attitude to innovations is based on the perception of innovation as one of conventional forms to sound their national exclusiveness.

The long-established perception of innovation, as it was exposed in the research, is based on a rigid division of the internal and external environment of the enterprises. Indegenous entrepreneurs believe that innovation activity, based solely on internal resources, primarily intellectual, can occur within any enterprise. That is why the interviewed entrepreneurs noted that their employees adequately perceive innovations but have no required qualifications for its' implementation. On the basis of this assumption, it was concluded by respondents that it is necessary to attract qualified employees, meanwhile they do not raise question how appropriate the existing organizational model of the enterprise is for innovative activities.

According to the position of rural indigenous entrepreneurs in Russia, disclosed in the survey, innovative activities at rural entrepreneurial companies are trusted by them to be based on the same principles as any other type of trade activities: the means of innovations are owned by economic entities and results of innovative activities are entirely owned by entrepreneurs. For any common, routine trade activity, the means of production are believed to be fixed assets, mostly material assets, and the right of disposition is possessed by business owners only. However, the main resource for innovative activities is the potential to generate innovations, knowledge and skills of researchers and developers, and entrepreneurs do not have the right to own it.

This attitude of indigenous entrepreneurs to the main resource of innovation as to a resource that should be in their ownership or disposal completely was formed in the twentieth century, and now it suits no longer neither possessors of innovation knowledge and competences nor entrepreneurs willing to implement it. For entrepreneurs, long-term hiring of highly qualified innovators becomes financially burdensome, for qualified innovators a long-term contract with one enterprise, full of bans on professional activity outside the enterprise, is fraught with a loss of innovative skills and, as a consequence, a decrease in qualification as an innovator.

To result the conducted research, it is necessary to acknowledge that hurdles are appearing on all steps of innovative activities of rural indigenous entrepreneurs. Any single entrepreneur is not able to possess all necessary resources to progress in innovative activities to gain effectiveness and provide social development of indigenous rural areas. The main role in developing innovative activities of rural indigenous entrepreneurs to surmount obstacles and overcome difficulties must be played by regional and local authorities. Regional and local authorities must play their important role in supporting rural indegenous entrepreneurs by developing information infrastructure with open access to marketing and technological information. This information will be the most useful resource for rural indigenous entrepreneurs to overcome difficulties and barriers.

Creating the First Entrepreneurial Law Course

David Postolski and Thomas Schmidt
Montclair State University, New Jersey, USA
david@gearhartlaw.com
tms493@nyu.edu

Abstract: It is well-known in the literature that most entrepreneurs fail to build a sustainable business, most of the time. Serial entrepreneurs are no more likely to succeed than new entrants to the field. This is the nature of the field, and a wide body of literature is focused on reducing the failure rate, ranging from Drucker to Christensen to Ries. Once past the initial causes of failure, however, the growing business faces challenges more exogenous than endogenous; in every country we have studied, legal standards and ethical norms become the foremost barrier to success. We discuss the research and practical challenges involved in creating what we observe to be the first course on entrepreneurial law in the United States and provide suggestions for programs seeking to include a formal course in the field.

Keywords: Entrepreneurship, Ethics, Law, Disruption, Entrepreneurial Law, Women and Entrepreneurship, Entrepreneurship Curriculum Development

1. Introduction

Entrepreneurship is the transformation of an innovation into a sustainable enterprise that generates value. An entrepreneur provides a new product or service or that develops and uses new methods to produce or deliver existing goods and services at a lower cost. Entrepreneurs take risks to develop a novel, sustainable enterprise—a new or improved organization that benefits the economy and society. Entrepreneurship can involve invention, creativity, and management, starting a small business, or becoming self-employed.

Entrepreneurship entails the commercialization of an innovation. New ideas, products, or organizational schemes matter little until they achieve market acceptance and traction. The market validates utility and need along with excellence. This ultimately means that the market also invalidates new ideas and the judgement that the idea is not good. The entrepreneur's risk, therefore, is as much a gamble as it is an informed calculation about the viability of the new enterprise in the market and about its capacity to meet a demand or need of others, though entrepreneurs are calculating not the odds of known risks, but reasoning under uncertainty.

Entrepreneurship is prevalent in many fields but is studied most thoroughly in commerce; intimately tied to science, entrepreneurship is another search through an uncertain space to uncover true knowledge about the state of reality, reflected in entrepreneurial profit. Business and commerce are deeply rooted in constitutional societies. Cultural and social values and economic policies and behaviors shape and validate one another. For entrepreneurship to be a mainstream and routine business practice, it must reflect its society's view of how the world should work and how human beings should behave. Social attitudes, political practices, economic policies, and the legal system must support creativity, risk-taking, and the implementation of new enterprises.

Innovators, scientists and entrepreneurs must feel safe to share their commercial ideas in exchange for protective rights such as Intellectual Property. Entrepreneurship cannot thrive if the society's values undermine it.

Entrepreneurship is a process of fundamental transformation: from innovative idea to enterprise and from enterprise to value. In America, our founders valued the innovation process by embedding notions and precursors to patent, trademark and copyright law in our constitution. It was these notions that propelled innovators and entrepreneurs to share their ideas and partake in the industrial revolution in America. In exchange for sharing one's ideas, America bestowed its entrepreneurial citizens with federal protection for original and improved intellectual property that benefited technology, culture, and commerce.

Entrepreneurship requires knowledge, imagination, perception, practicality, persistence, and attention to others. Entrepreneurship is a self-transcending activity that—through responsiveness to the market—integrates the entrepreneur with society. Entrepreneurship is an exercise in social responsibility. Impressing or pushing forward innovation, improvement, and its implementation addresses a society's needs and wants, and

propels that society forward. Entrepreneurship is the unique process that, by fusing innovation and implementation, allows individuals to bring new ideas into being for the benefit of themselves, others and society at large. It is the essence of freedom of expression and of a society.

2. Why Entrepreneurship Belongs in a Learning Curriculum

Entrepreneurship is critical to understanding and succeeding in the contemporary global economy. Entrepreneurship is already an expanding area of American interdisciplinary learning. Entrepreneurship has become a basic part of what universities and schools teach. Finally, entrepreneurship meets many of the goals of a quality undergraduate and graduate education. To neglect entrepreneurship or relegate it to the educational sidelines makes learning orthogonal to the world it is supposed to help students learn to understand.

Entrepreneurship has long been overlooked as a topic of economic study, but is now recognized as a major generator of wealth and job creation in the economy. The continual creation of new enterprises is a fundamental reason for the economic growth and technological innovation of economies, particularly the American economy. Entrepreneurship is the core of growth for a free society, from an economic and cultural perspective. Showing students how American politics, law, culture, and economics actually interact in the innovation process is a stimulating way for students to achieve a realistically comprehensive picture of the concrete machinery of their own economy and society, and to extend those insights to others.

Entrepreneurship has been a standard component of the curricula of business schools but it is now emerging as its own discrete area of study which has interest, overlap, and applicability to many core curriculum subjects. The science, technology, engineering, arts and mathematics is a prime example of where the concepts of entrepreneurship have profound overlap and open the minds of students to possibilities not originally thought of. Entrepreneurship is one of the fastest-growing subjects in today's undergraduate curriculums. In the past three decades, formal programs (majors, minors and certificates) in entrepreneurship have more than quadrupled, from 104 in 1975 to more than 500 in 2006. Entrepreneurship is ideal for general education because it is a practice that applies to many fields and because it provides a revealing lens for studying how cultural values, social institutions and ethics, economic policies, and legal practices correlate to shape human behavior.

This trend is self-evident, given universities themselves are agents of entrepreneurship. Through offices of "technology transfer," schools encourage and enable their faculty to create ventures that transform their research into products for the market. Now a university's students can begin to participate in this activity.

Research universities are an important source of innovation and the creation of new products and processes that become the foundation of new forms and enterprises. For universities to advocate entrepreneurship as a core activity for faculty and then fail to teach or involve their students disconnects the school's entrepreneurial mission from its innovation practice.

To further support the desire to create an entrepreneurial course or program it should be noted that entrepreneurship fulfills many of the established goals of a high-quality education. Entrepreneurship is not an isolated activity; it is the epitome of teamwork and cooperation. It is rooted in a society's regulatory and ethical constructs. Businesses do not exist in vacuums. In fact, they are integrated and interlock with law, economics, politics, finance, and cultural and societal values and behaviors. Entrepreneurialism focuses on the practical and pragmatic and can hone the ambition and talent of people into concrete and tangible projects.

Because of its practical focus, entrepreneurship's greatest teachers are its innovators and practitioners. Studying theory but also examining how the creators of new enterprises, firms, products, and services is a critical component of the curriculum. Entrepreneurship naturally and authentically draws together subjects usually taught and studied separately. It is by definition inter- and cross-disciplinary. For example, much of entrepreneurship depends on the legal concept of "intellectual property," the notion that ideas, once physically embodied, can be "owned" such that the owner can control the use and practice of that idea. This concept of ownership of property is directly related to the privacy and autonomy of an individual, and that our ideas come from within us and therefore belong to us as our property. The entrepreneurial lens illustrates how theory, philosophy, and sometimes theology constructs become real, practical, and affect everyday life—

in short, how values matter. In doing so, a course in entrepreneurship can fulfill business practice theory but also touch on the proprietary rights of individuals of their self's and their ideas. Such conversations spark ethical, moral and regulatory debates in light of emerging technologies.

3. Basics of entrepreneurship:

A major factor for entrepreneurial success is interest. This can stem from personal interest, solving other's recognized problems, or addressing a society's problem. It's this interest that fuels an entrepreneur's energy and passion in devoting time to the initiative at hand. It's this energy and passion that allows an entrepreneur to maintain a high level of work ethic. This interest must also translate into a vision for the resulting company's growth and expansion or at the very least achieving market traction, market acceptance, and if applicable, making a social impact. An entrepreneur must be able to wear many hats and do so effectively. For instance, if he wants to start a business that creates mobile games, he should have specialized knowledge in mobile technology, the gaming industry, game design, mobile app marketing or programming or create a team that does. In today's educational environment, a student's interest in a particular subject often dictates his or her success.

Similar to students investing in their own educational journey, an entrepreneur must invest in her interest and resulting company, from a financial aspect to hours worked which is sometimes referred to as sweat equity. This investment may be something less tangible, such as the time she spends or the skills or reputation she brings with her, but it also tends to involve a significant investment of assets with a clear value, whether they be cash, real estate, or intellectual property. An entrepreneur who will not or cannot invest in her company cannot expect others to do so and cannot expect it to succeed.

While many new businesses start as a one-man show, successful entrepreneurship is characterized by quick and stable growth. This means hiring other people to do specialized jobs. For this reason, entrepreneurship requires extensive organization and delegation of tasks, also similar traits to a typical student in an educational environment: juggling classes, workloads, friends and personal life and responsibilities is a mirror to the organized nature of an entrepreneur and student. It is important for entrepreneurs to pay close attention to everything that goes on in their companies, but if they want their companies to succeed, they must learn to hire the right people for the right jobs and let them do their jobs with minimal interference from management.

Entrepreneurship also requires risk, i.e. the operating under uncertainty and the need for courage to stand up to any risks. The measurement of this risk equates to the amount of time and money one invests into one's business. However, this risk also tends to relate directly to the rewards involved. Students who can appreciate and practice innovation, delegation, organization, team building, and risk assessment and appreciation, can only benefit from simulating the entrepreneurial journey in a classroom setting.

4. Emerging Technology, Responsible Innovation and Design Thinking and Entrepreneurship

Emerging technologies typically fall into the educational and regulatory institutional void. There are few regulatory structures or rules that govern them. There are few academic environments that are teaching about them. Emerging technologies straddle the ethical/moral line in a society's practice and use of the technology and the need for regulatory structure is often addressed too late once the emerging technology has taken hold of a society. Many of the emerging technologies in the world today are entrepreneurial-derived, generated and focused. According to this year's World Economic Forum top ten emerging technologies are:

- Brain-computer interfaces
- Mining metals from desalination brine
- Nanostructured carbon composites
- Grid-scale electricity storage
- Body-adapted wearable electronics
- Nanowire lithium-ion batteries
- Screen-less display
- Human microbiome therapeutics
- RNA-based therapeutics
- Quantified Self (Predictive analytics)

Many of these emerging technologies fall into the unregulated institutional void and thus it is incumbent on students, teachers, and entrepreneurs to be responsible researchers and innovators, i.e. wherein societal actors and innovators become mutually responsive to each other with a view to the (ethical) acceptability, sustainability and societal desirability of the innovation process and its marketable products. This would lead to a proper embedding of scientific and technological advances in our society. The student entrepreneur can work to further address the ethical and regulatory issues surrounding these and other emerging technologies by innovating in these fields from a responsible innovator approach.

Such questions to ask include:

Product questions	Process questions	Purpose questions
How will the risks and benefits be distributed?	How should standards be drawn up and applied?	Why are researchers doing it?
What other impacts can we anticipate?	How should risks and benefits be defined and measured?	Are these motivations transparent and in the public interest?
How might these change in the future?	Who is in control?	Who will benefit?
What don't we know about?	Who is taking part?	What are they going to gain?
What might we never know about?	Who will take responsibility if things go wrong?	What are the alternatives?
	How do we know we are right?	

Figure 1: Lines of questioning on responsible innovation.

To achieve a responsible innovation to an emerging technology, the entrepreneur can implement the five phases of Design Thinking:

- Empathize – with users
- Define –a users' needs, their problem, and their insights
- Ideate – by challenging assumptions and creating ideas for innovative solutions
- Prototype – to start creating solutions
- Test – solutions

Similarly, the 17 Sustainable Development goals of the United Nations were created specifically to address the need for responsible innovators to solve societal problems as a vehicle for entrepreneurship. Inspiring, creating or inspiring an entrepreneurial student to responsibly innovate a solution to a United Nations goal requires a plan of action for people, planet and prosperity ripe for academic curriculum. Eradicating poverty in all its forms and dimensions, including extreme poverty, is the greatest global challenge and an indispensable requirement for sustainable development. The ability of a student entrepreneur to innovate an entrepreneurial product or service to address or possibly solve, for example, poverty is a mission a student entrepreneur can get behind. The involvement of corporations in providing financial incentives to entrepreneurial solutions and products to address these goals also provides an additional incentivize to the student entrepreneur. The 17 Sustainable Development Goals are an excellent basis for creating the reason, the purpose, and the goals for a first entrepreneurial course. The goals and targets are in areas of critical importance for humanity and the planet and who better than entrepreneurs to solve these problems. The interdisciplinary nature of responsibly innovating and design thinking an entrepreneurial solution to an emerging technology that can solve one of the United Nation's 17 Sustainable Development Goals should be a crucial part of the work of a first entrepreneurial course.

5. Implementing the First Entrepreneurial Law Course

A first entrepreneurial law course must teach entrepreneurial culture and mindset. The academic institution must foster an entrepreneurial community and ecosystem. The academic institution should seek to work with community partners who can aid and assist in making porotypes and develop programs so that student's ideas go from paper to reality, perhaps the purchase of a 3d printer if one doesn't already exist. Curriculum should touch on present shocks to the commercial world that spark ethical and moral debates due to the lack of regulation such as 3-d printing, gig economy, sharing economy, cryptocurrency, and nanotechnology. The academic institution should promote the education of intellectual property of a student entrepreneur's ideas. Discussion of other regulatory schemes such as founder agreements between students who work together as

well as the need for a corporate entity should be discussed. Market Research and financial considerations during the entrepreneurial journey should be discussed as should the need for investment in student entrepreneurial projects whether they are based in a real life venture or a fantasy setting. The entrepreneurial course must address some of the legal pitfalls that haunt a venture. Some include the understanding of the regulatory tax implications facing small businesses, understanding the business structure that is best suited for one's business, the need for legally binding contracts and the definitions and implications between full time, part time, and casual employees, freelancers, and consultants, and intellectual property issues.

Finally, an academic institution should prepare itself for the desire of a student entrepreneur to have their solutions incubated and accelerated to a full fledge self-sustaining business or a candidate for the academic institutions technology transfer office. Creating a community that can hold follow on activities such as pitch and public speaking competitions where interested community and service partners at the state, local and federal level. Creating a first entrepreneurial course is a labor love, a term often used by entrepreneurs to describe their own ventures. From an educational standpoint, the course can enhance an existing curriculum and influence a student's current course of study in many interdisciplinary ways. Student entrepreneurs who can work to solve world problems is an added benefit that is still unmeasured.

The course would provide students a basic understanding of the legal and ethical issues facing startup and emerging businesses. The course is geared toward the non-legal student who have no background in law. The course will examine the legal and ethical issues and problems faced by entrepreneurs in their journey, specifically from conception of an idea, to the creation and operations of a company, to the launch of a product or service and finally to the sale of the company or investment by venture capitalists and everything in between. Topics include the legal, ethical and regulatory frameworks of the four main elements of Intellectual Property (Trade Secrets, Patents, Trademarks, and Copyright), business and corporate issues, operations and personnel, employee, interns and consultant work force, digital marketing, branding, social media and domain names, and raising capital through traditional and alternative methods.

The course would involve lectures, guest lectures, group projects, individual projects, case studies and problem sets. The course support entrepreneurship goals such as: demonstrating an understanding of the entrepreneurial process, understanding the basic elements of Intellectual Property and protecting your Idea/Concept, understanding the Regulatory and Legal Structure of the United States and International Jurisdictions; understanding the basic requirements of Corporate Structure, understanding the basic elements of Agreements between Founders, Investors, Key Employees and Contractors, learning when to get a lawyer involved and understanding the ethical decisions one must face when launching a new venture. The course will explore lean startup concepts for the creation of a new venture, conducting a customer discovery campaign, understanding and analyzing the options for new venture financing, using financial statements to analyze the financial performance of a new or existing venture, developing a marketing campaign for a new venture, and pitching a venture idea to potential funding sources.

1. Introduction to Regulations and Ethics (1 class session)

U.S. and International System of Regulations

What is Intellectual Property?

2. Trade Secret or Patent (2 class sessions)

Types of Patents

Patent Searching

Global Perspectives

3. Trademarks (2 class session)

What Makes a Great Brand?
Trademark Searching
Global Perspectives

4. Copyrights (1 class session)

Inspiration or Infringement?
Global perspective

5. Corporate Structure (1 class session)

Types of Entities?
Founder Agreements, Operating Agreements, By Laws, International Perspectives

6. Building your Team (1 class session)

Employees, Independent Contractors, Consultants, Interns

7. Key Agreements (1 class session)

Non-Disclosure and Non-Compete Agreements, Licenses

8. Raising Capital and Valuation (1 class session)

Crowdfunding
Investors- Angels, VC's

9. Internet or Brick or Mortar (1 class sessions)

Terms and Conditions, Privacy Policy
Insurance
Is a Domain Name a Trademark?

10. Raising Capital (1 class session)

Crowdfunding
Investors- Angels, VC's

11. Go to Market (1 class session)

Social Media, Privacy
Other U.S. and International Perspectives, Regulatory Frameworks- FDA, Consumer Product Safety Commission

12. Ethics v. Legal (2 class session)

3d Printing, Uber, Airbnb, VW, Bitcoin, and other Present Shock Hot Topics

Complex Models Supporting Innovation Processes

Beata Poteralska
Institute for Sustainable Technologies – National Research Institute, Poland
Beata.Poteralska@itee.radom.pl

Abstract: The effective development of innovations requires efficient management at all stages of the innovation process, including generation, development and implementation of innovations. Among the methodologies that effectively support these processes, it is necessary to indicate the following tools: future research, with particular emphasis on foresight, as well as technology assessment and executive capacity assessment. State-of-the-art analyses and the author's practical experience resulting from execution of innovative projects have demonstrated usefulness of individual applications of the indicated tools for the purposes of supporting innovation processes. They also allowed for identification of areas of potential mutual complementarity of tools in question. Recognising legitimacy of a fully integrated use of selected tools to support innovation processes, the author has conducted in-depth literature studies aimed at identifying theoretical models and practical examples of the combined application of the indicated tools. The analysis showed that the joint use of tools, i.e. foresight, technology assessment, and executive capacity assessment in R&D organisations aimed at support for the processes of generation, development, and implementation of innovations is the subject of few scientific analyses and only a limited number of practical applications. Their majority comprise joint use of two out of three analysed tools, which is usually future research and technology assessment. The article presents examples in this area, including attempts to develop specialised models and propose approaches to the joint application of selected tools and practical examples of the joint use of selected tools. The author indicates possible areas of the integrated use of the indicated triad of tools, both at the macro level concerning the economy and at the micro level, in relation to entities participating in the innovation processes, including mainly R&D organisations. Against this background, the author proposes development of an original methodology of supporting processes of generation and realisation of technological innovations. The methodology is based on the application of a triad of tools in an integrated and comprehensive manner.

Keywords: triad of tools: foresight, technology assessment and executive capacity assessment, complex models supporting innovation processes, methodology of supporting processes of generation and realisation of technological innovations.

1. Introduction

Effective development of innovation requires efficient management at the stages of generating, realising and implementing of innovation, including identification and overcoming of barriers and challenges as part of innovation processes (Mazurkiewicz, Poteralska, 2015; Mazurkiewicz, 2017). The author's area of research interest encompasses support for management of processes of generation, realisation and implementation of technological innovations in R&D organisations. Tools effectively supporting these processes include future research, mainly foresight, technology assessment, and executive capacity assessment.

Development of models of preparing and implementing innovation from linear to interactive (Rothwell 1994; Kotesmir, Meissner 2013) enforces a new systemic approach to application of these tools (Könnölä et al., 1994). Changes in foresight studies and development of research methods in this field are also consequences of global changes in recent decades involving economic, social, cultural, and other aspects (Krawczyk, Slaughter, 2010). Some authors (Hines, 2002) point out that, despite the unquestioned need for raising standards of innovation, tools employed as part of foresight undertakings remain largely traditional and require changes. The methods in place are insufficiently effective. New methods and new approaches need to be sought (Rohrbeck, 2012). The same applies to the approach to technology assessment developed since as early as 1960s, where new methods and models of technology assessment continue to be developed and their applicability to a variety of contexts is analysed (Ely et al, 2011; Bütschi 2014). With regard to executive capacity assessment of organisations, in turn, the most extensive set of methods applies to enterprises while procedures for executive capacity assessment of research organisations are available as well (Jakuszewicz, 2015). The need must be emphasised, however, for developing methods of R&D organisations' executive capacity assessment applicable in reference to innovation process support. Moreover, it is necessary to develop these methods in conjunction with methods of foresight and technology assessment.

Although realisation of foresight projects helps to generate forward-looking directions of technological, economic or social development, decision-makers usually need information about existing executive capacity that lays foundations for developing new opportunities and realisation of the forward-looking directions (Salo, Cuhls, 2003). Mobilisation of executive capacity is necessary for the purposes of foresight and implementation

of its results as technological innovations (Keenan et al, 2002; McDowall, Eames, 2006; Georghiou 2008). Selection of forward-looking technological solutions is carried out in consideration of the available executive capacity and based on results of assessments of innovative solutions that have already been developed and become a source of research problems addressed. Next, innovations being developed are assessed at successive stages of work, also in combination with analysis of required and available capacity, followed by analysis of practical applicability of solutions developed using results of technology assessment and executive capacity assessment. In view of the mutual complementarity and potential for complex application of indicated tools, it is reasonable to use them as a triad including: foresight, technology assessment and executive capacity assessment at the time of generating, realising and implementing innovative solutions. The author's literature reviews, case studies, and direct experience (Mazurkiewicz et al., 2013; Poteralska, Sacio-Szymańska, 2014; Sacio-Szymańska et al., 2015; Mazurkiewicz et al, 2015; Poteralska, 2017) in connection with realisation and particularly management of research projects confirm such an approach as reasonable.

2. Analysis of state of the art in complex models supporting generation, realisation, and implementation of technological innovations

Experience shows foresight, technology assessment and executive capacity assessment activities undertaken by scientific communities in a range of countries are commonly independent one from another (Loveridge, 1996), although these areas of innovative activities are interrelated. On the other hand, industrial organisations have the practical ability of combining individual tools in order to select technological solutions of a potentially high significance, both commercial and social (Kuhlmann, 2002). In enterprises, actions for idea generation, assessment of solutions developed, and utilisation of the potential in place are frequently integrated (Loveridge, 1996) and the need for their interlinking is understood.

Combining the tools in the triad: foresight, technology assessment, and executive capacity assessment by R&D organisations to support the processes of generating and realising innovation is the subject of few scientific analyses, with scarce instances of combining such tools in practice.

There are theoretical analyses concerning potential and reasons for combining the tools in question, attempts are also made to develop specialist models. Loveridge's model (1996) or proposed solutions combining foresight and another tool, i.e. technology assessment or executive capacity assessment to support generation and realisation of innovation, e.g. by Kameoka et al. (2004), Porter (1995), Rip (2002) and Kuhlmann et al. (2002a), are some of the instances.

Loveridge's model (1996) assumes presence of links between two out of three tools constituting the triad, namely, foresight and technology assessment. Foresight is the tool helping to project possible visions of the future. The models of future generated are then subject to assessments of technological capacity. The need to address two streams of technology assessment is stressed as part of the model: in the public domain, oriented towards extensive and general issues of technological policy, and in the industry, aimed at practical technology applications.

Kameoka et al. (2004), following analyses of projects undertaken in Japan, have suggested linking the methods of foresight and technology assessment. In Japan, foresight and technology assessment projects have traditionally been carried out on a separate basis. The so-called DSW: Delphi-scenario writing has been employed as part of foresight projects since 1977 to develop innovation development strategy, an integrated approach to scenario building. The method of technology assessment has in turn been used since early 1970s in a number of areas related to both advanced technologies and social phenomena. As social and economic issues increasingly need to be addressed as part of foresight undertakings, Kameoka et al. (2004) have proposed, based on analysis of case studies concerning foresight and technology assessment projects, it would be reasonable to prepare a new methodology to integrate the approaches utilised in the case studies they had analysed. They pointed out forward-looking technology analyses involved, inter alia, forecasting, foresight, technology roadmapping, and technology assessment, while these approaches should be integrated to more fully understand emerging technologies and address their significance for society.

The possibility of combining foresight and technology assessment is also emphasised by Porter (1995). He states a systemic approach to technology management is ultimately applied to technology assessment as it addresses not only technological and industrial but also social and environmental aspects. Technology

assessment relates to evaluating effects, consequences and risks inherent in technology applications while also playing foresight functions of projecting opportunities and potential for developing technological solutions as parts of strategic planning. Close integration of technology assessment, technology monitoring and forecasting is indicated. Porter also points to shifts in the idea of technology assessment that bring it closer to foresight actions suited to the nature and requirements of individual users.

The need to integrate foresight and technology assessment actions is underlined by Kuhlmann (2002a) as well. The integration is of particular use where utilisation of results of these undertakings is expected to support strategic actions including analysis of market expectations and user requirements. Kuhlmann (2002) proposes a novel approach he refers to as 'distributed intelligence', which envisages development of tools that can be employed, in a variety of combinations, to support the decision-making process. He cites foresight and technology assessment among the best known and most commonly used tools. They need to be employed more effectively and new approaches need to be explored, including some that could serve to aid the decision-making process. He goes on to stress there is no single best approach to combining tools. They should be selected on an individual basis depending on objectives and scope of the decision-making process.

Rip (2002) refers to earlier studies by Kuhlmann at al. (1999), among others, which imply the potential has been recognised for linking e.g. foresight and technology assessment which can be taken advantage of owing to the distributed intelligence. Rip (2002) points out, however, foresight (particularly with reference to application of the Delphi method) falls short of requirements as far as a broader inclusion of economic and social aspects is concerned. He believes technology assessment can be utilised to this end. In case of technology assessments covering new technologies like nanotechnology or genomics, additional application of foresight is reasonable. In the circumstances, assessments of technologies at early stages of development, including new products or services, must address scenarios of socio-technical development for results to be of real value to technology developers, for example.

These literature reviews concerning integration of foresight, technology assessment and executive capacity assessment detect examples of projects where the importance of executive capacity is highlighted. The need to address the capacity in foresight undertakings is due to the fact that, although foresight helps to indicate forward-looking directions of technological, economic or social development, decision-makers also need information on existing executive capacity that provides the foundation for developing new potential and realisation of specific futuristic directions (Salo, Cuhls, 2003). Foresight publications suggest mobilisation of organisation resources is a pre-requisite of foresight projects and implementation of their results (Keenan, 2002; McDowall, Eames, 2006; Georghiou et al., 2008). Aside from designation of forward-looking technological solutions, the possibility of their practical and effective development and use in an organisation are of importance as well. To this end, it is necessary to assess executive capacity of an organisation. SWOT analysis is the method of executive capacity assessment most commonly employed as part of foresight undertakings at national, regional, sectoral (Popper, 2008), as well as corporate levels (Sripaipan, 2006). It is a universally used method of strategic planning in business practice (Humphrey, 2005). Its limitations arise from its weak theoretical foundations – it is a simplified, static and subjective method unable to satisfactorily represent complex, dynamic and systemic phenomena that characterise each business organisation (Valentin, 2005). Application of the classic version of the method fails to provide information that would allow for an all-round support of strategic decision-making processes (Yüksel, Dağdeviren, 2005). Although SWOT is utilised in foresight projects (Fleisher, Bensoussan, 2015; Nazarko et al., 2017), due to its imperfections some specialists (Popper, 2008) point to the need to replace it with other methods for the purpose of effective support of foresight undertakings.

A limited number of instances of linking technology assessment and executive capacity assessment of an organisation have been identified in the available literature. Analysis of existing projects finds scant examples of technology assessments addressing capacity of an organisation intending to utilise a given technology in its operations. The approach to the process of technology assessment proposed by T. Daim et al. (2011) comprises the following stages: identification of an existing gap related to technology, identification of potentially applicable technologies, assessment and selection of technologies best suited to needs of a given entity. Technology assessments are conducted according to a set of criteria. The authors submit a matrix of criteria using the example of manufacturing technologies. The matrix represents three perspectives concerning technological aspects, institutions, and the market. With regard to each of the perspectives, technological, economic, social, and political issues are taken into consideration. In addition, two decision-making time

horizons are determined for each type of the issues: strategic, with a longer action time frame, and tactical-operational. Detailed criteria are provided in respect of each perspective and the time horizons indicated. The criteria relating to technological issues encompass those concerning assessment of executive capacity in place, including infrastructure, available space, flexibility of equipment use. The final stage of the matrix application consists in choice of technologies best suited to needs and capabilities of user institutions with regard to a broad range of criteria including those concerning executive capacity assessment.

Apart from the theoretical analyses concerning the potential for and rationality of combining selected tools from the proposed triad: foresight, technology assessment, and executive capacity assessment, some isolated practical instances of such combinations occurring in projects realised can be indicated.

These include a German foresight undertaking 'Technologies at the Beginning of the 21st Century' (Grupp, 1993, after: Kuhlman et al, 2002), as part of which reasons have been identified for supplementing foresight methods with aspects of technology assessment. Informal technology assessment competences were expected of the participating experts. At the first stage, the Fraunhofer Institute for Systems and Innovation Research ISI reviewed a list of key technologies developed in the US and other international foresight undertakings. Following from that, a list of technologies of potential economic or social use in the coming 10–15 years was compiled. The technologies were then assessed in accordance with the following criteria: time of application, economic significance, and non-economic benefits. The final stages consisted in indication of key forward-looking technologies for Germany.

As part of a project in the United Kingdom (Improving, 1999) designed to prepare development scenarios and determine prospects for manufacturing of building materials in view of the proven adverse effect of asbestos on human health, foresight and technology assessment tools were integrated by combining quantitative and qualitative methods with application of modelling. Technological development was planned in consideration of identified opportunities and issues in order to respond to requirements of anticipated sale markets, reflect regulations concerning application of building materials, and to ensure future competitiveness of such materials. These aspects were evaluated by means of a calculation model that was developed. The actions served to construct quantitative-qualitative scenarios which helped to indicate directions of economic development.

Regional foresight projects in Poland are examples of practical application of foresight and technology assessment methods in order to support decision-making processes. The project carried out in Podkarpackie province (Ziółkowski, 2013) was aimed at identification and evaluation of future development needs of the region, selection of technologies most appropriate for the area, and development of future scenarios in the field of research and development. As part of the foresight project, key sectors were designated. Next, technology assessment was employed to identify priority ecoinnovative technologies, defined as a group of solutions with maximum attractiveness, feasibility and effect on sustainable development which deserve especial support in the framework of the regional innovation policy. A foresight project pursued in Podlaskie province (Nazarko, 2013; Nazarko, Magruk, 2013) was in turn designed to determine strategic directions of the province's development based on the postulated quantum leap of productivity as a result of application of innovative production and processing processes using state of the art in nanotechnology. Selected aspects of executive capacity were addressed and technology assessment was utilised as part of this foresight undertaking. These projects were among the first foresight undertakings in Poland employing technology assessment and addressing selected aspects of executive capacity.

Instances of executive capacity considered as part of foresight undertakings include evaluation of the so-called 'industrialisation potential', proposed by Lucheng et at. (2010). It envisages linking foresight with technology selection and assessment in order to become capable of evaluating the industrialisation potential of emerging technologies. A hybrid approach was suggested, based on foresight and a matrix serving to choose and assess technologies. This evaluation of the industrialisation potential of emerging technologies is designed to identify promising, as yet not fully developed technologies whose implementation can pave the way for development of local industry, with the necessary infrastructural, human and financial resources available for the purposes of developing such technologies. The method was utilised in practice by China in its preparations for the 2008 Olympic Games in Beijing in order to select appropriate technologies in construction of the Olympic stadium and extension of the transport network in the city, inter alia.

The analysis of the state of the art covering theoretical approaches, models and practical examples of combining foresight, technology assessment and executive capacity assessment tools supporting processes of generating, realising and implementing innovation has helped to identify, both in literature and in practice, only a limited number of instances of such integrations. In practice all the instances concerned combinations of two out of the three tools analysed, most commonly future research and technology assessment. Attention must be drawn to the need for an integrated application of these tools in order to boost effectiveness of innovation processes, arising from growing expectations of management structures, among other things. No single way to integrate foresight, technology assessment, and executive capacity assessment tools to optimum effect can be indicated, though. Each combination is dependent on objectives and scope of a decision-making process in place. No comprehensive systems of this type are currently available for application in R&D organisations, they need to be created and their component tools must be improved. Improvement of foresight tools involves searching for new, innovative approaches and methods. In respect of technology assessment, a strong need for continuing development and application of more effective methods and systems can be observed as well. The development potential of these methods is palpable, demonstrated with the extent of the changes they have undergone in the last three decades in view of the growing complexity of innovation systems and the need to support processes of action strategy creation, inter alia. In the case of foresight, forecasting has been substituted by creation of development visions and scenarios and support for active future creation. With regard to technology assessment, a shift has in turn taken place from identifying possible consequences of applying a technology to an instrument enabling not only to determine possible positive and negative effects of a technology application but also to aid innovative process realisers with development and realisation of innovative products and services. As far as executive capacity assessment is concerned, certain established methods are applied to enterprise analysis. Methods suited to unique requirements of R&D organisations need to be developed, however, aimed at effective support of processes of generating, realising and implementation of technological innovations and at their integration with the remaining tools in the triad: foresight and technology assessment.

3. Directions of development for complex models

Loveridge (1996) writing in mid-1990s claimed synergies between foresight and technology assessment in formal or institutional systems appeared unlikely since technology assessment was seen as reactive, not proactive, interactive or future-creating like foresight was. That opinion arose from the then understanding of technology assessment as contrary to foresight. In spite of these doubts, Loveridge (1996) admitted the possibility of synergies between the tools and proposed a relevant model. Rip (2002) and Kuhlmann (2002a) stressed the need to combine these tools in their studies conducted in the late 1990s and early 21st century. Linking of technology assessment and future research is also reflected in the classification of approaches to technology assessment advanced by Van Den Ende et al. (1998) it addresses futuristic aspects in two out of four types of technology assessment distinguished. Firstly, it indicates forecasting of technological development as part of technology assessment aimed at knowledge acquisition and increasing awareness. Secondly, it indicates the development of desirable future scenarios in the group related to backasting. The classification represents close links between technology assessment and foresight.

The reviews of state of the art, practical examples, and the author's own experience with management and realisation of research projects point to the need to apply the triad integrating foresight, technology assessment, and executive capacity assessment for the purposes of effective support of the decision-making process related to generation, realisation, and implementation of technological innovations.

Possible fields of integrated application of the triad of tools at the macro level primarily comprise aiding processes of strategic choices concerning allocation of limited resources to financing of research and technology development. Application of the triad helps to select areas of R&D financing, that is, identification of research and development priorities in conditions of limited public funding and heavy competition for these resources.

At the micro level of organisations involved in realisation of innovative processes, chiefly R&D organisations, complex models can be employed to:

- Indicate areas of R&D financing – determine current research and development priorities in line with an organisation's action strategy using foresight methodologies and considering results of technology assessment and an organisation's executive capacity available;
- Generate forward-looking fields of research both in the short term (considering possible utilisation of the executive capacity in place) and in the long term (designating areas for possible development of the executive capacity) for the purposes of organisations involved in R&D, also using foresight methodologies considering results of technology assessment and the organisation's executive capacity available;
- Support the process of technology development at the level of an organisation by means of an ongoing technology assessment and analysis of the necessary and available executive capacity;
- Support development of research infrastructure including indication of R&D organisations' priorities in this respect considering the existing capacity by application of foresight, technology assessment, and executive capacity assessment methods;
- Support processes of technology propagation by identifying current or future demand for research results and technological solutions using methods of foresight and technology assessment, analysis of capabilities and scale of their propagation considering the available executive capacity.

In view of the number of possible fields of potential practical application of complex models employing tools of foresight, technology assessment and executive capacity assessment, and bearing in mind the persistent economic importance of innovations with changing models of their development and implementation, the integration processes concerning combinations of the tools under analysis can be assumed to proceed. Certain forms of this integration can already be observed, e.g. addressing aspects of executive capacity as criteria for technology assessments in progress. Continuing development of individual methods employed as part of foresight, technology assessment or executive capacity assessment, enhanced integration of the particular tools in the framework of complex models, and introduction of new forms of the integration can be anticipated, among other developments.

The proposed triad of tools including foresight, technology assessment, and executive capacity assessment corresponds to the progressive tendencies to integration of tools serving to support innovation processes and highlights new aspects of this integration.

4. Conclusions

The author's practical experience with management of research undertakings oriented towards generation, realisation and implementation of innovations points to the potential for and benefits from applying foresight, technology assessment and executive capacity assessment to support realisation of innovation processes. The literature review has affirmed rationality of employing the said tools and has helped to identify very few attempts at combining them as part of theoretical models and practical instances of application, overwhelmingly in dual systems comprising futures studies and technology assessment.

Recognising the rationality of applying these tools as a fully integrated triad, the author has set about developing a methodology of supporting processes of generation and realisation of technological innovations, comprising the triad of tools (Fig 1).

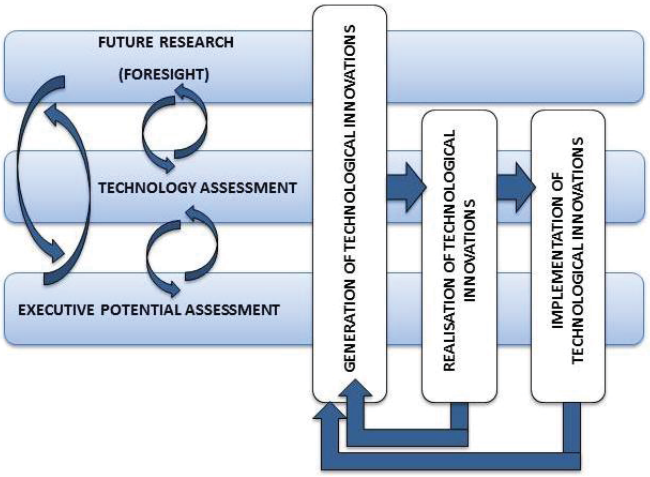

Figure 1: Application of the triad of tools: foresight, technology assessment and executive capacity assessment, at the successive stages of the innovation process

Source: Poteralska 2018.

The methodology employs foresight, technology assessment, and executive capacity assessment, to aid innovation process realisation by means of regular assessments of technological innovations developed and of the available and used executive capacity: material, human, organisational and financial, as well as prepare processes of implementing the results in economic practice using results of technology assessment and executive capacity assessment, and then employing these results for the purposes of initiating another process of innovation generation using foresight.

Abstract: This paper evaluates the success of an innovative web platform created in 2011 by the Institute for Financing Agriculture and Fisheries (IFAP) named "IFAP Private Account" in which the farmer was registered and accessed their data, their history of correspondence with the Institute, checking the forms they had already submitted as well inspections carried out in the field or administratively. In 2011 the ordinance 86/2011 was published that dictated new procedures by the Institute of Financing of Agriculture and Fisheries, I.P. (IFAP) as the institution allocated the managing of the EAGF (European Agricultural Guarantee Fund) and the EAFRD (European Agricultural Fund for Rural Development). Gradually, the functionalities included in this platform increased the possibility for farmers to submit application forms in their own private accounts. Later, in 2014, IFAP released an APP for Android and iOS smartphones where the beneficiary has access to his or her private account in a faster and more convenient way. For the enabling framework of the target audience of the study it was imperative to do a literature review to carry out an economic and social analysis of the sector and the population living in rural areas and manual labour and agricultural entrepreneurs. Therefore, to understand and characterize IFAP's target public (farmers / beneficiaries) as well as the wherewithal and knowledge they have to access their own private account in an autonomous way, quantifying and characterizing the type of access was a priority. Headquartered in low-density areas, agricultural entrepreneurs present unique opportunities for innovation and differentiation and, at the same time, experience several barriers to growth. Some of these barriers are mentioned in the article in order to raise awareness of the difficulties presented by farmers and inhabitants of rural and peripheral areas. Thus, surveys were directed to farmers and technicians in grassroots entities (associations and cooperatives) in order to understand whether users carry out access to the reserved area autonomously or if they need assistance from others in doing so.

Keywords: rural population, IFAP, agriculture, rural entrepreneur, private account, technological innovation

1. 1. The rural population and the agricultural sector's dynamic

Talking about inland Portugal (Pereira et al., 2018) is talking inevitably about agriculture and forestry, or the rural population. According to the National Statistics Institute (INE), in the last Agricultural Census conducted in 2009 (RA 2009), the rural population consisted of 793,000 individuals, corresponding to 7% of the national population and the 2011 Census revealed that 61% of the population resided in places with 2,000 or more inhabitants, although these represented only 18% of the national territory. According to the Territorial Portrait of Portugal, 15% of the population lived in medium-urban areas (corresponding to 20% of the national territory) in 2011 and only 13% lived in predominantly rural areas, whose territorial extension corresponds to 62% of the total area of the country. More recently, in 2016, the Territorial Portrait of Portugal indicates that the predominantly urban areas present a population density 19 times higher than in rural areas, being that the greater population densities are verified in coastline municipalities in contrast with the densities verified in the inland municipalities that had values in the order of 50 inhabitants per km2. These numbers are quite illuminating about the low population density in rural areas where the socioeconomic importance of the agricultural and forestry sectors is preponderant.

In 2012, the Planning and Policy Office of the Ministry of Agriculture, Forestry and Rural Development published a study entitled "Agriculture in the Portuguese Economy - environment, importance and recent evolution", which is quite illustrative of the national economic reality, in particular the internal consumption (which suffered a reduction) and exports of the agroforestry complex (which increased). Although the pace of world economic activity slowed down in 2011, the same document states that the primary sector and industry contributed positively to GDP, with the primary sector showing some stability between 2007 and 2011 through a period of recession, despite some abandonment faced by the sector in relation to previous years. Gaspar et al. (2014) points out, at a time of transition from the Community Aid Framework, that the promotion of the agricultural sector can play an important role in promoting post-crisis economic recovery. Not only as a measure of entrepreneurship and employability but recovery, maintenance and even accelerated pre-crisis economic growth rates, fostering Portugal's success in a globalized economic environment from a long-term

perspective and thereby helping the country achieve sustainable economic growth. In fact, the final report of the Rural Development Program for the period 2007-2013 (PRODER) shows that investment in agricultural activity increased between 2000 and 2014 (0.6% on average per year, at current prices), in contrast to the rest of the economy (-2.4% on average per year, at current prices) revealing the dynamism of the sector in the last CSF as a result of all the incentives of local, national, and Community decision-makers to attract rural entrepreneurs and to set the population in rural areas with a special emphasis on the implementation rate of the measure to support the "young farmers' establishment", which registered a growth of 111%, corresponding to a total of 8,314 farmers between 2007 and 2015. Despite the positive results of the current and previous CAFs, on the one hand the incentives to support investment in less favoured regions in the Mainland Rural Development Program and the Autonomous Regions and in the different Operational Programs that integrate Portugal 2020, the rural population is still quite aged and occupy territory with low density as shown by INE data.

2. Entrepreneurship and Innovation in the Rural Environment and its relationship with Information and Communication Technologies (ICT)

It is essential to state that the agricultural sector and the rural world have contributed positively to the trade balance, through production increases, the result of a more competitive and technologically developed sector, and the innovation and diversification of activities related to the sector, including processing, handicrafts, tourism and others. The Common Agricultural Policy (CAP) has tended to support sustainable modes of production that respect the environment and promote the economic and social development of local (rural) enterprises. The success of entrepreneurship in these regions is sometimes related to the complementarity between the various activities carried out by the companies. The valuation of endogenous products through the Certification of Quality Policy (EU) or cases such as the Demarcated Region of the Douro "where, in the case of winegrowing, there are several examples that show great vitality (greater scale and greater mechanization, for example) (Gaspar et al., 2014) have been very important.

The location of companies in rural areas may be a limiting factor, depending on the activities carried out. Access to communication routes, ensuring a good telecommunications network, may affect the performance of the activity. However, North & Smallbone (2000) argue that factors such as the high cost of innovation coupled with a lack of funding were the major constraints on the innovative capacity of rural SMEs in the UK between 1991 and 1996 (although the authors note that this restriction may reflect SME's views on indebtedness). Among other limiting factors, we emphasize the weaknesses in the supply of external resources and the difficulty of demand (the accessibility of the clients) and the lack of time for the SMEs to be involved in the development of products and services, due to the excess of concern of their managers with the day-to-day operations of their business which leaves them little time for new ideas, to innovate. On the other hand, Dinis (2006) affirms that the result of several studies of local production systems in more peripheral regions shows that companies are scarce and, because they are scarce, there is neither an entrepreneurial spirit nor a supportive environment. Social capital is a source of innovation and social innovation. In this way, the emergence and success of new companies is a very rare phenomenon. "Thus, innovation and marketing perspectives can be useful tools for the formulation and implementation of a sustainable strategy for these companies and territories" (Dinis, 2006), combating the effect of interiority and exploiting glocalization, especially through the communication of information, contributing to the construction of increasingly differentiated and distinct consumers or even new consumer traditions, which is intrinsically related to the global marketing strategies that defend that "diversity sells" (Salazar, 2005). Still, regarding development and economic growth, Gaspar et al. (2014) states that agriculture can play a key role in enabling the expansion of other sectors traditionally seen as driving economic growth through the transfer of resources and providing a market for the growth of non-agricultural goods and services. On the other hand, the agricultural sector can also benefit from technological improvements in industry and services that, by influence, could promote the growth of the sector.

Along with the technological improvements previously mentioned as leverages of growth of the sector, with regard to ICT, it is important, right now, to mention Riddlesden et al. (2014) that demonstrates, through a study of download speed in the United Kingdom in 2013, that average download speeds in a given region showed that higher speeds are generally grouped around large population clusters while in rural areas mean speeds are significantly slower. Warren (2007), in turn, presents several factors that may be conditioning communication such as ICT infrastructure which may be considerably weaker in rural areas than in urban

areas; that the benefits of online communication in rural areas may be relatively greater than in urban areas, since it brings all stakeholders together; that solutions for digital exclusion may depend on investments in specific locations and may face additional difficulties in rural areas. In fact, it is imperative to assume that ICT plays a key role in the success of rural enterprises. Whether it is in the technology adopted in production, such as precision agriculture, or in ensuring the connection to any point on the globe, anywhere where the entrepreneur can be found, so that he or she can easily maintain the existing relations at speed as demanded by the current market forces.

3. Technological innovation: communication and learning barriers

In general, the current publications on the information and communication network in agriculture (AKIS) link this process to the transfer of information to and from the farmer (dynamic process) to promote rural development. Figure 1 shows a modification of the model proposed by Rivera et al. (2005) and seeks to illustrate this network of relationships in which the farmer occupies the central place and is surely the greatest beneficiary of its functioning.

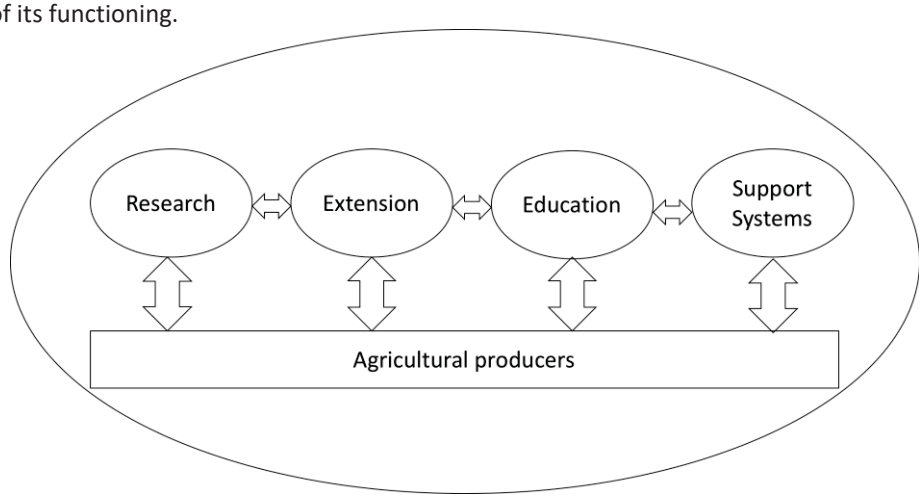

Figure 1: An idealized AKIS/Rural Development model, Source Adapted from Rivera et al. (2005)

Rivera (2000) states that agricultural information is undergoing a change in terms of content, the means by which it is transmitted, and the fact that this information is tradable (paid). Likewise, Rivera (2000) considers that the means of transfer advanced and evolved as a consequence of the modernization of telecommunications and the widespread use of computers, providing immediate access – for example, information on agricultural commodity prices worldwide and weather conditions. Despite all these changes, it is important to understand that there is sometimes a gap between the need for change and the willingness of farmers to adapt, and the inadequate capacities of innovation agencies and advisory / support services to effectively support change (Knickel et al., 2009).

Since the subject of this study focuses on the farmers' autonomy in the use of an online platform, and they often request help from the technicians of the grassroots entities (extension technicians), it will be important to draw attention to the fact that one of the gaps in the understanding of concepts in innovation processes (by farmers), presented by Knickel et al. (2009), addresses the outdated orientation of many institutions, administrations and extension services in support of rural innovation. Therefore, the author concludes that institutions, administrations and extension services, whose missions support and promote change, can become a limiting factor (Knickek et al., 2009). Thus, adapting this technological innovation introduced by IFAP to the previously discussed AKIS model, it is important to mention Rivera et al. (2005), which places particular emphasis on training as a process that minimizes the gap between AKIS actors. Farmers in many countries would profit from increased training in new technologies, and young farmers and farmers with higher education would benefit from training in problem analysis and participatory approaches (Rivera, 2005). In this sense, Sumane et al. (2018) states that farmers must also have a bureaucratic, administrative and legal knowledge to carry out the commercial side of agriculture (contract drafting, compliance with regulations, etc.) which supports farmers. Additionally, just as important is support for the establishment of farmers' organizations and farmers have important roles to play in these – not only as producers, but also as contributors to AKIS development processes (Rivera, 2005).

4. Methodology

After 7 years since the "IFAP private account" launch and observing how farmers use the platform on a daily basis, it is opportune to analyze their degree of autonomy in accessing and using the functionality. An anonymous online survey was conducted using Google Forms and involving farmers and technicians from grassroots entities who were asked to respond briefly to questions related to the use of the reserved area of the farmers. The collaboration of technicians was requested to validate the responses of farmers (as proficient users) and to understand the frequency that farmers ask technicians to access the platform on their behalf.

The survey was shared on social networks in public groups that had “agriculture” as the main topic and via a link sent by email to technicians and farmers. The questionnaire initially sought information on gender, the district and the type of respondent, and the latter question guided the respondent to different types of questions appropriate to their characterization. Multiple-choice and Likert-scale methods were used with 5 items ranging from 1 - Very Easy to 5 - Very Hard to evaluate the respondents' opinions about their experience of using the various operations in the private account.

5. Results

The survey administered had 117 valid responses, of which 61 were from male participants (52.1%) and 56 from female participants (47.9%). Survey respondents come from almost all the districts in the country, as illustrated in Figure 2. The highest number of responses were from the districts of Bragança (11%), Viseu (17%), Vila Real (11%), and Porto (12%); and the districts of Évora, Leiria and the Autonomous Regions of Madeira and the Azores did not obtain any answers. Although it is a non-probabilistic sample, the results obtained favour the study since the most responsive district was the district of Viseu, in which rural areas prevail. Among the respondents, the farmers stood out representing 52.1% of the responses against the 47.9% corresponding to the technicians of grassroots entities.

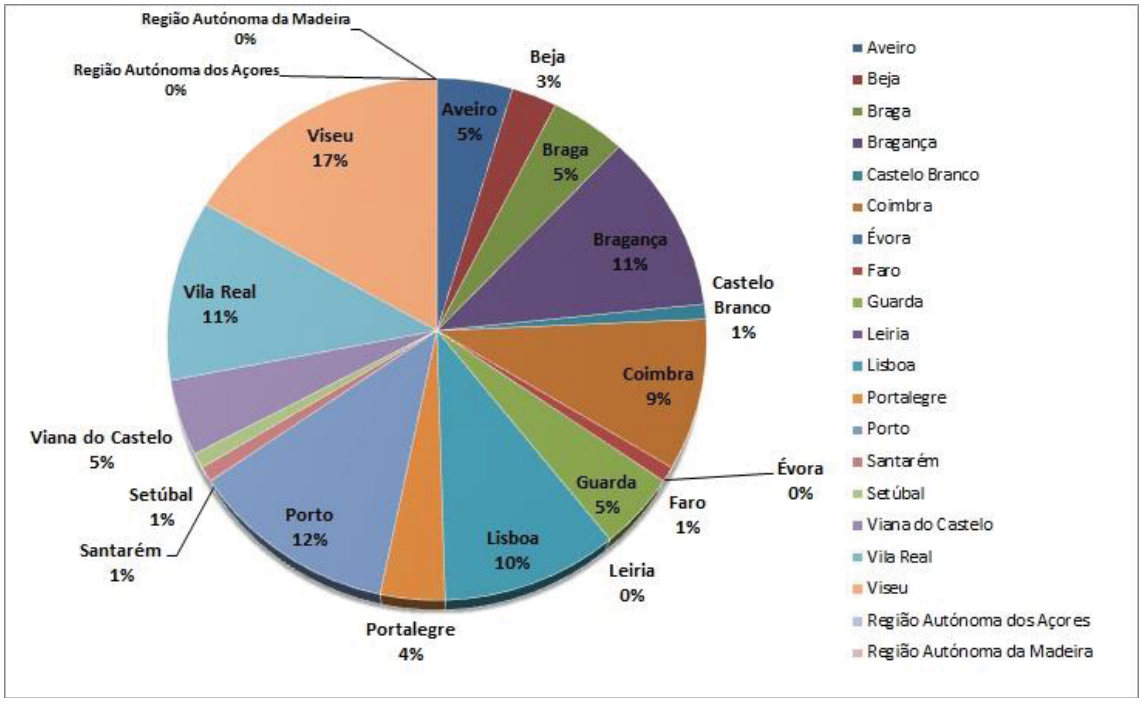

Figure 2: Percentage of answers by Portugal districts.

5.1 Farmer

Of the 61 respondents of the "Farmer" type respondents, half (46%) of the sample corresponds to "farmer" as shown in Figure 3. In addition to this legal entity there also exists the figure of "Agricultural entrepreneur" in which all the farmers were framed with Individual Corporations by Quotas, "Administrators" in which all the managers of Companies by Quotas are placed and the figure of "Legal Representative" where prosecutors, representatives of undivided inheritances, and the case of the chairmen of boards of directors of corporations are included. Regarding the age group, it was from the group of individuals aged between 45 and 65 years that

we obtained the largest number of responses (33) corresponding to 54% of the total, as can be seen in Figure 3; this was followed by the age group of individuals aged between the 35 and 45 years that represents 26% of the respondents, with 16 answers. Regarding the educational levels of the farmers, the majority selected higher education, corresponding to a percentage of 56%, which is the result of the sum of the respondents with a first degree (25) and a master or higher degree (postgraduate education) (9) as is shown in Figure 3.

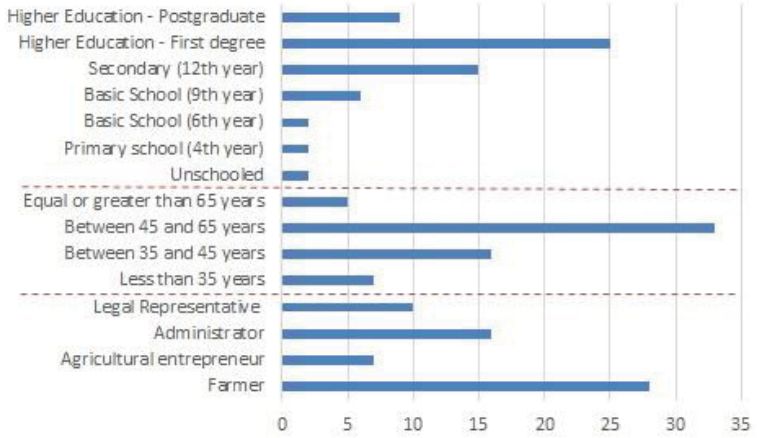

Figure 3: Diagram combining the three variables: legal nature, age group and educational levels of farmers.

Analysing figure 3, the farmers who answered the survey and who have a first degree are aged between 45 and 65 years and are individual farmers. According to RA2009 (a document which characterized the individual agricultural producer according to age classes and educational level) the profile of the "farmer" who registered the major number of answers corresponds to the group of individuals that represents 5% of the sample of the last agricultural census, and at the time of the census the greater percentage of individuals were over 65 years of age and, as far as level of education was concerned, the highest percentage fell to those who attended only primary education.

When questioned about the autonomy of access to the reserved area, 63.9% of the respondents (39) answered that they accessed autonomously while 36.1% (22) answered that they requested help from relatives or technicians of associations (grassroots entities) in order to access the platform. The way this access is performed was also questioned through the possibility of a multiple response between Web Access, App for Android and App for iPhone options. Access through the website had 60 responses, while APPs for Android and iPhone just recorded 4 replies each. In addition, to understand how farmers access their reserved area and the tools used, it is still important to understand what operations they routinely perform on the platform. In Table 1 we can see the parallel analysis between Farmers' answers and Technicians. In addition, they were asked to indicate their degree of difficulty on a Likert scale from 1 to 5 where 1 is very easy and 5 is very difficult as can be seen in Figure 4. These questions were of an optional nature since they depended directly on the individual experience of each user depending on the characteristics of his holding.

Table 1: Parallel analysis of the answers given by farmers and technicians about the operations most performed on the web platform

Operations most performed	Farmers	%	Tech.	%
Consultation of farm information (updated Land Parcelling and Beneficiary Identification Data)	**44**	**72**	**35**	**63**
Consultation of payment extracts	**48**	**79**	**45**	**80**
Payment clearance consultation	**26**	**43**	17	30
View of submitted forms	24	39	22	39
View of control report	21	34	26	46
Submission of forms (BI, "Single Application", among others)	25	41	**33**	**59**
Issue of cattle transaction forms	13	21	19	34
Operations related to Investments PRODER / PDR2020	24	39	18	32
Others	0	0	2	4

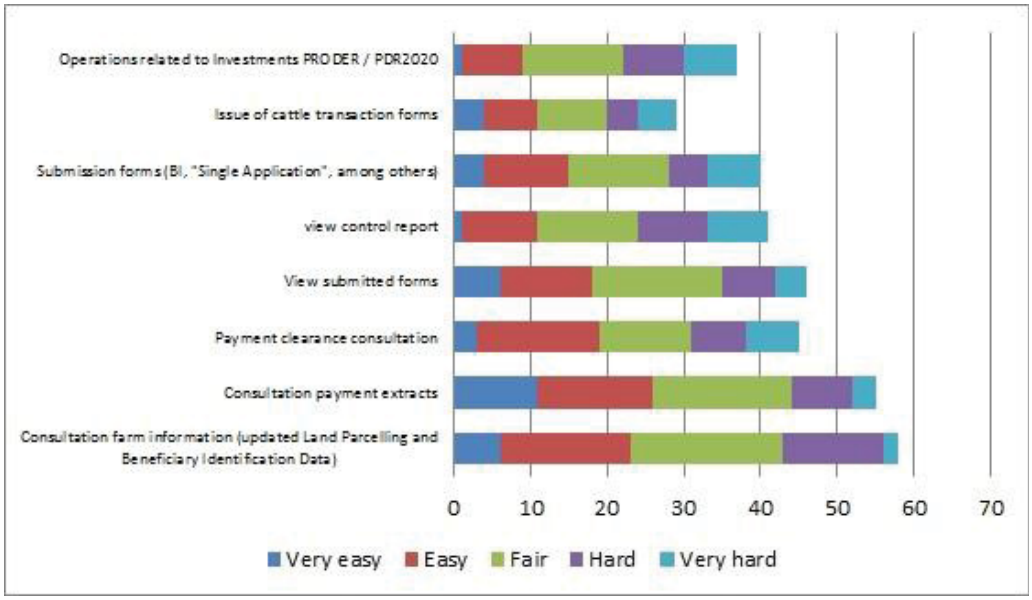

Figure 4: Difficulty verified with the several operations performed by farmers.

5.2 Technician

This group registered 56 valid responses to the survey. As mentioned before, the purpose of directing questions to the technicians was to understand how often they access the web platform on the farmers' behalf. Per week, 45% answered that "supported less than 10", 21% "supported 10 to 20", 13% "supported 20 to 30", 4% "supported 30 to 40" and 18% "supported more than 40" farmers accessing their private account.

Regarding the age group and educational level, as seen in Figure 5, technicians with higher education (first degree) and aged between 45 and 65 years old were more responsive.

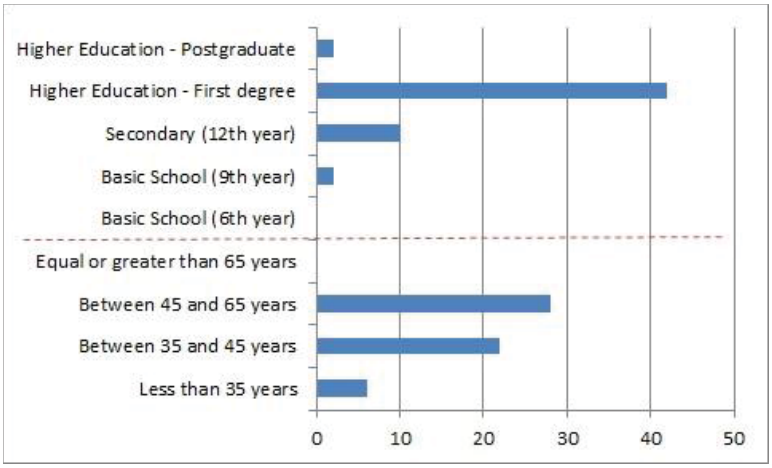

Figure 5: Diagram combining age group and educational levels of technicians.

As well as the farmers, they were asked to indicate their degree of difficulty on a Likert scale from 1 to 5 where 1 is very easy and 5 is very difficult, as can be seen in Figure 6. These questions were of an optional nature since they depended directly on the individual experience of each user and on the characteristics of the requests made by the farmers.

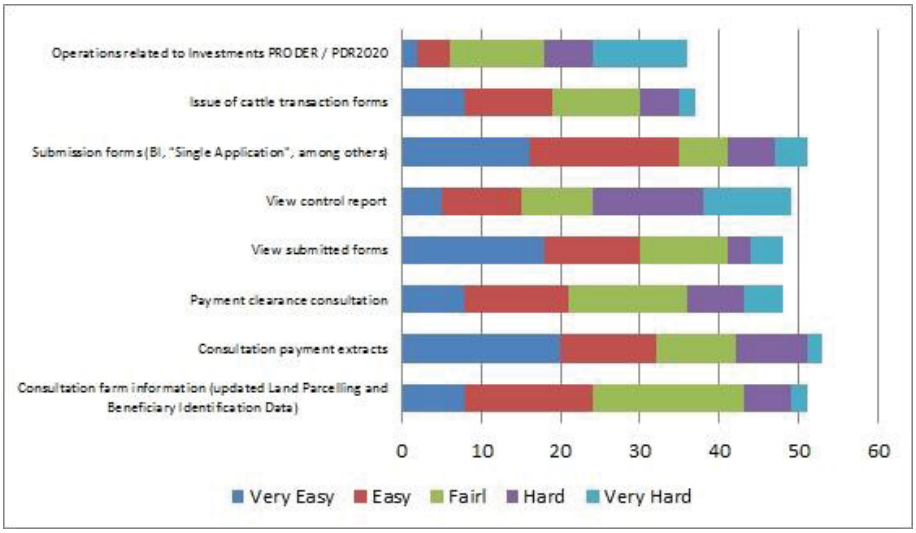

Figure 6: Difficulty verified with the several operations performed by technicians.

5.3 Analysing their opinions

A section of the survey had as an objective to supply a qualitative analysis where respondents answered questions related to their experience with the platform. As we can see in Table 2, they were asked to give their opinion about the existing barriers and both categories of respondents indicated the same top 3 barriers: "Computer-illiterate", "Age group of beneficiaries" and "Unawareness of form submission rules". However, we can say that the other options were generally chosen by most of the respondents and the other barriers indicated by the farmers were related to the interactions between application forms and browsers and some technical incompatibilities verified on the platform. Despite all the barriers mentioned, both categories consider that the Private Account results as a facilitator in the contact between IFAP and Farmers.

Table 2: Farmers' and Technicians' opinions about IFAP's Private Account

In your opinion, which factors do you consider conditioning the beneficiaries' autonomy in accessing the IFAP's Private Account?	**Farmers**	**%**	**Tech.**	**%**
Unawareness of form submission rules	**31**	**51**	**35**	**63**
Unawareness of document and procedural obligations of operations	28	46	29	52
Lack of computer facilities and access to the internet	21	34	34	51
Computer-illiterate	**34**	**56**	**41**	**73**
Age group of beneficiaries	**30**	**49**	**40**	**71**
Complexity of the rules of operations and its relation to legal issues	21	34	30	54
Insecurity	15	25	20	36
Difficulty in interpreting information withdrawn through available operations	27	44	27	48
Others	4	7	0	0
Do you think that the Private Account facilitates contact between IFAP and Farmers?	**Farmers**	**%**	**Tech.**	**%**
Yes	46	75	36	64
No	10	16	14	25
No opinion	5	8	6	11
Total	61	100	56	100

6. Conclusion

"Digital rural development means opening doors to the nearly unlimited possibilities to exchange information on a scale never before imagined" (Malecki, 2003). As already mentioned the digital world can represent an opportunity for the entrepreneur in terms of competitiveness. Whether in communication, marketing or transactions, web platforms can be facilitative as information travels at the speed that broadband allows.

However, we know that most of the rural areas are not prepared for this digital revolution because most of the farm population is aged and has low educational levels. The high percentage of respondents of the survey with higher education degrees shows us that the efficient users of the platform studied in this paper correspond to a very low percentage of the farm population, answering the main question of the paper: Who are we reaching?

Cruz-Jesus et al. (2016) studied related variables such as the use of mobile devices or access to home banking or e-Learning in EU countries. Through this study, they were able to state that despite the many efforts, there are still huge gaps between education and the proficient use of the Internet in EU countries and Portugal is one of the countries where this gap is more evident. On the other hand, Preston et al. (2007) studied the access to broadband in rural areas in the EU and mention that some socio-economic groups are resistant to broadband until they have compelling reasons to adopt it. "The primary drivers in this respect will be the availability of applications, services and content that are relevant and add qualitative benefits to their lives" (Preston et al., 2007). In fact, the ordinance that dictated the launch of the IFAP's web platform contained the following purpose: "with the aim of simplifying the process of communication with the beneficiary and, consequently, making the process of granting and payment of aid more efficient". This platform corresponded, theoretically, to the suggestion made my Preston et al. (2007) but after seven years of using the "private account" we can affirm that farmers are not yet autonomous users as mentioned in the results.

Although we cannot easily overcome the lack of technological means (computers, access to the internet, mobile devices), we reinforce the importance of training and support previously mentioned in topic number 3 and the link with rural extension. Grassroots organizations can play a very important role in transferring information and knowledge to farmers as they form the link between policy issues and the reality of rural areas.

7. Suggestions for future research

We suggest that future research focus also on millennials, as other research has done (Au-Yong-Oliveira et al., 2018), in this case however related to agriculture and how millennials perceive the technological future. Specific platform accessibility and usability may also be tested more in-depth (see for example Gonçalves et al., 2013, 2017).

Abstract: Nowadays entrepreneurship is a theme on the agenda of governments. Entrepreneurship is a dynamic process of vision, change and creation. Entrepreneurship is a process of fundamental transformation, from an innovative idea, to the value proposal to the creation a new venture. It requires an application of energy and passion towards the creation and implementation of new ideas and creative solutions. The essential ingredients include: the willingness to assume risks, the ability to join a venture team, the creative skill to get necessary resources, ability to develop a solid business plan and the vision to recognize an opportunity. As entrepreneurship is about devising and implementing new ideas and practices, a strong educational foundation helps ensure that new ideas will be effective and substantive. This paper starting from the theoretical framework of entrepreneurship based on different lines of thought and with different approaches, will try to describe the dimensions of the Entrepreneurial education process and how this process promotes students' attitudes and intentions favorable to create business start-ups. In a practical way, will be presented the successful case of an course of entrepreneurship of technological base, that has been going on for some years in a partnership between several universities. Examples of successful startups, resulting from the course will be mentioned.

Keywords: Entrepreneurship, Universities, Entrepreneurship Education, New Technologic Based Firm's

"Entrepreneurs are the heroes— they make the world livable for everyone else"

(Kuratko and Morris, 2018:20)

1. Introduction

Entrepreneurship is one of the most important activities of modern economic life. The creation and growth of new companies, as well as the closure and retraction of existing companies, are at the heart of "economic dynamism." Entrepreneurship is a dynamic process of vision, change and creation. It requires an application of energy and passion towards the creation and implementation of new ideas and creative solutions. The essential ingredients include: the willingness to assume risks, the ability to join a venture team, the creative skill to get necessary resources, ability to develop a solid business plan and the vision to recognize an opportunity. In this light entrepreneurship is more than the mere creation of a business.

It is in general, recognized that entrepreneurial activity is the driving force behind the development of countries' GEM (2008), economic growth (Verheul et al, 2001; Carree and Thurik, 2005), employment (Birch, 1979, 1987); Lundström and Stevenson, 2005), and innovation (Schumpeter, 1934; Acs and Audretsch, 2005).

For this reason entrepreneurship has become a preferred theme on the agenda of most governments.

Entrepreneurship as an important force in the actual economy, generates ongoing innovation and improvement of our goods, services, and institutions. It makes them more efficient, affordable, and, thus, effective. Entrepreneurship enhances the quality of our collective and individual lives. It changes the way we work, the way we communicate, the way we live. Innovation and improvement depend on intelligibility. If intelligibility is a fundamental goal of learning, than the higher education institutions should be dynamic, generate new knowledge, adaptable and have capacity to address the urgent questions of our society.

To Kuratko (2005) an entrepreneurial perspective can be developed in individuals. Peter Drucker, recognized as one of the leading management thinkers, has said, "The entrepreneurial mystique? It is not magic, it's not mysterious, and it has nothing to do with the genes, it's a discipline. And like a discipline, it can be learned" Drucker (1985:18). An additional support to this view, comes from Gorman, Hanlon, and King, (1997:63) "most

empirical studies surveyed indicated that entrepreneurship can be taught, or at least encouraged by entrepreneurship education".

Universities and other higher education institutions started to get aware of the relevance of teaching and learning entrepreneurship as it became evident that the Entrepreneurship Education (EE) could influence the predisposition to create start-ups, or at least could influence individuals to become more proactive and entrepreneurial in their lives and their jobs. Entrepreneurship and university education are closely linked one with another. So is possible to say higher education institutions have a relevant role in promote technological entrepreneurship through Entrepreneurial education and learning.

This paper starting from the theoretical framework of entrepreneurship based on different lines of thought and with different approaches, will try to describe the dimensions of the Entrepreneurial Education (EE) process and how this process promotes students attitudes and intentions in the face of entrepreneurship and business start-ups. In a practical way, will be presented the curricular contents and the way of functioning, of a course of entrepreneurship of technological base, that has been going on for some years in a partnership between several universities. Examples of successful start ups, resulting from the course will be mentioned.

2. Entrepreneurship as a field of study

Entrepreneurship is recognized as being fundamentally important for societies and economies (Gans and Stern, 2003). Some classical authors as, Cantillon (1755), one of the pioneers of the theories of entrepreneurship, presents entrepreneurs as economic agents, who produces new products and connect producers and customers. Say (1840) proposes that one of entrepreneurs' major roles is to create teams in order to achieve productivity. However Veciana (2007), consider that entrepreneurship as a scientific research programme, has its explosion and consolidation in the last three decades.

Introducing the Risk Bearing Theory, Knight (1921) claims that risk taking is a key aspect of any entrepreneurial activity. His perspective views risk takings as a factor of production in that the key role of an entrepreneur was to act in expectation of particular future occurrences. Thus taking risks would result in entrepreneurial performance and success. The theory supports that for entrepreneurship occur, an individual must have the capacity to take risks, or an individual would not be able to engage in business activities that would risk his investment.

Schumpeter (1934, 1947) views the entrepreneurship through the lens of his Innovation Theory. He believes that certain characteristics are essential for an individual to be considered an entrepreneur: being innovative, having foresight and being creative. McDaniel (2005), argues that according this theory, entrepreneurship happens when an individual introduces a new product, finds an alternative raw material and discovers a new market or a new way of doing things.

In the vision of McClelland's (1961), the entrepreneur is an individual with the ability to perform certain tasks and make good decisions when face with uncertainties. Thus an individual´s vision of success becomes much more important than any monetary or other external risks that are involved (Kuratko and Audrestch, 2009).

Davidsson (1995) highlights the scene experienced in 1970's, where large companies could not employ much more people, turning the focus to small businesses as mean to achieve economic growth and job creation. It is in this way that entrepreneurship diffuses, reaching academic legitimacy and interest in the psychological characteristics of business creators, developing explanatory models that consider the characteristics of entrepreneurs, but also personal antecedents and situational variables. (Davidsson,1995; Kuratko and Morris, 2018).

A large number of studies focus on the theoretical models and personality factors of the individuals and how they can influence the EI (Entrepreneurial Intention), where we highlight Boyd and Vozikis (1994) and Krueger and Brazeal (1994), as well as Behavior Theory Planned (TPB) of Azjen (1991), designed to predict and explain the human behavior in particular contexts. Frese (2009) added, related that the psychological approach is required to understand the entrepreneurship, and recently Fayolle and Líñan (2014) argue that EI literature evolve positively with theories of the field of social psychology and cognitive.

In his theory, Ajzen (1991) shows that all behaviors requires a certain planning, being a rational and planned action, making use of available information. The intentions are indicators of the level of effort that the individuals are willing to put into practice in order to carry out a particular behavior. This theory also presupposes that both internal and external factors can influence human action.

These and other works try to explain the concept of entrepreneurship. However, many other external factors could play a significant role in stimulate the entrepreneurial activity as well. Factors as technology, market, environment, type of customers, industry structure, strategy, support institutions and entrepreneurship education, all play important roles in the start event of new firm creation, survival and success. Considering those various factors our paper just focus on the role played by entrepreneurship education.

3. Entrepreneurship Education

Education seems important for stimulating entrepreneurship because several reasons (Reynolds, Hay, & Camp,1999; Sánchez, 2011). First, education provides individuals with a sense of autonomy independence and self-confidence. Second, education makes people aware of alternative career choices. Third, education broader the horizons of individuals, thereby making people better equipped to perceive opportunities, and finally, education provides knowledge that can be used by individuals to develop new entrepreneurial opportunities.

However, the idea that the entrepreneur is a result of hereditarily or that entrepreneurship is an innate characteristic of some individuals, no longer seems to have many followers in the scientific literature. Li (2006) argues that the theory of planned behavior is very useful and it provides a sound theoretical framework toward understanding the antecedents of entrepreneurial intentions. Instead, it seems to win strength, the stream that defends that it is possible to learn to be an entrepreneur, through the use of differentiated policies in education.

The innovation and creativity is critical to create a sustainable future. So we need people who know how to implement ideas and make them accessible to society. The creation of new innovative firms is fundamental to translate that knowledge. So it is needed to understand why entrepreneurship matters, how it works and how to sustain it. That understand is the result of education. So entrepreneurship is about devising and implementing new ideas and practices or improving old ones. In a Progressively technological, scientific, and interconnected world, the quality of innovation in large measure increasingly relies on superior advanced learning. A strong educational foundation helps ensure that new ideas will be effective and substantive.

Because entrepreneurship promotes, implements, and rewards innovation, it necessarily correlates with education (Kauffman Foundation, 2008).

One of the ways in which it has been intended to reinforce the interest for the development of new companies, was trough the higher education system, and some scientific literature has been studying the relationship between the levels of training and the creation of companies. Based in the Small Business Economic Report (2006), a review of the research measuring the impact of general education on entrepreneurship and entrepreneurial performance suggests three key generalizations. First, the evidence suggesting a positive link between education and entrepreneurial performance is robust. Second, although the link between education and selection into entrepreneurship is somewhat ambiguous, evidence suggests that when “necessity entrepreneurship” and “opportunity entrepreneurship” are considered separately and when country difference is considerate, the link is less ambiguous. Finally, the relationship between education and selection into entrepreneurship is not linear in nature. The highest levels of entrepreneurship are linked to individuals with at least some college education. Also according the report the main conclusion of great majority of entrepreneurship research, reveals a positive relationship between education and business activity.

To Hindle (2007), entrepreneurship needs no justification to study on the grounds of its importance to humanity. It is a wellspring of economic growth, social renewal and personal development. Such an important subject is worthy of deep research, significant reflection and sustainable dialogue. When a subject has the depth importance which entrepreneurship possesses, it is capable of being the foundation for great education.

Also Birch in Aronsson, (2004: 289), says that to encourage entrepreneurship, it should be trough some kind of apprenticeship that would be a wonderful experience.

Additionally, the education and training should center itself much more in changing personal attitudes than in knowledge, because the effects could be more significant to the process of business creation and to overcome the perceived barriers to entrepreneurship. The educational systems need to be oriented to emphasize and value entrepreneurship in order to promote an enterprise culture.

The research carried out on the influence of entrepreneurial education on entrepreneurship emphasizes that education facilitates the student a better knowledge of his possibilities to create a company, Raposo and Paço (2011). For Mogollon (2017), this demonstrates the need to understand the role played by universities in society, especially in the university environment, in training for entrepreneurship, and in motivating students to start processes to business creation.

In study of Dutta, Li and Merenda (2011) it was found that education specialized in entrepreneurship is positively related to the predisposition to create companies in the future. The education encourages entrepreneurship for several reasons, providing a sense of independence, autonomy and self-confidence. On the other way, it makes people aware of alternative careers, expand the horizons, perceives opportunities and offers knowledge to develop and explore new business opportunities (Dutta, Li and Merenda, 2011; Sánchez, 2011). A correct EE program enables individuals to acquire skills and necessary knowledge to found and develop new business (Sánchez, 2011)

A study developed by Raposo et al (2008), involving university students, had shown the important effect of *education* on the *propensity to start-up a firm*. The results point out the importance of the entrepreneurship education and the promotion of the entrepreneurial intention. That is, the entrepreneurial intention was predicted significantly by entrepreneurship education, other researches had similar conclusions (Brice 2004; Florin, Karri and Rossiter, 2007; Kennedy et al. 2003; Li, 2006).

A large number of universities offer certifications and master degrees in Entrepreneurship; others offer doctoral programs as a way to prepare a new generation of scholars. Other universities, organize their own training courses and methodologies to stimulate entrepreneurial skills and enable the transfer knowledge to the market. The rhythm of changes is accelerating, with more and more universities interested in developing their EE programs. The growth of the recognition of EE programs is another example of the evolution that is seen in entrepreneurial education (Liñán, 2004; Kuratko and Morris, 2018).

Krueger and Brazeal (1994) argue that entrepreneurship education is conducive to the initiation of new business, being the highest EI in students who attend these courses. Souitaris, Zerbinati and Al-Laham (2007) mention that EE programs lead to the development of entrepreneurial postures and intentions, demonstrating in their study that attending in entrepreneurship course increases the EI.

Also for Kuratko and Morris (2018) entrepreneurship courses prepare students for entrepreneurial life, setting up a business mindset with more emphasis on skills. It can empower them to create their own job, to design their future, to achieve wealth, to create jobs for others, to make their contribution to the world. For Fayolle and Liñán (2014) the empirical results reveal significant differences in attitudes and levels of EI among students who participate in EE courses and those who do not participate.

We can question where should positioned the entrepreneurship education inside the University. It is interesting to note that Withehead (1929:93), about the role of Universities wrote:

> *"The justification for a university is that it preserves the connection between knowledge and the zest for life, by uniting the young and the old in the imaginative consideration of learning. The University imparts information, but it imparts it imaginatively. At least this is the function which it should perform for society. A University which fails in this respect has no reason for existence. Their atmosphere of excitement arising from imaginative consideration to transform the knowledge".*

Having this in mind, probably there is no single and universal correct location for entrepreneurship education in University. Entrepreneurship belongs wherever we want to put it, so long is the key condition of imaginative transcendence of the immediately vocational is meet. So it can be teach wherever the right mindset prevails (Hindle, 2007).

4. The case of *CEBT Ibérico* - Entrepreneurship Technology Based Course

The *CEBT Ibérico* - Technological based entrepreneurship skills, presents itself as an advanced training program in Entrepreneurship area, inserting itself in the category typical programs of EE (Entrepreneurship Education) oriented to projects of companies of technological base.

The program was developed as part of the INESPO project – "Rede de Transferência de Conhecimento Universidade-Empresa Região Centro de Portugal" and "Castilla y León of Spain", funded by the Cooperation Program INTERREG A Spain-Portugal (POCTEP) 2011-2020. The project is a network of nine entities coordinated by University of Beira Interior (UBI), and involves the portuguese universities of Coimbra and Aveiro, the spanish universities of Salamanca, Leon, Valladolid, Pontífica of Salamanca and finally the business confederations of CEC/CCIC-Portugal and CECALE- Castilla y León.

In addition to the training contents, the program seeks to identify emerging ideas, new technologies, new products or patents, in those universities, which will be worked on in a team, during the training sessions. The idea is to develop a value proposition and a business plan, that supports the creation of technology-based companies capable of accelerating and overcome the nascent phase and assume an important role in the economic development and social growth of the cross-border region. This new ventures are also known for its ability to generate qualified employment, for its adaptability to the market, often leading to innovations through the development of products/services ahead of its time and contributes to affirm the regions in the RIS3 strategy.

In the genesis of the CEBT there is an innovative methodology, through advice and specialized consultancy composed of three lines of action: 1) Sessions of advanced consulting in the areas of Market Research, Business Model, Strategy & Marketing and, Communication & Negotiation; 2) Coaching and Mentoring for entrepreneurs, in order to ensure a correct follow-up of projects by specialists and at last; 3) Session of dissemination and promotion of business projects, as a way of disseminating of technology and knowledge among the various invited agents (companies, investors, business angels, etc.), enhancing networking between them. The same methodology is applied in the seven universities of both countries, through the same structure, trainers, consultants and mentors.

The Table 1 present the Sessions of advanced consulting promoted in a logic of advice and specialized consultancy, aiming the monitoring and development of the projects taking into account the needs of the market and the economic and financial viability.

Table 1: Sessions of advanced consulting

Session	Partner responsible for the session
1. Creativity and Business Idea	University of Coimbra
2. Proposal of value	University of Valladolid
3. Business Plan	University of Beira Interior
4. Research Market	University of Léon
5. Intellectual Property and Technology Transfer	University of Aveiro
6. Communication and Negotiation	University of Pontífica of Salamanca
7. Strategy and Marketing	University of Salamanca

Source: Own Elaboration.

It is a free action, open to all academic community that integrates the INESPO network, consisting essentially of teams of multidisciplinary areas, with a higher prevalence of participants from the areas of Health Sciences, as well as Engineering and Business science. On innovative approach of the CEBT course, result from the fact that the teams involved in the training sessions works with a new idea, patent, new technology or product resulting of the research carried out at each university.

The program is in its 8th edition, in global counted with about 800 participants, that submitted 130 project ideas and a few dozens of business ideas that resulted in the creation of TBF's where there appeared some new companies like Follow Inspiration and Inklusion, currently based in the interior region of Center of Portugal. As a success example, we are going to present synthetically these two startups that had their genesis in CEBT.

The training course was the starting point for two graduate students develop new ventures ideas, respectively under the name wiiGO and InKaos. After the course, these two final projects won several awards about entrepreneurship and innovation, which allows to demonstrate the technological viability of both projects, and how to convert the research done by UBI students in value propositions, allowed access at monetary prizes and the recognition of the merits of the projects at national and international level.

4.1 1st Case: Follow Inspiration – Improving Business like never before

wiiGO project was idealized by Luís de Matos (Msc in Computer Science in UBI), focused on the valorization of autonomous device developed to follow individual with disability or reduced mobility, wherever it moves, allowing the transport of objects autonomously, dynamically and safely, avoiding obstacles and dangers. With this robotic system, based computer vision and Artificial Intelligence, it is now possible for the individuals to carry out objects easily, comfortably and safely, through concept proof in shopping carts of Supermarkets.

This innovative technology has been winning numerous awards like “O Concurso de Ideias”, “Planos de Negócio Arrisca C” and it was second “MIT Venture Contest 2011”. Follow Inspiration it’s exactly the next step, said the young entrepreneur “that is the only way that you can continue to develop wiiGO and do with this get to the market”. Nowadays, Follow Inspiration is a TBC focused in the development of technology products in robotic field and they have got the first one business angel in 2012, “TIC Risco”, and in 2015 they entered in capital company of “Portugal Ventures”.

Currently, 6 years after the trigger event, the investment has been complemented with some monetary funds from “Portugal 2020” and the company is now a anonymous society, with 20 employees.

4.2 2nd Case: Inklusion – You dream it, we build it

Inkaos project aims to create a startup with a strong technological component, guided by innovation and focusing on the development of products with great quality and technological differentiation. This project aims to fill a gap in national market, such as the development of video games, or applications with interaction with three-dimensional environments and gave rise to the creation of Inklusion Entertainment.

According to the CEO of Inklusion, João Dias, the creation of the company had as initial goal to transfer to the market products that aim at a change of paradigm in the area of education, in conformity with the current highly computerized generations and accustomed from an early age to live in an era in which everything is digital.

The team intends to take advantage to introduce more interactive and appealing ways of educating young people through digital formats, either through video games or through applications that allow greater interaction with the subjects the intend to teach (eg. The possibility of interacting with three-dimensional objects, in order to have a greater perception of its real aspect). This business idea is geared towards a market segment that has not been explored at a national level (ie development of video games and 3D applications) and with great profitability at an international level. The company intends to make available all its products adapted to the generations of the digital era, can be filled by interactive and appealing digital formats. So, for those who want to teach and have fun learning, inKlusion provides interactive experiences with the human body and sensitizes to environmental issues. Unlike on the market, it ensures entertainment, teaching and 3D technology in a format similar to commercial games.

5. Conclusion

Entrepreneurial activity is determinant to achieve good levels of economic performance in any region or country. The evidences in scientific literature of entrepreneurship maintain that an entrepreneur, has certain personal characteristics such as capacity for innovation, vision, creativity, locus of control, willingness to take risks, which can be enhanced and improved through entrepreneurial education, particularly with training courses with innovative methodology, that encourage the creation of new companies resulting from ideas, or research results that can be valued and brought to the market.

Particularly, the *CEBT Ibérico*, considered an entrepreneurship training program with innovative methodologies, is a reference in a network of seven universities belonging to the two borders regions of Portugal and Spain. The course throughout its various editions, stimulate new ideas and business models, with special focus in creation of technology ventures, some of them already successfully recognized. In this line of ideas and based in the evidences presented, it is possible to concluded that entrepreneurship, as stated by many authors, can be effectively taught, and effectively contributes to foster the emergence of new technology ventures, essential to reinforce the competitiveness and specialization of countries and regions, act as innovative leading agents in field of technology, as well as in the generation of qualified employment.

Abstract: An innovation ecosystem is characterised by numerous interactions between its various components. Jackson (2010) argues that it is critical to manage and expand the benefits of this ecosystem, which requires mapping and creating metrics to identify gaps in its performance, and possibly correcting bottlenecks. The proper functioning of an innovation ecosystem is a necessary condition to increase the chances of successful innovative activities, thereby improving the likelihood of creating jobs and providing better conditions for the prosperity of a society. The Global Innovation Index (GII), created jointly by Cornell University and the World Intellectual Property Organization (WIPO), measures various dimensions of the innovation ecosystem in different countries. The index tracks innovation input, which is related to a favourable innovation environment (such as Institutions, Human Resources, Research, Infrastructure, Market Sophistication and Business Sophistication) and innovation output, which in turn is associated with proper innovation outcomes (Products of Knowledge and Technology; Creative Products). Based on the GII metrics, our research aims to investigate the possible relationship between input and output in the innovation ecosystem. Using annual country data, we estimate a quantile regression model to identify the (hypothesised) structural relationship between innovation input and output. The model includes control variables such as GDP (PPP) per capita. Our findings show that innovation input has a significant and positive effect on innovation output. This result confirms the main hypothesis and is similar to the findings of Dutta and Benavente (2011), Dutta, Benavente and Wunsch-Vincent (2012), Dutta, Benavente and Wunsch-Vincent (2013), Dutta et al (2014), Dutta et al (2015), Dutta et al (2016) and Dutta et al (2017). In addition, the more we move to the left tail of the innovation output distribution, the higher is the effect of innovation input. These findings are useful for national innovation policies, since they emphasise the need to promote better innovation incentives.

Keywords: The Global Innovation Index (GII), Innovation Input, Innovation Output, Innovation Ecosystem, Innovation Policies

1. Introduction

The result of new arrangements between the factors of production that lead to new goods, new production processes or new forms of industrial organisation is associated with the notion of innovation introduced by Schumpeter (1982).

Innovation is the key to a dynamic economy. Helpmann (2004) argue that it is not so much the accumulation of more capital that determines the long-term economic growth, but how capital is used, i.e., the innovation process (Easterly and Levine, 2001; Helpmann, 2004).

Innovation increases employment, income, competitiveness and consequently leads to economic development. Countries need creating incentives for innovation in order to raise their quality of living (Moretti, 2004; Helpmann, 2004; OCDE, 2010; Atkinson, 2013). However, the decision making of policy makers should be preceded by studies that qualify and quantify the specificities of innovation, in order to identify the state of the art and prepare adequate strategies to promote it.

The Global Innovation Index (GII), created in 2007, resulted from a collaboration between Cornell University, INSEAD (European Institute of Business Administration) and the World Intellectual Property Organization (WIPO). The goal with is to create procedures and metrics to measure the different dimensions of innovation in a number of countries (SaiSana, 2011). The GII tracks innovation input, which are related to a favourable innovation environment (Institutions; Human Resources and Research; Infrastructure; Market Sophistication and Business Sophistication), and output, which is defined as the results of innovation (Knowledge and Technology-based Products; Creative Products). The innovation input and output are sub-indices that generate the GII (Dutta and Benavente, 2011).

However, the methodology of GII does not empirically assess the possible linkage between innovation input and outputs over a particular time. The GII only synthesises the final annual result for the status quo of innovation in several countries based on the mapped categories.

Our investigation found no scientific studies that conducted a more specific analysis about the possible links between the GII sub-indices. Therefore, we aim to investigate the relationship between input and output in the innovation ecosystem. We test the hypothesis that innovation input affect output in the GII results between 2010 and 2016.

We estimate a quantile regression model to identify the (hypothetical) structural relationship between innovation input and output. Our study proposes a different view for analysing the innovation ecosystem that may be useful for global innovation policies.

2. Innovation ecosystem

Following Schumpeter (1982), other authors and organisations have proposed new concepts of innovation (OECD, 1997; Edquist, 1997; Sundbo and Gallouj, 1998; OECD, 2005). To summarize, innovation is now understood as the implementation of something new or significantly improved (Product or Service, Process, Marketing Method; Business Organisation Method, Commercial Models, Practices, Workplace Organisation or Foreign Relations). In addition, the innovation phenomenon has been systematically investigated and measured (Dosi, 1988; Lundvall, 1992; Nelson, 1993; Freeman, 1995; Moore, 1996).

Leydesdorff and Etzkowitz (1996) and Etzkowitz and Leydesdorff (2000) proposed the Triple Helix innovation model to identify the role of companies, governments and universities. In this model, the university encourages the relationship with companies and government in generating, accumulating and applying new knowledge (technological innovations) in favour of economic development. Campbell, Carayannis and Rehman (2015) broaden the notion of Triple helix by introducing civil society as a fourth helix, emphasising democracy and the importance of political and civil rights in the innovation system. Carayannis, Barth and Campbell (2012) and Carayannis and Rakhmatullin (2014) include sustainable development as another dimension in the helix models, resulting in a five-helix model.

The innovation ecosystem has become an organisational paradigm and has served as the primary reference in formulating strategies for innovation (Teece, 2007). The functioning of an ecosystem is characterised by multiple interactions between its different components. In this respect, it is important to manage and expand the benefits of the ecosystem, which requires mapping and creating metrics to quantify and identify gaps in its performance, possibly correcting any bottlenecks (Jackson, 2010). The proper functioning of an ecosystem is needed to broaden the effectiveness of entrepreneurial and innovative activities, creating jobs and providing the conditions for economic prosperity.

2.1 Global Innovation Index (GII)

The GII was created with the reasoning that innovation is important for driving competitiveness and economic progress in developed and underdeveloped economies. According to Saisana, Domínguez-Torreiro and Vertesy (2017), in 2017 the index was calculated for 127 countries based on 79 indicators; in that year, the index measured innovation ecosystems that covered 92.5% of the world's population and 97.6% of GDP (in USD).

The GII adopts the concept of innovation originally devised by the Oslo Manual and expanded by the European Community and the Organisation for Economic Cooperation and Development (OECD). Figure 1 shows that the GII consists of seven large innovation areas divided into 21 sub-areas.

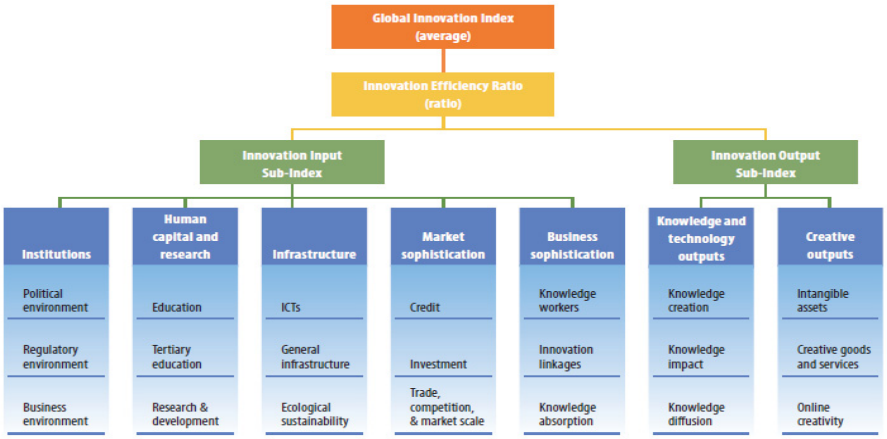

Figure 1: Composition of the Global Innovation Index (GII)

Source: Saisana, Domínguez-Torreiro and Vertesy (2017)

Five large areas monitor innovation input, which determine environmental aspects favourable to innovation, and two large areas monitor innovation output. The GII then aggregates the large areas into two sub-indices: Input and Output. Next, they calculate the Innovation Efficiency Ratio, which is the ratio between the sub-indices of Innovation Input and Output. Finally, the Global Innovation Index (GII) is calculated by arithmetic mean of the sub-indices.

The GII and its sub-indices are quantitative measures that range between 0 and 100; the higher the score, the more developed is the innovation ecosystem. At an elementary level, the methodology allows all sub-areas to be decomposed into 81 indicators. The complete GII methodology can be accessed in greater detail in the annual reports published jointly by Cornell University and WIPO.

SaiSana (2011), Saisana and Philippas (2012; 2013), Saisana and Saltelli (2014), Saisana and Domínguez-Torreiro (2015) and Saisana, Domínguez-Torreiro and Vertesy (2016; 2017) assessed the GII using the *Handbook on Constructing Composite Indicators: Methodology and User Guide*, produced by the Applied Statistics and Econometrics Unit of the Joint Research Centre (JRC) of the European Commission in Ispra (Italy) in partnership with the OECD. These authors tested the GII from two perspectives: conceptual and statistical coherence. They concluded that the multilevel structure of the GII is statistically coherent and has a stable structure, since it is not dominated by any of the sub-index. The ranking obtained by a country is reasonably robust given the methodological assumptions (estimate of lost data, weighting and aggregation formula).

2.2 Literature review

Al-Sudairi and Bakry (2014) explored the results of the GII for Saudi Arabia. Sohn, Kim and Jeon (2016) re-examined the GII using a structural equation model for 2013 data. These authors analyse innovation input (institution, human capital and research, infrastructure, market sophistication and business sophistication) and output (knowledge and technology, and creative solutions). However, they did not consider the possible structural relationship between the factors that affect a country's innovation performance.

Crespo and Crespo (2016) assume that countries can achieve high innovation performance in the GII using various combinations of input. The authors discuss the internal sub-pillars of innovation input and define two sub-samples (high and low-income countries). They find that several input combinations lead to high innovation performance in both groups, and that in the low-income group none of the individual conditions is sufficient to predict good innovation performance, while in the high-income group the infrastructure, human capital and research conditions are sufficient to obtain a better innovation performance. Carpita and Ciavolino (2017) found evidence of a positive relationship between Business Sophistication (explanatory variable) and Innovation Input (response variable), using the GII data for 27 European Union (EU) countries in 2012.

Vlasova, Kuznetsova and Roud (2017) investigated the results for Russia in the GII between 2013 and 2016. The authors analysed the strengths and weaknesses regarding progress in science, technology and innovation in the country. Jankowska, Matysek-Jedrych and Mroczek-Dabrowska (2017) used the GII to explain how national

innovation systems can transform innovation input into output in different countries. The authors assume that more innovation input generates more innovation output in a country. They used cluster analysis with 228 countries. Subsequent results obtained for Poland and Bulgaria contradicted the first results. The authors then try to explain how and why national innovation systems failed (or succeeded) in creating innovation.

There is also a series of studies available in the GII reports that discuss its theoretical-methodological concept and results (Dutta and Benavente, 2011; SaiSana, 2011; Dutta, Benavente and Wunsch-Vincent, 2012; Saisana and Philippas, 2012; Wunsch-Vincent, 2012; Slater and Wruuck, 2012; Saisana and Philippas, 2013; Hollanders, 2013; Xiangjiang, Peng and Kelly, 2013; Dutta et al, 2014; Saisana and Saltelli, 2014; Scott and Vincent-Lancrin, 2014; Dutta et al, 2015; Saisana and Domínguez-Torreiro, 2015; Reynoso et al, 2015; Goedhuys, Hollanders and Mohnen, 2015; Atkinson and Ezell, 2015; Chen, Zheng and Guo, 2015; Chaminade and Moskovko, 2015; Gopalakrishnan and Dasgupta, 2015; Ecuru and Kawooya, 2015; Dutta et al, 2016; Saisana, Domínguez-Torreiro and Vertesy, 2016; Poh, 2016; Gokhber and Roud, 2016; Dutta et al, 2017; Andrade and Domingos, 2017; and Lybbert et al, 2017).

Dutta and Benavente (2011), Dutta, Benavente and Wunsch-Vincent (2012), Dutta, Benavente and Wunsch-Vincent (2013), Dutta et al (2014), Dutta et al (2015), Dutta et al (2016) and Dutta et al (2017) report that, although the scores for Input and Output in the GII may differ substantially, leading to important changes in the countries classification, there is a positive relationship between them. To summarize, based on the data available for the respective years, these authors infer that the efforts made for better innovation input are rewarded with improved innovation results.

3. Methodology

3.1 Sample Design

The sample was based on the availability of the GII sub-indices (innovation input and output) and the data were obtained from the annual GII reports. The other control variable selected was Gross Domestic Product Per Capita based on Purchasing Power Parity (GDP PPP per capita) in 2011 United States dollars, obtained from the World Bank.

The sample includes all the available years of the GII (2011 to 2017). However, the current year GII is based on country data from the previous year. In order to estimate the empirical model, we consider that the results of the GII always refer to the year prior to publication.

Table 1: Number of countries mapped by the GII

Countries	2010	2011	2012	2013	2014	2015	2016
GII	125	141	142	143	141	128	127
GDP PPP per capita	146	146	146	146	145	145	141

Source: the authors

As we see, the non-homogeneous number of countries mapped each year by the GII requires some specific methodological treatment.

3.2 Empirical Model

The GII sub-indices use a variety of information on countries' innovation ecosystem (see Figure 1), which can support, at least in an initial investigation, the lack of other control variables included in the model. However, since the index covers several countries with varying economic performance, it is important to consider the possible high heterogeneity in the structural relationship between input and output in the GII environment. As such, we propose estimating a quantile regression model with fixed effects in a panel data setting in order to test the possible relationship between innovation input and output.

The quantile regression model with fixed effects is credited to different authors (Koenker, 2004; Bache, Dahl and Kristensen, 2013; Powell, 2017). In this study, we use the penalized quantile regression with fixed effects proposed by Koenker (2004),

$$Q_{y,it}(\tau|x_{it}) = x_{it}^{\top}\beta(\tau) + \alpha_i, \qquad (1)$$

where $Q_{y,it}$ is the conditional quantile of the response variable, i.e. innovation output for country *i* in year *t*. The individual unobserved characteristics are controlled by the various $\alpha's$, and the effect is restricted only to a location shift on the conditional quantiles. Moreover, the effect of α is, by assumption, identical across all quantiles of a same country. x_{it} is the covariate vector that contains the intercept, innovation input, GDP PPP per capita and dummy variables to identify the effect of different regions on innovation output. The regions' label is based on the United Nations criteria, as follows: EUR = Europe; NAC = North America; LCN = Latin America and the Caribbean; CSA = Central and Southern Asia; SEAO = Southeast Asia, East Asia, and Oceania; NAWA = Northern Africa and Western Asia; SSF = Sub-Saharan Africa. We selected CSA as the base region. The response variable and the covariates are in logs, except for the dummies.

The penalised estimator proposed by Koenker (2004) for model (1) consists on solving the linear programming problem

$$\min_{(\alpha,\beta)} \sum_{k=1}^{q} \sum_{i=1}^{n} \sum_{t=1}^{t_i} w_k \, \rho_{\tau_k} \left(y_{it} - \alpha_i - x_{it}^{\top} \beta(\tau_k) \right) + \lambda \sum_{i=1}^{n} |\alpha_i|. \quad (2)$$

The quantiles of interest are estimated simultaneously and w_k are the weights that control the relative influence of each quantile in estimating the $\alpha's$ individual effects. λ is a parameter that controls the penalty on the $\alpha's$: when $\lambda \to 0$ we have an estimator for a dummy-variable fixed effects regression, and when $\lambda \to \infty$ all the fixed effects are shrink toward zero, resulting in a cross-section regression estimator. In our model, we set $w_k = 0.2$ for each of the five usual quantiles and $\lambda = 1$. As shown in (2), the estimator allows unbalanced panels.

4. Results

Table 6 summarises the results. We find that innovation input has a significant positive effect on innovation output. This result confirms our hypothesis and partially corroborates that of Dutta and Benavente (2011), Dutta, Benavente and Wunsch-Vincent (2012), Dutta, Benavente and Wunsch-Vincent (2013), Dutta et al (2014), Dutta et al (2015), Dutta et al (2016) and Dutta et al (2017). As we move to the left tail of the innovation output distribution, the higher is the effect of innovation input.

Our analysis also includes GDP per capita as control variable. Interestingly, GDP per capita seems not to provide any substantial informational in explaining innovation output across the quantiles. The absence of statistical significance is a result that should be observed with caution, since a higher level of economic activity should promote more innovation output, as measured by the GII. However, the lack of significance may be attributed to three reasons: i) a decline in the economic growth rate in many countries during the period; ii) GDP per capita may be affecting innovation output differently in the short, medium and long run; and iii) the relevant information for explaining innovation output is already being captured by the innovation input sub-index.

Table 2: Results of quantile regressions for countries between 2011 and 2017

OUTPUT	10% Quantile	25% Quantile	50% Quantile	75% Quantile	90% Quantile

Source: the authors

The results for Europe and North America, which have the most dynamic and advanced economies in the world, are practically identical. This seems to strengthen the hypothesis that these two regions exhibit a sort of spatial effect that has a positive impact (relative to CSA) at the left tail of the innovation output conditional distribution (roughly, it means that these regions encourage more innovation output using input when output levels are lower). On the other hand, the non-significant effect of Europe, North America and Canada at higher quantiles may be associated with stagnant innovation results. LCN, NAWA and SSF showed no significance at all. There are some reasons why no significant effect was found for these regions, the most likely being related to the fact that these regions have underdeveloped economies with low innovation levels.

5. Conclusion

This study presents evidence that innovation input affect positively innovation output as measured by the GII. However, the results reveal that the effect of innovation input on innovation output is more intense at lower quantiles. The effect seems to decline the more we move to the right tail, which would contradict, to a certain extent, part of the literature that argues that more efforts directed to innovation input are always rewarded with better innovation results. This argument seems to be more plausible at lower quantiles, whereas encouraging more input when we are at the right tail might moderately affect innovation results.

The relationship between input and innovation output in the GII has already been recognised, but we attempt to broaden the discussion by monitoring all countries included in the GII. Furthermore, we observe a longer period than that of past studies. In addition, we include regional dummies in order to capture more information on the behaviour of innovation output. Only the regions of North America and Europe exhibited a significant positive effect across the quantiles. The non-significant effect found for the regions demonstrates the need for more efficient policies, in order to reverse the stagnation trend in the upper quantiles, and enhance the effectiveness of input in materialising innovation products in countries with developing economies.

The evidence presented is not definitive and should be compared with additional studies. We suggest future research using alternative methodologies, such as using finite distributed lag models or test the hypothesis of a dynamic effect on the response variable (innovation output).

Sustainable Internationalization of Hi-Tech Small Firms: Meta-Synthesis

Mehran Rezvani, Ali Mobini Dehkordi and Samineh Soltanzadeh
University of Tehran, Iran
M.rezvani@ut.ac.ir
Mobini@ut.ac.ir
S_soltanzadeh@ut.ac.ir

Abstract: The fragmented literature of internationalization has not yet been structured in a coherent framework or model. Especially this is true about Sustainable internationalization of Hi-tech small firms. To build a comprehensive framework in this regard this research study involved collecting academic and peer reviewed articles that addressed the issue of Sustainable internationalization of Hi-tech small firms. The application of the inclusion and exclusion criteria on the 51 articles yielded eleven articles that were appropriate for the meta-synthesis. The results suggest sustainability themes are in six categories: economic, social, environmental, company specific factors, location, industrial factors and human capital.

Keywords: Sustainability, internationalization, Hi-tech, Meta-Synthesis

1. Introduction

Among multiple objectives of firms, two objectives can be particularly important for firm growth: internationalization, and innovation/quality (Skrt and Antoncic, 2004). The importance of internationalization for small businesses growth has been in the international entrepreneurship literature (for example, see reviews by McDougall and Oviat; Antoncic and Hisrich; Zahra and George). Many studies in the field of internationalization have led to a variety of internationalization theories and models. In general, international theories and models can be categorized as follows: (1) Product Life Cycle Model (PLC): In this model, firms become international once their products have passed their maturity stages and can produce standard products on a scale (Gankema et al., 2000), (2) INV model: Based on this model, product nature, industry norms and trends of managers and entrepreneurs of that firm are the main determinant factors in the internationalization of a firm (Zahra, 2005); (3) global birth model: this model is quite the opposite Process models, and it is argued that some companies operate globally from the moment of birth. And do not necessarily take internationalization steps (Weerawardena et al, 2007), (4) Network Approach: In this approach, it is believed that the business network in which an enterprise operates plays a crucial and decisive role in the internationalization of firms (Senik et al., 2011), (5). Process models: These models consider internationalization a step-by-step process. In these models, it is believed that firms must go through different stages of internationalization (Anderson, 1993).

However, research shows that there are many open questions in this regard. For example, it should be noted that the issue of providing stable internationalization models and models, as well as on technology-driven businesses, has been considered very little in literature (Senik et al., 2011). But there are some studies pointing out some aspects of this phenomenon. For example, Kowalski (2014) points out that networking and clustering can contribute to the process of internationalization. On the other hand, it should be noted that most of the research in this area was about businesses other than technology-based businesses (for example, Chety et al., 2014; Lefgren, 2014). Lack of attention to this issue can not address the issue of sustainable internationalization of technology-oriented businesses and deprive them of the benefits of this issue. The presentation of such a model can simultaneously provide internationalization and sustainability benefits (Box, 2014). On the other hand, considering the different dimensions of this phenomenon discussed, the ground for this model seems to be presented. But there are still many challenges in this area-such as taking into account the particular conditions of advanced technology-based businesses (Sanic et al., 2011). Cedrola et al. (2015) cites a challenging issue in a study that presents sustainability internationalization patterns, drawing researchers' attention to the characteristics of their firms in particular. As a result in this research, we will focus on "providing a sustainable internationalization model for technology-driven businesses" to give an effective response to the concerns of sustainability in international arena. For this purpose, a system perspective will be used.

Sustainability means continuity in something like activity and the creation of a dynamic balance between many effective factors such as the natural, social, and economic factors required by humanity. Sustainability as a descriptive aspect of development is a situation in which the desirability and facilities are not reduced over time, and the meaning of keeping the hold of the word Sustenere (Sus means from the bottom and Tenere means keeping it alive) It refers to long-term support or long-term durability. Sustainability, in its broadest sense, refers to the ability of the community, ecosystem or any current system to operate indefinitely in the future, without necessarily leading to the degradation of the resources to which the system relies or due to imposing excessive burden on them. To be weakened (Gold, 1996).

On the other hand, the system's capability for endurance and reliability is inevitably dependent on the success that the system gains in communicating with the outside world; in other words, the stability of the system is entirely dependent on the system's ability to adapt, adapt, and It is evolving and responsive to the environment, and since the environment in turn is constantly changing, this adaptation and adaptation system should be a dynamic and sensitive process.

Therefore, the sustained system requires proper internal function and environment-friendly relationship, in other words stability to inside and external stability (in interaction with the environment), in general, to act as a sustainable system. In fact, sustainability is in practice a balance between environmental imperatives and development needs, and is achieved in two ways: reducing pressures and increasing existing capacities.
Therefore, the main conditions of sustainability are:

1. Systems must be compatible with local and environmental conditions.
2. Systems must be compatible with future needs and intended purposes.
3. Systems must be adaptable to changes, and should be repaired in the event of a system failure due to unplanned incidents.
4. The expansion of systems should not cause harm to systems that protect human life, such as climate, soil and biological systems.

2. Sustainable internationalization

The fragmented literature of internationalization has not yet been structured in a coherent framework or model (Krishna, 2012; Lane and Guan, 2015; Hajimarco et al., 2015). Therefore, a process model can produce a more specific image of this process. As Zhian et al. (2008) acknowledge, an integrated process model can encompass and interact with each other factors that contribute to the sustainable internationalization process of high technology companies. In his view, the process model offers a better explanation of this phenomenon.

Penn and Kelly Deberl (2002) also point out the importance of presenting a process model in this regard.

The acquisition of sustainable competitive advantage determines sustainability. Competitive advantage of any kind can be either sustained or temporary in terms of competitive performance. The temporary advantage refers to a short-term and transitional advantage. For example, American Airlines's Intelligent Automated Booking System introduced the company at the time of introduction in terms of exploiting capacity and quick access to customers and other operational aspects. It can be said that the more obvious the features and the simplicity of the competitive advantage are, the more potentially its capability.

However, if a company has an innovative enterprise-oriented culture and high market-leading innovation, it can, firstly, intelligently use its own feature and improve its position advantage, secondly, before competitors have a temporary advantage To create a new advantage and always have competitors behind them. In the face of a temporary competitive advantage, there is a lasting competitive advantage, which is, firstly, long-term and non-transitory, and secondly, easily accessible by competitors. A striking example of that is the strong brand and the Coca-Cola brand that has continued for over a century and enrays all competitors.

In general, it can be said that the sustainable competitive advantage of such features as durability, high throughput, good tolerance, tolerance, high bioavailability, high support and support, high acceptability, reasonable power and satisfactory reassurance And there is considerable negotiating power that, of course, will fit all or some of the above features according to the strength and strength of the competitive advantage.
For example, if an organization is compelled to protect its values against its competitors, then the term sustainability is more consistent with tolerance and capability, or if the competitive advantage of the

organization is to enable it to design and implement a strategy The aggressive nature of the market in various fields, the term sustainability of competitive advantage is more dependent on its aggressive capabilities.

Grant considers sustainability a competitive advantage with a long, vibrant, and reflective dimension. Prolonged in terms of the ability of competitors to mimic or obtain the source of the competitive advantage, it is argued that the sustainable competitive advantage is essentially related to a large number of subfields and of a dynamic nature. Each aspect of the sustainability of competitive advantage depends on the nature of the strategic task at different levels of the organization, and therefore sustainability is considered instead of a static concept as a dynamic process, and thus it can be said that the competitive advantage of a destination is not a specified interval. But an infinite journey that depends on the ability of the passenger and his goals. With this concept, the competitive advantage of tomorrow is close, but it never comes, because of the dynamic nature of the environment and the rapid changes in market demands and expectations, as well as the changing behavior of competitors, as well as its complex nature, is a competitive advantage. Another important point is that there is a relationship between a temporary competitive advantage and a sustainable competitive advantage, so that in some cases, a sustainable competitive advantage derives from a sum of a series of temporary competitive advantages. For example, in the computer industry, Intel's dominance of the cheap computer market has been achieved through the creation of a set of tangible benefits, which further creates a new advantage and, based on that, delivers a new product and, as a result, competitors who seek Imitation and copying have to start a new business in order to achieve the new advantage, and this is the secret to continuing the competitive advantage of Intel in the computer industry over the past two decades.

Therefore, it should be noted that the issue of providing stable internationalization models and models, as well as on technology-driven businesses, has been considered very little in literature (Sanik et al., 2011). But there are some studies pointing out some aspects of this phenomenon.

For example, Kowalski (2014) points out that networking and clustering can contribute to the process of internationalization. On the other hand, it should be noted that most of the research in this area was about businesses other than technology-based businesses (for example, Chety et al., 2014; Lefgren, 2014). On the other hand, considering the different dimensions of this phenomenon discussed, the ground for this model seems to be presented. But there are still many challenges in this area-such as taking into account the particular conditions of advanced technology-based businesses (Sanic et al., 2011). Cedrola et al. (2015) cites a challenging issue in a study that presents sustainability internationalization patterns, drawing researchers' attention to the characteristics of their firms in particular. In general, the problems faced by small and medium enterprises in this regard can be divided into two categories (Al Rawi, 2007):

Major internal barriers, including lack of information, lack of sufficient capital or credibility, (a) the difficulty of creating a position on the international market and maintaining international business relations, (b) the difficulty of using commercial finance services, dealing with growing costs, Prolonged credit and tolerable losses, (c) lack of timely access to loans and loans needed), and inadequate managerial skills (a) many small and medium enterprises are more productive and technology-oriented than market-oriented, and more affordable Energy, time and resources for international marketing and marketing; b) the lack of management with International experience and foreign language skills).

Major external barriers: technical commercial constraints (such as standardization, compliance with qualitative requirements, assessment of product compliance with market demand, packaging and labeling, compliance with environmental requirements), administrative procedures, marketing and distribution problems in the target market , Lack of risk insurance, high transportation costs and communication problems in distant countries.

3. Method

This research study involved collecting academic and peer reviewed articles that addressed the issue of Sustainable internationalization of Hi-tech small firms. Forward and backward tracking of citations was used to further complement the research efforts. The articles used for this study were retrieved from the following academic and research databases: MPDI and ScienceDirect. Google and Google Scholar search engines, were also used for search on relevant articles. The research team used subject headings, author names, and keywords to search for relevant sources. The keywords used for the academic peer reviewed articles included

Sustainable internationalization ‘‘+”Hi-tech small firms, Sustainability, internationalization, and Hi-tech. As there are several established authorities on the topic of internationalization, the search terms also included the names of authors.

The searches on Sustainable internationalization and related topics produced 51 articles. Following the guidelines of the conventional systematic review methodology, inclusion and exclusion criteria were applied to the 51 studies by two independent researchers. This was done to ensure that the sample of articles used for the analysis was appropriate for the meta-synthesis. The inclusion criteria for the qualitative component included the following: (1) publication was qualitative in research design; (2) publication was academic and peer reviewed in nature; (3) publication dealt with investigation of Sustainable internationalization; (4) the study used primary data; and (5) researchers had a defined sample.

The exclusion criteria were applied to: (1) papers with an entirely conceptual or theoretical background and no research design; and (2) studies with close-ended survey questions as the data collection instrument. The application of the inclusion and exclusion criteria on the 51 articles yielded eleven articles that were appropriate for the meta-synthesis. 40 articles were excluded from the analysis because they failed to meet the criteria stipulated given the design of the current research.

4. Sustainability themes

Sustainability themes are categorized in most articles in seven categories: economic, social, environmental, company specific factors, location, industrial factors and human capital. Accordingly, it is suggested that themes such as improving the level of national income, production conditions, living standards (nutrition, housing, health and education), working environment conditions, institutions and policies for measuring sustainable development are suggested (Steretin's comment on development, known as the vision of sustainable development, is a fundamental requirement). And in another article by Gunnar Myrdal, he has proposed other indicators for assessing sustainable development, including indicators (rationalism, knowledge development and effective implementation planning, productivity enhancement, living standards, social and economic equality, and improvement Institutions, behaviors and habits, national solidarity, national independence, broad-based democracy, social discipline).

From the series of articles, "themes of Sustainable Development have been categorized from the indicators in four areas: economic, social, environmental and institutional.

Construct	Theme, article (#)	Theme description
Social	Participation in the cultural and social (1) Durability of the product (2) Performance (2) Management of the products (2) The following participation of stakeholders (3) Security of operation (3) Encouraged staff (3) Participation and development of the organization (4) Supply chain, customers, consumer products / services (4) Business Ethics / fair operating practices (4) Observance and compliance with social rules and regulations (4) Workers and employees of the investor company (4)	Staff training The impact of employee diversity and sustainability in the production of various products business Of the active role of communication / Community participation in sustainability and business development Yield loss based on the landfill The quality and efficiency of manufactured products Employment of local community The creation of jobs processing your product Repeats its customers The amount of customer consent The number of complaints to its customer s Financial staff turnover Securing local resources Products with innovation and growth A Yi or through a savings in valuable resources, to the benefit of its community Recent securing percent of the total resources of the feet of the Watch behind the securing and development in the growth and sustainable impact? 5. Conclusion

The meta-synthesis of 11 studies on Sustainable internationalization of Hi-tech small firms resulted in deeper insights into questions formulated for this research. To recap, the main antecedents of Sustainable internationalization of Hi-tech small firms are economic, social, environmental, company specific factors, location, industrial factors and human capital.

The results suggest that Internationalization is one of the ways in which companies can benefit from international market activity. The least benefit to internationalization for companies and countries is the transfer of technology across borders. Internationalization was first introduced in 1966 in the theory of the Vernon product life span. It is very difficult to discuss the theory of internationalization because the term itself is not yet fully defined. Nevertheless, extensive definitions have been internationalized, such as internationalization as a process to increase international engagement, and define international business as the business that has two or more countries to be included. Researchers consider internationalization as an outsider for international operations. Internationalization has also been defined as reflecting the interests of the country of origin and the enthusiasm of decision makers (entrepreneurs) for operating on the basis of opportunities in foreign markets (outside the boundary of the country of origin) (Prahadan & Das, 2016).

In 2001, there was no definition in which definitions and previous findings were included. And internationalization is considered as a process in which companies are aware of the direct and indirect effects of international exchanges on their future and therefore trade with other countries. In 1989, Bilas and Calif introduced the internationalization process to the implementation of the company's operations (strategy, structure, resources, etc.) with the international environment. Internationalization of a company is not a one-dimensional concept and cannot be considered only in the operational dimension, so the research approach should identify its full dimensions (ibid).

As mentioned earlier, in this study, we will use a process approach to provide a sustainable internationalization model in technology-driven businesses. In our view, the application of a system of process sets, together with identifying the relationships and interactions of these processes and their coherence to create optimal output, is referred to as a process approach. The ever-increasing need for speed and decisiveness in complex decisions regarding product development and production operations has encouraged firms to focus on different processes - contrary to the traditional approach that has focused on the entire firm. The main processes can be divided into two main groups (Gregory, 1995; Canon and Oguto, 2015):

1. Business Processes: The business process represents the flow of information and materials from the supplier to the customer (consumer). The benefits of these processes include: Describing and revealing the normal activities of a business; providing a framework for evaluating completed processes; providing a basis for analyzing the value of each activity within the process; and making it possible for employees who can engage in activities that involve them. Are identifying and evaluating.
2. Management processes: Management processes are activities that will implicitly determine how key decisions are made within the organization. Such decisions require the input of data and the perception and receipt of information from different parts of the organization, and not necessarily in terms of mathematical modeling. For example, management processes include formulating strategies and analyzing and designing policies and procedures. The audit of production strategies and the identification of capabilities (capabilities) are examples of such.

In general, a process approach offers opportunities and solutions to overcome existing problems. As a result of using this approach, it is possible to identify issues related to the internationalization of technology-based companies, to integrate them into operational and, consequently, with other current management activities.

In addition, technology management may be considered as a business flow and not as seen in the flow of operational information and flow of materials. It may also be possible to identify the technology management activities, their continuity and their evaluation of the business process approach. Business processes and management processes together provide tools for deploying a technology strategy. On the other hand, internationalization or, in other words, the internationalization of activities is being studied in various aspects, and in fact the concept is ambiguous, and has a different meaning in relation to any field of study. The word goes back to the various elements in the organization, such as strategy, organizational structure, products, and the like. Internationalization is also a process of engagement in international operations. A different view of Kalouf and Bezhish (1995) states that internationalization means the process of aligning the operations of companies (such as strategy, structure, resources, etc.) with international environments, that is, in fact, the international Activity is considered as a dynamic process (Rundh, 2007).

Future Worlds, Post Anthropocene: New Approaches to Sustainability

Pete Rive
Auckland University of Technology, New Zealand
prive@aut.ac.nz

Abstract: This paper presents research emanating from a deep concern about the existential health of our planet; my personal pursuit of effective teaching in the area known as creative technologies; and the responsive engagement of the students facing the insurmountable problems we all confront. The Anthropocene is one of those problems that demands a response, but denies singular, simplistic solutions. Paradoxically, the Anthropocene is the result of the human impact on the earth, however, it is apparently beyond individual, and probably, even technological control. Just as there has been the emergence of a global environmental and social consciousness there has been a dawning suspicion that the wicked problems of the Anthropocene may elude our technological solutions resulting in planetary anxiety and neurosis. I have undertaken a number of novel approaches to teaching creative technologies in order to explore positive teaching methods with the ambition to liberate students, and ourselves from cognitive and physical paralysis and to open metaphysical boundaries for future innovative research and creativity. Over the course of the past 4 years I have experimented with numerous approaches to assist students in coming to grips with this and other intransigent problems that trouble humanity and nonhumanity alike. Despite the fact that many of these problems relating to the Anthropocene are over 60 years old, wave after wave of student graduates have failed to critically address design innovations and entrepreneurial opportunities that might ameliorate human impact or contribute to sustainable businesses. The military-industrial-academic legacy of creative technologies suggests a wider exposure of education to the pathologies of cyber weaponry. Known as the Great Acceleration of the Anthropocene, exponential technological growth may correlate with the worst excesses of human production, consumption and waste. Through the multidisciplinary Bachelor of Creative Technologies I seek to provide students with the cognitive skills to imagine alternative worlds and speculative futures that enable students to escape the 'transparent cage' and the weaponisation of education. The limitations and successes of student projects will be reviewed and critically assessed in order to provide insights into opportunities for novel pedagogical methods in addressing sustainability and wicked problems.

Keywords: Post Anthropocene; Speculative Realism; Object Orient Ontology; Sustainability; Future Worlds.

1. Introduction

This paper documents the philosophy and methods behind teaching creative technology undergraduates with respect to the theme of the Anthropocene. Over the course of the past 4 years I have experimented with numerous approaches to assist students in coming to grips with this and other wicked problems that trouble humanity and nonhumanity alike. At times this paper will take a personal, somewhat auto-ethnographic approach, intended to assist the reader with the context of my experiments. Due to the limitations of space I will provide a brief summary of student projects that will illustrate how speculative methods have helped students think and design projects considering current and future design challenges using speculative theoretical frameworks.

Despite the fact that many of these problems relating to the Anthropocene are over 60 years old, wave after wave of student graduates have failed to critically address design innovations and entrepreneurial opportunities that might ameliorate human impact or contribute to sustainable businesses. It would appear that design thinking with it emphasis on critical reflexivity has been inadequate to the task of addressing what appears to be the insurmountable problem of humanity's anthropogenic and pathological impact on the earth system. Indeed, philosophically we are now being challenged by thinkers who state that the human perspective must accept a place alongside the astronomically large collection of nonhuman objects that sense the universe in their own alien and mysterious way (Bogost, 2014; Harman, G. 2017; Shaviro, 2014).

While critical thinking can offer a method of evaluating some of the causes and symptoms of our anthropogenic impact a number of philosophers and theorists have begun to critique the legacy of Kantian correlationism and the Enlightenment's current hold on our imagination in the 21st century. Speculative realism, and more specifically Object Oriented Ontology, or OOO, have begun to gather support from those who point to the shortcomings of anthropocentric social theory and scientism. Speculative realists such as Harman, Meillassoux, Bryant, Morton, Bogost and Shaviro regard the likes of Kant, Hume and Descartes as the architects of our 'transparent cage' (Meillassoux, 2017). My concern has been to not only free students from a

suffocating sense of helplessness but to explore novel means of unlocking the cage. My pedagogical approach has been to explore creativity, humour, speculative design and philosophy in the hope of exposing the cognitive bars of our imprisonment. These playful 'experiments' align closely with practiced based research methods and have begun to reveal insights into a new symbiosis between our species and the alien majority of nonhumans that occupy the multiverse.

This transdisciplinary re-imagination of reality is not only essential for our sanity but must be assisted by future generations charged with what Donna Haraway calls 'response-ability'. The Anthropocene demands a response from those who could apply their creative abilities in a responsible way. As Haraway warned there are two fatal paths many have chosen in response to the Anthropocene: 1) childish technofixes, the terra-transformer geoengineering of Hollywood fantasies or 2) the self-defeating, if not suicidal, inaction of critical and cynical academic theorists or scientists who declares it is too late to do anything (2016). These two paths have been popularised through the media, including the Internet and are common popular responses. Haraway insists we should 'stay with the trouble' through 'sympoiesis', mutual making, as opposed to autopoiesis, self-making 'worldings', imagining new worlds for livable futures, 'becoming-with' our nonhuman kin. She uses creative speculative futures to reimagine the past, present and future by dispensing with the Anthropocene and replacing it with the Chthulucene, a subterranean and watery epoch bound to fictional monsters and primitive symbionts, such as "choanoflagellates, microscopic aquatic creatures whose body type and genes place them right next to the base of the animal family tree" (McGowan, K., 2016). Haraway offers us a third speculative path, what she describes as SF, an acronym that encompasses 'string figures, science fact, science fiction, speculative feminism, speculative fabulation' (Haraway, D., 2016). Haraway writes "The Anthropocene marks severe discontinuities; what comes after will not be like what came before. I think our job is to make the Anthropocene as short/thin as possible and to cultivate with each other in every way imaginable epochs to come that can replenish refuge." (Haraway, 2016). To her list I would add speculative realism, speculative fabrication, and speculative design, thinking by making, and making by thinking, a playful approach to 'staying with the trouble' that Haraway would approve, and theorist, such as game designer and philosopher, Ian Bogost (2012), encourages. We are charged with the responsibility of researching, imagining, and teaching about future worlds in the post Anthropocene.

The speculative realists go beyond just reintroducing us to the importance of botanical and biological storytelling by delving into the secret lives of objects, things, and units; a new materialism that includes every *thing*: fictional realities; quarks; and pogo sticks, to copy a typical absurdist list perfected by Bruno Latour. Bogost asks "Why do we give the dead Civil War soldier, the guilty Manhattan project physicist, the oval-headed alien anthropomorph, and the intelligent celestial race so much more credence than the scoria cone, the obsidian fragment, the gypsum crystal, the capsicum pepper, and the propane flame? When we welcome these things into scholarship, poetry, science, and business, it is only to ask how they relate to human productivity, culture, and politics." Bogost shouts, "We've been living in a *tiny prison of our own devising*, [emphasis added] one in which all that concerns us are the fleshy beings that are our kindred and the stuffs with which we stuff ourselves." (2012, Kindle Locations 107-110)

There appears to be an urgent necessity for significant numbers of educators, politicians, and entrepreneurs to begin creative and radically alternative ways of looking at how we live with the nonhumans of this planet.

Speculative realism and OOO are philosophical frameworks to consider how we might provide students and others the tools for our attempted escape from a prison guarded by Latour's 'epistemological police' (Harman, 2017).

2. The Reality of the Anthropocene

While there were earlier insights, prior to this new millennium, even before the Russian scientist Vedansky (1926) in the early 20th century, it was the concerted effort of the International Geosphere-Biosphere Programme scientists that revealed the astounding and dramatic impact of homosapiens on the earth. The geologists Paul Crutzen and Eugene Stoermer are credited with the modern coinage of the word in 2000. In a short peer reviewed article in Nature, The Geology of Man. Crutzen traced the beginnings of human impact back to the beginnings of the industrial revolution with a litany of anthropogenic disasters, and the dire warning that there has been a recent acceleration in the onset of the Anthropocene. He wrote "Unless there is a global catastrophe — a meteorite impact, a world war or a pandemic — mankind will remain a major

environmental force for many millennia. A daunting task lies ahead for scientists and engineers to guide society towards environmentally sustainable management during the era of the Anthropocene." (2002, p.23). I would add to his list designers, artists, and speculative futurists.

There has been a surprising and growing consensus between the Earth Systems' scientists who completed an extraordinary thirty year project before they concluded their anthropogenic theory. They have been followed by the traditionally slow moving geologic community who are close to a consensus that we are now in a new geological epoch, the Anthropocene, which is notably marked by the 'great acceleration' of 1945.

I will not present in detail the arguments for and against the title and theory, 'the Anthropocene', described by some as a new epoch (see Ian Angus, and Donna Haraway for a discussion of the name). The name is useful as it has been recognised by a wide range of scientists, artists, and social theorists. It follows the relatively stable climate of the past 10,000-12,000 years of the Holocene. Here I present a short list of impacts to give some weight to the gravity of the problems we have caused and to set the stage for my main focus of this paper, how I have set about coming to terms with the impending existential crisis and the tools I am trying to provide to my students who are learning creative technologies.

Here are just some of the features commonly related to the Anthropocene.

- A tenfold human population growth in three centuries.
- Maintaining 1.4 billion methane-producing cattle.
- Exploiting 20–50 percent of Earth's land surface.
- Destruction of tropical rainforests.
- Widespread dam building and river diversion.
- Exploitation of more than half of all accessible fresh water.
- A 25 percent decline of fish in upwelling ocean regions and 35 percent in the continental shelf.
- A 16-fold increase in energy use in the twentieth century, raising sulphur dioxide emissions to over twice natural levels.
- Use of more than twice as much nitrogen fertilizer in agriculture as is used naturally in all terrestrial ecosystems combined. Increasing atmospheric concentrations of greenhouse gases to their highest levels in over 400,000 years.
- The sixth mass extinction on earth. The first to be caused by a biological species.
- A thin layer of radionuclides from nuclear weapons testing is now spread all of the planet. (Angus, I., 2016, Kindle Locations 504-507)

3. Philosophical Traps

Why is it that for sixty years educators have been aware of a deep groaning pain coming from our planet buried deep in the chthonic strata, and still our graduates have ventured forward to create businesses and innovations that do not relieve the pain. The efforts of the few to salve the welts caused by vicious mineral extractions are overshadowed instead by the majority that have contributed to the growth of a global economy that have accelerated these savage attacks. As educators we must ask, were we unaware? Did we deny the harm? Did we not care? Or were our pedagogical means inadequate to the task?

One possible root causes may be that educators assumed a social responsibility to the neoliberal goal of economic growth based on a 19th century Malthusian belief in scarcity and the economic fallacy of 'survival of the fittest'. These ideologies or paradigms go back much further, even before the Enlightenment, and the birth of liberalism. The radical political and epistemological philosophy of the Enlightenment began to settle into a reified strata that has fossilised our thoughts in the past. While some social theorists and Earth Systems' scientists may argue that the Anthropocene began with the advent of industrialisation, as early as the invention of the steam engine in 1784; others have argued that the troubles began with the Mesopotamians, the fertile crescent, and the invention of agriculture at the beginning of the Holocene. Jared Diamond claims that agriculture was the 'worst mistake humanity ever made' and Timothy Morton (2018) claims we are still Mesopotamians, while Bruno Latour claims, "We Were Never Modern". Latour argued modernity attempted to split reality into two halves, human and nature. The human was conceived as multifaceted and complex, whereas nature and the material was only ever allowed to be singular and simple (Bogost, 2012). In his final expression of his philosophy, Alfred North Whitehead, in *Process and Reality* (1929) set out to overcome this

epistemological bifurcation of nature. Whitehead argued that there are two sides to reality, the world's phenomenal appearance, and the hidden physical reality beyond the human senses. He set out to rebut Immanuel Kant's eighteenth century claim that "phenomena depend upon the mind to exist" (Braver 2007, p.39). It is this assumption, above all, that speculative realism seeks to overturn." (Shaviro, S., 2014, Kindle Locations 132-134)

A growing body of Earth System scientists, geologists, and social theorists are not just petulantly blaming their parents for the mess we are in, but their parents, parents, parents etc., preceding us by 12 millennium. More recently a new community of philosophers, the speculative realists, have been pointing the finger at the patron saints of contemporary philosophy, Rene Descartes and Immanuel Kant. Of course, this is unfair as they tried to battle their way out of the paper bag that an oppressive politico-religion had fabricated for Western philosophy in the service of the powers that be. Eventually, the paper bag turned into what the speculative realist, Meillassoux described as 'the transparent cage' (Meillassoux, 2017).

In the early part of the 21st century the speculative realists, and the OOO, or object oriented ontology, have been supported by technologically savvy philosophers and software theorists such as Ian Bogost, Benjamin Bratton, Alex Galloway, and Ed Finn. Since the GFC of 2008 there has been a decisive shift of mood amongst critical theorists, some educators, and public opinion in general, from technological optimism towards a dark scepticism about the Internet and information technology (Bratton, 2016). The rise of Donald Trump and American escapism; the Russian state sponsored cyber attacks; and the improper use of Facebook data by Cambridge Analytica that exposed 83 million Facebook users, are just a few examples of recent events that have troubled our students.

Coinciding with the Great Acceleration, information technology developed during the first Cold War, and supported by what became known as the US industrial-military-academic complex, provided the infrastructure to support global consumer economics. This weaponisation of education and the global spread of US platforms such as Google, Facebook, Twitter, Apple, and Microsoft, to name a small handful of American multinationals, has infected the planet's education and our cognitive capacity to imagine alternative worlds and preferable futures (Rive, 2018, unpublished).

4. Speculative Futures

Creative technologies embrace speculative design and the positing of 'what if?' (Connor, A., & Sosa, R., 2018). This can be seen in contrast to what Dunne & Raby has described as 'affirmative design' that is typified by commercial design that contributes to the near future, 'faster, better, cheaper' (2013), or innovation as defined by the OECD Oslo Manual (2005). The shortcomings of mainstream design and the apparent failure to avert the onset of the Anthropocene, and the immanent effect of multiple environmental and existential crises, suggests that alternative, preferable, or even dystopian futures can frame questions that have been neglected by the technological 'closed worlds' of the past (Edwards, 1997). Creative technologies aspire to break out of the 'transparent cage' of neoliberal capitalism, and to provide cognitive tools that can reimagine a 'universe of things' within a flat and democratic ontology. Dunne & Raby in their book, Speculative Everything: design fictions and social dreaming (2013) point to Fredric Jameson's claim that "it is now easier to imagine the end of the world than an alternative to capitalism." (p.2). Design's affirmative objectives, that have sought solutions to problems, have appeared to make the big problems worse. "Design's inherent optimism leaves no alternative but it is becoming clear that many of the challenges we face today are unfixable and that the only way to overcome them is by changing our values, beliefs, attitudes, and behavior." (p.2) Creative technologies is sensitized to design's cheer leader approach, and assumes that "Design speculations can act as a catalyst for collectively redefining our relationship to reality." (p.2)

These are but a few suggestions to inoculate students against the viral attack of mainstream design, and the insidious threat of algorithmic cyber warfare that is spreading throughout the Internet, to the point that we face the weaponisation of education. In Finn's analysis of the pervasive influence of algorithms he argues that these now define and constrain our cognitive processes (2017). This is supported by Galloway (2004) who cites both Foucault and Deleuze in his claim that we now live in a 'protocological' world controlled by information and communication protocols. Galloway demands that we must decode these hidden protocols in order to free our minds from these controls, writing that, "You have not sufficiently understood power relationships in the control society unless you have understood "how it works" and "who it works for." (2004).

Speculative realism offers a radical philosophical challenge to allow us to dream beyond the Anthropocene and to envisage a world whereby nature and culture are no long divided by the dangerous mindset of consumer economics. The speculative realist, Graham Harman extends Latour's 'parliament of things' to encompass a 'democratic ontology' that equates the reality of all things both human and nonhuman while acknowledging that this in no way implies a symmetry of power, or existential equality of things (Harman, 2014).

5. Design Futures

One of the first learning outcomes that we pursue in the Bachelor of Creative Technologies is critical reflexivity. Over and above this course prescriptor is the New Zealand Education Act (1991) that states that our universities are charged with the responsibility to be the 'critic and conscience of society'. Yet, despite this clear legal demand on universities and scholars in New Zealand, and indeed, around the world, we have not managed to either persuade, or instruct society; its politicians; its business leaders; or our students about how to live harmoniously with each other, and the massive nonhuman population of the planet, or indeed the universe. The world has begun to wake up to the perpetual nightmare that our species may have caused irreparable damage to the planet and our nonhuman co-inhabitants. Our students may well have learned critical reflexivity but have these cognitive skills helped them to ameliorate the harm they have designed once they have graduated? For those of us in the so-called 'developed' world we all share the shame and the responsibility for the approaching existential crisis caused by anthropogenic global warming. According to the Earth scientist, Paul Cruzen, environmental problems such a acid rain, photochemical smog, and global warming have "have largely been caused by only 25% of the world population." (Angus, I., 2016, Kindle Locations 508-509). As Donna Haraway puts it "expressing an explicit "game over" attitude that can and does discourage others, including students, is facilitated by various kinds of futurisms." (2016, pp. 3-4). Haraway points out that there is a disturbing discourse amongst both experts and popular discussion that gravitates towards either technocratic geoengineering fixes or wallows in despair that 'coinfect any possible common imagination" (2016, p.56). Clearly, many of our past pedagogical methods have either: not been up to the task, simply ignored the problems, or worse, contributed to this crisis. Is Timothy Morton correct, because global warming is now happening, that we face 'the end of the world' as we know it (2013), or can we make a positive contribution through speculative design; playful experimentation; and building preferable future worlds.

In an effort to explore new possibilities I have been experimenting with various pedagogical techniques with the humble expectation that any possible success may never be known or attributable to those experiments. Graduates may never remember or credit their future designs, and businesses with their university education, I personally do not recall many of my own learning outcomes, although they were undoubtedly influential on my future decisions. My return to university research after thirty years in the screen industry, and my experience of start-ups has led me to investigate speculative design as a possible means of re-imagining the future. I have chosen some of my favourite speculative student projects to illustrate innovative approaches to wicked problems.

6. The Future of Design Management

In the late 90's I had realised that my advertising editing business was under attack by a fragmented media market, and the looming threat of the Internet. I pitched a global solution to Saatchi & Saatchi's Worldwide to enable virtual creative collaboration in a virtual world between all of their offices and their clients (Rive, 2008). The first facility was planned for their HQ in Manhattan. 9/11 brought an end to that, however, it inspired me to undertake twenty years of research into creativity, innovation, and world building, including a doctoral thesis on the subject (2012). At the time of my university research I had taught Design Futures and contributed designs and builds in virtual worlds. During these adventures I designed a number of worlds; some virtual, some conceptual, including virtual educational islands, sci-fi and fantasy screenplays, and executive produced a 3D animation feature in China.

Teaching Design Management was my first job at AUT. The students were business undergraduates studying with a design major. I was immediately struck by a general lack of imagination and creativity and concerned about their ability to eventually manage designers and the design process. Innovation is heavily dependent on creativity, and the successful design process requires the designer to imagine a future reality, something that does not yet exist.

Initially, I taught traditional design models of innovation, however, while these theoretical models seemed valid they did not address the creative praxis of modern design, i.e. 'plural, distributed, and collaborative' (Mau, 2004). The students who presented case studies of successful companies observed co-design and human centred design first hand, but they were in desperate need of a more playful practice based research.

To appreciate design practice and creative collaboration they needed to get their hands and brains dirty! They needed to build worlds and strange objects from scratch; they needed to speculate about futures worlds; they needed to ignore their teachers who had imprisoned their minds in a single unitary world, the global extractive consumer economy.

7. Pedagogical Review

In conclusion, I will review some of the successes and limitations of my teaching experiments. The course, Design Futures, was modified to be near future focused with some discussion about megatrends such as GRIN (Genetics, Robotics, Information Technology, and Nanotechnology). Simply by getting the students to envisage a hypothetical company 3 years into the future there was a significant improvement in the quality of ideas, creativity, and innovation. There were also some interesting examples of environmentally sustainable projects, such as 'GreenAir' designed to reduce 'negative environmental effects that building can have on a site's imminent surroundings'. One of the noted limitations of this near future approach was that students failed to fully comprehend the accelerating exponential rate of change (Kurzweil, 2005) and so many of the projects were relatively pedestrian based on linear assumptions.

This encouraged the evolution of new teaching approaches that explored design utopian and dystopian futures in the next ten to twenty years. Students were required to create infographics, and essays based on their research, and to research with brainstorming and collaborative online tools such as MindMup. The creative quality of the student work once again improved significantly with one example contemplating the future business opportunities of robotics for an ageing population while considering the unintended consequences of AI warfare, and the future fate of humanity. As they cited in their report, "Human beings of tomorrow may not be human at all. They may be artificial designer humans or some combination of humans and machines" (Waslekar, 2011). It appeared that the more speculative the design brief, the more the students were able to imagine alternative futures that considered social, environmental, and economic innovations. On reflection the student assignments and classes were limited to more theoretical than practice based research.

While it is still important to provide students with a theoretical framework for their design praxis, constructivist team coursework included a film assignment based on speculative and playful design concept, the 'SPIME', invented by eco-activist and science fiction writer, Bruce Sterling. In his design manifesto, Shaping Things, (2005) Sterling explains his neologism, "The SPIME is a set of relationships first and always, and an object now and then. The key to the SPIME is identity. A SPIME is, by definition, the protagonist of a documented process. It is an historical entity with an accessible precise trajectory through space and time. A SPIME must therefore be a thing with a name. No name, no SPIME." (2004, p. 77) Sterling's concept was based on the widely read ecological book by McDonough, W., & Braungart, M. (2009), *Cradle to cradle: remaking the way we make things*. Sterling created a conceptual design for designing things by incorporating RFID track and trace technology that would allow anyone to interrogate a 'thing', understand who made it, from what, when, how and even why? SPIMES are networked, connected to all knowable things; are capable of sensing multiple inputs; contain a record of all ownership; and are made from synthetic eco-matter capable of composting itself while communicating all of this known metadata (2004). A SPIME was designed to foster social, economic, and environmental responsibility. The students were asked to complete a short film based on the speculative design of a SPIME. This conceptually challenging assignment required that students creatively collaborate, research and physically create a design project that imagined a preferable world. The result was a successful collection of short films by business students (with little film experience), and first year creative technology students. The outstanding examples included films about a swarm of 'bioplastic' drones, known as Bumble, that replaced dead bees killed in a speculative environmental disaster; and a Augmented Reality device that allowed consumers to review the history, origin, material, and manufacturing ethics of clothing before they decide to buy. The limitation and strength of this project was that the design principles were so novel to most of the students that they struggled with radical speculation and tended to design commercial prototypes.

Virtual worlds provide an interesting platform to experiment with creative collaboration and allowed the business students to research co-design with creative technology students. An assignment on co-design provided a focus for students to use a mixed reality, physical and virtual environment to observe and test designs of studios on students who were studying creative technology. Interestingly, the creative technology students were not given an assignment to use the virtual world, Second Life, and despite a majority admitting enthusiastic use of Minecraft before university, they were sceptical of the Second Life platform. The business students showed more enthusiasm for the platform. This limitation supported earlier research that had shown that for students to explore speculative design they must either embrace the technological affordance or overcome their prejudice through incentives such as graded assessments using these technologies.

Due to the course description of the business degree with a design major there were notable limitations of time and content that could be taught. There was more success with greater freedom and experimental flexibility in the undergraduate degree in creative technologies due to the Studio format. In an open plan design studio students were introduced to the concept of the Anthropocene and were given freedom to design any project, with any technology based on the theme of Future Worlds. The studio was almost entirely practice based except for an introductory lecture on how to apply the cinematic arts to a design project, and the concept of speculative design. The students were introduced to the programme leaders for a project at USC, (University of Southern California), Spaceship Earth 2050. The students studying creative technologies at AUT in New Zealand used the USC project as the foundation for their self defined brief. This studio programme provided clear evidence that practical speculative design projects can provide a powerful teaching experience for students to imagine preferable futures and engage in playful 'what if?' research questions that can assist in revealing the 'transparent cage' and limitations of mainstream cognition and design praxis. Collaborative student projects included speculative film projects that included virtual and physical scenarios that considered brain uploads with unintended consequences, this was produced a year before the Netflix series, Altered Carbon; and a virtual identity hack where a boyfriend has his life ruined by a jealous girlfriend who controls his avatar. One team created an AR (augmented reality) model and animation of a future city in the Maldives that allows the citizens to remain in the islands in a floating city that rises and falls with the sun; and a solo student project that created a dystopian interactive audio installation based on factual research into a victim of abuse, set in the future when rising water levels has made the city a watery ghetto. One team created a game trailer that used a vintage 8 bit game design to depict the moral dilemmas faced by those affected by global warming. The limitation of this practice based studio was that the students did not do sufficient research into some of the theoretical underpinnings of the Anthropocene in their impatience to begin making. There have been discussions with colleagues about a more integrated approach to mixing theory and practice.

Finally, I will describe a personal speculative research project that has informed my teaching of creative technologies. I undertook research into e-waste (electronic waste) based based on reflection with regards my decommissioned editing business. It entailed a literature review, an IoT (Internet of Things) electronics project that connected a hacked printer/scanner to the Internet; and a DJ/VJ installation and performance using video performance software, VDMX. This informed my teaching and provided me with practical examples of my research to inform students of the huge social, economic, and environmental costs in a high impact emotional and humorous way (Rive, 2017). My research successfully informed student film and design projects based on the e-waste theme to communicate questions and propose possible future solutions.

This brief review of my experimental teaching methods over a 4 year period illustrates how an increasingly speculative approach resulted in more creative and engaged student projects. The design challenge of considering wicked problems that may not have a technological solution, such as the Anthropocene, requires educators to reflect on the educational deficiencies of the past with respect to equipping design innovators and entrepreneurial graduates with the cognitive skills and practical abilities to create preferable futures for a planet in an existential crisis. Speculative design, supported by the philosophical pragmatism of speculative realism and OOO have been useful approaches to consider the design challenges of the future.

Abstract: An innovative, forward-looking organization has a different kind of internal structure, different Marketing and a different way of processing things. Innovative organizations have methods and processes that help them avoid stagnation. In the 21st century we have embraced a whole new technological world. Communicating through social networks is a new phenomenon and organizations must follow this trend, otherwise they will not endure. Companies need to be close to clients and the best way to achieve this is by exploring the new tools that online social media provide (social media includes e-mail and social networks and other such applications). The way people are exposed to information and publicity suffered a real change, as nowadays almost everything is also advertised online. Internet usage and social networking will be the focus of this article. The main research question of this paper is: what is the impact of using social networks on the performance and competitiveness of organizations? This question is relevant since almost every company has access to the Internet, as do their employees. Social networks may also be used for professional purposes as networks that connect everyone to expedite and facilitate communication. On the other hand, social networks may influence productivity negatively. To better discuss the main issue, we will use a Portuguese company as a case study. Thus, we interviewed an employee at BRABBU – the head of the BRABBU Press & Communications department – to establish patterns in the usage of social networks for internal communication during working hours. BRABBU is an award-winning company which won the Best Viral Instagram award, in January 2018, attributed by the Maison et Objet. Furthermore, a sample of the general population was surveyed (we received 352 answers to the survey) to deepen the study of this topic and so as to ascertain whether people think that online social networks help or hinder business performance. The result was clear: social networks may be a great help for internal communication, but this does not replace human contact. Finally, this usage of social networks in the work environment has to reach a consensus amongst the younger generations (e.g. millennials, in favour of this usage) and older ones (e.g. baby boomers, not so receptive to new technologies).

Keywords: Innovation; Strategy; Internet; Social Network; Competitiveness; Internal Communication.

1. Introduction

Technological innovation has changed direct communication. Online communication through social networks (such as Facebook, Instagram, WhatsApp, LinkedIn, Twitter and Google +) has replaced much of conventional face-to-face communication. We can communicate with a person that is on the other side of the world while we, at the same time, see their image; and we can now be connected to each other 24 hours a day and seven days a week to share information. The use of smartphones and the ease of accessibility to technology has nurtured this reality. Social networks play a very important role in society, and statistical data indicates that in 2018, 3,196 billion people (approximately 42% of the world population) use social networks (Chaffery, 2018).

Can communication through social networks have the same importance in companies (communication between employees) that it has in society at large? Should employees be allowed to use social networks during work hours? Does this interfere with a company's competitiveness? We will discuss these topics throughout this article.

At a time when the competitiveness of firms in a number of industries is at a peak many companies have chosen to block access to social networks during work hours. However, we shall discuss how this may hinder more than help competitiveness. People have a need to be online and to communicate and firms would do well to embrace this need by granting access to social media during work hours. Openness, rather than prohibition, is the answer that our research favours. It is up to senior leadership in corporations to make sure that social media is used wisely and appropriately, to the firm's advantage. This may well involve having employees use WhatsApp to communicate between themselves as well as using Facebook to post important firm messages.

Social media, as discussed herein, refers to the digital world and to "a number of applications […] to connect […] potential knowledgeable informants who could assist with providing information and data" (Remenyi and Greener, 2016, p.vi).

After the literature review, the paper has a series of topics about the research, the survey and the interview that have been performed. The article finishes with a section where the group discusses all the research findings and much of the information found in the literature. Communication through social networks, especially at work, is not a topic of global consensus, since the opinions are divided about its benefits and disadvantages.

2. Literature Review

Social networks in the business context are mainly present in two ways: external communication and internal communication (Leonardi, Huysman and Steinfield, 2013). In the first instance, companies use social networks to introduce themselves to their customers and tailor their products to their needs. In the second instance, the subject of this article, social networks are present as a way for internal communication between workers, and for social interaction within the company. According to (Leonardi, Huysman and Steinfield, 2013), the concept of social media in the business context is as follows:

> *"Web-based platforms that allow workers to (1) communicate messages with specific co-workers or broadcast messages to everyone in the organization; (2) explicitly indicate or implicitly reveal particular co-workers as communication partners; (3) post, edit, and sort text and files linked to themselves or others; and (4) view the messages, connections, text, and files communicated, posted, edited and sorted by anyone else in the organization at any time of their choosing."*

Social networks may have several uses. However, when inserted in different environments, do they continue to have the same type of use and motive? Or depending on the context will, in this case, workers know how to distinguish these motives? The questions go beyond the functions and hierarchies of organizations. Are social networks an amplifier of knowledge, allowing it to be transmitted more quickly and intuitively? Or can it be an inhibitor of work, contributing to procrastination, and be a source of distraction for workers?

The evolution of Web 2.0 has allowed online applications to be used more transversally. The Internet is seen as a platform above the level of a single device (O'Reilly, 2018). According to O'Reilly (2006), cited by (Badea, 2014) "Web 2.0 is the business revolution in the computer industry caused by the move to the Internet as a platform, and an attempt to understand the rules for success on that new platform". Several social networks have emerged, and virtual communication has become more developed and attractive; not only for individuals but also for companies. On this account, applications have been created within social platforms that allow companies to sell their products and to be closer to their customers. Nowadays, people are usually users of more than one social network, with different purposes, and companies follow this trend, establishing a strong online presence. Social networks have changed the way society communicates. Sharing information and knowledge among different groups of people is one of the main reasons (Baruah, 2012). People feel closer to each other, as well as companies to their clients, establishing virtual relationships and interacting with each other; that is, a more active communication exists and, in this moment of evolution, all in real time.

We live in an era of instant messaging, of the posting of live videos to broadcast events; anyone around the world may know what we are doing at any given precise moment.

In this sense, it is revealed that, in 2017, according to (GlobalwebIndex, 2018), on average, 135 minutes (2 hours and 15 minutes) per day were used for the application of social networks worldwide, and this use has been growing steadily since 2012. The number of people active in social networks in January 2018 was 3,196 billion (42% penetration rate) in a universe of 4,021 billion (53% penetration rate) of Internet users (*2018 Digital Yearbook*, 2018).

Even in more remote countries and continents, such as Africa, the Internet has had an important impact. Though superior Internet access and connectivity is not the rule, even so social media, including YouTube.com, has revolutionized access to information and knowledge.

Since the scenario for this study will be a Portuguese company, it is important to understand how these numbers behave in this country. Portugal is still above the world average, when compared in the right proportions. The number of people using the Internet is around 7.73 million (penetration rate of 75%), while those active in social networks point to 6.60 million (penetration rate of 64%) (*2018 Digital Yearbook*, 2018).

Yet the number of active users in social networks through mobile devices points to 5.70 million (penetration rate of 55%) (*2018 Digital Yearbook*, 2018). Thus, it may be stated that the Portuguese business context may benefit from this scenario, if a company incorporates an internal communication policy that values social networks. In 2017, Portugal ranked in position Nº44, in a ranking of 176 countries around the world, in the index of information technology and communication (GlobalwebIndex, 2018), which is seen to be quite positive.

For the present study we assume two types of communication within companies: classical communication and modern communication. The former refers to communication tools which have been used by companies for a longer period, such as e-mail, which came into being in 1978 (Nightingale *et al.*, 2008). E-mail is a formal communication mode, considered to be distant and time consuming. The excessive number of e-mails received nowadays, in the corporate context, is cumbersome and hinders oftentimes more than it helps. Thus, we are seeing new legislation appear in an attempt to curb inappropriate e-mail usage. Firms may now incur very heavy fines (e.g. €20 million or 4% of annual revenue) for not respecting consumers' privacy. The latter type of communication (what we call modern communication) refers to a more dynamic, intuitive and fast communication process, associated to new technologies and new forms of communication – social networks.

Social networks may have considerable impact on workers' productivity. According to (*How Social Media Can Boost Your Productivity*, 2016), social networks can help the employee to be engaged with the company and enhance teamwork, unlock communication barriers, allowing everyone to be informed in this way to make employees feel valued. In addition, there are specific social networks for corporate internal communication (e.g. Asana and Trello), making the feeling of loss of focus at work not so present. Social networks in the corporate context can boost workers' performance, if they are willing to do so. In a Pew Research Centre study (Olmtead, Lampe and Ellison, 2016) that delves into the use of social media in the workplace, the motives are divided between strictly professional and job-related, and other more personal usage. Thus, some care and attention to this issue is required of senior management in organisations.

A good boost to workers' performance (and an increase in productivity of the company) is present due to the use of social networks in the corporate environment and if job-related. According to (Badea, 2014) "new media increase the volume, speed and daily flux of communication, connecting people, giving them a voice and stimulating discussions on shared interests". Thus, firms need to embrace modern forms of communication as these will aid their performance, if managed properly.

3. Methodology

For this article, a mixed research method was followed (Remenyi, 2014). The authors thus performed a survey (made available online, using Google Forms, in March 2018) to know the opinion of a sample of the population about the main research question: are social networks helpful or a distraction to a company's efficiency? The survey was shared on the authors' personal social network pages as well as with the University of Aveiro community, by e-mail. We received 352 answers to the survey. The questions asked in this survey, apart from personal data, were related to the respondents' opinions about the usage of social networks during work hours and what they think about social networks as a way of promoting internal communication in companies.

Furthermore, we also interviewed an employee at BRABBU. The employee was the head of the BRABBU Press & Communications department, which involves a significant amount of quite complex decision-making in the communications area, and involving a number of different stakeholders. The interview was not performed on-site, since the interviewee was not available for that type of interaction. Therefore, we sent our interview script by email, and the employee answered all of the questions, so we can say that our interview followed quite a rigid structure. The questions asked in the interview were related to the functions that the interviewee performs in the company. We thus gathered the interviewee's opinion about the firm's organizational culture, the role social networks play in the company and the importance of social networks for internal and external communication. The reason for doing the interview – "whereby the researcher seeks to obtain data related to

the research question" (Remenyi, 2014, p.95) – was to enrich our research data and to support our argument further that social networks may be used to the advantage of firms. BRABBU was chosen as the authors had previous knowledge that they were a modern firm in the sense that they embrace new technologies and their usage in the workplace. Thus, we used a mining framework, as described in Remenyi (2014, p.945): "the researcher believes that the informant has "the answer" which is being sought". For example, BRABBU won the award for the Best Viral Instagram, in January 2018, attributed by the Maison et Objet.

4. History of the company

The *Covet Design Group "thinkers and makers"* was founded in 2003. It is a revolutionary company based in the north of Portugal. The group has 15 luxurious brands and more than 500 workers, involving 5 different business levels: Industry, media, retail, luxury design brands, and brand & design Management. They produce and trade luxury products around the world with average prices in the tens of thousands of euros. The group forecasts a growth of around 30% in 2018, reaching a consolidated turnover of 35 million euros. In 2020, with an investment of around 50 million euros, the new headquarters of the group will be built, in Covet Town, Gondomar, with a capacity for 2,500 people. The products of the group's various brands are present in about 80 countries, exporting more than 90% of the production mainly to the United Kingdom, USA, Europe, Canada, China, Latin America and the United Arab Emirates.

> *"Our clients want an experience, we design for surprise and to move them, it is like a culture." - Amândio Pereira, CEO, (Lobo, 2018).*

Boca do Lobo was the first design brand of the group, and it has developed successful businesses that elevates new design worldwide. Despite that, our work will focus more precisely on *BRABBU*, a brand that emerged in 2011 intending to design and produce pieces that tell stories from nature and the world through design. The products are handmade in Porto, Portugal, by a team of highly qualified and dedicated artisans specialized in the craftsmanship of upholstery, case goods, lighting and rugs. Their design team works together with artisans every day to ensure the high-quality standards of their pieces.

The brand aims to *"reflect an intense way of living, bringing fierceness, strength and power into an urban lifestyle (…) BRABBU design pieces are a gift for the senses. Every day our tribe of designers and craftsmen search for the most innovative materials and techniques to bring the comfort and function that your spaces deserve"* (Brabbu, 2011).

The company has showrooms in its headquarters in Porto, Portugal and in London, the UK, but the brand commercializes its products in numerous countries such as Belgium, Switzerland, Germany, the USA and Russia. *"BRABBU loves the unknown, the adventure and the challenge. Our strong inspiration on nature makes BRABBU an attitude, a powerful way of living."* (Brabbu, 2011).

5. Findings

5.1 Survey about the use of social networks

In a universe of 352 respondents 82% were female and 18% were male. This significant difference could also be related to the fact that, in the academic world, in Portugal, women are in the majority – in higher education in Portugal over 194 thousand were women and just under 168 thousand were men (Pordata, 2017).

Approximately 50% of the respondents were between 18 and 25 years old (younger millennials, born from 1993 to the turn of the century). 21% of the respondents were aged between 26 years old and 35 years old (millennials). 11.6% of the respondents were aged between 36 and 45 years old (baby boomers). 12.2% of the respondents were aged between 46 years old and 55 years old (baby boomers). Finally, the rest were over 55 years old (baby boomers). The majority of the respondents (57.7%) live in Aveiro, Portugal.

Only four (one woman and three men) of the 352 respondents (Figure 1) answered that they do not use social networks. Among these people, only one person (a woman) answered that she should use social networks. Considering the question about the social networks that they know, those four people said "Facebook". Two of them referred "Instagram", "Google +", "Skype" and "Youtube". Only one of them said "Twitter", "Badoo" and "Whatsapp". In relation to the reasons why they do not use social networks, the majority referred facts such as

"lack of interest", "difficulties in the use of social networks" and "preference for personal contact". According to this survey, only 0.28% (one person) considers social networks are not important at all.

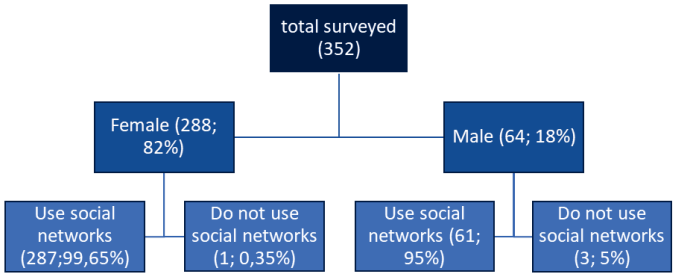

Figure 1: Total surveyed

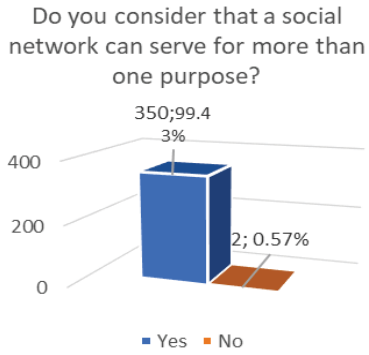
98.9% of the people surveyed said they use social networks. The most popular social networks, according to our survey, are Facebook, Instagram, Youtube, Whatsapp and Skype.

When asked if social networks can fit more than one objective (Figure 2) 99.43% of the total people surveyed answered "Yes". Keeping in touch with the family and friends, entertainment and to search for information were the most common responses. Furthermore, two of the people surveyed referred that social networks can be used for Marketing, Sales and Promotion purposes (Figure 3). 76% of our sample said it is possible to have an efficient communication between workers through social media inside the company (Figure 4). This opinion prevails in every age group (Figure 5).



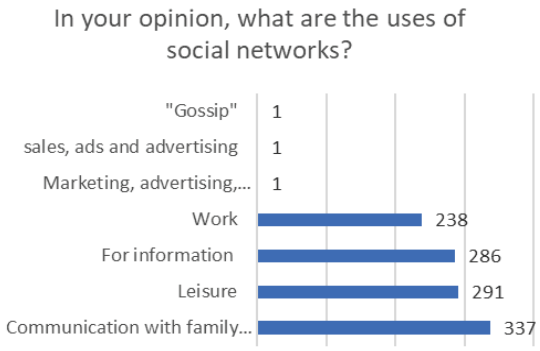


Figure 2 (on the left): Do you consider that a social network can serve for more than one purpose?

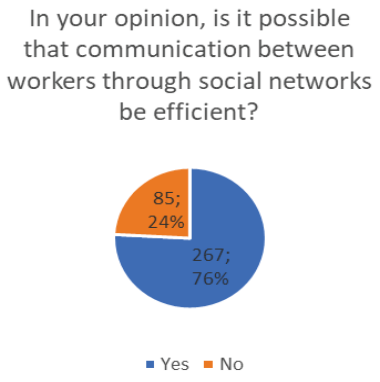
Figure 3 (on the right): In your opinion, what are the uses of social networks?



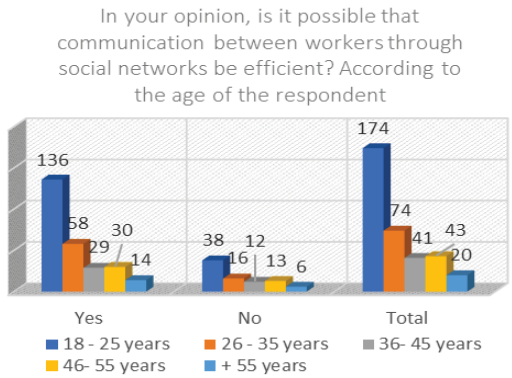


Figure 4 (on the left): In your opinion, is it possible that communication between workers through social networks be efficient?

Figure 5 (on the right): Can social networks be efficient? – According to the age of the respondent

Approximately 66% of the people surveyed think that the communication between colleagues in a company should be done personally (35.67%) or by e-mail (30.06%). In this question, only 11.93% of the people

surveyed answered Social Networks. Mobile phones (21.64%), Intranet (0.58%) and Portable Radios (0.12%) were also mentioned (Figure 6). It is important to refer that, amongst the people who referred Social Networks as a way of communication inside a company, only 35% are more than 25 years old (born before 1993), which means there is a trend for younger people (e.g. especially younger millennials) to take social networks more seriously, giving them space in business communication (Figure 7).

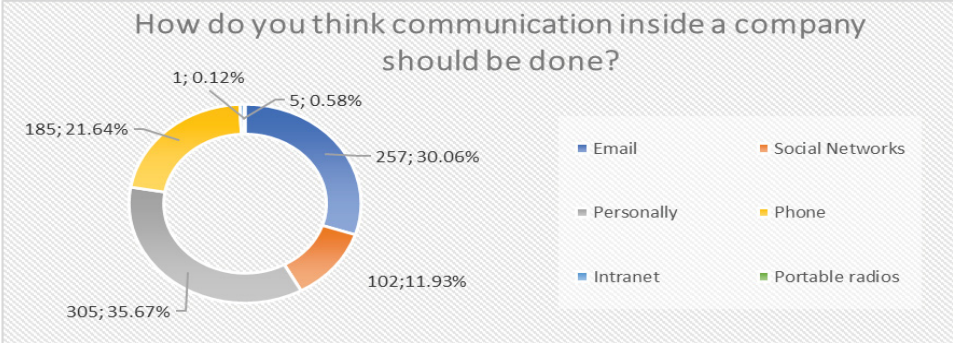

Figure 6: How do you think communication inside a company should be done?

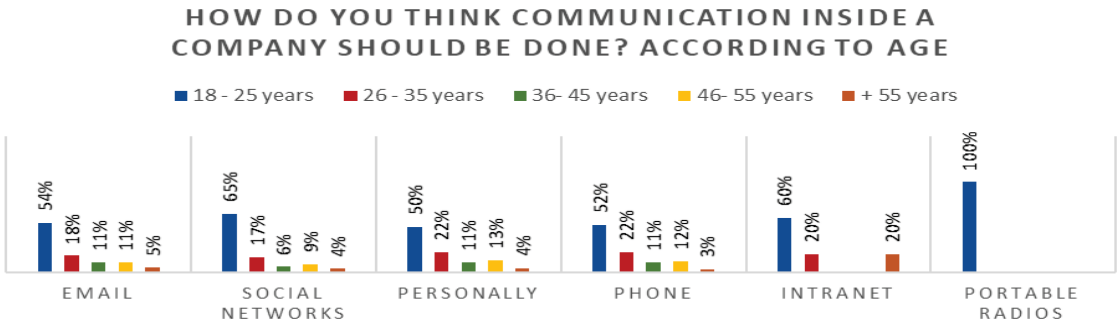

Figure 7: How do you think communication inside a company should be done? According to age.

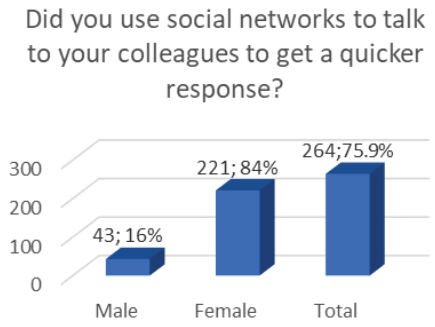
When asked if they ever used this means of communication to talk to colleagues inside their company, 75.9% said yes (Figure 8). Facebook is the most used social network for this purpose (58%) (Figure 9).
There is no doubt that people think social networks are a great help when it comes to keeping in touch with expatriate workers (Figure 10**Error! Reference source not found.**), since 96% replied affirmatively.



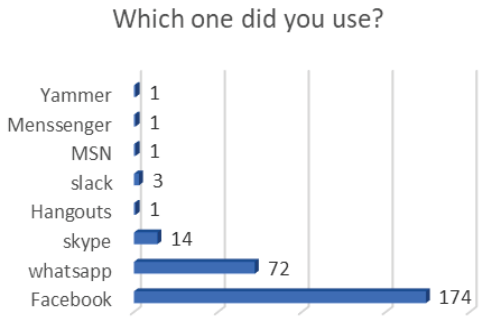


Figure 8 (on the left): Did you use social networks to talk to your colleagues to get a quicker response?

Figure 9 (on the right): Which one did you use?

.

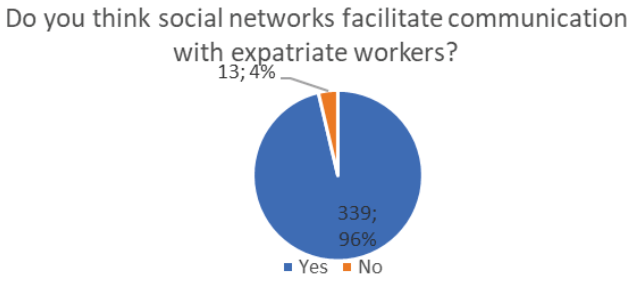

Figure 10: Do you think social networks facilitate communication with expatriate workers?

Although many people are not sure about this topic (34% of the males and 41% of the females), 50% of the male and female respondents think that Social Networks will be critical to all companies in the future. Men are surer than women, as a greater percentage of women are unsure (Figure 11).

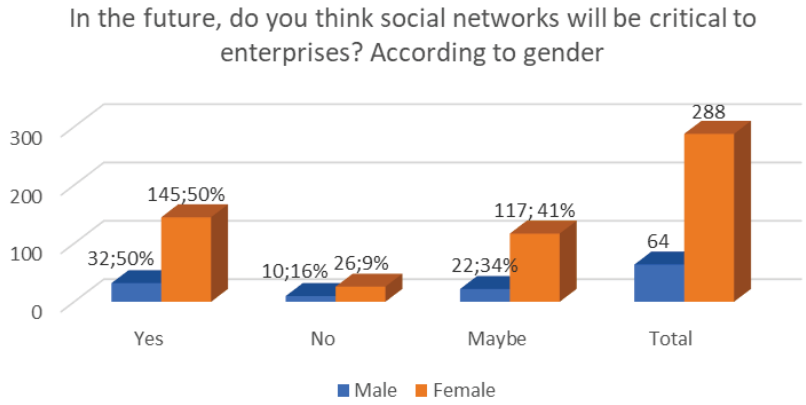

Figure 11: In the future, do you think social networks will be critical to enterprises?

In table 1 we present relevant opinions of the survey respondents about the use of social networks as a communication tool at work. Easy and effective communication, no barriers between employees, information storage, Marketing tool and good stimulation of informal and transversal communication between colleagues at different levels in the hierarchy and of different functions are some of the most popular answers, in terms of positive aspects. When it comes to negative aspects, people stated that social networks can be a distraction and, consequently, a bad tool for a company's effectiveness.

Table 1: Opinions gathered in the survey about the use of social networks as a communication tool at work.

Opinion about the use of social networks as a communication tool at work	
Positive aspects	Negative aspects
✓ Facilitates communication between developers who are working on a specific project;	× Means of distraction;
✓ Quick and effective communication;	× Tools for online communication between employees exist especially for work (example of this kind of social network: Slack) and so Facebook and Instagram should not be used (for example);
✓ Publicizing the work by creating greater consumer confidence;	× Used at work only in cases of extreme necessity
✓ Eliminate barriers between employees or companies;	× Use for other purposes
✓ Essential;	× Unnecessary
✓ Good stimulation of informal and transversal communication between colleagues at different levels in the hierarchy and functions;	
✓ Advantageous for people who are not in the same workplace, as for example in different branches;	
✓ Strong free working tool;	
✓ Enables simultaneous contact with various workers;	
✓ Information storage.	

5.2 Interviews

According to the interviewee Ana Pedro Lebre, head of BRABBU Press & Communications, it is very important to be well known in the market, to create interest. “We try to inspire the world with the latest trends, so that BRABBU Design Forces can win a place in the interior design, decoration and architecture’s world” (Ana Pedro Lebre). The Covet Group fights to keep alive Portuguese arts and craftsmanship that are almost extinct.

Besides all the design innovation, the strategy in the market takes a very important place in the group’s evolution; “the Covet Group has thinkers and makers: the ones who think about strategies and the ones who give life to all the projects” (Ana Pedro Lebre). The communication at its varied levels is still a challenge, despite of all the technological evolution. The sharing of knowledge between the different departments and even between the 15 brands of the group creates a unique synergy, essentially when we are talking about webmarketing, sales and press departments, which are fundamental for the company’s success. The importance of the Internet and social networks are undeniable for BRABBU: “Social networks are an art in the marketing and webmarketing domain. BRABBU won the award of the Best Viral Instagram in January of this year [attributed] by the Maison et Objet.” (Ana Pedro Lebre). The Internet world works well as a way for the brand to be closer to their clients: “we can guarantee that everyone who cannot be with us knows everything, and does not miss the fun” (Ana Pedro Lebre). The way news and information are exposed by BRABBU distinguish the brand by their originality and creativity, “we try to communicate in the most original ways, trying to offer daily materials and vibrant content that make us well known. We avoid communicating in a massive way. In the Press Department we try to pass the right message to the right person, which will guarantee the quality and not the quantity” (Ana Pedro Lebre). Regarding communication with the outside world, Ana Pedro Lebre thinks it is very important to consider classic communication. There are still good practices and strategies we should follow or adapt, bringing the innovation to classic methods. “One of the things we try to keep from getting old is precisely the communication channels of the brand. We always try to make both social networks, just as e-mail and e-mail marketing, fresh and inspirational…”. (Ana Pedro Lebre).

One of the advantages of this new technological era is the fact that a company can get to know better the profile of those who seek them in some way, and maintain the interest by creating a relationship, offering more of what is to the client’s interest. BRABBU uses social networks to establish communication between employees, using Whatsapp and Skype for internal communication and everything else is exclusively used for

external communication. “The use of these social networks facilitates information transmission and its organization itself. I think these tools are useful, but it also has disadvantages in terms of social and human expression: it is easy to become dependent on this contact and we can never forget that we are dealing with people and that from a motivational point of view human contact is the most useful and effective way to achieve great success.” (Ana Pedro Lebre).

Interviewee Ana Pedro Lebre, when asked if social networks are in fact more useful for internal communication or for external marketing, stated with no doubts that it is more important for external marketing. “We have at our disposal bold ways to communicate through social networks, in addition to having the possibility of creating an almost unlimited audience and from which we guarantee that those who like us, but do not have the possibility to see us up close, may have an approximate experience of our designs, stories and inspirations.” (Ana Pedro Lebre).

The interviewee considers that human communication is one of the oldest problems of humanity: “even if machines help us be faster than a few years ago, it all depends on how we use the tools… as I think there are still many people who do not deeply understand the importance of human relations in the efficiency of communication.” (Ana Pedro Lebre).

6. Discussion

By analysing the survey and the interview, we can point out two main perspectives of the main topic in discussion: the perceptions of millennials (born in or after 1982 and until the turn of the 20th century) and the perceptions of baby boomers (born after World War II and before 1982) (Au-Yong-Oliveira et al., 2018). If on the one hand millennials have the capability to see social networks as a tool for communication, on the other hand for baby boomers it is hard to consider them that way. As we can see through the interview with Ana Lebre, BRABBU is a young company, with young employees, with their innovative capabilities at their peak, thus, the brand uses social networks. This concept is already ingrained in the working environment, so BRABBU’s workers do not see social networks as a way of becoming distracted. The analysis of the survey leads us to conclude that this idea is not present in baby boomers’ minds, because in their point of view, the use of social networks during working hours is useless and restrains companies’ competitiveness.

After analysing all the information collected, we can consider that baby boomer executive boards and older generations of workers, in contrast to the millennials, did not grow up with technology around them. Furthermore, the lack of knowledge and to a certain point a fear of the consequences, leads to them completely disregarding the possibility of the use of social networks for the purpose of work.

As the survey shows, baby boomers prefer classic communication (including e-mail), while millennials value modern communication (the embracing of social networks). From an evolutionary perspective, it is considered that administrative frameworks are being renewed by younger generations, such as millennials, and so the methods used in the workplace will also be renewed. Thus, it is expected that the use of social networks in the work context may be a more present reality in the future.

There is thus an evolutionary trend in the type of tools that can be used for internal communication. Today, e-mail is still used as an example of classic communication. However, other ways of communication may provide faster, more intuitive and more dynamic communication, such as social networks. Social networks are already introduced in people's daily lives. However, are they already used in companies, in addition to being used for external marketing? Classic communication is still maintained, and modern communication, represented by social networks, has already been introduced in corporate relations, in particular in the case study analysed herein – BRABBU – where one may verify a coexistence of these types of communication.

Despite Skype and Whatsapp being the only social networks used at BRABBU, there are other working platforms that companies can use. People’s focus will not be questioned, if they use platforms made especially for work. An example of this kind of social network is Slack.

According to interviewee Ana Lebre, questioning the efficiency and effectiveness of a firm when using social networks, will depend on the type of purpose of the usage. If people use them for leisure, when they have to

use them for work it is normal to question if this will be effective and efficient. When work through social networks is already a work habit, the question is no longer posed.

In accordance with the literature, social networks are capable of boosting employees' performance and to contribute to their evolution as professionals, if the purpose of the use of social networks is job-related. According to (Jeanetta, 2017), "posing a question on social media is a simple and quick way to get several possible solutions. Even if none of the answers are used to solve the problem, the information they provide may spark a new solution". Also, "co-workers can use social media to interact with one another and build better relationships. A stronger relationship among employees leads to more cohesive and productive work teams" (Jeanetta, 2017). The use of modern tools to communicate, such as social networks, will depend on the predisposition of corporate employees.

According to (Herlle and Astray-caneda, 2012), who quoted Skeels & Grudin, and Stafford & Mearns, "due to the ease of Internet connections and access in the workplace, organizations can enhance business operations and employee communications by having their own inter-office social media platforms. This offers employees the opportunity to share knowledge and collaborate with each other".

In interviewee Ana Pedro's perspective, to achieve good results at work, when using social networks, it is essential to have discipline in their use; if not, there will be a dispersion of information which will lead to disorganization. We can conclude that to be effective and efficient in communication leading to good performance, organization is the key word. Nowadays the generation that leads, i.e. the executives of companies are still more engaged in classic communication (e.g. e-mail rather than social networks).

Nevertheless, it is understood that there is a tendency for social networks to lead internal communication efforts in the future. For now, there is still a need to innovate within what we call classic communication; innovation leads to more innovation, and in our perspective, this is the way to show that there is more than what the baby boomers are used to using. Social networks are positive and need to be used more – for internal corporate communication also and not only for external Marketing purposes.

7. Conclusions

Bearing in mind that the mixed methods approach followed in this article gave us a range of different information, we can conclude that social networks are still a controversial topic. It is unanimous that social networks are very convenient when there is a need to contact someone, but in the professional context there are still many doubts and "grey areas" which, in the near future, will perhaps be resolved.

Significantly, 65% of the survey respondents who referred to Social Networks as a way of communication inside a company were younger than 25 years old (e.g. young millennials, born after 1993).

As we discussed previously, people are still suspicious about the use of social networks during work hours, even though the great majority of the population uses them in their daily lives.

Albeit, even in a company where social networks are used for internal communication, we cannot replace human communication. This is an important issue that, in Ana Lebre's opinion, our interviewee, should be considered. According to Ana Lebre, "human contact is a source of motivation".

Considering the collected data, we can conclude that according to the survey, most of the respondents consider social networks as a possible source of distraction at work. However, according to the perspective of the interviewee, Ana Lebre, they are undeniably useful and essential when used in an organized and professional manner. We assume that we live in an era of continuous evolution and that we will have to wait until we get used to all of these communication tools available to us, taking advantage of the best benefits possible from them.

It should be noted how people were receptive to answering this survey, which is a sign of interest about this subject.

In the future, it would be interesting to research about the issue we pointed to previously: are social networks making us less "human"? Do we prefer to contact other people through social networks instead of via personal contact? This requires further studies.

Finally, limitations of the research include the fact that due to time (and space) constraints only descriptive statistics were performed on the data. In future, and given more time and space, we recommend that inferential statistics be performed, for example the chi-square test (for testing associations between variables).

Abstract: The aim of this paper is to present results of learning processes for gifted children, using the Action Regulation Theory on entrepreneurship in learning a basic vocabulary of the 6 major languages of the world. Why the focus on giftedness? The idea to develop a specific learning method for children that are gifted, evolved from the notion that the learning demands of these gifted children are not (enough) met. Children are gifted when their ability is significantly above the norm for their age. The major requirement for the learning processes of these gifted children, is challenge. The presented challenge for them is to communicate in the six major languages of the world: Chinese, Russian, Arabic, Hindi, Spanish and English. We earlier published that it is possible to combine language learning with entrepreneurship learning (edupreneurial method) that allows the participants to learn the basic vocabulary of a totally unknown language. A specially developed entrepreneurship LEGO-game (the simulation game LA- Game) provides an authentic entrepreneurial setting. The learning method has been tested in several experiments using languages such as Chinese, Korean and Hindi. We now present the results of learning experiments with gifted children: measuring their basic vocabulary Russian before and after LA-Game. In our view Frese's Action Regulation Theory is a general theory of learning entrepreneurship, that can be applied universally in any (action) learning process. All elements of this Action Regulation Theory are present in LA-Game as we published earlier. We will show that all of them: the facets of active performance, the differentiated steps in sequence of action regulation,the hierarchical structure in 4 levels of action regulation, the foci of action regulation and the action oriented mental model, fit also in the learning needs of gifted children. This theory is specifically relevant because it focuses on the regulation of learning actions. The identified specific 'market need' in learning and teaching processes for gifted children, explains 'innovative entrepreneurship' applied in our learning programs, so the "why, who, what, when, where, how and for whom".

Keywords: Action Regulation Theory, psychology of learning entrepreneurship, edupreneurial method, LA- Game, giftedness, entrepreneurship LEGO-game

1. Introduction

The psychological theory on learning entrepreneurship (Action Regulation Theory, ART) can be applied for other learning processes using an entrepreneurial teaching method that applies to a receptive mindset of gifted children who specifically want to learn in such a way. For this group, it is:

- relatively easy to organize experiments with new learning methods (there are specific school groups of gifted children, school organizations are open for experiments on teaching)
- Acquire observations of entrepreneurial learning. This due to what ART mentions as 'the cognitive ability and qualifications that are needed to be able to regulate on this meta-level'. Gifted children have these abilities.

In this paper we present the why (need), the who (gifted children), the what (basic vocabulary of a totally unknown language, Russian, so an easy to identify learning process), the when (sequence of ART), where (LA-Game), how (levels of regulation of ART) and for whom (gifted children with the need). The learning results by Kahoot surveys: before LA-Game, after LA-Game and 1 week after LA-Game, are presented. The process or the sequence of ART is demonstrated with short YouTube-movies of the experiment (links in are in a non-public mode, privacy!) which gives an indication of the validity of several elements of Action Regulation Theory for entrepreneurial learning.

2. Giftedness and their need for entrepreneurial learning processes

Gifted children have abilities significantly above the norm for their age, generally these children learn more quickly, deeply, and broadly than their peers. Gifted behavior occurs when there is an interaction among three basic clusters of human traits: above-average general and/or specific abilities, high levels of task commitment (motivation), and high levels of creativity. Gifted and talented children are those who possess or are capable of

developing this composite of traits and applying them to any potentially valuable area of human performance. As noted in the Schoolwide Enrichment Model, gifted behaviors can be found "in certain people (not all people), at certain times (not all the time), and under certain circumstances (not all circumstances)." (Renzulli, 1978). Characteristics are: high reasoning ability, creativity, curiosity, a large vocabulary, an excellent memory, able to master concepts with few repetitions, be perfectionist, often question authority, have trouble relating to or communicating with their peers.

The perception of his "school-teaching " by a gifted child (Bart)	The perception of learning processes by a gifted child (Bart)
	
"negative"	"positive"

Figure 1: different perceptions

According to specialists on education of gifted children like Linsen and Goethals (2003) teaching to gifted children need to: avoid routine jobs; steps in learning should be large; a reasonable level of abstraction should be present; divergent thinking should be needed and creativity ; internalization should be as independent as possible. Bronkhorst (2001) has similarly requirements for teaching gifted children: appeal their creativity; open assignments; high level of abstraction; high complexity; generate added value in relation to the regular learning content; activate an investigative attitude; evoke an attitude of reflection on operating; appeal to their meta-cognitive skills; provoke interaction; appeal to the self-dependence.

One of the key principles of gifted children is the holistic approach in thinking: the so called "top-down thinking". Instead of the question: "why?", it focuses on the question "how?". The meaning of the knowledge is essential for gifted children to store it as useful. The approach in school-education is generally bottom-up: stepwise built up with at the last step the goal and meaning. So the usefulness of knowledge in practice, the answer to the why-question is not essential.

Formulating learning goals is the main element of top-down learning: generating the perspective of the final goal. A gifted child than understands that his hard work will lead to a goal which he or she has not yet accomplished at the start of his or hers learning process. Top down learning implicates learning from the explicit level (generic, declarative level) to the implicit level (specific, procedural knowledge) and is analytic in nature (Sun, Merrill & Peterson, 2001)

Because gifted children request new learning methods, the teaching methods should change too and made applicable to the mind-sets of these gifted children. Teaching might otherwise lead to mislearning. For example, "instant payoff". Illeris (2009): '*in education, at workplaces and many other situations, very often people do not learn what they could learn or what they are supposed to learn. Mislearning due to misunderstandings, lack of concentration, mental resistance, etc. Because young people are highly engaged in a process of personal identity development*'. Illeris (2009) means '*that young people fundamentally meet all learning initiatives with questions such as: What does it mean to me? Or: What can I use this for?*' - implying that it is only worth paying attention to if it is subjectively accepted as a usable contribution to the present demands of the identity process.

In an earlier publication (Roelofs, 2012) we showed that it is possible to combine language learning with entrepreneurship learning to create such a new learning process. The process of conscious and unconscious learning referred to as "Reference Creation"; an "edu-preneurial" method of teaching that allows the participants to learn the basic vocabulary of a totally unknown language using an entrepreneurial network set up. The learning method has been tested in several experiments using languages such as Chinese, Korean and Hindi and a local dialect (Drents). In this paper, the focus is on Russian and gifted children.

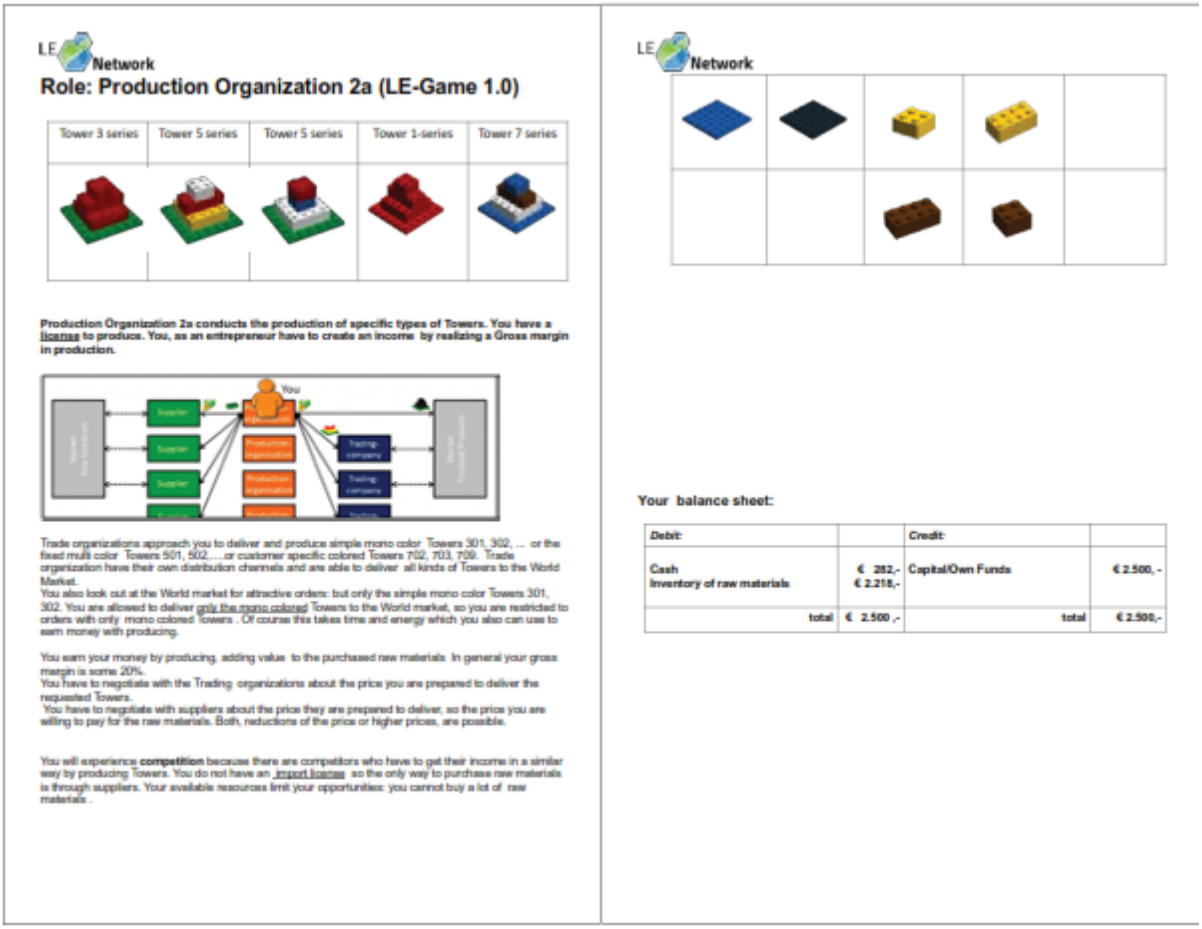
Language is a complex skill, where the learning process is similar to learning entrepreneurship. A well-known definition of Entrepreneurship is "the pursuit of opportunity without regard to resources currently controlled." Hence, learning a language could be similar, that is, the pursuit of communication opportunities. A basic vocabulary is necessary to be able to communicate actively. Similar to entrepreneurship, acquiring a new language vocabulary does not necessarily require conscious study of theory, such as the study of grammatical rules. Learning a new language happens naturally (and automatically) when you get lots of interesting and meaningful input, which can be provided by an authentic learning environment. As soon as a person has learned a reasonable amount of vocabulary, it is a lot easier to set the next step in the process of learning a language.

3. LA-Game explained

The simulation role game, LA-Game, is an entrepreneurial context using LEGO to teach and learn in a playful manner. In the simulation, several markets are created, where LEGO products are traded. Participants buy and sell commodities, produce and /or trade LEGO towers or LEGO parts. The use of LEGO makes LA-Game also quite sustainable.

The essence of the simulation game LA-Game lies in the conflict of interests among the different market players. In LA-Game, participants are exposed to real uncertain market situations and have to communicate with the markets in a foreign language. In LA-Game the objective is learning, but there is also a competitive element on making profit. The rules of LA-Game are:

- Everybody is entrepreneur in his/her role. In the simulation, several markets are created, where LEGO products are traded. Participants buy and sell commodities, produce and /or trade LEGO towers or LEGO parts;
- There are three variations in the roles: Traders, Producers (see figure 2) and Suppliers. The added value is created by the entrepreneurs by trading the raw materials, which can be bought (using Russian language!) at the Market Raw Materials and the finished products which can be sold (using Russian language!) at the Market Finished products;
- The market consists of two types of products: mono-coloured towers (sold by Producers & Traders) and multi-coloured towers (sold only by Traders);
- All participants are limited in their resources, have a (small) competitive advantage in their stock and have the same starting capital: € 2500 in cash and in kind.



LE Network

Role: Production Organization 2a (LE-Game 1.0)

Tower 3 series	Tower 5 series	Tower 5 series	Tower 1-series	Tower 7 series

Production Organization 2a conducts the production of specific types of Towers. You have a license to produce. You, as an entrepreneur have to create an income by realizing a Gross margin in production.

Trade organizations approach you to deliver and produce simple mono color Towers 301, 302, ... or the fixed multi color Towers 501, 502,....or customer specific colored Towers 702, 703, 709. Trade organization have their own distribution channels and are able to deliver all kinds of Towers to the World Market.
You also look out at the World market for attractive orders: but only the simple mono color Towers 301, 302. You are allowed to deliver only the mono colored Towers to the World market, so you are restricted to orders with only mono colored Towers . Of course this takes time and energy which you also can use to earn money with producing.

You earn your money by producing, adding value to the purchased raw materials. In general your gross margin is some 20%.
You have to negotiate with the Trading organizations about the price you are prepared to deliver the requested Towers.
You have to negotiate with suppliers about the price they are prepared to deliver, so the price you are willing to pay for the raw materials. Both, reductions of the price or higher prices, are possible.

You will experience **competition** because there are competitors who have to get their income in a similar way by producing Towers. You do not have an import license so the only way to purchase raw materials is through suppliers. Your available resources limit your opportunities: you cannot buy a lot of raw materials .

LE Network

Your balance sheet:

Debit:		Credit:	
Cash Inventory of raw materials	€ 282,- € 2.218,-	Capital/Own Funds	€ 2.500, -
total	€ 2.500 ,-	total	€ 2.500,-

Figure 2: An example of a role in LA-Game

Participants experience market competition in combination with scarcity of resources: pressures of scarcity of money, time and competitors. So, being continuously exposed to the market transactions and the risk during the game. The dynamics caused by these pressures of scarcity create both linear and non-linear learning processes. The context is Russia, each participant is triggered by senses and emotions (Damasio,1994). Positive emotions in experiencing successful transactions support the learning by doing process.

4. Methodology

Our methodology in publications is based on systematic generation of theory from data that contains both inductive and deductive thinking, like the grounded theory method, a systematic methodology in the social sciences involving the construction of theory through the analysis of data. Here one does not begin with a theory ... one begins with an area of study and what is relevant to that area is allowed to emerge [Glaser & Strauss, 1967 and Strauss & Corbin, 1990]. We did and do not aim for the “truth”, but we conceptualize what is going on by empirical research, especially by observing what is going on in our simulations. We formulate hypotheses based on conceptual ideas on learning (and teaching) processes in these simulations and test and re-test them in experiments with these simulations. So a kind of ‘simulation grounded theory’ that is shown in previous publications.

We apply the experimental method as a research method, because LA-Game can be played again and again, so our hypothesis can be validated or falsified whenever the experiments are repeated. This is exactly what we do. Here we use the testing environment of LA-Game, which offers participants the opportunity to experience the learning of a totally unknown language in a safe and simulated environment. LA-Game using LEGO is literally playful, as the word LEGO is Danish for “toy”.

We assume that our hypotheses on the learning and teaching process are valid; we have tested them with the help of the experimental method during simulations, by testing participants “before” and “after“attending an

LA-Game session. The effectiveness of the learning process is measured by the retention rate of the learned words. The elements of Action Regulation Theory are shown by videos of the participants.

5. Language learning as action learning of "tacit knowledge"

The idea that learning a language is consequently the creation of images which can be related to the dispositional representation in the personal, so subjective mind-set is supported by Damasio (1994). It is basically what is called constructivist learning, where it is assumed that the learner him-or herself actively builds up or construes his/her learning as mental structures, mental schemes in the brain. Damasio sees the brain as a "safe harbour" where the signals of the senses arrive in specific sectors, which are the basis for topographically organized representations, the source of mental images.

Damasio states that we share our mental image-based concept of the world with other humans and that there is a remarkable consistency in the constructions different individuals make of essential aspects of the environment (textures, sounds, shapes, colours, space), where these images can be perceptual or recalled. Damasio suggests that mental images are momentary constructions.

For language communication, Damasio adds: "Most of the words we use in our inner speech, before speaking or writing a sentence, exist as auditory or visual images in our consciousness". Damasio refers to Roger Shepard (1980) and Stephen Kosslyn (1982) when he argues that the value accorded to images is a recent development, part of the cognitive revolution that followed the long night of stimulus – response behaviourism. Also Damasio quotes Albert Einstein: "The words or language, as they are written or spoken, do not seem to play any role in my mechanism of thought. The psychical entities which seem to serve as elements in thought are certain signs and more or less clear images which can be 'voluntarily' reproduced and combined…" Damasio speaks of **dispositional representations** with which one is able to reconstitute a picture, dispositional representations are in his view 'dormant firing potentiality which comes to life when neurons fire.' For learning processes it is relevant how these images can be recalled to be able to communicate in a foreign language.

Because you need to recall the words in your 'inner speech' to be able to use words functional for communication, these dispositional representations in our view are related to the effectiveness of a learning (and teaching) process.

The psychological approach to this 'inner speech' is similar to Vygotsky's (1978) concept of "internalization" that evoked from Action Theory. Similarly "internalization" can be interpreted as the internal reconstruction of an external operation.

Language can be regarded as a kind of tacit knowledge (Nonaka, 1994), the kind of knowledge which is highly personal and hard to formalize. The internalization of the knowledge where explicit knowledge is transformed to tacit knowledge is the key of learning processes.

LA-Game is an educational method based on experiencing successes, and learning from failures (Popper, 2006). It is "action learning" (Argyris C. , Schön D.A., 1978), learning by doing, so the effectiveness of the learning process is better than other learning systems such as lectures (Sousa, 2006). A learning environment based on pull learning, since the development of communication skills is far more demand driven than supply driven. LA-Game is also a "neutral-Kolb environment"(Roelofs, 2013) , where each participant can apply their individual specific Kolb-learning style. The role game simulation has the dynamics that makes it possible to learn from making mistakes and from experiencing successes in a safe learning environment. The difference between this kind of learning environment and a professional environment is that it is allowed to make mistakes, sometimes even encouraged to make mistakes. Making mistakes is regarded positive learning (Popper 2006). Playing makes people free: they dare to make mistakes.

6. Action Regulation Theory (ART) in LA-Game

The Action Regulation Theory (Hacker, 1986) originally focused on modelling working conditions. Frese cs. (2018) have applied it to entrepreneurship and we pointed out that Action Regulation Theory is a theory of learning entrepreneurship. (Roelofs, 2018). This Action Regulation Theory (ART) focuses on the regulation of

the activity process which is applied to the gap between the visible activity and the non-visible cognitive processes by using a hierarchical-sequential structured model of the stepwise actions.

In general the ART distinguishes three levels of regulation of activities:

- the intellectual regulation-level, the highest level of the mental action-plans, the goal setting and selection of goals. These goals are realized through concrete actions. So the hierarchical highest level of thinking about what to achieve and which action steps to take to do so.
- the perceptual-conceptual regulatory-level, the control process of the continuously monitoring of the actions using a feedback-loop to ensure achieving the planned goal or make adjustments otherwise. This is the level about the monitoring and making adjustments.
- the sensory-motor regulatory level, the automated , "internalized" routine actions. The not-having-to-think level. Often in language learning focuses on this automated level: learning words without any structure to increase the "automated" level.

Frese distinguishes four levels and more "building blocks" in ART, each of them fits in the characteristics of giftedness!

6.1 The facets of active performance,

Frese and Fay (2001) distinguish three facets of being active: self-starting, long-term proactivity and persistence/overcome barriers. All three facets of active performance are present in LA-Game:

Each role in LA-Game implies **self-starting**, that is activated by the pull aspects of the simulation context. There is no superior present who tells the participant what to do or not to do. In LA-Game, self-starting of information collection is based on active search, active exploration of the environment and the information available. (https://youtu.be/36jJKJNeMk4)

Each role in LA-Game implies **proactivity** of not to wait until a demand is explicitly made to which one must respond. We observed that even during the coffee breaks the actions continue.

Each role in LA-Game implies **persistence** because there are always bottlenecks and limitations due to changing prices, scarcity of LEGO materials of specific colours , etc. Each participant has to overcome adversity (" no one wants my yellow LEGO bricks..") and of course to communicate in Russian requires persistence.

6.2 The differentiated steps in sequence of action regulation

Before the sequence of action regulation can start, Frese adds a pre-phase of the regulation: 'the consciousness of regulation'. (https://youtu.be/Hvb17mS4KII) As we experienced, this is an important phase: as an individual you have to know that entrepreneurial behaviour is required. An "entrepreneurial mode", so a context that entrepreneurial operating is needed. In LA-Game we bring participants in such a mode (colored jackets, specific badges, https://youtu.be/9ZT4pHwgYc0)

6.2.1 First step: goal development and selection,

'Goals', according to Frese, 'are proactive, when future opportunities are transformed into goals, … Frese refers Austin & Vancouver (1996) that goals are 'internal representations of desired states in the future' and Hacker (1985), that an 'action is the smallest unit of behavior that is linked to a goal'. (https://youtu.be/gUOjOkJl6vg)

6.2.2 Second step: orientation or mapping the environment,

According to Frese, "individuals regulate their action based on information or signals they receive from the environment, and they also change their environment through action". The 'change of the environment' is literally observable in LA-Game.

Regarding information collection and prognosis, Frese states that : "Proactive information collection appears if owners systematically search and scan for potential future opportunities or problems. Overcoming barriers in information collection implies that one continues on when it is difficult."

This information collection can be observed constantly during LA-Game. The systematic search for opportunities is literally observable, because the participants are cruising through the games location, moving from one participant to another. (https://youtu.be/rRSK63hIF1U)

6.2.3 Third step: planning (plan development and plan selection),
Frese: "This phase involves the creation of and selection among different plans that are instrumental in attaining a goal… "as bridges between thought and action..". In LA-Game this planning process is executed within seconds or minutes. The mental simulations illustrate the learning process of Action Regulation Theory. (https://youtu.be/wgGrdjS5d6Q)

Figure 3: Impression of LA-Game

6.2.4 Fourth step: monitoring of execution,
Frese: *"People need to monitor their actions. This involves a comparison between the goal and the associated plan and the actual execution of behavior. .... During execution, ….can respond more or less flexibly to unexpected situations, adapt their goals and plans",* ..(Frese & Zapf, 1994).

This monitoring and adapting goals and plans are manifest in the dynamics of LA-Game. 'Adapting' means implicit that in Action Regulation Theory there is a learning process.

6.2.5 Fifth step: feedback processing
Especially in this fifth step of the action sequence, the learning aspect is highlighted. Frese: "Feedback provides people with information from the environment about their current performance or progress toward attaining the goal. Moreover, feedback enables learning which types of plans can be most successfully used in the future.. They then regulate their behavior to reduce any discrepancies and to achieve the goal". (https://youtu.be/RY9NpYGCXgk)

In LA-Game the feedback is a constant process on the actions of the participants which in communicating in Russian are stimulated to help each other with Russian words.

6.3 The hierarchical structure in 4 levels of action regulation
Frese identifies a **hierarchical structure** in the regulation of actions. Action sequences on lower levels (less conscious and more routine behavior) are regulated by higher levels that require more conscious operating, more cognitive effort and feedback. So a higher level of action regulation requires more learning (and teaching) effort. Four hierarchical levels are distinguished:

1. The sensorimotor level which does not require conscious attention.
2. The level of flexible action patterns. In LA-Game these flexible actions patterns can literally be observed. Participants moving more or less random trough the room of the playing session.

3. Intellectual or Conscious Level. This 'consciously regulate' is the challenge for each participant when playing LA-Game. This intellectual level sees Frese related to the mental simulation: "*This level is* concerned with conscious regulation of goal oriented behavior. (https://youtu.be/f1DrZRf-DLM)
4. Level of Meta-Cognitive Heuristics. According to Frese this is a complex level of regulation, because it embraces both conscious as well as non-conscious forms of regulation. At this highest level of action regulation, meta-cognitive templates, strategies, and abstract heuristics are used, to guide goal and plan development, and feedback processing as well as understanding the environment (Frese & Zapf, 1994). "*These meta-cognitions allow individuals to approach similar problems in an effective way* "illustrates the relevance of learning for future acting. The learning aspect of Action Regulation Theory is implicitly presented by Frese as "*freeing up higher levels of regulation*".

6.3.1 The foci of action regulation and the action oriented mental model

Because all actions are done within a certain situation or context, Frese differentiates three foci of performance:

1. Task focus. A strong task focus is generally associated with high efficiency and effectiveness of action regulation, because it links goals with relevant plans, behaviour and feedback. In LA-Game we see this task focus in delivering the order in Russian, or buying LEGO bricks in Russian.
2. Social focus. Actions are performed within a social context. Interactions with other people influence the action sequence. In LA-Game a social focus can be observed: personal networks clustering together, also in helping with Russian. (https://youtu.be/RY9NpYGCXgk)
3. Self-focus. The self as a focus of regulation, implies that the impact of the individuals' actions on their self -emotions and self-beliefs- are in the foreground. Frese: "*The self-system is regulated on the meta-level*". It implies that a cognitive ability and qualifications are needed to be able to regulate on this meta-level. Gifted children are supposed to have these abilities.

The action oriented mental model is the need to communicate in Russian with the markets. (https://youtu.be/FRZms8I3Gbw)

6.4 Basic vocabulary needed to "survive"

The major pull learning is caused by the need to "survive", therefore basic communication is needed: the basic vocabulary! As Damasio states: "*An organism is designed with automatic survival mechanisms, and to which education and acculturation add a set of socially permissible and desirable decision strategies that, in turn, enhance survival,…*". The simulation activates the power for associations, which result in the capabilities of participants to adapt to this realistic context which need communication in a completely new language to be able to "survive". Associations (word images) are activating dispositional representation through reasoning strategy. Damasio: "*emotion is needed for mastering the know-how" (Introduction, p.xxv).*

In the LA-Game simulation each participant is set back into an "unknown" context, basically "back to zero" and confronted with a totally new language. To be able to have success, communication is necessary. By confronting each participant with the language handicap, each participant is placed in a kind of "survival mode", where communication is demanded. This requires active and collaborative learning processes, not "pushed" but "pulled", any participant will apply and remember the words which are needed in communicating to 'survive'. (https://youtu.be/wob5qVcHdqc)

Theory like Damasio's, made clear that for learning a language, to communicate in a foreign language we had to create learning elements which activate or stimulate this making of 'mental images', these dispositional representations. To be able to communicate in such a new language you have to create your personal 'mental images'. This aspect of subjectivity emphasis the subjective element of learning processes. An element that is also highlighted for teaching gifted children.

For each language the basic vocabulary consists of circa 50-100 words, which can be compared with the first level of learning a language: "the Common European Framework A1"

7. The results of the test on Russian

We tested a number of words of a basic vocabulary Russian. So colors, simple numbers, greetings etc. We tested by using Kahoot survey, before and after the LA-Game course. The results showed an increase of 52% in

a few hours. Due to the chance element in testing (just gambling generates 25% good answers), the increase was even larger when corrected for this aspect. We repeated the same survey a week later: the results were even better: an increase of 61% good

8. Conclusions

To bridge the gap between scientific knowledge and what is put into practice, it is possible to use LA-Game; an authentic learning environment with the dynamics, that makes it possible to learn from making mistakes and experiencing successes. Often it takes time and a great deal of energy to set the first step in learning a new language. LA-Game is a successful entrepreneurial learning environment for learning a basic vocabulary Russian because teaching takes place in a playful way. The challenging teaching method of this role game simulation, fits in the learning needs of gifted children, like the experiment of LA-Game shows.

The experiment visualizes and confirms several elements of Action Regulation Theory (shown in short YouTube-movies of the experiment) and the Kahoot surveys demonstrate clearly positive learning results (before LA-Game, after LA-Game and 1 week after LA-Game)

The experimental method we used with LA-Game shows again that learning a basic vocabulary of a complete unknown language, like Russian, is possible. For gifted children entrepreneurial learning is a market need that fits in their “entrepreneurial learning mind-set”. Entrepreneurial learning by gifted children applied in the LA-Game experiment, demonstrates also the validity of several elements of the psychological theory on learning entrepreneurship: Action Regulation Theory.

Entrepreneurial Research through Design

Michele Rusk
Newcastle Business School, Northumbria University, Newcastle upon Tyne, UK
michele.rusk@northumbria.ac.uk

Abstract: This Paper reports on a longitudinal study of Entrepreneurial Leadership by Design. It takes a new perspective through a 'designerly' approach to research, conducted simultaneously with generative activity (Cross 2006). In doing so it highlights the similarities in cognitive approaches common to strategic design and entrepreneurial leadership. The methodological approach is based on abduction; the core reasoning process that underlies design, as the starting point for focusing on the design practice of problem framing as the foundation for innovative activity. Donald Schön's (1987) views on design as a reflective activity and the central role of frame creation (Dorst 2016) are taken up as situated action and situated cognition. In particular, the improvisational nature of reflection-in-action and subsequently reflection on reflection-in-action, are considered appropriate when investigating the complicated realm of socio- economic value creation. The research was conducted in the shared setting of studio practice known as Strategic Design Labs. Here collaborative design was employed as research methodology through a process of naming, framing and sense-making. In particular naming that which warrants attention (problem or paradox) and framing the context as a problem setting activity. Frame creation is a design-based approach that is purely problem-focused; as such it is the fundamental underpinning of a repertoire of generative methods employed in Strategic Design Labs. Here entrepreneurial leaders, be they expert designers, managers and/or stakeholder, platform strategic design activity so as to co-evolve multiple solutions in a co- creation process. This participatory action led to retrospective sense-making and subsequently yielded new hybrid research methodologies. The paper concludes with a holistic Design Dynamics Research Model Canvas that aggregates a range of design and business approaches into a combined methodology; its phases, methods, activity and instruments. This new model is of relevance to those seeking to investigate how entrepreneurial leaders engage in developmental innovation.

Keywords: Entrepreneurial Leadership, Design Dynamics Research, Socio- Economic Innovation.

1. Introduction

This paper seeks to articulate a new methodology that is simultaneously investigative and generative with respect to innovation. This approach is grounded in design led mindful experiential learning through the collaborative practice of shared value creation.

Etienne Wenger (1998) maintains that communities of practice are not amenable to design, instead they must be allowed to emerge. By extension presumably the same might be said for entire ecosystems that encompass the three pillars of Higher Education Industry and Government that make up the Triple Helix (Etzkowiitz, 2012).

We do, however, have to acknowledge that some kind of catalyst is required to accelerate innovation wholesale to create shared value at the societal level (Porter and Kramer, ,2011). Here the dynamism of Entrepreneurial Leaders (Hazy, 2015) is key to envisioning a preferred shared future and setting a strategic direction to attain it. Such Entrepreneurial Leaders navigate complexity and purposefully engage in developmental innovation to create new social and economic value. To do this they engage in a process of Strategic Design (Steinberg 2012, Varganti 2009). In this context, design is taken to mean intent and is consequently described as strategic design following Vasari's definition as 'the animating principle of all creative processes'.

Research into what entrepreneurial leaders actually do in practice has particular relevance to fostering entrepreneurial ecosystems that enable sustainable socio- economic innovation through open systems networks. In this paper the aim is to highlight the role of design for developmental innovation so as to expand the conceptual field to encompass multidisciplinary arenas. It follows then that if Entrepreneurial Leadership is crucial to the development of sustainable ecosystems that encourage innovative, how then do we in Higher Education foster more individuals with Entrepreneurial Leadership competencies?

The first step has to be a clearer understanding of how Entrepreneurial Leaders learn through their practice of Strategic Design – specifically how 'Research through Design'. This phrase connotes a symbiotic relationship between the enquiry that is the research and design that generates the innovation.

2. Nature of the research

> *"Everything can be taken from a man but one thing: the last of the human freedoms—to choose one's attitude in any given set of circumstances, to choose one's own way."* (Frankl, 2014)

In the belief that unique and uncertain situations come to be better understood in an attempt to change them, this research has been a longitudinal study based on over 30-year reflective practice in developmental innovation. The motivation for research and professional practice in socio- economic innovation was forged in the context of 1970s conflict in Northern Ireland, to conflict resolution and the requirement for social innovation for positive socio economic value creation. The research has adopted ethnographically-inspired or workplace-oriented perspectives (Nilsson, 2005) to conduct analysis of particular socio – economic development projects, in order to reveal the central role of design as reflection-in-action (Schön,1983) in the hypothesised modus operandi of entrepreneurial leadership. The inquiry has culminated in a concerted 8-year period of design led reflection and analysis to contextualize and conceptualize, and thereby make explicit, the tacit knowledge gained in the reflective practice of strategic design for developmental innovation.

In totality the work represents a journey of discovery where the milestones have been the published outputs as markers for new plateaus of insight and understanding. Thus the research has been episodic and exemplifies iterative development over time. The events having been assignments or roles, intentionally sought out as research opportunities, in different contexts to test and refine ideas and hypotheses. The choice of activities has been purposeful in order to triangulate, sense check and test an evolving understanding of the role of design in socio economic value creation in regional economic development, academic, and international contexts. The overarching quest being to arrive at core principles or threshold concepts (Meyer and Land, 2006) of Entrepreneurial Leadership that have been generalizing from the specific in different domains be it in the context of, regional government policy, higher education curriculum development or international enterprise development.

In essence the research sought to understand expressions of the creative process as applied to socio-economic developmental innovation and to test the hypothesis that business design – also otherwise known as entrepreneurship was a strategic design function employed by entrepreneurial leaders in a number of different developmental contexts. It further sought to establish that how entrepreneurs operate is essentially 'desigerly' action. (Cross,2006). Consequently, the overarching aim was to further the establishment of Strategic Design as a conceptual field with core principles that are applicable in a number of different problem scenarios in different domains and/ or in a multidisciplinary arena. And further to hypothesise that Strategic Design is the modus operandi employed by entrepreneurial leaders to effect developmental innovation.

3. Why Design?

The case for a scholarly or a scientific approach to research is a given, however with respect to developmental innovation understanding the strategic design process of working from the general to the particular and then extrapolating back to the general again is a specific and unique design dynamic of oscillating between the divergent and convergent. Design is directed towards meeting a particular need or function in a commercial and social context. But design is also a process that involves investigation, inquiry, analysis and evaluation leads to insights and new learning whereby designers construct new realities in accordance with Schön's theory of reflective practice. In this sense research can be said to be conducted through design.

In pursuit of creative inventiveness, design draws from many fields and is thus integrative and multidisciplinary. Consequently, the body of knowledge in support of design has to be regarded formally as unbounded (Archer 2007). It is this crossing of boundaries, multidisciplinary inquiry and synthesis that enables research and innovation by design; episodically engaging in generative design to create tangible outputs, then employing a post solution analytical evaluation before reframing to re-enter the generative phrase. It is this fluid movement between the divergent and convergent; the generative and evaluative that allows for a simultaneous satisfying of the potentially conflicting considerations of traditional sense of design and research.

For solving the seemingly irresolvable is in itself the kernel of the design process. (Whitbeck,2011)

4. Research Context

This Paper reports on entrepreneurial leadership research conducted in the shared setting of studio practice known as Strategic Design Labs. Consequently, the research context was invariably communities of inquiry, learning and practice; made up of actors from different perspectives in a setting for studio practice where a naming, framing and sense-making approach was employed as a strategic design research methodology. The tactic was termed the Strategic Design Lab. In these co creation laboratories for change research was conducted through a problem setting and solving approach enabled by the process of naming, problem framing, sense-making, boundary setting, (Schön 1987)

This method brought a dynamic, creative and innovative approach to team based reflective practice that engenders dynamic multifaceted research. In this manner the strategic design competencies employed by entrepreneurial leaders were revealed in communities of practice in reflective practicums or studio workshops. These were displayed in communicative contexts, normally developmental situations, that were used to collect the observations.

5. Research Philosophy

It is perhaps a truism to say that the relevance of the discipline of design in social, cultural and economic domains has increased exponentially over recent years and with it the recognition of the quest for different academic tools that are redolent of the discipline's cognitive force and agency (Ralf 2007). Thus cognitive design theory (Schön 1983, 1987, Archer 2007, Kolko 2010) is central to the methodological approach; specifically research through design.

A 'designerly' approach (Cross 2006, Bonsiepe 2007, Jonas 2007) to research, conducted simultaneously with generative activity, affords a new perspective on entrepreneurial leadership. Seen through the lens of strategic design, similar cognitive approaches that are common to design and entrepreneurial leadership are highlighted. For the strategic design process, of working from the general to the particular and then extrapolating back to the general again, is a specific and unique design dynamic of oscillating between the divergent and convergent. Accordingly, Donald Schön's view on design as a reflective activity and the central role of frame creation (Dorst 2016) were taken up as situated action and situated cognition. In particular, the improvisational nature of reflection-in-action and subsequently reflection on reflection-in-action, were considered appropriate when investigating the complicated realm of socio- economic value creation.

In essence, the research philosophy employed a constructionist view (Krippendorff 2006, 2007), where reconciliation is enabled by collaborative action. It was strongly influenced by Wenger's (1998) work on communities of practice, as these are continually engaged in sense making (Goodman 1978, Schön 1987). Unlocking creativity (Robinson 2009) at the societal level across the triple helix (Etzkowitz 2012) underpined the philosophy as did systems thinking (Senge 1990).

6. Design as Research Methodology

Some maintain that design is resistant to rigorous empirical inquiry because of its multifaceted nature and the complication of measuring the outcomes (Liedtka 2015). However, the methodological approach is based on abduction; the core reasoning process that underlies the design practice of problem framing as the foundation for generative activity (Stappers 2007, Dorst 2015).

The research methodology employed throughout has been participatory action specifically that of the reflective design practitioner through a process of naming, framing and sense-making. In particular naming that which needs attention (problem or paradox) and framing the context for this as a problem setting activity.

Frame creation is a design-based approach that is purely problem-focused. As such it is the fundamental underpinning of a repertoire of generative methods employed in Strategic Design Labs. Here entrepreneurial leaders, be they expert designers, managers and/or stakeholder, are able to platform their strategic design activity so as to co-evolve multiple solutions in a co- creation process. Table 1, below depicts the range of research methods as a holistic Design Dynamics Research Model Canvas. It illustrates the combined methodological approach; its phases, methods, activity and instruments.

Numerals in brackets through this submission pertain to different developmental enterprises

The research approach was characterised by a two-fold process of episodic toggling between:

1. Reflection in Action: during the generative, solution making Strategic Design Labs.
2. Reflection on Reflective Practice: Post outcome analyses and evaluation research yielding sense-making through mapping and model making.

This resulted in a cumulative build-up of knowledge derived either by reframing in a quest for more and better solutions in the same problem space; or in a different context, application of knowledge gained in an unrelated sphere.

Three distinct phases that were in turn **Exploratory, Generative and Evaluative** made up a sequential approach:

1. Exploratory: In the first phase strategic design is an exemplar of expert design practice, where designers and stakeholders engage in reasoning from desired outcomes via frames for possible design solutions (Schön and Wiggins 1992).

2. Generative: During the second phase, Strategic Design Labs enable a network of interested parties to come together around a problem, which they collectively view from a novel standpoint. They address the multifaceted nature of the problem by creating a new and broader context. This produces underlying themes that lead to the creation of a framework for action. The activity is recorded in template proformas, photographic and video evidence and public exhibition. In the Strategic Design Lab both the problem and the solution are developed and refined in concert in a co-evolution process (Dorst and Cross 2001) to simultaneously satisfy potentially conflicting considerations (Whitbeck 2011). Through this activity entrepreneurial leaders create new concepts for developmental innovation with respect to curriculum, enterprise, platforms and policy frameworks. In this way Strategic Design Labs initiate the practice of open innovation. Where:

the investigation is initiated by problem based inquiry or thought experiment

- stakeholders design and co-create their strategic direction
- a primary investigator takes on the role of catalyst, and reflective practitioner.

1. Evaluative: The third phase constitutes analytical research and evaluation. It is a process of sense-making that articulates relationships through the use of visual diagrammatic schema. This phase takes place at the interface between Reflection – in - Action and Reflection on Refection – in - Action.

   Reflection on the ensuing trail in practice informs the deliberate proactive choice of the next inquiry as the subsequent step in the learning journey.

The research employed a range of design and business instruments (Martin and Hanington 2012). These are aligned into six sequential methods. These methods have been identified during the retrospective sense-making of participatory action during the longitudinal study. Each method is employed, to a greater or lesser extent in all of the research contributions, with variations in emphasis being contingent on subject matter or context. The methods are: - **Domain Orientation, Issue Scoping, Elemental Analysis, Reconfiguring and Evaluation and Reflection: -**

1. **Domain Orientation** describes elicitation and modelling of the area, analysis from different perspectives and issue intelligence gathering. The research involved information gathering from industry sources; reference to knowledgeable expert actors through Focus Groups; as well as Stakeholder (market segmentation) and Territory (position) Maps.

2. **Issue Scoping** defines the problem architecture through identification of components and their relation to core values. Typical research techniques used were: Conceptual Enquiry, Design Ethnography, Image boards, Laddering and Focus Group.

3. **Elemental Analysis** helps understanding of complex issues by atomisation into constituent parts. Mind Maps, Thematic Networks, Stakeholder walk though, as well as Relational Schema were employed.

4. **Reconfiguring** is concerned with the practice of strategic design for innovation through alternative permutations and syntheses generation. The primary research techniques being Problem Based Thought Experiments.

5. **Deployment and Evaluation** is by trial for verification of functional appropriateness through situational testing. Methods include: Focus Groups, User trials, Design Ethnography.

6. **Reflection** describes post project analysis that involves reviewing success factors and limitations, as well as unintended consequences, to draw inferences through new cognitive connections. Data analysis informs the development of principles and conceptual models that make new contributions to knowledge, simultaneously interpreting and anticipating patterns of unmet emerging needs to form new lines of inquiry.

7. Outcomes

The research process and subsequent knowledge building has been an experiential journey steered by design principles and practices illustrated below in figure 1. Research Through Design. The inquiry into design as a research methodology centres on how developmental innovation is practiced by entrepreneurial leaders in concert with other actors across the triple helix so as to create new shared value creation (Porter and Kramer, 2011).

The research has led to issue scoping and elemental analysis through mapping Regional Economic, Educational and Policy Development initiatives onto a Framework of Transformational Drivers and Triple Helix Challenges.

This has yielded threshold and transfiguring concepts. Threshold Concepts (Meyer and Land 2006, Yip, and Raelin 2012) are the ideas that need to be comprehended as keys to understanding the field. Whereas

Transfiguring Concepts are generative devices, normally the province of creativity, that need to be mastered as part of a design process.

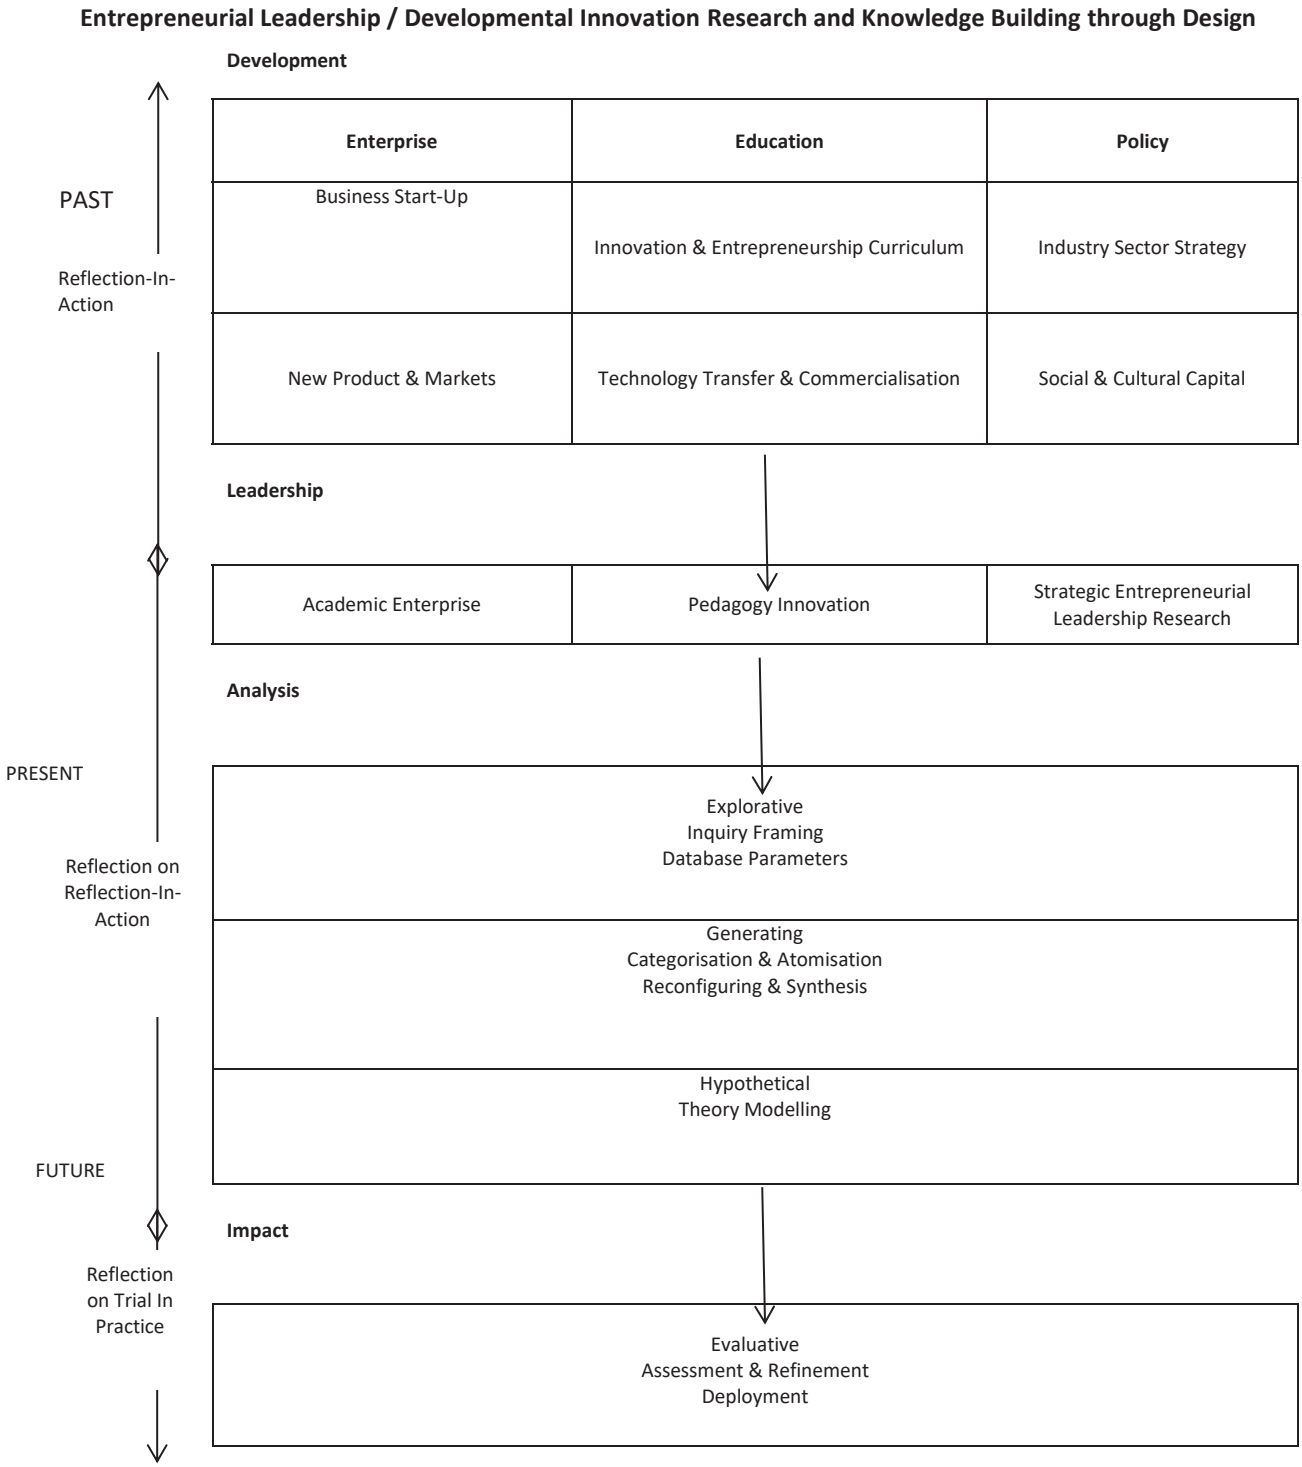

Figure 1: Research through Design

8. Conclusion and Recommendations

Reflection on the process of entrepreneurial leadership as practiced in different contexts has contributed to the extant body of knowledge through the construction of a Design Dynamics Organising Framework.These elements have coalesced to form a coherent theory of Design Dynamics that positions design as a pivotal, generative metaskill for adding value; specifically, as a set of cognitive and practical methodologies employed

by entrepreneurial leaders to deal with instability and adapt accordingly whilst engaging in developmental innovation. Future research is called for to test the theory of Design Dynamics in entrepreneurial ecosystems.

As one of the pillars of the Triple Helix, it is incumbent on Higher Education to play its part in shared value creation, both social and economic, by demonstrating Civic Entrepreneurial Leadership for regional development. This can best be done by building sound pedagogic foundations through attention to the research informed teaching and learning nexus. New methodologies that are a distillation of reflective practice, reflection in action, and trial in practice are all part of mindful experiential learning.

Research through design is an example of investigation and generative innovation that looks at iterative generative practice differently to draw parallels with entrepreneurship. As such it is an important new perspective when leading entrepreneurial academic design – the next stage in curriculum development, new studio practice methodologies and multifaceted ways of learning and knowing. Such underpinning holds out exciting prospects for a new generation of Masters level provision that are amenable to academic apprenticeships and grounded in complex ecosystems for example National Health Service, Frontier and Boarder Management, Good Governance, to name but a few.

Clearly there is a there is a need to apply, test and refine this new research by design methodology in different complex contexts, before creating new academic programmes that address leading innovation and strategic co creation so that future Entrepreneurial Leaders can navigate complexity and create shared value.

Stereotypes as a Barrier to Introducing Innovations in Food Products

Agnieszka Rybowska and Aleksandra Wilczyńska
Gdynia Maritime University, Poland
a.rybowska@wpi.am.gdynia.pl
a.wilczynska@wpit.am.gdynia.pl

Abstract: In studies of consumer behaviour on the market, a lot of attention is paid to the factors determining the choice of products. Among these factors there are also barriers and limitations, affecting consumers' decisions. The limitation in making decisions about the purchase of new, innovative products is the risk resulting from: ignorance of some new product components, lack of information about handling such product, inappropriate or unknown sensory experience of products, inappropriate sensory experience, fears of buying a product that may turn out unsatisfactory. The barriers associated with the purchase of such products include: difficulties in perceiving the product on offer, fears about new products, lack of information about the product, no possibility of comparison with other similar products, critical comments of the environment. These factors include stereotypes - well-established in society beliefs about a product, not always consistent with the latest knowledge. More and more often products appear on the market with new, atypical organoleptic features that cause mixed feelings for the consumer. It is caused by stereotypical thinking about products. The aim of the research was to show the influence of stereotypes on the selection of innovative food products. The research was carried out in a group of both: young people considered to be open to new things, and older, conservative one. The survey method, a projection method and a method of successive associations were used. It has been shown that respondents perceive sensory values of food products through the prism of stereotypes. This may negatively affect the process of commercialization of innovative products.

Keywords: barrier, innovation, consumer, stereotype

1. Introduction

The process of introducing new food products on the market is very complicated, and its effects depend primarily on behavioural responses of consumers, as a consequence, negative and suspicious feelings towards food technologies may lead to product failures. (Chen at al. 2013) When choosing a food product for itself, the consumer is guided by various factors that have the character of stimuli, brakes or conditions, and thus have a stimulating or inhibiting effect on changes in eating behaviour. Sojkin (2012), examining the factors of the commercialization process of a food product, as the main pointed out consumer's needs and behaviours. The consumer, by choosing innovative food products, is guided by messages reaching him:

- traditional (advertising, billboards, press advertisement, commercial leaflet),
- public relations (culinary programs, recipes in the press, information on the label)
- trade information (shelf display, information from sellers).

In addition, the consumer's innovativeness (curiosity, willingness to try new products or an impulse to buy) and the influence of the environment (family, price level) were considered important in this process. The limitation in making decisions about the purchase of new products is the risk that results from: adverse changes in the composition of the product, lack of information (problems with preparation), inappropriate sensory quality (flavours, taste), fear of losing funds. In addition, the author pointed to the barriers to purchase such products, which he divided into four groups: difficulties in perceiving the product on the offer, fear of new products (neophobia), lack of information about the product (insufficient information, no possibility of comparison, price of a new product), critical comments of the environment (family's assessment, lack of incentives for promotion) (Sojkin 2012). In turn, Jeżewska-Zychowicz (2014) presented a model of factors affecting the acceptance of innovative products, which she divided into three groups: social system (economy, politics, culture, religion, social norms, social trust), factors related to the innovative product (price, convenience of use, taste, appearance, presence of pro-health ingredients) and factors related to the consumer. The last group included socio-demographic factors (age, sex, education and income), psychological characteristics (tendency to explore, nutritional neophobia, dietary preferences, innovation) and psychosocial features (knowledge of food and food technologies, views on benefits and health risks, attitudes towards food).

Many authors believe that it is impossible to separate treatment of individual factors. Each of them must be seen in the context of the others. A thorough knowledge of these factors and the strength of their mutual connections creates the opportunity to influence the selection, acceptance and consumption of certain food products more effectively. Consumers are faced with numerous restrictions and barriers when choosing a product. These barriers include lack of knowledge about the object, uncertainty, risk (e.g. related to the purchase of a new, unknown product), perceived threats and prejudices. Prejudices against food arise from the individual's experience or social beliefs conditioned by stereotypes functioning in society. It can therefore be assumed that stereotypes affect the choice of food and nutritional behaviour.

2. Stereotypes and a food choice

The stereotype is defined as functioning in society generally well-worn belief on the subject, not always in line with current knowledge. A stereotype was defined as an image of some people, things or phenomena, fixed in the consciousness of many people and difficult to change (Bańko 2000). Stereotypes can also refer to non-human objects. Stereotypes play an important role in human life, in its cognitive processes, in the perception of other people or groups and in interpersonal communication. They facilitate and economize the lives of individuals and societies. Aronson et al. (1997) and Stephan and Stephan (1999) found that the use of stereotypes allows for time-saving and energy simplistic categorization and facilitates object without the need to learnt it in detail. Similarly, Domachowski (2001) treats the stereotype as a scheme emerging in the process of cognition, involving the inclusion of a person or an object into a certain category on the basis of the characteristic features that are assigned to it. The issue of stereotypical thinking about products and its impact on consumer behaviour, including the choice of food has been the subject of very few studies. The analysis of the results of these studies allows the thesis that stereotypes may concern various objects and their individual features, which determines the choice of products and consumer behaviour.

The evaluation of products, their quality and importance as well as the predisposition of people to generalization and categorization of objects are often based on stereotypical perception. Stereotypical perception of the product on the one hand may be a barrier for the consumer, and on the other hand, motivation in choosing, buying or consuming it. Stereotypical beliefs cause the exclusion or inclusion of products from the diet, which may determine dietary mistakes, bad eating habits, shortages or excess nutrients. It also affects the functioning of the market, the demand for specific products, sales volume and income obtained. Stereotypes can be a barrier when introducing new or innovative products to the market.

3. Experimental

3.1 Method

The aim of the study was to determine the effect stereotypical thinking on the choice of selected food products by getting to know consumers' opinion on selected products with typical and atypical features. Fruit and vegetables were chosen as the subject of the study. The study was conducted in a group of 177 people, which were both young people, open to innovation (88 people - 50%) and people in late middle age, more conservative (56-70 years) (89 people - 50%) (Rybowska 2018). The direct question method was used. The questionnaire contained two questions regarding the perception of products with typical and unusual features and the willingness to consume them. In the first question, the respondents were asked to give the colour of products with which these products are associated. For this purpose, the successive association method was used. The results of the research were presented as a percentage of indications. In the next question, the surveyed presents photos of selected vegetables with different appearance features (colour, shape). These products were divided into two categories: typical products (T), which were characterized by known features to which the consumer is accustomed and untypical, which differed in appearance from typical products. We made a deliberate choice of objects, suggesting their popularity, availability and market differentiation. Four vegetables were chosen (tomatoes, cucumbers, carrots and peppers in different varieties).

The respondents were asked to determine the willingness to consume the products shown in the pictures and rank them in the order from "I definitely want to consume" to "I definitely do not want to eat" (scale of rank), and then assigned numerical values to these terms. The obtained results were presented as an average value ($\bar{x}$), which was used to prepare a ranking (R) of varieties depending on the declared willingness to consume them. The lowest average value corresponded to the high intake of the product, while the highest average indicated products that the respondents would not like to consume. Using the Student's t-test, the significance of differences between typical and untypical products was assessed.

3.2 Results

All respondents associated tomatoes with the red colour, which was in the first place, followed by yellow (75% indications), raspberry (68%), green (24%) and black (12%). Tomatoes with an unusual colour were known by the younger part of population and it was they who indicated the colour of the vegetables. Older respondents (after age 56) indicated tomatoes with typical red (100%) and raspberry (78%) colour and yellow tomatoes (35%). Polish cucumbers, popular in Polish cuisine, were associated by consumers only with green colour (100% indications). Cucumbers with an unusual white or yellow colour are rarely available in Poland and therefore unknown to consumers. In the case of carrots, the respondents indicated two colours: orange (100%) and dark purple (15%). Carrot varieties with orange colour are the most popular on the Polish market, and those with a different colour are available from recently. Peppers were associated with red colour (100% indications) and green (100%) in the third place were yellow (63%) and white (15%) peppers. Older people most often indicated red and green, while young all mentioned colours. This research confirmed that consumers associate vegetables with typical colours, which is proof of stereotypical thinking.

In the next stage, respondents were asked for opinions about the different varieties of vegetables presented in the pictures, which were distinguished by different organoleptic features and ranked them in order according to the willingness to consume.

The subjects presented in the pictures were nine tomato varieties, which differed in the colour and shape of the fruit. It was shown that respondents would like to consume vegetables with typical, known appearance features that consumers are accustomed to (Table 1).

Table 1: The rankings of varieties of individual vegetables according to the declared intentions of consumption

Variety	Characteristic features	$\bar{x}$	SD	R
Tomatoes				
Zyska	Red colour, Extended cylindrical shape (T)	2,82	2,3421	**3**
Indigo Rose	Dark violet colour on the outside, red, spherical, medium-sized flesh	8,01	1,4838	8
Tigerella	Red in orange-yellow stripes, round, large	7,11	1,4548	7
Denar Polski	Red colour, pear shape	4,91	1,7626	5
Złoty Ożarowski	Colour: yellow, round, medium size	5,21	2,2391	6
Zebrina	Black colour, spherical shape	8,25	1,3356	9
Atol gruntowy	Red, spherical, medium-sized (T)	1,81	1,2465	**1**
Costoluto Fiorentino	Red colour, with flattened, ribbed fruits	4,22	1,5404	4
Faworyt	Red, round, large (T)	2,16	1,8672	**2**
Cucumbers				
White Wonder	Skin colour celadon-white, covered with a small number of warts, oblong shape, bulging (oval)	3,56	2,3597	4
Carosello Barese	Greenish-white skin, on the surface you can see distinct longitudinal ribs and delicate pubescence	4,98	1,1935	5
Lemon (Citrone)	Yellow colour, round shape	3,46	1,6726	3
Octopus	Green skin colour, oblong (T)	1,11	0,2601	**1**
Delicius	Green skin colour with white streaks, oblong (T)	1,87	1,1143	**2**
Carrots				
Deep purple	Purple bark colour and orange root core, typical shape	1,99	1,4872	**2**
Karotka	Orange carrot, typical shape (T)	1,14	0,4872	**1**
Gold Nugget	Yellow carrot, typical shape	3,10	1,2525	**3**
White Satin	White and crayfish carrots, typical shape	3,25	1,2537	4
Peppers				
Ożarowska	Red colour, typical shape (T)	1,34	0,7528	**1**
Marta	Yellow colour, typical shape (T)	1,42	0,8365	**3**
Quatro	Green colour, typical shape (T)	1,39	0,7695	**2**

Etiuda	Orange colour, typical shape	2,53	1,6273	4
Oda	Dark violet colour, typical shape	3,38	1,7501	5
Diament	White colour, typical shape	4,53	2,2423	6

(T) – typical; source: own research.

The first places in the ranking included tomatoes with a typical red vegetable colour and spherical or elongated shape, while on the last two places with a dark (purple and black) colour of the fruit. The age of the respondents did not significantly differentiate their opinions, although young people would eat tomatoes with unusual values more willingly than older ones. The respondents stated that they would eagerly eat cucumbers with a typical green colour and green with white streaks and a smooth skin, and would not like to eat cucumbers with a light skin colour. Cucumbers with an unusual celadon-white and yellow skin colour and unusual oval or round shape did not encourage them to eat. In the last place in the ranking there was a variety of cucumber with a typical oblong shape and a greenish colour of the mossy skin. Consumers expressed their willingness to consume carrot varieties with a typical orange colour, and those with unusual features were on the last places in the ranking. Respondents would be more likely to eat peppers with a typical than unusual colour, but in this case the greatest reluctance was found with regard to the pepper with a white skin colour, which was not sensory attractive. The dark colour of the peppers did not inspire their decisive reluctance. Pepper is used in the kitchen as an addition to dishes, and as a component of salads and the addition of its many-colored varieties affects the visual attractiveness of the dish.

Table 2 presents the results of the comparison of the willingness to eat vegetables with typical and atypical features. The respondents declared a greater willingness to eat vegetables with known characteristics recognized as typical for him. There were statistically significant differences in the willingness to eat vegetables with typical and atypical features.

Table 2: Declared willingness to eat vegetables with typical and unusual characteristics.

Product	**Varieties**	$\bar{x}$	**SD**	
Tomatoes	typical	1,96	0,8453	t= 15,329, p<0,001[a]
	untypical	6,58	0,3145	
Cucumbers	typical	1,55	0,5843	t= 12,651, p<0,001[a]
	untypical	4,87	0,8566	
Carrots	typical	1,24	0,4643	t= 11,561, p<0,001[a]
	untypical	3,67	0,7532	
Peppers	typical	1,75	0,6753	t= 13,322, p< 0,001[a]
	untypical	4,67	0,7484	

a - statistically significant difference, source – own research.

4. Discussion and conclusion

In recent years, more and more unknown fruit and vegetables have appeared on the Polish market. They are often popular products in other regions of the world, and sometimes completely new ones obtained by crossing varieties with others. They are often characterized by organoleptic features that are unusual for a given species (colour, shape, taste, smell) different from those to which the Polish consumer is accustomed. Such action is aimed at making the market offer more attractive and allowing the consumer a wider choice. The variety of food products can significantly affect the choice. Attachment to known attributes may be a barrier to choice, and at the same time to encourage the emergence of new stereotypes. The product must be of interest to the customer, and hence performs a specific marketing function. Such new products differ from typical products (prototypes) by different organoleptic characteristics. Most often it concerns the appearance of the product: its colour, size, shape and quality of the skin and its texture. It may also differ in the colour of the pulp or its texture (consistency). The change of these characteristics determines the culinary usefulness of new varieties (vegetables for salads, for cooking, for preserves). Definitely less often, such differences relate to taste or aroma, although examples of fruits and vegetables in which these characteristics have changed may be given: pineapple-flavoured strawberries, pear-flavoured apple etc. Often, the generation of new varieties also aims to create new functional products. In the case of fruit and vegetables, obtaining a dark colour was associated with an increase in antioxidant properties, thus increasing the health-promoting potential of these products, but also the culinary attractiveness desired by the catering industry and consumers. New varieties give the possibility to choose vegetables in colour, for example only purple (eggplant, broccoli, chicory, kale,

carrot, tomato, lettuce, radish and others). This selection influences the variety and attractiveness of the dishes served.

A product with typical features was a kind of message about its quality. The name caused the automatic association of the product with its characteristic features, evoking specific emotions and attitudes towards it, eg. the willingness to consume. So it can be talk about the symbolic meaning of typical products. This typicity also facilitated verbal communication, making it possible to shorten the message, which does not require additional, detailed description of the product. To determine it, it was enough to use the product name, and the message was correctly received and interpreted by the recipient. With the introduction of new varieties, the situation has changed dramatically, and simple and easy to communicate until now requires more time and commitment. A new group of stereotypes is emerging. In the era when products with an unusual colour are available on the market, using a typical colour to describe them becomes a stereotype. A good example of this can be tomatoes. At the moment when tomatoes appear on the market with a different colour, it is stereotypical to say that the tomatoes are red. The same applies to other vegetables and fruits. The thinking about these products and their qualities will also be stereotyped.

The occurrence of typical products with permanent unchanging features constituted a kind of order and facilitated communication, including market communication. Consumers perceive the quality of the product through the prism of colour, for example, red apples associate with ripe, sweet fruit, and green on the contrary: with sour and immature fruit (Baryłko-Pikielna and Kostyra 2007, Śmiechowska and Dmowski 2014). The introduction of new varieties with changed traits causes a disruption of this condition, and may even arouse fear and insecurity. A known product is considered safe, and this awareness is one of the determinants of attachment to a specific product or brand. A new, unknown product or product with changed characteristics may cause psychological discomfort to the consumer. Unusual changes in the product are associated with genetic and food GMOs. They arouse anxiety among consumers who do not know what to expect from such products, what organoleptic properties they possess and what effects they have on the body.

Consumers' habituation to constant, invariable features of the product in its original form resulted in automatism when making decisions and making purchases. He also expressed himself in thinking about the product, its features and application. Meanwhile, the change in the appearance of products causes disturbances in this thinking and, as a result, a barrier in its choice.

As a conclusion it could be said that stereotypical thinking may negatively affect the process of commercialization of innovative products.

Entrepreneurship in the Tourism Sector: The Błędów Desert as an Area of Entrepreneurship and Innovation Development

Krzysztof Sala
Pedagogical University of Cracow, Poland
krzysztofsal@onet.pl

Abstract: Nowadays, tourism is one of the largest phenomena and the most important economy sector in many countries around the world. The number of participants of the global tourist traffic has already exceeded 1 billion people who perceive tourism as a way of spending free time. The aim of this publication is to present and evaluate entrepreneurial activities in the field of revitalization and stimulation of the tourist development of the Błędów Desert as a unique but relatively unknown desert area in Europe. The subject concerns its exceptional tourist value both in Poland and abroad. Deserts in Europe are a rare and distinctive element of the landscape. The analysis of a wide range of activities undertaken in recent years to develop the tourist destination of this once neglected area is worth discussing in the form of an article. The scale of activities, entrepreneurial initiatives and manifestations of innovativeness of many stakeholders can be considered as a model for other tourist resorts. This paper characterizers and discusses the tourist valuation of the Błędów Desert. It also describes the functioning of this tourist attraction in the past and lists special elements influencing its tourist potential and attractiveness for tourists. Next, the article analysis the activities of non-governmental organizations, local communities and self-government authorities in the Błędów Desert, presents the positive effects of joint activities of all interest groups and demonstrates the most important achievements and successes in this field. The main research problem of this work is the assumption that the joint activity of non-governmental organizations, local self-government and local communities can be a significant stimulus in the development of entrepreneurship and innovation in their areas of activity. The article is written with the use of dense book materials, magazines as well as netographic information and telephone conversations with representatives of local organizations and entrepreneurs associated with the tourism industry. The research methods used while writing this publication is literary criticism. The test results positively verify the thesis.

Keywords: Desert area, non-governmental organizations, local government, local community, tourism.

1. Introduction

Contemporary tourism belongs to the most dynamically developing areas of the economy. Tourism creates jobs, brings income, and has a significant impact on its surroundings. The vast majority of existing countries in the world feel the benefits of participating in the global tourism movement.

The purpose of the publication is to characterize and evaluate entrepreneurial and innovative activities on a example of the Błędów Desert, analyzed as a rare and fairly unknown desert area in Europe.

The work presents the history, characteristics and values of the Błędów Desert. It also indicates the most important elements shaping its tourist potential and attractiveness for tourists.

The analysis covers the effects of the work of non-governmental organizations, local communities and local government authorities operating in the Błędów Desert; as well as presents the results of joint activities and the most important achievements and successes in this field.

The main thesis in the work is the assumption that the joint activity of non-governmental organizations, local self-government and local communities can be a key impulse in the development of entrepreneurship and innovation in their areas of activity.

The article is based on books, magazines and netographic information and telephone conversations with numerous stakeholders. The research method used in the article is literary criticism and telephone interview.

2. Characteristics and touristic potential of the Błędów Desert

The Błędów Desert, popularly known in the literature as the "Polish Sahara", is the largest area of post-glacial origin sands in Poland, situated in the border of the Silesian Upland and the Olkusz Upland. It is also the largest area of inland sands occurrencing in Europe. The desert is located within the boundaries of the Eagles' Nests Landscape Park and is included in a network of nature protection areas “Nature 2000” (Skała 2005).

The desert is named after the village of Błędów (Dąbrowa Górnicza district), which at the same time is its western border. The eastern boundary of the Błędów Desert is the Klucze municipality. The northern border of the desert is the village of Chechło, and in the south it borders with a large forest area and the national road No. 94. In terms of administration, the "Polish Sahara" is located in the province of Silesia and Lesser Poland (Figure 1).

Figure 1: Location of the Błędów Desert

Source: https://www.gridw.pl/.

The desert covers an area of about 33 km². Its length is approximately 10 km, and the width approaches 4 km. The average thickness of sands is 40 m (up to 70 m maximum). The desert is divided by an overgrown belt stretching along the Biała Przemsza riverbed into two parts: northern - smaller one, and southern - larger one (Figure 2). In contrast to the northern part, the southern part is characterized by a more varied and deflating type of sculpture. There are many convex forms here (Szczypek and others 2001).

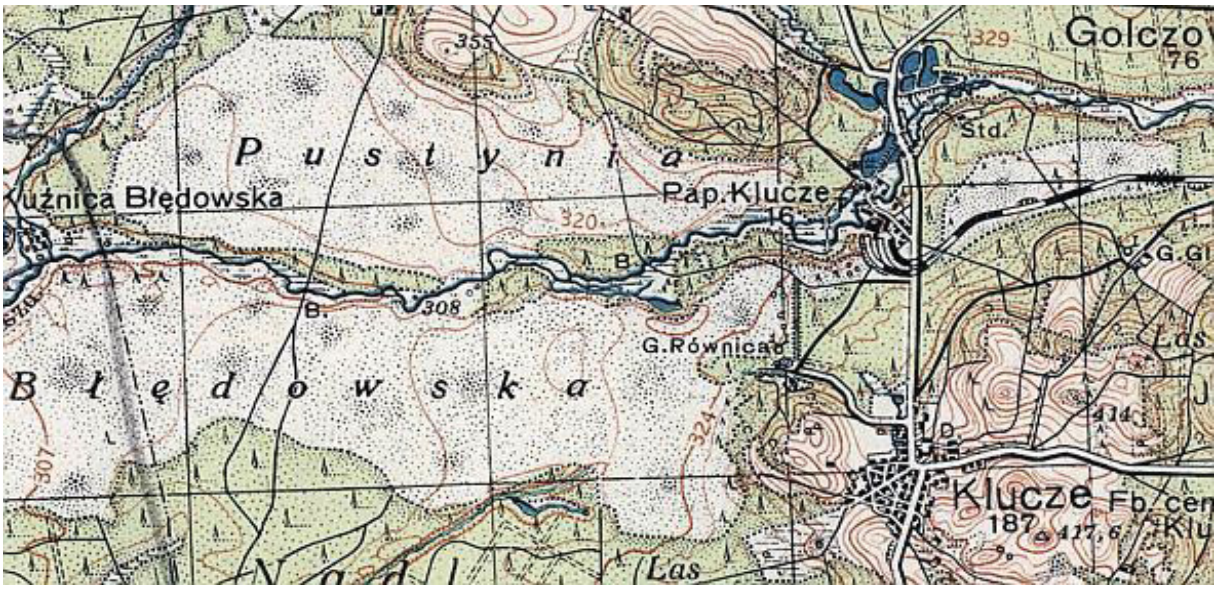

Figure 2: Map of the Błędów Desert

Source: http: //www.dabrowa.pl/DG_MAPOWNIK_PLAN_1929/19290000_m4_pl_dg_pustynia_cala_wig_4b-.jpg.

Unlike most desert areas in the world, the Błędów Desert does not have natural origin. Deserts such as the African Sahara or the Asian Gobi were created as a result of a persistently low rainfall, high temperatures and lack of water in the soil. In Poland, such natural conditions do not occur (Bryś, Gołuch 2009).

For the first time the term *Błędów Desert* was introduced to the literature in the mid-19th century and referred more to the specificity of the landscape than to the nature of the desert itself (Klimaszewski 1972).

The Błędów Desert was created as a result of human interference in the natural environment. About 10,000 years ago the area of today's desert was covered by dense pine forest. The intensive development of the mining industry and metallurgy in the area of Olkusz, dating back to 13th century, resulted in deforestation, the timber served as a material to strengthen the construction of shafts and drifts. As a result of intensive exploitation of wood resources, significant areas of the forest were cleared. Then, the thick deposits of sands located here were exposed by activating the aeolian processes (wind blowing caused by wind force) forming a desert area. The changes in the environment caused by the human interference lead to the creation of a specific microclimate in this area. Even in the 1920s, it was possible to observe the phenomena characteristic for natural deserts (mirage, sandstorms, dunes) (Leńkowa 1988).

Since the 1950s, the appearance of the desert has been transformed. As a result of the actions taken, a significant part of the desert was plowed and planted with the common pine, the red oak and the Caspian willow. In addition, pine and birch pine trees were planted in the western part of the desert. Such actions were aimed at stabilizing sand movements which posed a threat to the people living in the neighboring villages. These actions combined with the industrial dust and the observed rising water level caused a significant reduction in the surface of the discovered sand. (Alexandrowicz 1962).

The result of the above-mentioned activities was a significant change in the desert image for many years. Its current appearance with exposed sandbars has been preserved only in fragments near Klucze and Chechło. In addition, a sandstone main running through the "Polish Sahara" terrain completed the process of the destruction of a large part of the desert in order to supply sand for filling the nearby mines (Kazimierowski 2001). The derivative of the changes was also a clear loss of valorization of the desert tourist and a decrease in interest from tourists.

The desert area is characterized by outstanding natural values. In the Błędów Desert, especially its southern part, there are about 350 species of plants, many of them desert-like and typical for coastal dunes. Among the unique and protected species, the spiny broadleaf, the broadleaf and red-veined helleborine, the clam-do clematis, the sand dormer and the psammophyte (fescue, brush-gray) are worth mentioning (Kulpiński 2012).

Mainly birds and insects belong to the desert fauna. The birds worth mentioning are the bittern, the white-headed lapwort, the lonely wader, the lark frond, the pipit, the river plover, the turtle-dove, the golden wagtail, the nightingale, the nut-nut. There was also a stone-curlew and grouse here.

Among many species of insects which occur here, the following are particularly noteworthy: many species of beetles, the predatory ant and the Polish cochineal. The latter was mass-produced in order to obtain a red dye for fabrics in the fifteenth and sixteenth centuries. At that time, Poland was the main Europe’s supplier of this dye. Additionally, i. e. the common toad, the grass frog or the sand lizard can also be met in the area (Bogdanowicz et al, 2010).

In the past, this desert was used as a training ground for military purposes. During the World War I, the legionary infantry battalion trained there. During World War II, the desert served as a training field for German airmen and the soldiers of the famous Africa Korps. Currently, only the northern part of the desert serves as a military training field. In 1999, the desert was the place of NATO's maneuvers. Today, only a parachuting exercise takes place here, which may be a kind of attraction for observers. Only a few fragments of the bunkers, observation shelters and other military facilities have survived to the present day. As a curiosity, it can be added that the Błędów Desert was one of the locations for shooting the film “Pharaoh’’ based on Bolesław Prus’s novel.

The desert has been used for many years for tourist purposes. As a specific area in the country, as well as Europe, it is the destination for hiking and horse riding. Some tourists also travel through its expanses by bicycles or quads. Viewpoints and marked tourist trails also serve tourist development of the area.

In the Błędów Desert there are two interesting viewpoints – Klucze - Czubatka located 382 m above sea level; and Chechło- Dąbrówka, 355 m above sea level. Both points provide interesting views and are tourist destinations.

The Błędów village is connected with the Klucze village by the Yellow Desert Trail. The trail is about 25 km long. It runs through the entire desert area, mainly through the forests on the Jurassic hills where, from time to time, small outcrops of limestone rocks can be seen. The only horse raiding trail passing through the desert area is the Trans-Jurassic Horse Trail with a branch towards Chechło, through the ford on the Biała Przemsza river. The trail is about 250 km length in total and is marked orange. In addition, the following educational trails can help explore this area:

- Educational trail around the Błędów Desert (3 km) - red signs,
- Educational trail around the Klucze Land (1.5 km) - black signs,
- Educational trail of the Błędów Swamp (3 km) - brown signs.

The first of the trails leads through the hills characteristic for the Jura with rocky outliers and reclamated areas of the burnt sites after the great fire in 1992. Many species of protected flora and fauna can be seen there. The entire trail consists of eight thematic stops (Lamorski 2014).

An undoubted advantage of the Klucze Land trail is the large diversity in a relatively small area - from the most fertile, wet alluvial forests, through beech and mixed forests, to pine forests and the poorest and driest habitats in the Błędów Desert (Szczasny 2001).

The third trail makes it possible to discover marshlands near the Biała Przemsza river, numerous meanders, oxbow lakes and rare travertine rocks. The death place of Francesco Nullo from 1863 is also an attraction. The trail has two stops.

3. Błędów Desert as an area of entrepreneurship and innovation development

In the last few years, the economic situation of the Błędów Desert has begun to change significantly. The area, which was previously slightly forgotten, with relatively poor infrastructure and tourism development, has gained a new life and become a large tourist attraction even on a supra-regional scale. Until recently, the tourist traffic was small and mainly generated by the local residents, and now has clearly increased.

The key initiator and originator of the changes taking place is the Klucze municipality located in the desert. Thanks to the efforts of the municipality, the funds were raised for two important projects which effectively contribute to the development of entrepreneurship and innovation in the "Polish Sahara" area.

The first, important initiative was the *Active protection of a complex of priority habitats on sand in the Błędów Desert* project co-financed by the European Union. The objective of the project was related to the achievement of the proper level of protection of the largest complex of two sandy Polish habitats: the thermophilic grasslands and the inland dunes. In a broader sense, the project involved the restoration of the part of the Błędów Desert its typical desert features.

The solution to the problem was related to the removal of trees and shrubs on the area of about 300 ha of the Błędów Desert. Additionally, a buffer zone of approximately 100 ha was created for scientific and monitoring research, which will enable comprehensive analysis of vegetation dynamics and biodiversity changes (Figure 3).

Figure 3: Map of the "Błędów Desert" project

Source: http: //www.pustyniabledowska.eu/index.php? Option = com_content & view = article & id = 18 & Itemid = 19 & lang = en.

Implemented in the period 01.01.2011 – 31.11.2014, the project had a budget of about 2.5 million euro. Fifty per cent of the funds came from the European Commission’s Life Plus programme, the rest, or forty-five per cent, was contributed by the National Fund for Environmental Protection and Water Management in Warsaw, while the remaining amount was contributed by the Klucze municipality. It was the first such a complex project since the 1950s in this area. As part of the obtained funds, the following goals were achieved:

- cleaning and removal of unexploded ordnance and unexploded ordnance from the revitalized desert area,
- inventory of natural resources and scientific expertise,
- removal of trees and shrubs,
- implementation of environmental monitoring and measurement of the effectiveness of activities carried out,
- creation of new educational trails with infrastructure,
- creation of the Desert Information Centre,
- organization of a series of workshops and international conferences,
- development of a manual for the protection of sandy grassland habitats in Polish and English.

The results of the clearing of trees and shrubs can be assessed by comparing the situation in the desert in 2006 and in 2016 (Figure 4).

Figure 4: The appearance of the same fragment of the Błędów Desert in 2006 and in 2016

Source: http://malopolskie.fotopolska.eu/864995,foto.html.

One of the most important achievements of this project was the establishment of the Desert Information Centre in the village of Klucze. According to Kamil Wołek, an employee of this organization, the Desert Information Centre is the key coordinator of the development of local entrepreneurship and the promoter of the values of the Błędów Desert beyond this region.

The organization runs numerous thematic workshops, conferences and trainings. The promotion is also carried out through its own website and co-organizing numerous cultural events.

The activity of the Desert Information Centre bore important fruit in the creation of two new educational trails each 3 km long. The theme of the trails concerns eolitic processes and is addressed especially to geotourism enthusiasts. The trails marked red and green have 2 gazebos and 2 lookout points on the route. In the future, it is planned to enrich the paths with elements of the military equipment found here which would create the foundations for the development of military tourism. At the same time, an 18-meter high observation platform was built in the shape of an equilateral triangle on the Dąbrówka hill. This significantly improved the tourist valorization of this part of the Błędów Desert.

As part of the Life Plus programme, the consortium of Habitat Selection S.C. and Naturalists' Club from Świebodzin has made a physical inventory of the current state of preservation of valuable species of plants, fungi and animals found in the Błędów Desert. The results of the research showed the need to increase the area of desert habitats, in order to allow the expansive spread of specific species of flora and fauna.

The positive results of the project also include the issuing of several new professional publications which contribute to the popularization of the Błędów Desert. The publications relate to the protection of sandy grassland habitats, desert trails or natural issues related to the desert. In order to attract foreign tourists to the desert, some of the articles are available in the English version. However, bearing the youngest tourists in mind, the a special guide called “A maddening guide” (“O-błędny przewodnik") was created which, in addition to the sightseeing content, includes a description of desert games and activities. The guide intends to inspire teachers and parents to spend time with children in a desert environment.

Another plan implemented by the Klucze municipality is the project "Protection of the valuable natural area of the Błędów Desert and its promotion". The project is planned for 2014-2020 and received a budget of about half a million euro. As part of the undertaken activities, the removal of suckers of such species will take place: the Caspian willow, the poplar, the silver birch, the Scots pine, the sand reed and the sand blast. Other intended activities assume making the desert attractive for tourists.

The key and at the same time innovative achievements under the currently implemented project include the construction of the “Desert Village" in 2017 with gazebos, viewing beams, pedestrian bridges and sanitary infrastructure along with monitoring. The complex has also been equipped with information and educational boards. The “Desert Village" due to its avant-garde shape was called the “Desert Rose". The investment was built to the south of the village of Klucze and was intended to facilitate the tourist penetration of the eastern part of the Błędów Desert. According to the information of the Klucze municipality office, several thousand people visit this new tourist attraction every weekend (Figure 5).

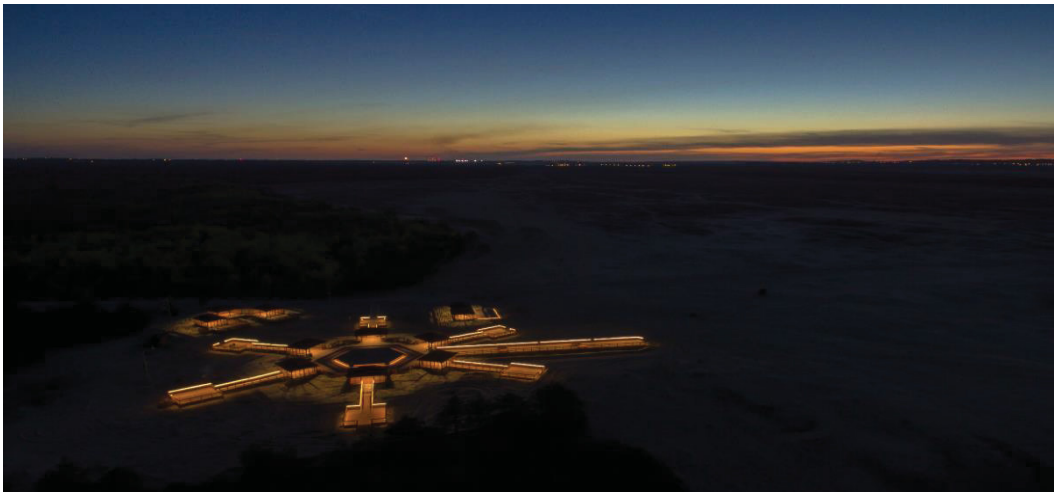

Figure 5: Desert Village ''.

Source: http://www.gmina-klucze.pl/art,2265,pustynna-wioska-dla-turystow.

In addition to the Klucze municipality and Desert Information Centre, an important contribution to the development of entrepreneurship in the Błędów Desert is played by Lokal Action Group (LAG) "Over the Biała Przemsza River" ("Nad Białą Przemszą") based in Klucze village. This non-governmental organization established in 2007 deals primarily with promotional activities. Jolanta Motyczyńska, a member of the board of the LAG "Nad Białą Przemszą", claims that by publishing folders, brochures and press publications, the organization contributes to the promotion of knowledge about the Błędów Desert and presents its qualities to potential tourists. The organization also plays a role of a coordinator in the field of obtaining EU funds under the "Rural Development Programme" for various economic projects concerning, among others, the development of the "Polish Sahara" tourist product. In the future, the efforts are planned to include for the construction of Nordic walking paths that would run through the desert area and the introduction of animals (e.g. goats) into the desert, which would prevent it from overgrowing. The idea of bringing camels to the desert is also considered an innovative and also interesting idea. It would give the opportunity to expand and enrich the existing tourist product.

The organization also activates the residents, the local government and tourists by organizing joint cultural events and festivals. During these events, among others, the local gastronomic products such as "bread with Jurassic lard", "spawn of a spring" or, "soup from Bydlin" are promoted. Thanks to the efforts of the LAG "Nad Białą Przemszą'', the desert has its own original gastronomic product, namely the "charm of the desert". The "charm of the desert" is a 51-per cent alcohol beverage produced for generations in the Błędów Desert, according to the unchanged recipe which entered the Minister of Agriculture's List of Traditional Products on December 21, 2012. The beverage is produced on the basis of rye growing around the Błędów Desert and water with sugar or local honey.

The growing interest in the "Polish Sahara" also translates into the development of accommodation and catering facilities in its neighborhood. The current state of the accommodation base in the Keynes municipality is presented in Table 1.

Table 1: Accommodation base in the Klucze municipality in 2018

Name	Type of object	Lokation	Established year
Manor House over the Backwaters	Hotel	Klucze	2014
Cottage at Funia	Holiday Home	Golczowice	2011
Jurna Cottage	Agritourism Farm	Godawica	2013
Forest Corner	Recreation Centre	Jaroszowiec	2013
Agrotourism Farm, Family Mrówka	Agritourism Farm	Golczowice	2008

Name	Type of object	Lokation	Established year
Valley of Frog Ponds at Tukaj	Holiday Home	Chechło	2007
Agrotourism at Felek	Agritourism Farm	Golczowice	2012

Source: Own study based on data: http://www.gmina-klucze.pl/p,92,noclegi

The analysis of the data contained in Table 1 indicates a significant increase in the number of accommodation facilities in the Klucze municipality in the period after 2011. The main role on the local tourist market is played by inexpensive agritourism farms.

4. In conclusion

The present-day Błędów Desert is certainly an area of developing entrepreneurship and innovation. Thanks to the cooperation of non-governmental organizations, local governments, as well as the residents themselves, the measurable progress has been made in increasing the attractiveness of tourism and the promotion of this undoubtedly unknown tourist attraction in Poland. For the first time in many decades, the Błędów Desert has gained new life. The thesis put forward in the publication has been proved. The cooperation of these entities can be a significant stimulus in the development of entrepreneurship and innovation in their areas of activity.

The progress of tourist development of the desert has also significantly influenced the situation in the field of the local entrepreneurship. The increase in the number of tourists or the expansion of the accommodation base prove the positive tendencies to which activities in the desert have led. More and more people are also employed in the tourism and tourist sector. It is to be hoped that the current plans will contribute to even more positive results.

On the basis of the arguments cited, we can answer the research question, that joint activity of non-governmental organizations, local self-government and local communities can be a significant stimulus in the development of entrepreneurship and innovation in their areas of activity.

Sustainable Food Systems: How Important are Bottom-Up Innovative Experiments?

Isabel Salavisa and Maria de Fátima Ferreiro
DINÂMIA'CET-IUL and ISCTE - Instituto Universitário de Lisboa, Portugal
isabel.salavisa@iscte-iul.pt
fatima.ferreiro@iscte-iul.pt

Abstract: The paper aims to analyse sustainable innovations in food production, commercialization and consumption, notably in the form of new production practices, new means of commercialization and new patterns of consumer behaviour. The main goal is to determine the importance of these recent experiments in the shift towards a more sustainable sociotechnical food system in Portugal, in a comparative perspective. In fact, there have been social, technological and organizational innovations in the food system in Portugal: novel forms of organic food production; new specialized retail chains; the transformation of food departments in large stores; and the creation of short food supply chains. These experiments – innovations deployed in "niches", or protected spaces -, may become more widely adopted depending on their degree of compatibility with the dominant regime or, conversely, their ability to substitute the dominant regime (Ingram et al, 2015). Tensions at the mainstream regime (Smith, 2016) or pressures exerted by the landscape (Geels, 2004) may boost the diffusion of these innovations, favouring a complex transition process. When developing initiatives to achieve a sustainable food system, the role played by institutions (local and national authorities and legal framework) is crucial, as is the involvement of a wide range of actors (e.g., farmers, food processing companies, retailers and consumers). New social practices are crucial to this shift, due to centrality of consumers in this shift (Spaargaren, 2011). Policies may support or hinder the emergence and deployment of experiments in the form of new products, processes, business models and practices. The theoretical framework draws on niche strategic management (Smith, 2006), sustainable transitions multilevel approach (Geels, 2004) and social practices approach (Spaargaren, 2011).
The paper aims to contribute to the literature by making a critical assessment of the impact of these experiments on the transition in the food system in Portugal, taking into account successful cases reported in the literature. It also aims to contribute to policy formulation regarding a sustainable food system.

Keywords: sustainability transitions, food system transition, social innovation, innovation in food production and retail, sustainable food policies.

1. Introduction

The need to move to a decarbonized economy within a relatively short period is one of the major issues facing society today. Making such a commitment implies dramatic shifts in the workings of the economy and the way we live. This means that large sociotechnical systems have to change in order to meet very demanding sustainability goals.

Large sociotechnical systems perform the major social functions, which include the production, distribution and application/use of energy, transportation, communication, housing and nutrition. Although energy and transportation are perhaps the focus of most attention, the food sociotechnical system has already originated a substantial body of research. In fact, as this system is the most directly linked with nature, it is acknowledged as being responsible for soil and water degradation and the decline of biodiversity through the continuing spread of cultivated land and livestock.

This paper aims to contribute to the study of the food system transition in Portugal. It analyses innovative cases taking place in food production and commercialization in Portugal. To conduct this study, we draw on the niche strategic management approach (Smith, 2006), the multilevel perspective (Geels, 2004) and the social practices approach (Spaargaren, 2011).

The paper is structured as follows. In section 2, we introduce the theoretical framework. In section 3, we address the specificity of the food system transition to sustainability. In section 4, we analyse the evolution of the Common Agricultural Policy and its contribution to transition. In section 5, we present some successful innovative cases in developed countries. In section 6, we analyse the Portuguese case. Finally, we discuss the results and draw some preliminary conclusions.

2. Theoretical background

Transitions, defined as regime shifts, are complex processes socially, economically and in policy terms and their study has given rise to a new research field: transition studies (Markard, Raven and Truffer, 2012).

In the transition process, large sociotechnical systems undergo major shifts. The socio-technical system (STS) is defined as a set of linkages between elements required to perform societal functions such as energy, transport, communications or nutrition. Its resources are knowledge, capital, labour, natural resources and the assignment of meaning. STS comprises production, dissemination and the use sub-functions (Geels, 2004).

Socio-technical systems are the result of human activity. The human actors, producers and users are integrated into social groups, who share roles, responsibilities, norms and perceptions. Many specialized social groups are linked to resources and sub-functions of the socio-technical system, acting within the limits and rules established by regulators, despite their relative autonomy and internal coordination. (Geels, 2004).

The actors reproduce and transform the system under the aegis of rules and institutions, and in an environment populated by technologies materialized in goods and infrastructures of various types. This context influences the perceptions of the actors. Therefore, the technological regime is now a broad concept because it encompasses the productive practices and technologies, the characteristics of the products, the skills, the ways of dealing with goods and people and of defining the problems, all this embedded in institutions and infrastructures (Rip and Kemp, 1998, *apud* Geels, 2004).

The actors' role is a major theoretical issue. Spaargaren (2011) has criticized the STS approach (systemic approach) on the grounds of its implicit 'determinism', due to the central role of technological innovation, infrastructures and products, and implying the neglect of the actors. He has also rejected the individualist approaches, whereby individuals are 'left alone' at the core of the decisional process (Figure 1). Conversely, he proposed an approach based on social practices, which are at the junction of structure and agency.

Individualist Paradigm **(social psychology/economics)**	**Systemic Paradigm** **(sociology/science studies)**
Individuals and their attitudes are key units of analysis and policy	Producers/states and their strategies are key units of analysis and policy
Behavioural change of individuals is decisive for environmental change	Technological innovation within the production sphere is decisive for change
Individual choices are the key intervention targets (micro level)	Socio-technical systems are the key intervention targets (macro-level)
End-users/consumers determine the fate of green products and ideas	Technologies and markets determine the fate of green products and ideas
Key policy instruments and approaches: social (soft) instruments (persuasion through information provision)	Key policy instruments and approaches: the use of direct regulation targeting providers (laws, market based instruments)

Figure 1: Individualist versus systemic approaches

Source: Spaargaren, 2011.

Smith (2006) and others (Kemp, Schot and Hoogma, 1998) see transitions arising from the interaction and co-evolution between innovations occurring in niches and the mainstream sociotechnical system. Geels (2004, 2010) and others (Smith, Voß and Grin, 2010) see transitions as multi-level dynamics, involving niches, dominant socio-technical regimes and the exogenous landscape. In both approaches different forces are involved - technological, economic (market), social, and institutional. In both, radical innovations play a major role and are mostly generated in niches (Kemp, Schot and Hoogma 1998; Hendry, Harbrone and Brown 2007; Schot and Geels, 2007; Lovell, 2007). Path dependency and lock-in in the installed regimes hinder this change. The sources of path dependency include cognitive frameworks, routines, habits, and attitudes; technical artefacts and dedicated infrastructures; incumbent practices enjoying economies of scale and network externalities; institutions and policies which evolved in parallel with the dominant regime (Smith, 2006).

In the paper, we adopt a sociotechnical systems approach but also resort to the concept of social practices, to study the food system transition.

The food system is a broad system defined by "the activities, infrastructure, and people involved in feeding the global population (eg. the growing, processing, distribution, consumption, and disposal of goods)" (Popkin, 2017, p 73). Its intrinsic features explain its specificity, namely:

- The intimate connection between food consumption and lifestyles.
- The nature of radical innovations fostering sustainability. These are mostly social, cultural and organizational innovations; however, technological innovations have been important in the modernization of agricultural practices. Examples include irrigation systems, mechanization and motorization, chemical fertilizers and pesticides, and the creation of genetically modified organisms.
- Disruptive technological innovation is occurring at the regime level, and is expected to continue to do so in the future.
- The multiplicity and diversity of producers.
- The integration of agriculture products within an entire and globalized food supply chain, which mediates the relationships between farmers and final consumers.
- In many subsectors, the great relevance of food processing companies, importers and retailers who have similar or even greater power than farmers.

Since consumers perform a major and transformational role in the the food system transition, they deserve attention and appropriate analytical tools. The diversity of experiments consumers carry out constitutes the basis for the proposal of a specific taxonomy, which is one of the contributions of this research. An analysis is also made of the link between policy and bottom-up forms of governance arising from social experiments and social innovation.

3. Food system transition

3.1 Food system evolution

Modern agriculture and agro-industries have been as much the outcome as the condition of the modernization model of food production since WW II (Grin, 2012); this has been driven by targets to increase productivity and improve efficiency that have resulted in the intensive use of pesticides, fertilizers, energy and water.

The modernization of agriculture practices coincided with the emergence of a mass consumption model characterized by the rationalization of commercial circuits (with the generalization of packaging, labelling, and branding), the increasing supply of conserved, deep-frozen and convenience food, and growing concern about hygiene and safety. New outlets were created – most notably supermarkets and mega-markets -, that offered a diversified and vast array of products, much of which was sourced from distant locations (Grin, 2012). In fact, the liberalization of the markets provided access to a much larger assortment of food.

This consumption model developed at a time of changing lifestyles (Grin, 2012), which involved:

- the mass entry of women in the labour market with the correlative simplification and rationalization of domestic tasks;
- the standardization and certification of food products;
- the emergence and spread of supermarkets and mega-markets;
- the deployment of innovative conservation techniques and devices;
- changes in dietary norms, with the increase in consumption of processed and ultra-processed food (Popkin, 2017) ;
- the diffusion of fridges and freezers in the households.

In advanced European countries, these transformations rapidly took hold following WWII – in large part due to the adoption of the American lifestyle -, and government policies contributed greatly to the speed of these changes. In food production, the Common Agricultural Policy, launched in 1962, both steered and reflected the major shifts in agriculture. It is therefore no surprise that consumers' growing concerns about food security and ethics are echoed in the revised versions of the CAP, namely for the current 2014-2020 period. The

question to be addressed here is whether the scope and speed of change are sufficient. Transition to sustainability is also necessary in this domain.

3.2 The emergence of alternative forms of food provision

Cristóvão and Tibério (2009) propose a categorization of alternative forms of food provision. It addresses different dimensions: i) consumption of locally produced food; ii) establishing direct relations between producers and consumers; iii) revitalization of distribution, transformation and production structures; iv) network building between producers, local governments, entrepreneurs and other leaders; v) promoting the local economy and rural development.

The above authors note that these movements emerged in Japan and the United States in the mid-20th century and extended to countries in Southern Europe, among others. They point out a need to clarify the multiplicity of concepts (e.g., 'foodshed', 'civic agriculture', 'alternative supply chains', 'localized agri-food system'- in Tibério and Baptista, 2013) related with the alternatives found in agri-food system. A systematization carried out within the 'Strategy for the valorization of local farm production' (Order nº 4680/2012, 3 April) had already clarified the concepts of 'local agri-food system' and 'agri-food short chains'.

A local agri-food system is a set of interconnected activities where production, transformation, distribution and consumption of food products aim to foster the sustainable use of territorial, environmental, economic, social and nutritional resources. The agri-short supply chain is defined as the commercial form that takes place through direct (producer-consumer) or indirect supply with no more than one intermediary. It is associated with both geographic and relational proximity between producers and consumers. (MAMAOT, 2013).

In terms of food system transition, a closer relationship between producers and consumers is important for several reasons:

- it allows consumers to take informed decisions;
- it may help producers to retain a larger share of the value created;
- it may therefore improve their income and the viability of their businesses;
- more traditional productive forms may remain cost effective and viable;
- land preservation is improved;
- the environmental impacts of transportation and distribution are reduced.

In some countries, "buying local" campaigns have been made; this includes promoting seasonal products as an alternative to buying goods imported from afar and the implicit negative impact of transportation.

Other studies point out the emergence of 'alternative food networks' (Roep and Wiskerke, 2012; Bui et al, 2016), which represent entirely new forms of provision, and begin with modest experiments in production, retail and consumption. These new practices take place in niches, or protected places.

While new practices in production and retail seem to be main driver, the consumers' role is very relevant here. Health concerns may become a lever of change, together with increasing awareness of and commitment to sustainability on condition that 'natural' food becomes more affordable and available. Bui et al (2016) describe the case of local and fresh food procurement for school canteens led by a parents' association in Drôme Valley, France. The purpose was to provide pupils with seasonal and quality food. Another case presented by the authors is the creation of a community-support agriculture box-scheme by a group of city-dwellers from a peri-urban area of Paris. Their aim was the preservation of a farmland area threatened by urbanization (Bui et al, 2016). In both cases, local authorities joined or supported the initiative at a later stage.

Different forms of government action are therefore crucial: examples of measures taken include the setting and implementation of safety norms in production, transportation and commercialization; the implementation of informative labels and the provision of information to enhance transparency; the granting of pecuniary incentives to support sustainable practices by farmers.

The complexity, multifaceted and slow nature of transition in the food system is explained by a number of factors; for example, the diversity of actors and the powerful interests at stake, and the historic persistence of nutritional habits.

To address the transition process, Roep and Wiskerke (2012) propose an approach based on three dimensions: governance, embedding and marketing. The coordination of activities deployed in the three areas is key to the success of emerging food supply alternatives. Each food network unfolds in a specific way. Using some main criteria (initiators, main objective, initial focus, and strategy adopted) the authors distinguish three main trajectories:

- Chain innovation – i.e. the construction of a new food supply chain, the main objective of which is to improve the farmers positioning;
- Chain differentiation – where new products are produced and commercialized within an existing chain;
- Territorial embedding – where a food supply chain is re-built to become a vehicle of regional development.

The authors present telling examples of each trajectory. In the Netherlands, a small pork supply chain, De Hoeve, is a case of chain innovation. It has innovated in housing systems with less environmental impact and managed to put together an association of pig farmers, a meat wholesaler and a number of independent butchers under the same hallmark. In Switzerland, they describe the case of a new beef label (Naturabeef) that managed to become commercialized by one of the two big Swiss retailers (Coop) as an example of chain differentiation. As to territorial embedding, they present a German example associated with a specific region, Rhon. Rhongut became a brand of high-quality organic food (originally meat and bread). This brand was launched by the founder of a chain of specialized organic food stores and a dedicated organic packaging and trading company, both operating under the name Alnatura (Roep and Wiskerke, 2012). These successful cases date back to the 1980s or 1990s; they proved economically viable while offering high-quality products and meeting demanding environmental norms and animal welfare concerns.

These cases do not represent yet a substitute for more intense industrialization of agriculture, resorting to intensive use of technological and scientific breakthroughs ('The Economist', 11 June 2016). However, they constitute emergent forms of production, distribution and consumption (Ingram et al, 2015), which should be encouraged, not only to preserve diversity but also to keep options open to the future of human nutrition.

4. Policies

The role of policies is of the utmost importance here. In the EU particularly, the CAP's updates have reflected a new vision of the linkages between increased efficiency + market mechanisms + farmers' income support + rural development + sustainability. This is the first dimension to be explored herein.

CAP should be considered in this reflection on transition. In fact, since its inception, CAP performs an important and decisive role in terms of farmers' decisions, land use, and, therefore, in food markets and consumption patterns.

The Mac Sharry reform of 1992 constituted a turning point in CAP's greening and sustainability path with the introduction of agri-environmental measures. The deepening of CAP's sustainability concerns through a multidimensional approach have led to further developments and milestones, including the financial strengthening of Rural Development Policy and its constitution as the second pillar of the CAP Agenda 2000. Nowadays, the financial support of the Common Agricultural and Rural Policy comes from a single European Fund - The European Fund of Agriculture and Rural Development – and contains several measures focused on sustainability.

It is necessary to investigate whether CAP's two pillars are environmentally and ecologically effective in terms of food production and consumption regarding nutrition and health. In fact, we are dealing with a sector-driven policy with established objectives in its two pillars, namely food supply and farmers' income support (pillar 1) and rural development (pillar 2), but without a clear and direct link with food security and safety in a broad sense, that is, the guarantee of food in quantitative and qualitative terms.

According to Walls et al (2016), "[A]n important determinant of diet is food price and availability, which is directly influenced by agricultural policy. (Walls et al, 2016, p 12). As recognized by the "WHO's Global Strategy on Diet, Physical Activity and Health (2004) [….], it seems essential for agricultural policy to be designed with nutritional priorities" (James et al, 2006, *apud* Walls et al, 2016, p 12).

In addition to food security, the European Commission also presented climate change and balanced territorial development as main challenges for the 2014-2020 CAP. It responds to these challenges with concrete measures and financial support from European funds. In the case of food security, the measures are related to the support and stabilization of the farmers' income and improving farms' competitiveness, including the improvement of the producers' positioning in the food value chain. Climate change is addressed through sustainable production practices, and 'green growth' through innovation and the development of mitigation actions. The promotion of a more balanced territorial development involves the structural diversity of agricultural systems and improved living conditions in the case of small farms as well as the development of local markets.

The development of local markets has been integrated in the European Regulation Nº 1305/2013 (17 December) on rural development support from the Agricultural European Fund on Rural Development. This regulation presents some policy measures that introduce a more integrated approach (supply-side; demand-side), namely through the "promotion of food value chains related with the transformation and commercialization of farm products […]" (Official Journal of the European Communities L347, p 500).
More specifically, it is possible to find measures associated with 'short circuits and local markets' and the 'promotion of local-quality products'. Therefore, CAP not only supports sustainable agriculture through agri-environmental measures, but it also addresses the food value chain through financial aid directed to short circuits.

In the Portuguese case, 'innovation and knowledge' are important drivers of change in Rural Development Policy (2014-2010) and correspond to central axes of financial support for farmers and other actors involved in the landscape of rural territories, namely research centres and rural development associations.

To sum up, CAP must be considered in the debate regarding the food system transition in EU countries. This policy has become greener and more market-orientated in its first pillar, while enhancing the role and budget of rural development (second pillar), namely through measures focused on value chain and the promotion of local products and local markets. It envisages diversifying the rural economy and thus affecting food security in the broad sense (including nutrition and food quality).

5. The Portuguese case

While experiments are less frequent in Portugal than in other developed countries, traditional forms of food production and distribution managed to survive the modernization surge of the second half of the 20th century. A prime example is the fact that the first mega-markets only appeared in the 1980s. Despite the massive destruction they caused in many traditional retail branches, small food outlets still operate in villages, small towns and city neighbourhoods by drawing on proximity relationships. Short supply chains are therefore both old and new, and sometimes old and new at the same time. This is the case of the revitalization of traditional farm production by using the internet for commercialization.

The Portuguese Rural Network proposes the following typology of short supply chains:

1. Markets of producers: "market dedicated to food and agri-food producers which sell their own production; products with local certification".
2. Markets of Bio producers: "market exclusively dedicated to agri and agri-food producers with certification in Bio Production; producers sell their own production; products with local certification".
3. Markets of local products: local or regional markets with direct sale of a local product or various related products.
4. Collective supply point: organization of farmers and agro-industry supplying their own products.
5. Agri-Food baskets: direct and regular supply of local and seasonal agri-food products. The baskets are delivered to a predefined place (e.g., consumer home, enterprise, cooperatives and shops).

Examples of these experiments are found in Portugal. Bio producer markets have opened up in Lisbon municipalities: Príncipe Real and Campo Pequeno in the centre of Lisbon; and AGROBIO markets in cities such as Algés, Almada, Amadora, Carcavelos, Cascais, Loures and Oeiras.

There is a long history of local or regional markets that sell local products directly. Some current examples involve wine production: Festa das Vindimas (Vintage Fair), in Palmela, and Festa do Vinho e das Vindimas

(Vintage and Wine Fair), in Loures. In other regions of the country, similar events take place annually and focus on their own regional products.

There are a number of successful cases of agri-food baskets. While the most outstanding is PROVE, the following should also be mentioned: Poiso da Abelha, Cabaz Horta Verde, Cabaz QPB, Marinhoa (meat), Quinta do Arneiro, Cabaz da Semana BioSOLO, Cabaz Dona Horta, Cabaz Papafigos, Cabaz da Horta.

PROVE – Promover e Vender – aims to supply local products, improving proximity relations between producers and consumers, and establishing short chains of commercialization among small farmers and consumers using ICT. The experiment started in 2006 in the municipalities of Palmela and Sesimbra. It has spread very successfully across the country through Local Action Groups (GAL), producers, consumers, but also municipalities, farmers' associations and other local partners. The baskets contain only seasonal products produced locally with sustainable techniques and respecting good farming practice.

In addition to short circuits, specialized organic and quality food retailers developed mostly in the metropolitan areas of Lisbon and Oporto. This is the case of Brio supermarkets (later Go Natural). More recently, some big retail chains entered this market, by creating departments of organic food or even buying the bio retail shops themselves.

However, the new practices are still limited in scope. As mentioned above, unlike other countries, these practices have been unable to create their own national chains or to integrate significantly in big distribution channels.

6. Conclusions

This paper is a first attempt to address the transition of the food system in the Portuguese case. We present three dimensions of the research: 1) a draft of the conceptual framework, drawing mainly on the sustainability transitions literature, with the contributions of social practice theorists; 2) a preliminary assessment of the European agricultural policy with regard to the transition to sustainability; 3) the identification of existing bottom-up experiments in food production, retail and consumption in Portugal.

At this stage, only provisional conclusions are drawn, namely:

1. The experiments in short chains emerged at the same time as the start of organic food retail shops, which are now expanding, and the rise of a new generation of farmers devoted to high quality organic products.
2. Provided they are able to scale up and become more cost effective, bottom-up experiments may become the basis of alternative food networks.
3. This option is not yet a substitute for the continuing industrialization of agriculture, resorting to technological and scientific breakthroughs.

Nevertheless, the new experiments constitute either a complementary or an emergent form of production, distribution and consumption that should be encouraged.

In order to improve our knowledge on the Portuguese case, we will conduct more in-depth case studies. Our aim is to contribute to the debate on the food system transition and to policy formulation.

Absorptive Capacity as a Factor of Firms' Innovative Behaviour

Svetlana Samovoleva and Yulia Balycheva
Central Economics and Mathematics Institute of Russian Academy of Sciences, Moscow, Russia
svetdao@yandex.ru
yulia.balycheva@gmail.com

Abstract: The paper aims to analyse firms' innovative behaviour and identify its connection with their absorptive capacity. Firstly, we study the innovation behaviour of Russian enterprises at a regional level. Toward this nd, the decomposition of innovation process into sub-processes is used. Four types of innovation product were specified depending on its level of market and technological novelty. Each of the types of innovation product is the result of some innovation processes implementation. Secondly, we distinguish different types of absorptive capacity for the transfer of technological knowledge from abroad. In the study, the absorptive capacity for technology transfer is defined as the ability to acquire advanced technologies. To that end, we analyse the import of embodied and disembodied technologies. Moreover, the disembodied form can be divided into two types. The first one is the adoption of R&D results and the second one is the acquisition of patents, licenses, and know-how. At the same time, we take into account that companies can not only buy R&D results but also can absorb them in partnership and cooperation. The ability to absorb technological knowledge from abroad is essential for firms' innovative strategies in developing countries. The four regions of the Russian Federation with developed manufacture were chosen to demonstrate the results obtained. The results of the study show that, if the development level of regional industry is relatively high, but lags behind the international technological level, the scaled process of innovation creation is based on the firms' capacity to adopt foreign technologies. Particularly, when firms both intensively invest in R&D and adopt disembodied technologies, they get able to change the structure of innovation process and thus become more creative. It is also established that intensive investment in in-house R&D is an essential factor for efficient application of technological knowledge transferred from abroad.

Keywords: innovation process, innovation behaviour, absorptive capacity, type of knowledge, regional companies.

1. Introduction

It is not infrequent that the neoclassical paradigm has a strong impact on the study of innovation (Hollingsworth, 2000; Nelson, 2008; Lundvall, 2010). Although the NIS concept is "a refutation of the neoclassical economics approach to the study of innovation" (Sharif, 2006, p.763), it uses specific arguments of the neoclassical theory (particularly regarding market failures). Moreover, empirical studies can be based on suppositions that contradict the nature of innovation. For instance, researchers use the concept of absorptive capacity (Cohen and Levinthal, 1990) frequently under the assumption about the homogeneity of knowledge (for example, Fabrizio, 2009; Tsai, 2001; Costa and Monteiro, 2016). This hypothesis does not allow to grasp not only the sources of firms' competitive advantage (Barney, 1991) but also the various forms of innovative behaviour. The existence of particular types of absorbed knowledge (e.g. George et al., 2001; Schmidt, 2010; Li, 2011) mainly explains the occurrence of these differences. For example, Li constructs a model which considers the impact of three types of investment in acquiring technological knowledge (in-house R&D, foreign technology import, and domestic technology purchase) on firms' innovative capacity in 21 high-tech sectors (Li, 2011). The paper aims to analyse firms' innovative behaviour and identify its connection with their types of absorptive capacity.

2. Definitions and methodology

Absorptive capacity is "the ability of a firm to recognize the value of new, external knowledge, assimilate it, and apply it to commercial ends" (Cohen and Levinthal, 1990, p.128). Cohen and Levinthal demonstrated that absorptive capacity has a great impact on innovation activities. These activities are "all scientific, technological, organisational, financial and commercial steps which actually, or are intended to, lead to the implementation of innovations" (OECD, 2005). Innovation activity is usually considered as the consistent combination of different but connected innovation events to one another (Landau and Rosenberg, 1986; Guan and Chen, 2011). Within this framework, innovation activity is divided into a number of complementary and independent stages (Bernstein and Singh, 2006). These stages are the sequence of actions from the search for knowledge resources to the creation and launch of new products to the market (Roper et al., 2008). In the first studies on innovation process modeling (Utterback, 1971), innovation activity is represented as a set of primary steps, including the idea generating, the solution to engineering problems, the innovation introduction to the market and its diffusion. In further researches, the innovation process is considered as the linear (Clark and Fujimoto,

1991; Wheelwright and Clark, 1992; Cooper et al., 1997, 2002) or nonlinear sequence of structural phases (Cantisani, 2006; Kostas, 2006) which can overlap in time (Pavitt, 2006).

It is important to emphasize that there is no generally accepted classification of innovation stages. The allocation of innovation activity stages is typically not general and depends on the purpose of the particular study. The most widespread scheme (Hansen and Birkinshaw, 2007) is the dividing into the following three integrated stages: research and development, idea implementation and product launch, which is accompanied by its large-scale production.

Firms' innovative behaviour is broadly determined by absorptive capacity (George et al., 2001; Van Den Bosch et al., 2003; Nieto and Quevedo, 2005; Van Beers et al., 2008; Liao et al., 2010). The ability to absorb technological knowledge from abroad is essential for firms' innovative strategies in developing countries (Li, 2011). This is due to the fact that the majority of industries in these countries does not reach the level of technology of countries on the stage based on their own innovations (Golichenko and Samovoleva, 2015).

Foreign knowledge is often the base for the development of inner science and technology potential for the national companies.

To answer the research questions, we analysed Russian firms' innovation process inside-out and identified the connection with their absorptive capacity at a regional level. Four regions of the Russian Federation related to the group with developed manufacture (Aivazian et al., 2016) were chosen for this purpose. The data used in the study were provided by Russian innovation surveys dated 2009 – 2013. The firm data was collected from a random sample based on the Federal State Statistics Service database including industrial sectors numbered 15-37 and selected service sectors numbered. The design of the survey is based on the Oslo Manual (OECD, 2005) and is universally accepted as compatible with the Community Innovation Survey. The database includes more than 35000 firms. The questionnaire was sent to the managers of these firms aiming to identify their innovation activities.

In the study, we use the innovation process decomposition into sub-processes for the analysis of regional innovation processes (Balycheva and Golichenko, 2015). For that purpose, four types of innovation product were specified depending on its level of market and technological novelty:

1. new-to-market and newly introduced or significantly improved innovation product;
2. new-to-market and only modified innovation product;
3. new-to-firm and newly introduced or significantly improved innovation product;
4. new-to-firm and only modified innovation product.

Each of the types of innovation product is the result of some innovation processes implementation. The first type product can result from the new product creation process or from the innovation imitation process. In this case, the product copy is new to the local market but already known outside. Besides, this product can be manufactured by these processes combination. When the significant factor of innovation activity is R&D, the innovation process is likely directed to new product creation and introduction. If the large-scale acquisition of technologies takes place, there is every likelihood that innovation imitation process was implemented. If companies have the higher level of absorptive capacity to adopt technologies in disembodied forms, that absorptive capacity can be used as the basis for the creation process of new-to-market products.

The production of the second type is not considered in the study because the cases of the implementation of products that are new to the market and only modified are not separated in the statistics used. It is supposed that new-to-firm and newly introduced products (the third type) are the results of the imitation process of products that are already known in the local markets, or essential modifying of earlier innovation. It should be noted that the imitation processes can be accompanied by the processes of products modifying and production processes changing. The import of technologies in embodied forms can be applied for these processes implementation. The implementation of new-to-firm and earlier introduced products (the fourth type) means products modifying which does not affect the characteristics of market and technological novelty.

As characteristics of innovative products, the volume of shipped innovative products of manufacturing enterprises in Russian regions was used. Additionally, the degree of market and technological novelty was taken into account.

With the aim of analysing the connection between firms' innovative behaviour and capacity for foreign knowledge transfer and integration, it is useful to distinguish three types of absorptive capacity. The first and the second ones relate to the acquisition of knowledge in disembodied form. The first type specifies firms' ability to acquire and use R&D results. In the study, they are called "disembodied technologies of the first type". At the same time, we assume that companies can not only buy R&D results but also can absorb them in partnership and cooperation. The second type of absorptive capacity relates to the transfer of patents, licenses, and know-how ("disembodied technologies of the second type"). The third type describes the transfer of embodied technologies. It is worth noting that such absorptive capacity is similar to realized absorptive capacity (Zahra and George, 2002). We assume that if firms acquire foreign technologies, the majority of them are able to apply this knowledge. There are certain cases when companies purchase intellectual property to overcome entrance barriers though.

As characteristics of absorptive capacity, the number of imported technological knowledge of each type is used. Additionally, the number of joint R&D projects with foreign partners is taken into account. However, there is no information about the results of these projects in statistics, the indicators reflect the ability of firms to transfer and absorb external knowledge. We do not consider in detail the share of firms importing technology among all innovative firms. It is related to the fact that both innovation process and technology acquisition implemented mainly by large regional enterprises.

3. Innovation process and types of absorptive capacity of Russian regional firms

3.1 The Nizhny Novgorod region

The majority of innovative regional products is made by firms of the following branches: manufacture of coke and refined petroleum products; metallurgy; automobile manufacture. In such a case, the firms engaged in the manufacturing of coke and refined petroleum products make the most significant contribution to the sectoral structure of the regional industry. The secure growth of the share of innovative products in the total output is observed during the studied period. In 2010 there was the brisk change of the characteristics of products quality. The essential part of firms turned from the manufacturing of innovative products known in the local market to the release of products which are new and not-known in the trading area (see Figure 1). It is likely possible due to the change in the cost structure of innovation. For example, the share of costs of new products R&D in the total costs increased more than 4.5 times in 2010 in comparison with 2009 and made 23%.

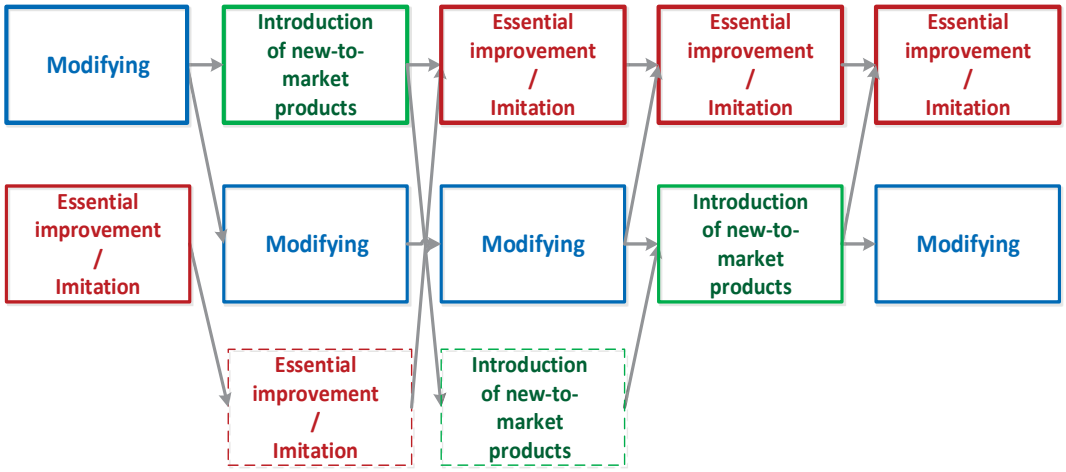

Figure 1: The structure of innovation process of Nizhni Novgorod regional companies (2009-2013).

These regional firms are also actively involved in the cooperation in the process of R&D. In 2010 they acquired first type disembodied technologies connected with foreign companies R&D results. It allows to do the groundwork for the further quantum growth of innovation activity and successful scaling of the results (see Figure 2).

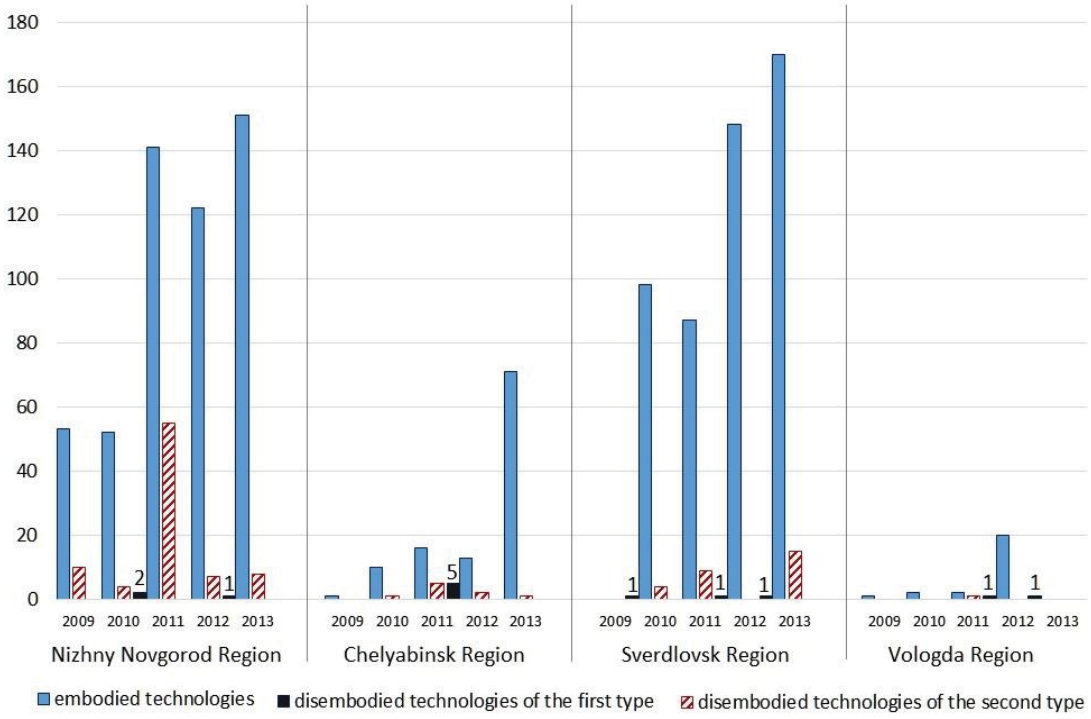

Figure 2: The number of technologies imported by product and process innovative enterprises.

In 2011 firms both acquired embodied technologies and continued to develop early introduced innovations to reach the necessary scale of production. For this purpose, they used in-house developments and foreign technologies of the second type. The companies intensively acquired patents, licenses and know-how, and in the end, there was the high scale of production achieved.

This goes to prove that the creation of new competitive advantages in the local market through new product launch is primarily based on the adoption and adaptation of imported technologies. Companies have to increase their absorptive capacity investing in in-house research to have the possibility of this technology adoption. It is proved by the essential growth of research and development of new products, services, and production methods within the period researched. Consequently, firms do proceed from innovation activity based on the insignificant modifying of former products to the innovation creation and imitation of products not-known in the local market but already known outside.

The acquisition of disembodied technologies and participation in cooperation have decreased from 2012 to 2013. It is possible to connect to the gain of competitive advantages of the companies capable of absorbing non-domestic technologies. They accomplished the innovation cycle for some period. The earlier laid groundwork (2010-2011) appeared insufficient for the maintenance of remarkable product novelty for a more extended period. In 2013 the drop in the sales of new-to-market products was observed. Besides, there is the tendency of sales decreasing of newly introduced innovative products. However, this tendency is not stable due to the products copying by the follower enterprises.

3.2 The Chelyabinsk Region

The vast majority of innovative products belonged to the metallurgical companies. They produced 85% of regional innovation output and 58% of all products. The innovative products with the essential market and technological characteristics prevailed in innovative metallurgical enterprises. More than 45% of total innovative products were new-to-market, and more than 94% of these products were newly introduced or significantly modified (see Figure 3) in 2012. These firms were vastly superior to the average characteristics of the metallurgical sector of the country. The other branches contribution to the sectoral structure of industry did not exceed 5%. Mainly, it is the enterprises engaged in the manufacturing of non-metallic mineral products.

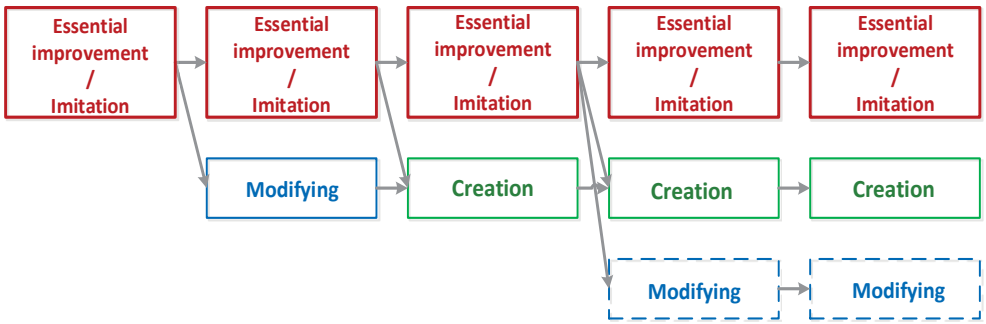

Figure 3: The structure of innovation process of Chelyabinsk regional companies (2009-2013).

Although the regional innovation activity is not high, it is possible to see its significant growth and changes in the structure. The share of innovative products in total output increased from 2% to 8% during the studied period. The growth of diffusion is caused by the essential change of innovation products quality. The sales share of new-to-market products increased from 1.6% in 2009 to 39% in 2012. This result was reached due to the increase in costs of research and development of new products as well as the acquisition of foreign technologies. For example, the repeated growth of investment in research projects, directed to new product creation and launch, was seen in 2010. As a consequence, sales of new-to-market products increased more than twice in 2011 in comparison with 2010. From all appearances, firms' inner potential was not enough for a further advance that is why they began to acquire foreign technologies (see Figure 4). Specifically, in 2011 the highest activity of the acquisition of all types of technologies was observed. These technologies applications lead to the increase in the sales of new-to-market products from 14% in 2011 to 39% in 2012. The companies, having achieved the high degree of products novelty, directed efforts toward the diffusion. With this objective in view, they raised the buying of embodied technologies.

Despite the relatively low sales of innovative products at the beginning of the studied period, the companies apparently possessed sufficient absorptive capacity to be able to significantly improve the fundamental characteristics of the activity in a short period. This hypothesis is also confirmed by the fact that firms did not incline to insignificant modifying allowing only to maintain the status of innovation products during the whole studied period. The base of their activity was the essential modifying of products and manufacturing processes and the introduction of products new to the market (see Figure 2).

3.3 The Sverdlovsk Region

The enterprises of the following industries make the most prominent contribution to innovative regional production: metallurgy, explosives manufacture, chemical production, manufacture of ships, aircraft, spacecraft and other transport equipment. Low sales of new-to-market products characterize all these branches. In other words, regional firms tend to produce new-to-firm products which are already known in the local market. Meanwhile, the dominant part of an innovative product is newly introduced or significantly improved. The firms engaged in modifying of early introduced products (see Figure 5) through technology acquisition and in-house R&D. Besides, they intensively use process innovation to decrease the production cost. The only exception is the metallurgical sector, where more than a half innovation production volume was insignificantly modified. In this case, the basis of innovation activity is the technology acquisition in embodied form (see Figure 2).

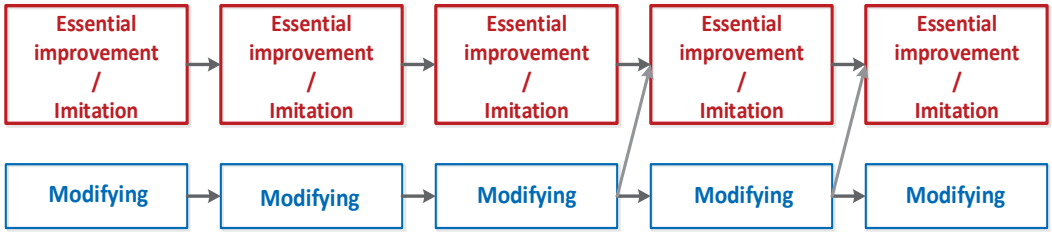

Figure 4: The structure of innovation process of Sverdlovsk regional companies (2009-2013).

Unlike Nizhny Novgorod companies, the absorptive capacity of the regional civil firms is not apparently enough for complex foreign technologies adoption allowing to introduce fundamentally new market decisions and participate in R&D cooperation projects. Firms do not tend to practice research projects results and actively

use disembodied technologies of the second type to improve previous innovations. After the period of active technology acquisition in 2010-2011, the growth in sales of newly introduced products was to observe. With the purpose of the process providing necessary equipment in 2012, firms bought it abroad. Consequently, by 2013 companies relied on insignificant modifying of earlier introduced products in much smaller degree and turned to release the products with high technology. Besides, technology acceptance and adoption stimulated firms to increase their R&D investment. These series of steps allowed to expand the sales of new-to-firm products with technological novelty. The share of such products increased from 53% in 2010 to 80% in 2013.

The basis of innovation activity was formed by essential products modifying as well as the imitation of products already known in the local markets (see Figure 4). In spite of the growth of quality of innovative regional production, firms did not manage to change widespread innovative processes and significantly increase innovation diffusion.

3.4 The Vologda Region

The innovation activity of the region is densely concentrated in the metallurgical sector, which also makes the highest contribution to the sectoral structure of industry (71% and 59% correspondently). The second place in product sales is taken by chemical industrial firms (10%), next are the enterprises engaged in electrical power distribution and transmission (7%), and food production companies (7%) follow further. For the metal manufacturer, the diffusion scale and characteristics of innovation products novelty are on low levels. The share of innovative products does not exceed 6% of which 94% of products are already known to the market.

In other words, companies maintain the innovation status of the products through insignificant modification which changes neither market nor technological products novelty. It is to note that firms do not aim to purchase technology in embodied or disembodied forms. Moreover, their activity in R&D cooperation with foreign partners is of negligible importance. It also stands to mention that not all Russian metals companies show low novelty of innovative products. It is possible to consider the companies of the Volgograd, Kirov and Chelyabinsk regions as examples.

The quality of innovation process of the Vologda region is rather low. A basis of regional innovation activity is the developments of external companies. Additionally, the used technologies are neither groundbreaking nor even new to the local market. The processes of earlier implemented innovations modifying and imitation of products already known in the market prevailed during the period 2009 – 2011. Low quality of the products did not allow companies to reach large-scale diffusion of innovation. Within that period there was the growth observed in expenditures on Russian technologies acquisition. It enabled companies to enhance the level of market innovation distribution throughout the 2012-2013 period. The diffusion scale remained low in comparison with the average Russian level, though. Insufficient level of firms' financial and absorptive capacity allowed them to participate neither in the processes of innovation creation nor in imitation of foreign technologies adoption (see Figure 5). Due to this reason, it was impossible to significantly increase the scale of innovation distribution and to generally improve the quality of innovation process.

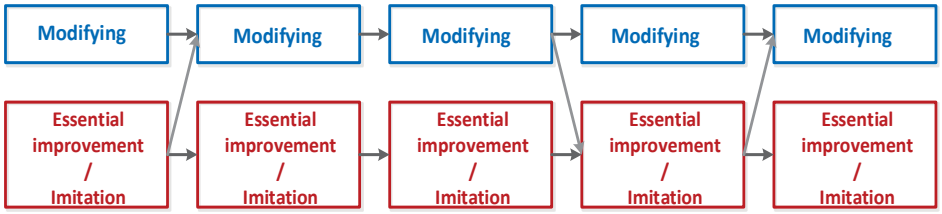

Figure 5: The structure of innovation process of Vologda regional companies (2009-2013).

4. Conclusions

The analysis of sample regions reveals that firms' innovative behaviour and, accordingly, the structure of innovation process relay to their absorptive capacity. Thus, it is possible to enable the widespread creation of products with high novelty when firms both actively invest in R&D and participate in international technology transfer, most primarily, in disembodied forms. Cooperation in research projects and acquisition of intellectual property rights provide a significant contribution to the innovation process structure.

When firms have the absorptive capacity allowing them to adopt foreign technologies in disembodied forms, it serves as an incentive for the beginning of a new innovative cycle to obtain the competitive advantages using new products creation. This situation prevails in the Nizhny Novgorod and Chelyabinsk regions.

When absorptive capacity is not enough to actively transfer the R&D results and participate in joint research projects, the acquisition of disembodied technologies of the second type forms a basis for improvement of previous innovations. The ability to adapt and adopt embodied technologies can be used for innovation diffusion. The example of the Sverdlovsk region also confirms it. When firms do not possess sufficient level of absorptive capacity to transfer foreign n technologies and not invest in in-house R&D, they introduce new-to-firm products and cannot increase the scale of production (the Vologda region).

The available statistical data shows that the innovative business of developed countries has a higher realised absorptive capacity of embodied knowledge compared with Russian firms. In Russia, for example, the share of innovative enterprises engaged in the acquisition of machinery, equipment and software is about four times smaller than in Finland or France. However, the percentage of innovative enterprises engaged in external R&D activities is 1.2 times larger in Russia than in France. In Finland, the value of this indicator is more than 1.4 greater than in Russia (CIS, 2014; RIS, 2014).

On the one hand, «importing foreign technology alone does not facilitate innovation» (Li, 2011, p.1240) since the most advanced technologies are not adopted. On the other hand, adoption and usage of disembodied technologies allow to improve firms' knowledge base and also create the opportunities to introduce innovations based on their ideas and experiments. As a whole, the insufficient level of absorptive capacity of regional companies is one of the reasons that interregional economic disparities are very stable in Russia (Bakhtizin et al., 2016). The lack of absorptive capacity represents a crucial obstacle to the gain of competitive advantages.

The research has been supported by Russian Science Foundation (Project No 16-18-10296).

Abstract: In an increasingly globalized world, companies face the challenge of expanding into foreign markets. In the internationalization process there are cultural, governmental, geographic and economic issues that can affect the success of the company in its implementation process overseas. Marketing strategies and the standardization or adaptation levels of each element of the marketing mix can be seen as critical success factors that directly affect business success in the new market. Companies must decide between adapting their marketing strategy to local markets or rather standardizing them globally. Some companies use as a competitive advantage the adaptation of their strategy (partially or totally) through knowledge of the culture of the country to which they are internationalized. Adaptation has been the key to success for a number of brands, and L'Oréal is one of them. This study intends to focus on the internationalization strategy and knowledge of the culture of the countries to which they are internationalized, applied to cultural differences. It also aims to highlight the importance of product innovation in consumer markets at present, and to analyse beauty satisfaction and tendencies amongst millennials.

Keywords: Culture, internationalization, marketing, innovation, customer needs, adaptation

1. Introduction

In an increasingly globalized world, companies face the challenge of expanding into foreign markets. Markets are continuously enlarging and opening up, competition is ever-increasing, and digital evolution and technological innovation (Oliveira and Ferreira, 2011) have picked up the pace. Therefore, companies must progressively be able to respond to all challenges thrown their way. Internationalization is one of the business responses to the challenge of globalization. In recent decades, the world economy has been characterized by high growth in international trade. Increasingly, national markets give way to a global market, new formal integration spaces are created to facilitate trade, and new actors and new business models emerge. Hence, internationalization has been the slogan for business strategies.

Companies wishing to approach international markets have to make three types of decisions, involving: choosing the countries where they will sell their products and adopting a mode of implementation for each country; defining marketing strategies for the countries in which they are based, striving to reconcile two contradictory imperatives - that of adapting to local markets and adopting a coherent approach globally; and finally, equipping themselves with structures and methods of organization to ensure effective coordination of their international activities (Lindon et al., 2008).

The dilemma of standardization or adaptation of the elements of the marketing compound is one of the main challenges companies face in the internationalization process. Companies must decide between adapting their marketing strategy to local markets or standardizing it globally. Some companies use as competitive advantage the adaptation of their strategy (partial or total) through knowledge of the culture of the country to which they are internationalized. This adaptation has been the key to success for some multinational brands that seek to study, know and adapt to the culture of the country where they are internationalized, as is the case of L'Oréal.

Therefore, the present study intends to analyse the strategy of internationalization of L'Oréal and answer the research question "Are the Portuguese millennials satisfied with the current offers on the beauty market and with the L'Oréal Paris brand?", since no research has yet been made on this subject and beauty has gained increasing importance among young people. Therefore, an analysis of secondary data related to the brand (public brand reports, published articles and dissertations), three brainstorming sessions involving millennials

of different ethnicities (African, Latin, Caucasian and Eastern) and a questionnaire for Portuguese millennials were carried out to verify their satisfaction level with the current offers on the market (for hair and skin) and the offer of the L'Oréal Paris brand.

2. Key Concepts

2.1 Strategy

In order to respond to the challenges of the global market, many companies opt to internationalize (Sousa and Au-Yong-Oliveira, 2015) their business. Internationalization, as a strategic result, represents a solution to the problems arising from global economic crises and, when successful, constitutes a competitive advantage for companies. However, this process should not be taken lightly, because like any strategy, it involves certain risks.

In a highly competitive and globalized market, where companies carry out a daily fight for a prominent place and constantly strive to ensure their continuity, corporate strategy has acquired special importance.

Technological advances (Gonçalves and Oliveira, 2010), global economic crises and environmental problems are some examples of the transformations that the world today is experiencing and that can lead to business turbulence. Thus, it is necessary for business managers to be able to follow these changes in order to not be surprised by the competition and to ensure the survival of their companies.

It is in this field that strategy stands out as being a key factor in business success. Strategy, according to Hitt, Ireland and Hoskisson (2011), is an integrated and coordinated set of commitments and actions designed to exploit core competencies and gain a competitive advantage. This competitive advantage is achieved when the company implements a strategy that its competitors are unable to duplicate or that is too costly to replicate (Hitt et al., 2011). For Wild et al. (2005) a *"well-defined strategy helps the company compete effectively in increasingly competitive international markets."*

In sum, strategy involves creating a unique and valuable position in the market and, on the other hand, it is linked to the concept of "differentiation", since it is up to the company to decide which set of activities the company will accomplish to achieve its goals and which are distinct from those of its competitors.

All decisions and actions taken in the definition stage of a business strategy are part of the so-called strategic management process, which will allow the company to achieve strategic competitiveness and obtain above-average returns (Hitt et al., 2011). The process of strategy formulation seeks to involve all the departments of a company so that its policies and actions are coherent and directed towards the same set of objectives (Porter, 1980).

2.2 Positioning

Philip Kotler (1993), defines positioning in the market as the action and ability to project the product and communication of the organization, in order to be able to reach a differentiated position in the choice of the target audience. Positioning is one of the parts that builds a marketing strategy. *"It is possible to define positioning as a strategic choice that seeks to give a credible, different and attractive position to an offer (product, brand or insignia) within a market and in the minds of customers"* (Lindon et al., 2004). The voluntary choice of a positioning strategy by any company plays a fundamental role, since it influences the purchasing decisions of clients. It is therefore important that the company communicates this position clearly so as to build a solid image in the mind of the public. If this communication is not effective, there may be a spontaneous positioning created by the market, which often does not reflect the company's strategy.

Market positioning involves *"arranging for a product to occupy a clear, distinctive and desirable place relative to competing products in the minds of target consumers"*. It is about formulating competitive positioning for a product and a detailed marketing mix (Kotler et al., 1999).

According to Kokemuller (n.d.), *"positioning and differentiation are very closely related marketing strategies"* - positioning is the strategy for conveying what makes a company or a product bigger, different or better than the competitors, and differentiation is the way a company carries out its positioning by promoting distinct attributes or benefits.

2.3 International Marketing and Culture

Cateora and Graham (2002) define international marketing as the execution of business activities designed to determine the planning, price, promotion and distribution of goods and services of a company in more than one country.

The challenge of international marketing becomes more intimidating, because there are uncontrollable factors that vary from country to country - such as the competition, legal restrictions, government controls, climate and culture - that often affect the profitability of the good. *"The marketer cannot control or influence these uncontrollable elements, but instead must adjust or adapt to them in a consistent manner with a successful outcome."* (Cateora and Graham, 2002).

The task of cultural adjustment is the most challenging and important one that international marketers are currently facing. According to Wild et al. (2005) "culture is a set of values, beliefs, rules and institutions held by a specific group of people". Culture also includes what people consider beautiful and tasteful, their beliefs, their traditional habits and the way they relate to those around them. Aesthetics, values and attitudes, customs and manners, social structure, religion, personal communication, education, and physical and material environments are major components of culture. Culture often forces companies to adjust their business, policies and practices (Wild et al., 2005).

A company can opt for one of two strategies of internationalization – adaptation or standardization. The first is to adapt the marketing strategy and the marketing mix to the macro and micro international environment of each new market. The second is to develop a unique cross-border penetration strategy.

According to Cateora and Graham (2007), "*To appreciate the complexity of standardized versus adapted products, one needs to understand how cultural influences are interwoven with the perceived value and importance a market places on a product. A product is more than a physical item: it is a bundle of satisfactions (or utilities) that the buyer receives. These include its form, taste, colour, odour, and texture; how it functions in use; the package; the label; the warranty; the manufacturer's and retailer's servicing; the confidence or prestige enjoyed by the brand (…). In other words, a product is the sum of the physical and psychological satisfactions it provides to the user.*"

3. Methodology

A mixed methodology (qualitative and quantitative) was followed for this research project. In a first approach brainstorming was performed in order to raise possible pertinent questions concerning millennials' opinions. In order to draw conclusions for this work, an analysis of secondary data concerning the brand and a questionnaire (millennials residing in Portugal) were conducted.

3.1 Brainstorming

Brainstorming is a technique, generally used in a group setting, to quickly generate a large number of ideas about a specific problem or topic. According to Isaksen (1998), *"the word "brainstorming" has taken on a variety of popular meanings"*: for some it means simply to get together and have a casual discussion in order to come up with a few ideas and some believe that the term is the same thing as idea generation.

Krishnaswamy et al. (2009) defines brainstorming as *"a group process in which members, usually from different backgrounds, respond to a central question/theme."* The method is especially useful for tackling new problems or for identifying new ways of looking at old problems (Krishnaswamy et al., 2009).

This method was used for this study in order to analyse the difference of opinions among people of different nationalities and to identify pertinent questions to be analysed in the survey - and in a future focus group interaction (Morgan, 1997). In this sense, three brainstorming sessions were carried out in a classroom setting (in mid-March 2018) at the University of Aveiro (Portugal) with a total of 86 students from several countries (Portugal, Mozambique, Spain and the Czech Republic). The first session lasted for 2 hours (from 9am to 11am), with 24 students; the second session lasted for one hour (from 11am to 12pm), with 19 students; and the third for one hour (from 2pm to 3pm), with 43 students. During the sessions participants were shown images of adverts, products, ambassadors and L'Oreal digital influencers from different countries, and some issues were debated, namely:

- What do you think about L'Oréal?
- Do you use beauty products?
- Do you think it is important to use specific products for each type of skin or hair?
- Which products do you use?
- What public figures do you associate with the L'Oréal brand?

3.2 Analysis of secondary data

The analysis of existing secondary data has become an increasingly popular method of enhancing the overall efficiency of the health research enterprise. According to Vartanian (2011), *"secondary data can include any data that is examined to answer a question other than the question(s) for which the data were initially collected"*. The advantage of secondary data is that it can be located quickly and inexpensively.

The analysis of secondary data related to L'Oréal was used to study its strategy – namely, public annual financial reports of the brand, and published articles and dissertations on the brand. To study the international marketing strategy of the L'Oréal Paris brand, hypermarket websites from several countries were also analysed.

3.3 Questionnaire

According to Parasuraman (1991), a questionnaire is a set of questions designed to generate the necessary data in order to reach the objectives of the project. Although the author states that not all research projects use this data collection instrument, the questionnaire is very important in scientific research, especially in the social sciences.

For this study, a clear, short, precise and easy to understand survey was sought (and thus created by the research team), since a clear opinion of the respondent was intended. The objective of the questionnaire was to analyse the satisfaction of millennials in Portugal with the current offers of beauty products available in the market. The questionnaire took approximately five or six minutes to complete. Relatively to the population sample, millennials were surveyed, in Portugal, randomly selected, without any selection criteria discriminating literacy, sex, age, ethnicity and nationality, in order to obtain the most diversified answers possible. Approximately 124 valid responses were obtained. The questionnaire was elaborated with the use of the Google Forms platform and its administration was done by electronic means.

The questionnaire is composed of closed answers, in order to foster a clear opinion of the respondent, with three categories of questions – single answer questions, multiple answer questions and scale questions – in the latter category the Likert scale was used. The questionnaire was divided into three parts, the first containing questions concerning the personal data of the respondent, the second part asking about the satisfaction with beauty products in general, and the last part containing questions about the satisfaction of respondents with the L'Oréal brand.

4. Results

4.1 L'Oréal - International and Culture Knowledge Strategy

The beauty industry is a growing market – it grew 4% from 2009 to 2017 (L'Oréal Group, 2017). With a sales turnover of over 25.94 billion euros in 2016 and an increase of 2.3% over 2015, L'Oréal is the world's leading cosmetics brand, followed by Unilever (EUR 18.54 billion), P&G (EUR 12.45 billion), Estee Lauder (EUR 9.22 billion) and Sisheido (EUR 6.22 billion) (WWD, 2017).

L'Oréal is a French multinational cosmetics company specialized in hair products, perfumes, sunscreen and dermatological products. It was founded in 1909 by Eugène Schueller and is based in Clichy, France. The L'Oréal Group is present in 150 countries and has a portfolio of 34 cosmetic brands divided into four categories: consumer products, professionals, luxury products and active cosmetics.

L'Oréal's mission is "Beauty for All", which offers all women and men around the world the best in cosmetic innovation in terms of quality, effectiveness and safety, to satisfy all desires and needs. L'Oréal's strategy consists of "Universalization", which means globalization, and captures and respects differences - differences in desires, needs and traditions - offering tailor-made beauty products that meet the aspirations of consumers from all parts of the world. Over the years, L'Oréal has pushed the boundaries of science to invent beauty and

provide men and women around the world with the best of cosmetics, offering them products in harmony with their needs, culture and expectations, in their infinite diversity.

L'Oréal is aware of how different its consumers are: "*Consumers in India are not the same as in China or in Europe. Your cosmetic needs and aspirations are different.*" (L'oréal Group, 2012). In order to meet the needs and desires of all markets and since L'Oréal's mission is to offer beauty to consumers from all parts of the world while respecting their uniqueness, the most valuable assets to L'Oréal are Research and Innovation. The international development of the Group meant that L'Oréal had to adapt its organization to the need to coordinate the establishment and development of its brands on all continents. Thus, several geographical areas were created, each with operational responsibility by the subsidiaries in the countries of its region, as follows: Western European Zone; North American Zone; Asia Pacific; Latin America Zone; Eastern Europe Zone; and Africa, Middle East Zone.

To adapt to consumers around the world, L'Oréal research teams are present in all geographical areas.

Research and Innovation are reinvented to create cosmetic products adapted to the world's immense diversity. To this end, research platforms have been created, true centres of expertise that have Research and Innovation at the core of their development model. These research poles invent new products that can become successful around the world. In total, there are 20 research centres grouped in six regions (United States, Japan, China, India, Brazil and South Africa), 3 global centres in France and 16 evaluation centres. In 2017 the group spent 877 million euros on Research and Innovation and registered 498 patents (L'Oréal Group, 2017).

In a symbiosis with the local environment, these centres identify needs, scientific knowledge and cosmetic practices. The data collected enables researchers to develop new products that are perfectly attuned to the consumers' needs. The innovations developed will then be shared with other research centres in a coordinated way, and the needs identified in one country can subsequently lead to success on a global scale. The exploration of new scientific and technological territories is being enriched by this global dimension: with its deep knowledge of skin and hair, L'Oréal's research creates cosmetic products adapted to the diversity of the whole world.

To meet the needs of its customers in their diversity, L'Oréal has created a Consumer & Market Insights Department within the Innovation Division to generate a global database of consumer data by product category and by major regions of the world (L'Oréal Group, 2012). The development of innovative products and their adaptation to market demands is a continuous priority for the Group. If L'Oréal fails to anticipate or interpret changes in consumer behaviour and new trends, its sales may be affected. The Consumer & Market Insights Department, which is part of the Innovation Division, constantly watches for changes in consumers' cosmetics expectations by product category and regions of the world. This work allows L'Oréal researchers to develop new products that are aligned with the needs of the market.

4.2 L'Oréal Paris International Marketing Strategy

For the present study we analysed the Marketing Mix of L'Oréal Paris, a brand belonging to the Consumer Products Division of the L'Oréal Group, which aims to offer high quality products at affordable prices. It is the number one beauty brand worldwide (L'Oréal Group, 2017).

According to the L'Oréal Group (2017), L'Oréal Paris offers male and female beauty products of all types (makeup, skin care, hair care, styling, hair colour), on all continents. Regarding L'Oréal's products, the brand is divided into Makeup, Hair Colour, Hair Care, Hair Style and Skin Care. In Makeup, L'Oréal Paris offers consumers brands such as Infallible, True Match, Magic Nude and Colour Riche. In terms of Hair Colour, L'Oréal Paris provides consumers with brands like Colorista, Excellent Age Perfect and Féria. L'Oréal Paris has 3 different sub-brands, specializing in Hair Care: Elvive, L'Oréal Kids and Ever. Regarding Hair Style, the brand has Elnett and Studio Line. In Skin Care, the brand offers sub-brands such as Age Perfect, Men Experts and Revitalift. For the spring and summer seasons, L'Oréal Paris has Solar Expertise, a brand of sun care products.

All these brands are under the umbrella of L'Oréal Paris and not all of them are sold in all countries (L'Oréal Paris, 2017).

L'Oreal has an international standards portfolio of brands covering a wide range of products while satisfying the needs of every customer present in any part of the world. All its products pass the international standards when it comes to testing. Although the products are standardized, since a great investment is made in making products tailored to all the needs of each consumer, as mentioned previously, some packaging is adapted and public figures and the language of the package are also adapted for each country.

The price policy is the same for all countries, and varies according to the living standards of each country, maintaining a strategy of affordable price to consumers, typical of a mass market brand.

With regard to distribution, L'Oréal Paris being a brand of consumer products, it is distributed through retail channels, making it available to the mass market.

L'Oréal creates its promotions differently in each of the countries it targets. They also have a very strong advert slogan, "Because we're worth it," with a strong message to attract customers. The brand has an aggressive promotional strategy. In addition to the universal brand ambassadors, as is the case of Jennifer Lopez, L'Oréal Paris has local ambassadors in several countries. Local ambassadors are often public figures, actresses, or digital influencers. In Portugal, for example, the brand has Claúdia Vieira as an ambassador, in India, Katrina Kaif, a model and actress of Bollywood films, in China, Fan Bingbing, an actress, and in Brazil, Tais Araujo, Grazi Massafera and Juliana Paes.

4.3 The Satisfaction of Millenials with the Beauty Market and L'Óreal

According to Howe and Strauss (2007), “millennials” is a concept that refers to the generation that was born between the early 1980s and mid 1990s. This generation developed at a time of great technological advances, being characterized essentially by growing up with access to the Internet and all the new technologies related to it; and having an ambition and an orientation to success; and the fact that they are community-based (Freitas, 2014).

To answer the research question "Are the Portuguese millennials satisfied with the current offers on the beauty market and with the L'Oréal Paris brand?" three brainstorming sessions and a questionnaire were done. According to Pordata (2018), there are about 2,368 million millennials residing in Portugal.

4.4 Brainstorming

The brainstorming revealed that all millennials agreed on the importance of using specific products for each skin and hair type and that they are generally satisfied with the beauty products offered by the market.

Regarding L'Oréal's products, most millennials were satisfied with the brand's products; only one millennial African woman did not find products for her hair type at L'Oréal, saying that despite having already tried the branded products indicated for her hair type, they did not work on typical African hair. She also revealed that she has difficulties in finding L'Oréal foundation for her skin colour in most of the hypermarkets in Portugal.

All millennials were very price-sensitive when it came to choosing beauty products, claiming that they only bought L'Oréal when it was on sale, as they felt that the price of the products did not outweigh its benefits.

Although they consider L'Oréal to be a brand with quality and prestige, they find many cheaper substitutes in the market. Few millennials have shown themselves to be loyal to any brand of beauty, most having been heavily influenced by price or by their parents in choosing a brand, claiming that they use the brand that their parents buy or that they buy whatever is on sale.

As far as L'Oréal's promotion strategy is concerned, the millennials showed that they are easily aware that the adverts are very sales-oriented, feeling a little deceived. Many consider L'Oréal's advertising to be *"too artificial”* and that *“the results of using the products are not what they advertise."* Most say they do not feel influenced by the marketing used by the brand and that what influences their buying decisions most are the recommendations of friends or family.

4.5 Questionnaire

In the questionnaire, 124 millennial responses were obtained from participants between the ages of 20 and 35, of which 60 were males and 64 females. 65 respondents were Caucasian, 42 Latino, 7 African, 6 Asian and 5 from another race.

Most respondents agree or agree completely that their physical appearance is important (89%), that beauty is important to them (73%) and that they care about their physical appearance (84%); the most mentioned were hair care (68%), skin care (67%), exercise (61%) and healthy eating (52%). Most respondents agree or agree completely with the statement *"I often use beauty products"* and most of them use products specific to their skin and hair type.

Regarding satisfaction with the current offer of beauty products in the market, most agree that if prices were lower, they would invest more in beauty products; nevertheless, they were satisfied with the diversity of products existing in the market and consider that they find all the products they need in hypermarkets in Portugal.

Regarding satisfaction with the L'Oréal brand, almost half of respondents said they "*sometimes*" bought brand products and 23% only "rarely" bought them; only 7.1% *"always"* bought L'Oréal and 13.5% *"almost always"*.

Most respondents agree that L'Oréal has specific products for their skin and hair type. Generally speaking, most respondents are "satisfied with L'Oréal products", considering that they find all the products they need under the brand's umbrella; however, only 37% consider that L'Oréal has a larger variety of products than other competing brands. 42% of respondents say they do not agree or disagree that they identify with the L'Oréal brand packaging and ads; 35% agree, 13% agree completely and the others disagree or completely disagree. The majority of respondents consider buying L'Oréal products for their quality and because they are of a recognized brand, but they are hesitant about price accessibility. Most respondents said they have recommended L'Oréal brand products to a friend or family member.

5. Conclusions

The purpose of this case study was to study L'Oreal's internationalization strategy and to answer the research question "Are the Portuguese millennials satisfied with the current beauty and L'Oréal offerings?"

After analysing secondary data, it was possible to notice that L'Oréal Group's internationalization strategy is consolidating a global brand with local knowledge. In order to know locally its consumers and their needs and aspirations, the leading cosmetics group has research centres spread all over the world, and its strong commitment is in Research and Innovation. The development of innovative products and their adaptation to the demands of the local markets is a continuous priority for L'Oréal, which allows the developing of new products that are aligned with their needs. The brand bets on a strong strategy of internationalization of its marketing mix, and after analysing the marketing mix of the L'Oréal Paris brand it was possible to verify that the most adapted to the local markets is the promotion through local brand ambassadors present in commercial adverts and product packaging.

By analysing the results of the brainstorming sessions and the questionnaire, it was possible to verify that millennials residing in Portugal give a fair amount of importance to their physical appearance and to beauty care. They are generally satisfied with the beauty product offers in the market. Although most recommend the L'Oréal brand to friends or family, considering it to be a brand of quality and prestige, they have shown that they are not very loyal to the brand and that they tend to be very sensitive to pricing in their purchase decisions.

Abstract: There is consensus that the Crafts sector represents a high potential for the creation of economic and social value, notably through the creation of jobs as well as for the promotion of youth employment. The Crafts Sector has embraced major challenges over the times, including, substantial losses in the overall competitive edge of artisans Against this background the sector currently faces important challenges concerning the development of artisans' competences related to entrepreneurship and innovation, in order to promote the competitiveness and sustainability of their activities. Remarkably, though, the sector has survived the industrialization process largely due to the fact that the craftsman producers who survived have done an excellent job by innovating and reinventing their products, services and value models. Some studies emphasize the importance and the opportunities that the current technology and consumption contexts offer for other sectors, namely the crafts sector. Digital facilitators have been acknowledged as sources of opportunities for innovation in the production and processes of production and delivery of in the crafts sector without altering the identity features of the products. However, this potential can remain untapped if artisans fail to make of use of the technological opportunities. This article addresses the existing calls for contextualizing the crafts sector and for fostering innovation and entrepreneurship in this area, by investigating key obstacles and problems faced by craftsman, as well as by exploring existing experiences in overcoming them. The article builds on data collected in five European countries, under the scope of the Erasmus+ Project Craftsmanship+ "Fostering a New and Competitive Approach to Crafts and Semi Industrial high added-value sectors"1 , and involved desk research and interviews with CEO's, Founders and Co-Founders from existing business in crafts and semi-industrial activities. This article contributes in a timely manner to the understanding of the crafts sector by paying attention to the difficulties that artisans face in order to ensure the sustainability of their business initiatives. The importance and the economic contribution of the crafts sector is sizeable and undeniable but still does not attract the attention of support agencies at the same level as other sectors.

Keywords: Entrepreneurship, innovation, crafts sector, barriers, sustainability.

1. Introduction

The craftsmanship sector has experienced quite a few challenges over the times. In recent years we have observed a consistent decline in the craftsmanship activity, largely explained by the prevalent market demands that encourage large scale and low-cost production models (Blundel and Smith, 2013; Aguiar *et al.*, 2016; Alexandre *et al.*, 2017). The value and the cultural, social and economic importance of the craftsmanship activity to local communities is undeniable (Aguiar *et al.*, 2016). Nevertheless, consumers often look for quick solutions to meet their needs (Alexandre *et al.*, 2017). The cost of crafts products is often advanced by craftsmen as a factor which hinders the success of their sales (Ferreira, Neves and Rodrigues, 2012). These, so far, dominant perspectives led to the loss of competitive edge from craftsmen (Alexandre *et al.*, 2017). Many craftsmen who have survived are those who have adapted and reinvented their products by joining their traditional crafts knowledge with new ways of technological and scientific development (Blundel and Smith, 2013). The technological advances in industrial sectors show a strong responsiveness when it comes to the demands of our society (Alexandre *et al.*, 2017). The need for artisans to focus on a new attitude towards current markets and trends is real and digital facilitators are highlighted as a key opportunity to optimize the processes of production of artisans, without altering the identity features of a product. The problem seems to arise when craftsmen are unable to benefit from the advantages of technology and innovation (Ferreira, Neves

[1] This research has been developed in the context of the Project Craftsmanship+ "Fostering a New and Competitive Approach to Crafts and Semi Industrial High Added-Value Sectors" (http://www.craftsmanship-plus.eu), which has been funded with support from the EU under the Erasmus+ Program. This publication reflects the views only of the authors, and the Commission cannot be held responsible for any use that may be made of the information contained therein.

and Rodrigues, 2012; Alexandre *et al.*, 2017). The interaction and integration of different areas of knowledge when it comes to the development and creation of quality products assumes an increasing role in this sector.

Some argue that changes in mentality are vital (Ferreira, Neves and Rodrigues, 2012). In this vein we are observing new approaches between craftsmanship creativity and business (Blundel and Smith, 2013; Alexandre *et al.*, 2017). Sustainability is also seen as an extremely important asset for craftsmanship (Ferreira, Neves and Rodrigues, 2012). The pressure to innovate is enormous and change promotes the development of competences and means of facilitation that connect innovation with sustainability (Ferreira, Neves and Rodrigues, 2012). Long-established artisanal or craft-based products such as cabinet-making, ceramics, jewellery-making, weaving, among others, are regarded as 'far' from innovation largely because of the importance of tradition in the design of production processes – a tradition which is deeply ingrained and subscribes to a conservative approach (Blundel and Smith, 2013). It should not be forgotten that craftsmanship production is focused on the artisan's mastery during all phases, including the core production activities as well as the delivery to the final market and consumers (Ferreira, Neves and Rodrigues, 2012). Like in many other business, the crafts sector constantly faces challenges determined by external constraints, as well as from internal drivers, including subjective issues related to the personality and the skills of the craftsman (Dragin *et al.*, 2015). Often the artisan is the sole intervenient from the beginning until the very end of the process of production and delivery. The craftsman has a role in all phases of production and is the sole author of the product, from the moment where the idea was first conceived to the acquisition of the final product (Ferreira, Neves and Rodrigues, 2012).

In the European context, in most countries, craftsmanship has developed around specific national traditions. This has turned possible the diversification of the crafts sector in Europe. There are several jobs with a wide range of products and services which are vital to the sustainability and identity of local communities across Europe (Dragin *et al.*, 2015). Being able to create added value leveraging the regional production ecosystems, while exploring the origins of traditional know-hows of each region, creating jobs, retaining the population, and valuing the territory are being increasingly embraced among the goals of businesses in general (Ferreira, Neves and Rodrigues, 2012:37). It is known that small and medium enterprises (SME) play an important role when it comes to the competitiveness of the European economy. Micro enterprises, among which crafts businesses are commonly found, are part of the clear majority of SMEs in Europe. It should be pointed out that these businesses are also the biggest source of employment in the European Union (Dragin *et al.*, 2015). The importance of the crafts sector lies in job creation, as well as on the flourishing and appreciation of rural and urban areas and on the wellbeing of the population. In order to start their own business, craftsmen need to be equipped with a vast amount of skills related to entrepreneurship (Dragin *et al.*, 2015). To have a successful craftsmanship business "it is necessary to have skills combining work processes and market activities together with organizational skills and technical/legal skills as well as communication and personal skills" (Dragin *et al.*, 2015:77).

The wide geographic distribution of crafts artisans across Europe makes it imperative to foresight the sector beyond national borders. This article offers a timely contribute into the extend the understanding of the crafts sector, notably by addressing the difficulties that artisans face in the particular context of two different European countries to ensure the sustainability of their business, but also on how these companies managed to overcome their challenges and adversities.

2. Methodology

The present article addresses the results of three case studies whose aim is to contribute to extend the knowledge about key obstacles and problems faced by artisans in conducting their businesses, building on the analysis of their experiences in overcoming them. This research builds on a study conducted in five European countries: Portugal, Spain, Italy, France and Greece, under the scope of a transnational project whose aim is to develop knowledge to support creativity and innovation in in traditional crafts and semi-industrial business areas. Data was collected in 2016 through desk research and interviews with CEO's, Founders and Co-Founders from existing entrepreneurial and market approaches in crafts and semi-industrial activities. The interviews were prepared and piloted according to prevalent research methodology good practices, leading to a script with a set of structures questions. Data collection covered the analysis of 10 cases, in the 5 countries within the scope of the project, according to criteria described below, to ensure the theoretical validity of the samples. Therefore, there were 3 cases selected. These are descriptive cases, of well succeeded

Entrepreneurial and Market Approaches in crafts and semi-industrial activities and were collected in Italy and Greece. The paper offers also a comparative discussion regarding the main obstacles found, the factors which contributed to the success of the business, as well as the main ways of overcoming difficulties and issues found, which can inform the action of future and current entrepreneurs in the crafts sector.

2.1 Case studies selection

A preliminary task concerned the identification of representative cases in the crafts and semi-industrial activities in the 5 countries involved in the research project. A set of guiding criteria were defined to select activities in a consistent manner across all partners, targeting crafts and semi-industrial activities with growth potential. Moreover, a set of other pragmatic criteria were considered in the selection process with the purpose of enabling an effective and timely conduction of the activities. To this end, the process involved: i) a process of identification and selection of crafts and semi-industrial activities with growth potential; ii) a set of criteria to assess the growth potential of semi-industrial activities; iii) a set of criteria to assess the feasibility for final inclusion of 3 crafts and semi-industrial activities, from the sample identified in ii). The process for identifying and selecting crafts and semi-industrial activities with growth potential followed some steps: Scope Definition; Preliminary Identification; Growth Potential Assessment; Feasibility Assessment; and Submission for Joint Assessment by Project Partners.

The first step in the selection process aimed at specifying the scope for the identification of relevant activities, particularly the choice of a sectorial approach, or the identification of any other country-specific criteria, when applicable, that could justify a particular selection of activities.

In the following phase of preliminary identification, each partner conducted an exercise towards the identification of a wide range of crafts and semi-industrial activities, whose relevance for inclusion was assessed in the next step. The preliminary identification could be built on organizational knowledge and contacts, as well as on key factors that could be useful in providing clues for the identification of relevant activities. The identification process could rely on the conduction of consultation or personal interviews to these actors in order to gather the relevant information.

The next step was aimed at assessing the relevance of the preliminary set of crafts and semi-industrial activities based on their growth potential. To this end, a set of growth potential criteria was defined. The rating results were used as a guide for a shortlist of candidates. The calculation of the overall rating was obtained by averaging the ratings attributed to each criterion (e.g. using an ordinal metric for 1 – Very Poor to 5 – Very Good). Partners were advised to only include in the final selection those cases which obtained an overall rating above the group average. Table 1 shows the criteria used, as well as their definition.

Table 1: Criteria for characterizing the growth potential of crafts activities

Criterion	Description
Marketability	If the activity or technique has distinctive and unique production characteristics
Use sustainability	If the activity or technique has the potential to attract differentiated types of uses
Market sustainability	If the activity or technique has the potential to attract a substantial volume (national and/or international) of consumers
Productive ability	If the activity or technique can be performed with currently available and accessible technologies
Resources availability	If there is ease of access to relevant resources and raw materials
Value added	If the activity or technique has the potential to add value to existing or innovative products
Heritage value	If the activity or technique is a unique or exceptional testimony to a local or national cultural tradition

The phase of feasibility assessment stage, involved the examination of the selected shortlist of candidate activities towards a set of pragmatic criteria – geographic closeness; potential for a quality data collection and record; willingness of the artisan to participate in the project and to be involved in continuous contact; willingness of the artisan to share knowledge about the craftsmanship technique. After these steps, each partner identified two activities that were subject to a final assessment that was undertaken jointly by the project partners.

At the end, each partner submitted the list of the four pre-selected activities to the project partners and their corresponding information concerning the ratings attributed and any other relevant features so that a final joint an assessment by project partners was conducted. The purpose of this step was to exclude the

overlapping of activities, and check for any other potential consistency and relevance issues of the cases. After sharing this information, an agreement on the final selection was reached by all partners.

On Table 2 we present the characterization of all cases of the selected sample of entrepreneurial and market approaches in crafts and semi-industrial activities.

Table 2: Characterization of the sample

Case Study	Country	Craft Sector	Type of Entrepreneurial and Market Case	Goal
1 - Handmade leather sandals. The case of "Ancient Greek Sandals"	Greece	Handmade footwear/ Handmade leather sandals/ Design, manufacture, sales.	Promoting Entrepreneurship; New Technologies; Internationalization; Access to external funding (public and private); Skills and human capital; Promotion of Knowledge; Marketing.	Footwear design, manufacture; wholesale/retail; export/import
2- Handcrafted wooden eyewear. The case of "Zylo Eyeware"	Greece	Handmade wooden crafts/ handmade wooden eyewear/ Design, manufacture, sales	Promoting Entrepreneurship	Wooden sunglasses, eyeglasses, frames design and manufacture; wholesale/retail; export/import
3 - Maioliche Ficola	Italy	Ceramics	New Technologies; Internationalization; Skills and human capital; Promotion of Knowledge; Marketing	Transforming volcanic stone, terracotta and ceramic products

3. Analysis and results

3.1 Case study "Ancient Greek Sandals" - Handmade leather sandals

Handmade leather sandals inspired by ancient Greek patterns and shapes are very popular in Greece, especially among women, but also among tourists who visit Greece during summer. The company addressed in the study was created in 2012 and was active at the date of the study. The main activities of the Ancient Greek Sandals included footwear design, manufacture and wholesale/retail.

The case of Ancient Greek Sandals, an export-oriented Greek company operating in this specific footwear sector, was selected due to its clearly distinguishable fashion brand which enabled its dynamic presence in international markets from the very beginning. According to its CEO, marketing had a crucial importance for the company's development in order to reach international consumers and expand sales; this was offered as a rationale to explain why the company was heavily investing in its marketing strategy. Ancient Greek Sandals were handmade locally by skilled craftsmen using traditional techniques which have existed for centuries. Both co-founders have extensive experience in the footwear business, either in shoe designing or in shoe manufacture and wholesale/retail. When they came up with the idea of making leather sandals, they knew that brand building was among their top priorities if they wanted to carry through with a feasible business in the international arena, so they sought advice at an independent agency that provided integrated solutions to sales and communications. In 2014, the entrepreneurs behind Ancient Greek Sandals received the Award for Young Entrepreneur of the Year in Greece by the Stelios Philanthropic Foundation. Ancient Greek Sandals can be ordered at the company's website or can be directly purchased from several shops in 46 countries around the world.

3.1.1 Main barriers to be overcome and lessons learnt

According to an interview given by the company's CEO to Kathimerini newspaper in early 2014, taxation – especially regarding VAT refund – and the relevant legal framework regarding entrepreneurship was not perceived as being very favorable towards business operation, especially when it comes to newly established companies which need to invest their initial capital in promotional and other related activities. Even so, strong will and determination to carry through with the original project, along with a well-structured and export-oriented marketing plan, could bring about the desired results and help overcome some of the problems arising from burdensome and outdated administrative procedures or other unstable market conditions affecting local businesses. Moreover, Ancient Greek Sandals has quickly become a top foreign fashion brand for ancient Greek-style sandals largely due to its design and quality of raw materials and to its many followers on social media (e.g. Facebook); it is also a completely self-funded company with zero debt.

3.2 Case study "Zylo Eyeware" - Handcrafted wooden eyewear

The path from ideation to creation may be long and it usually takes a lot of effort and hard work to transform an original idea into a feasible business. The case of "Zylo eyewear" was selected precisely due to the entrepreneurial spirit of its co-founders who, back in 2012, decided to design and manufacture wooden sunglasses in the Syros Island. By that time, they had little experience with wooden handcrafts – however, this did not halt them from experimenting with wood and learning more about the material with which they really enjoyed working. Although aware of the challenges they were faced concerning the execution of their project, they were very optimistic and excited about it and joined forces with other designers, craftsmen and a photographer living in the same island at that time to start developing their project. The company was founded in 2013 and is still operating. All Zylo Eyewear items are created through a handcrafted process. The philosophy behind the company is that wooden eyewear should not be a luxury item but rather an artifact that comes from good technique, attention to detail and care for the material and the outcome; something that everyone should enjoy wearing. In this respect, the quality of materials is of primary concern for people of Zylo Eyewear, who carefully choose the lumber they use and refine it by hand. Apart from the aesthetic features in lines and shapes evoking the waves of the sea or the flow of the sand on the golden beaches of the Mediterranean, special attention is given to the ergonomics of the sunglasses' wooden frames, which are feather-lite, making them lightweight and easy to wear for hours. Finally, the company uses high quality lenses and does not use any chemicals or finishing products other than beeswax and olive oil salve. In 2015, Zylo Eyewear was invited as a best practices case to participate in a conference at the European Parliament regarding the strengthening of youth entrepreneurship. Zylo Eyewere handmade sunglasses can be purchased in 34 exclusives stores in Greece and abroad.

3.2.1 Main barriers to be overcome and lessons learnt

As with any entrepreneurial endeavor, turning an original idea into a feasible business is usually accompanied by issues and worries which must be addressed. According to the Zero Eyewear co-founders, the main difficulties were mostly concerning financing their project and having access to the required materials for sample testing and for experimenting with lines and shapes of the items they planned to create. Regarding financing, they decided to explore the possibilities of a global fundraising, so they started a crowdfunding campaign on Indiegogo, an internet platform for financing creative and entrepreneurial ideas, which – to their surprise– turned into a total success, vastly surpassing their initial expectations. After ensuring their seed capital, the next logical step to follow was to take careful and well-studied decisions as to avoid unnecessary expenses when it came to the material they needed to work with. However, it was again this obstacle that taught them how to handle and use wood in a correct way, taking full advantage of its potential in creating wooden eyewear.

3.3 Case study "Maioliche Ficola"

Umbria is one of the few regions in Italy that can boast of having four towns with the ancient tradition of ceramics (Deruta, Gualdo Tadino, Gubbio and Orvieto). Maioloche Ficola's main goals include transforming volcanic stone, terracotta and ceramic products. The majolica industry is an evidence of the economic/productive evolution of ceramics in Umbria. Of all the traditional crafts, the production of terracotta and majolica is the one for which Umbria is most well-known globally and also the one which has reached the highest levels of technical and artistic expression. Deruta exports 50% of its production of handcrafted ceramics abroad. A recipe that combines tradition, innovation and, above all, a connection to the territory.

Faced with crisis in the sector, the ceramic arts must defend themselves. The Grandi Maioliche Ficola case demonstrates the ability to offer products that are always up to date due to the great value linked to research and innovation. It is a company that has been operating in the ceramic and volcanic stone sector for many years, based in Deruta, in the heart of Umbria, where the whole production takes place. Grandi Maioliche Ficola offers a wide range of products such as indoor and outdoor tables, bases for tables, chairs, gazebos, coverings, tops for bathrooms, sinks, tops for kitchens, flooring, stairs, mirrors, ceramics, pottery and many other items. Its core business is the creation of hand-decorated volcanic stone tables and terracotta decorated pots, aimed at any domestic or public environment. The volcanic stone is a natural material formed from the rapid cooling of basaltic lava, usually used in construction. Tables are waterproof, frost proof, resist salty air and any other atmospheric agents, including very low temperatures; they are highly resistant to stains, scratches and shocks and resist the effects of any type of cleaning agent. All the decorations are exclusively hand-painted and can be chosen from hundreds of designs in the catalogue, or such decorations can even have an input from the customer himself, thus creating a completely customized table and making the customer's

dreams of owning a unique piece come true. Along with tables, Grandi Maioliche Ficola produces a wide range of volcanic stone, terracotta and ceramic products, such as kitchens and bathrooms countertops, flooring, ornamental panels, consoles, big pots and many more. Carrying out its production with passion and extreme attention to every detail, this company offers an original and high-quality product, making it the very best of what is made in Italy due to the strength, versatility and high technical features of the materials it uses (such as volcanic and lava stone) and the ability to combine the beauty of the decoration with the functionality of the product. The company was founded in 1987 and is still operating.

3.3.1 Main barriers to be overcome and lessons learnt

The case study revealed the relevance of innovation and technology even in handicraft enterprises, especially concerning its development on foreign markets. Innovation, whose foundation is the creation of new products or more efficient production processes, must necessarily raise the quality level of artistic craftsmanship that has suffered a negative bending over the years mainly due to the need to bring down prices in order to encourage the competitiveness and the lack of an adequate training of the workforce system.

4. Conclusions

The study cases addressed in this work offers a perspective about the diversity in craftsmanship businesses, even though only two different European countries are reported. The cases enabled the identification of problems or obstacles that artisans had to face in order to establish and manage their companies. It should be noted that, on the first case study, the issues related to taxation, especially regarding VAT refund, as well as the existence of a non-friendly legal framework, were the main obstacles mentioned. The case of Ancient Greek Sandals is a success because it has implemented an integrated marketing strategy from a very early stage, building on a distinguishable fashion brand, with the aim of improving the business competitiveness of the specific craft activity in international markets. In addition, it is a good practice example as it effectively promotes entrepreneurship and marketing policies taking into account the craft sector's needs to achieve successful results. Furthermore, Ancient Greek Sandals is a very inspiring as a successful project that invested on a local product in a different perspective, shifting the focus towards the design and high quality, thus competing successfully with other well-established foreign brands, in the handmade footwear sector. In this respect, it is an endeavor that could motivate other craftsmen or entrepreneurs in identifying potential in traditional local crafts and in applying efficient marketing strategies to enhance visibility and profitability of their local production. Finally, as already mentioned, Ancient Greek Sandals is a good practice example in that it employed a fresh and innovative way of promoting its products through effective communication strategies adapted to its target audience (e.g. website, social media, other promotional events, etc.) in order to expand sales worldwide and compete successfully with other players in the relevant market.

The case of Zylo Eyewear is a successful example of how an original idea can turn into a viable business, including non-favorable financial conditions, when the people behind the project put all their creativity and effort into fulfilling their goals and improving the business competitiveness of this specific craft activity. The way Zylo Eyewear started and developed its business activity as a craft enterprise has undeniably contributed to promoting learning-by-doing and risk taking, which are essential aspects of entrepreneurship. Apart from creating income for its co-founders – who were affected by the financial crisis as many others in Greece by the time they launched their project – Zylo Eyewear sought to form a small team with other professionals and craftsmen living in the same island in order to shape the future of their endeavor in terms of design, manufacture, marketing and sustainability. In addition, Zylo Eyewear, which is based in a small Mediterranean island, could inspire other craftsmen at a local level to try new ideas, experiment with materials and create high quality fashion items targeting new markets and expanding sales abroad. It is also a good practice example for improving the situation of craft enterprises within a certain region since it highlights their potential and prospects, especially within the context of creative industries. Finally, the case of Zylo Eyewear is an original and innovative project build upon the enthusiasm, hard work and creativity of its people that set clear goals and take small but steady steps towards achieving them.

Regarding the "Maioliche Ficola" case, towns of ceramic and small crafts traditions, endowed with a rich artistic heritage, are nevertheless facing severe problems: globalization exacerbating competition and ageing population of craftsmen, both leading to a continuous decline of the sector. The lack of development and marketing strategies and techniques at the enterprises pose a major obstacle for the much-needed improvement. The case of Grandi Maioliche Ficola is a successful case because it demonstrates the importance

of innovation when the goal is to bring pottery into everyday life, not only by making ornaments but also by making practical objects.

All responsibility is placed on the artisans (from the process of production to the commercialization of their product) and the obstacles that they face concerning the management of their businesses are numerous and artisans must have a wide range of entrepreneurial skills which shall enable them to effectively manage their businesses. The barriers they face are very speckled, as are the strategies they use to overcome them. In our opinion, the crafts sector requires more coverage and understanding across Europe and this study should be seen as a first approach towards a guidance that needs further development. The cases presented serve as a motto for already established artisans as well as for those who intend to start their own business once it alerts them to the existence of various barriers inherent to each business. It also intends to motivate them to struggle to succeed in their business, since other artisans have already experienced difficulties and have devised strategies to overcome them. With a superficial approach of the cases, this article sought to raise awareness of the need to study different realities associated with the craft, leaving as a suggestion the deepening of cases such as those that were presented and that may provide useful guidelines to other craftsman.

An Empirical Study of the Production Technology Cluster and Regional Economic Growth in Russia

Vladimir Schepinin, Angi Skhvediani and Tatyana Kudryavtseva
Peter the Great Saint Petersburg Polytechnic University, Russia
shchepinin@spbstu.ru
shvediani_ae@spbstu.ru
kudryavtseva_tyu@spbstu.ru

Abstract: This paper presents results of the identification of the "production technology" cluster in Russian Regions and provides evidence of an existing significant relationship between volumes of gross regional product and main cluster characteristics. Firstly, we discuss the main theoretical and methodological aspects of using a top-down approach for cluster identification. We focus on the top – down approach for cluster identification, which was introduced by M. Porter, developed by Lindqvist, G. and applied by the "Institute For Strategy And Competitiveness", Harvard business school and European Cluster Observatory. Secondly, we calculate the main characteristics of the "production technology" cluster in 80 Russian Regions for the 2008 – 2015 period following the works by M. Porter and G. Lindqvist. After that, we provide conclusions concerning regional features of the discussed cluster and present calculation results for the regions, where the presence of the cluster is the strongest. Thirdly, we test hypotheses concerning the existence of the relationship between the degree of cluster localization in the Russian regions and volumes of real gross regional product using regression analysis tools. We find that there are positive relationships between cluster features and volumes of gross regional product. When we control the volumes of investment in fixed capital made by organizations and the work force volumes in the region positive relationships remain stable. However, in models with time effects some of the models show insignificant coefficients, what can be attributed to the multicollinearity effects between time effects and dependent variables. In conclusion, we discuss the importance of the "production technology" cluster as a factor of innovative regional economic growth.

Keywords: production technology cluster, regional development, economic growth, cluster identification.

1. Introduction

Regional economic growth is a current focus of research (Rodionov D. G., Rudskaya I. A., 2017; Rodionov D. G., Rudskaya I. A., 2018; Rodionov D. G. et al., 2017). Issues on the assessment of cluster structure development in regions are also widely looked at in scientific literature (Porter M. E., 2012). At the same time, parameters reflecting the economic, innovative, social, and ecological levels of growth in a region are distinguished as a result of the development of a cluster structure. (Ketels C., Protsiv S., 2014; Shabunina et all., 2017). It is worth noting that in most of the works it is the relationship between the general level of development of a cluster structure in a region and the indictors reflecting regional performance which is evaluated (Lindqvist G., 2009).

Meanwhile, questions on the development of separate clusters in the regions and on the analysis of their influence on a region remain of little focus in literature (Gutman et all., 2017; Rytova et all., 2016; Zhogova et all, 2017).

Thus, the goal of this study is to search for a relationship between regional economic growth and the development of a "production technology" cluster in Russia. To achieve this goal, the authors have uncovered the main theoretical and methodological positions relating to the issues of cluster identification using a top-down approach. They have assessed the level of localization, size, and focus of the "production technology" cluster group in 80 regions of Russia for the period of 2008 to 2016. They have also identified significant clusters and built four groups of regression models, which reflect the positive relationship between the development of the "production technology" cluster and the real GRP growth in the region.

2. Cluster and cluster identification

One of the key issues of cluster theory is the problem of cluster identification in individual territory regions. As foreign experience has shown, the existing methodical approaches with a low variety of tools differ significantly in practice. A number of paired categories can be identified in order to characterize the process and techniques of cluster identification; however, most of them come from two main approaches. In the first, which can be called "bottom-up", the clusters are identified for a specifically chosen territory, based on the

presence of previously known enterprises and industry leaders. The second approach uses a method, tentatively called “top-down”, where spatially localized production, focused on a specific kind of economic activity, is sought out. Further on, the national sample Etalon is used for the detection and initial analysis of specific regional clusters.

The point of standard (“etalon”) clusters is to determine the kinds of economic activity which are most often located near each other and subsequently possess a complementarity effect. Since “the degree to which sectors actually coalesce in a space speaks to the importance of local intersectoral contacts» (Porter M.E., 2012), if there is spatial proximity between two or more sectors, then it will serves as a mutual reinforcement for the specialization sectors of the cluster.

The “top-down” approaches to cluster identification take into account two constant cluster characteristics, functional connectivity and geographical proximity, which are traditionally subdivided into two kinds: 1) functional, focused on identifying specific kinds of clusters; 2) spatial, focused on identifying geographical clusters.

It is generally accepted nowadays that the best results of “top-down” cluster identification are reached by combining functional and spatial approaches. These synthetic approaches include the approach of M. Porter.

M. Porter’s method has become a classic and one of the most widespread methods in other countries. Many European and a few domestic attempts at identifying and mapping clusters do not just use the Harvard approach as a technique, but base themselves on its results.

As a result of the multiple studies by M. Porter, we fully managed to determine the structure of standard clusters, based on the diversity of activity presented in the American classifier SIC (Standard Industrial Classification) (Porter M.E., 2012).

Subsequently, the standard cores of cluster groups have been widely used by the US Department of Commerce, which supports the US project of cluster mapping (U.S. Cluster Mapping, 2018). In the European Cluster Observatory project on the identification and mapping of economic agglomerations of E.U. countries, the composition of cluster reference cores was adapted for the European Union taking into account the application of the European classifier NACE (European Cluster Observatory, 2018).

The complete adaptation of foreign classifiers of economic activities to the Russian counterpart OKVED has not taken place as of yet.

Solving this problem by adapting the structure of cluster standard cores to the Russian economy in accordance with the classification of activities by OKVED will allow the composition of the most probable cores of cluster groups of Russian federal subjects to be determined and can be widely used as an adequate basis for the approbation of foreign methods of cluster analysis.

3. Top – down approach for cluster identification

Within the top-down approach, the filling of cluster groups on the territory of federal subjects in accordance with the identified standards allows for the formation of conditional clusters. However, cluster identification suggests confirming the hypothesis of their existence on a given territory. This is achievable through the use of statistical tools according to the methodology proposed by the European Cluster Observatory (European Cluster Observatory, 2018).

The presence and development of positive economic externalities that influence the activity of businesses within the cluster is determined by the presence of a specific “critical mass” of the cluster group core. Due to this, the formed standard cores of the cluster groups should be examined for the presence of this “critical mass”, which determines the relative strength and competitiveness of the local cluster.

At the basis of this method is the assumption that the volume and level of quality of the knowledge being circulated between businesses and organizations included in the examined cluster depend on the size of the cluster, the level of its specialization, as well as the degree to which the examined region is aimed at

manufacturing products in related areas within the cluster. These three factors are defined by the European Cluster Observatory as the "Localization coefficient" (1), "Size" (2), and "Focus" (3). The value of the factors, within the threshold values, reflect whether or not the examined cluster has achieved a sufficient "critical mass" to generate positive external effects and relations. These indicators are calculated using employment statistics and are reflected in formula form as the following:

$$Focus = \frac{Emp_{ig}}{Emp_{g}} \quad (1)$$

where LQ is the "Localization coefficient"; Emp_{ig} is the number of employed in the cluster group i in region g; Emp_g is the total number of employed in region g; Emp_i is the number of employed in the cluster group i; Emp is the total number of employed.

$$Size = \frac{Emp_{ig}}{Emp_{i}} \quad (2)$$

where Size is the "Size" of cluster group i; Emp_{ig} is the number of employed in the cluster group i in region g; Emp_i is the number of employed in the cluster group i.

$$Focus = \frac{Emp_{ig}}{Emp_{g}} \quad (3)$$

where Focus is the "Focus" of cluster group i; Emp_{ig} is the number of employed in the cluster group i in region g; Emp_g is the number of employed in region g.

G. Lindqvist (2009), a Swedish economist from the European Cluster Observatory, establishes the following criteria as the threshold values which mark the significant cluster groups in a region:

1. "Localization coefficient" (3.1) ≥ 2;
2. the region should be included in the 10% of regions leading in "Size" (3.2);
3. the region should be included in the 10% of regions leading in "Focus" (3.3).

Fulfilling the constraints for each indicator earns the cluster group one "star". Thus, the maximum any cluster group can receive is three "stars". The number of "stars" determines the strength of the cluster group.

Apart from this, none of the "stars" can be assigned if the total number of employees at the cluster core does not exceed 1,000 people.

In the end, implementing the methodology described allows data on the number and strength of the examined cluster groups to be obtained for all regions of the country (group of countries) being studied.

It is worth noting here that the constraint for the indicator "Localization coefficient" is of a variable value.

Thus, when studying the "core" of clusters (i.e., clusters in the "narrow" meaning of the word), M. Porter determined the threshold value of the localization coefficient to be at the level 1.0 (Porter M.E., 2012); however, the US Department of Commerce uses a threshold value of 1.3 (U.S. Cluster Mapping, 2018). We suggest using a threshold value of 1.3 for our study when identifying strong clusters.

In this way, adapting the results of the synthetic approach to the Russian economy in the process of cluster analysis allows cluster "standards" characteristic of the examined territory to be identified. Meanwhile, the use of criteria from the European Cluster Observatory makes it possible to, first of all, use employment statistics to check the hypothesis put forward on the strength of specific cluster groups in one region or another according to the number of assigned "stars", and second of all, to identify regions in which the examined clusters are significant. Identifying such regions allows us to talk about both the existence of inter-territorial clusters, the accounting of which allows a more effective regional policy to be conducted, as well as about the existence of competing "foci" of concentration in the corresponding industries, which are capable of

taking for themselves the employment of other cluster groups due to the effect of more significant positive agglomeration externalities on their territories.

Applying the criteria for the level of cluster group development allows us to identify strong clusters on the territory of the country and its regions. However, it does not provide enough information about the factors of the geographic concentration of the cluster, i.e., the agglomeration external effects which determine the level and potential of growth for the cluster group on the examined territory.

4. Results of the growth assessment of the "production technology" cluster in Russian regions for the period of 2008 to 2016

In order to assess the development of the "production technology" cluster in regions of Russia, the authors have compared the kinds of activities from the classifier NACE, which were attributed by M. Porter to the "production technology" cluster, with the activities corresponding to them from the classifier OKVED-2001 (see table 1).

Table 1: Relationship of activities included in the cluster "production technology", according to the classifiers NACE and OKVED - 2001

Types of activities according to NACE (Europe)		Types of activities according to OKVED (Russia)	
25.3	Manufacture of steam generators, except central heating hot water boilers	28.3	Manufacture of steam generators, except central heating hot water boilers; manufacture of nuclear reactors
28.15	Manufacture of bearings, gears, gearing and driving elements	29.14	Manufacture of bearings, gears, gearing and driving elements
28.22	Manufacture of lifting and handling equipment	29.22	Manufacture of listing and handling equipment
28.29	Manufacture of other general-purpose machinery n.e.c.	29.24	Manufacture of other general-purpose machinery n.e.c.
28.41	Manufacture of metal forming machinery; Manufacture of other machine tools	29.4	Manufacture of machine tools
18.91	Manufacture of machinery for metallurgy	29.51	Manufacture of machinery for metallurgy
28.96	Manufacture of plastics and rubber machinery;	29.56	Manufacture of other special-purpose machinery, n.e.c.
28.99	Manufacture of other special-purpose machinery n.e.c.		
30.99	Manufacture of other transport equipment n.e.c.	35.5	Manufacture of other transport equipment n.e.c.

Further on, the authors calculated the level of localization, size, and focus of the cluster for 80 regions of Russia over the period of 2008 to 2015 and identified 31 regions where there was at least one cluster during this period in accordance with the criteria presented above (see table 2). The results of the calculation are presented in graphic form for the eight regions where the "production technology" cluster developed the most successfully (see figures 1 and 2). As of 2015, the largest focus of the cluster is in Ryazan, Vologda, and Belgorod oblasts and makes up 1.5%, 1.2%, and 1.15% of all those employed in the region, respectively. The largest size of the cluster is in Moscow Oblast, Saint Petersburg, and Sverdlovsk Oblast, where the employed make up 5.9%, 5.8%, and 5% of all those employed in the cluster in Russia, respectively. Likewise, the leaders in the parameter of localization are Ryazan, Vologda, and Belgorod oblasts with the values 3.04, 2.44 and 2.3.

5. Relationship between regional economic growth and the development of the "production technology" cluster in Russia

5.1 Model, hypotheses, and research method

The relationship between the regional economic growth and the development of the "production technology" cluster in Russia was measured using tools of regression analysis available in the program STATA MP14. For the base tool of the study we chose Linear regression with panel-corrected standard errors, proposed by Beck and Katz (1995) as an alternative to the feasible generalized least squares (FGLS) based algorithm, which was proposed by Parks and Kmenta in 1986 (Hoechle D., 2007).

Within the framework of the study, 12 models were built and tested, in which the presence or absence of a relationship between the characteristics of the "production technology" cluster and the size of the GRP was assessed. These models were split into four groups depending on the hypothesis being tested.
The first group of model can be presented in equation form as follows:

$$\ln GRP_{it} = \beta_0 + \beta_1 \ln RIiFA_{it} + \beta_2 \ln TRE_{it} + \Upsilon_i Cluster_{it} + \phi_t Year_t + \varepsilon_{it} \quad (4)$$

Where:

$\ln GRP_{it}$ – is the natural logarithm for the GRP value (rub., in constant prices of 2008) being generated in region i at moment t;
$\ln RIiFA_{it}$ – is the natural logarithm for the investments (rub., in constant prices of 2000) in fixed assets being carried out in region i at moment t;
$\ln TRE_{it}$- is the natural logarithm for the number of employed in a region of workers (mil. people) in region i at moment t;
$Cluster_{it}$ is the binary variable, taking on a value of 1 if there is a "production technology" cluster in the region, and 0 if not.
$Year_t$ –is the binary variables, taking on a value of 1 if the observation refers to a specific year t, and 0, if not.

The functional form of the natural logarithm was used for the dependent and independent control variables with the aim of smoothing the heteroscedasticity that occurs as a result of the uneven social economic situations of the regions. Along with this, the logarithmic specification of the regression equation allowed us to linearize the presented function in line with the Cobb - Douglas production function. This makes it possible to interpret the coefficients for them as elasticity.

Within the first group of models, the H1 hypothesis is tested, according to which a statistically significant relationship between the GRP volume and the existence of the "production technology" cluster in a region exists.

The second, third, and fourth groups of models were constructed similarly to the first:

$$\ln GRP_{it} = \beta_0 + \beta_1 \ln RIiFA_{it} + \beta_2 \ln TRE_{it} + \Upsilon_i LQ_{it} + \phi_t Year_t + \varepsilon_{it} \quad (5)$$

$$\ln GRP_{it} = \beta_0 + \beta_1 \ln RIiFA_{it} + \beta_2 \ln TRE_{it} + \Upsilon_i Size_{it} + \phi_t Year_t + \varepsilon_{it} \quad (6)$$

$$\ln GRP_{it} = \beta_0 + \beta_1 \ln RIiFA_{it} + \beta_2 \ln TRE_{it} + \Upsilon_i Focus_{it} + \phi_t Year_t + \varepsilon_{it} \quad (7)$$

Where:

LQ_{it} is the value of the localization coefficient of the "production technology" cluster in region i at moment t;
$Size_{it}$ is the size of cluster group i at moment t, in %;
$Focus_{it}$ is the focus of cluster group i at moment t, in %.

Within the second model, the H2 hypothesis is tested on the presence of a statistically significant relationship between the level of localization of the "production technology" cluster in a region and the GRP volume. The third model tests the H3 hypothesis about the presence of a positive relationship between the size of the "production technology" cluster in a region and the GRP volume. The fourth tests the H4 hypothesis about the presence of a positive relationship between the focus of the "production technology" cluster in a region and the GRP volume.

In model groups 2, 3, and 4, the indices of 1 correspond to models constructed for 80 regions of Russia; 2 – for 13 regions, where achievement of the minimum required value for two of the three parameters was recorded at least once from 2008-2016 in the "production technology" cluster; 3 – for 13 regions adjusted for annual fixed effects.

5.2 Empirical results of the study

The main empirical results of the study are presented in the appendage. Based on the calculations, we can conclude that there is a relationship between the GRP volumes and the main characteristics of the "production technology" cluster (see tables 3 and 4).

Table 3: Empirical results of the estimation relationship between "production technology" cluster characteristics and Gross regional product (models 1 and 2)

Natural logarithm of total regional employment		0.287***	0.421***		0.326***	0.465***
		-0.051	-0.109		-0.0584	-0.1
Constant	11.88***	4.397***	5.985***	12.02***	4.245***	6.041***
	-0.017	-0.51	-0.9	-0.0222	-0.56	-0.895
Observations	400	320	76	400	320	76
R-squared	0.504	0.954	0.976	0.127	0.952	0.975
Number of RegionID	80	80	19	80	80	19
Year FE	No	No	Yes	No	No	Yes

Thus, according to the results of models 1.1 – 1.3 there is a statistically significant relationship between the GRP volumes and the existence of a cluster in a region. That is, in regions where the presence of this cluster has been recorded; the GRP is on average higher (hypothesis H1 is confirmed).

Models 2.1 – 2.3 show the presence of a positive relationship between the levels of localization of the "production technology" cluster in a region and the GRP volume. That is, in regions with a higher employment level in the "production technology" cluster; the GRP is on average higher (hypothesis H2 is confirmed).

Models 3.1 – 3.3 show the presence of a positive relationship between the size of the "production technology" cluster in a region and the GRP volume. That is, in regions where the employment share in the "production technology" cluster is greater in relation to all those employed in the region; the GRP is on average higher (hypothesis H3 is confirmed).

Models 4.1 – 4.3 show the presence of a positive relationship between the focus of the "production technology" cluster in a region and the GRP volume. That is, in regions where the employment share in the "production technology" cluster is greater in relation to all those employed in the region; the GRP is on average higher (hypothesis H4 is confirmed).

Therefore, these relationships are maintained in the models even when we control the volumes of investment in fixed capital made by organizations and the work force volumes in the region. However, in models with fixed annual effects, the coefficients for the variables "Focus" and "LQ" were not significant. This can attest to the fact that the effect from these variables is completely absorbed by fixed annual effects.

6. Conclusion

It is hard to overestimate the relevance of measuring the influence the development of information technologies has on the GRP level in today's world. This paper shows that the assessment of this contribution can be carried out from different sides including with the use of macroeconomic data across a cluster structure of regions. Based on the theoretical and methodological developments done by M. Porter and G. Lindqvist, the authors have analyzed the basic characteristics of the "production technology" cluster, chosen on the basis of employment data, in regions of Russian. Using the method of econometric analysis, the authors identified an existing positive relationship between GRP volumes and the characteristics of the "production technology" cluster on the example of regions in Russia. Whereby, the positive significant relationship was maintained both in models constructed for all regions and in models constructed for regions in which there was a cluster recorded at least once during 2008 – 2015.

It is worth noting that the conclusions made in this study reflect the situation in Russia, and the authors of future studies will need to carefully interpret the results during their extrapolation onto other regions.

As for the focus of future studies, the authors consider it relevant to conduct a more detailed examination of the "production technology" cluster and its influence on the GRP in regions. In particular, along with the cluster characteristics based on level of employment, the issues of assessing "Jacobian" proximity effects and "Marshallian" proximity effects and their relationship with GRP volumes in the regions are also relevant.

Research-by-Design: Stimulating Entrepreneurship and Innovation

Sarah Serneels, Francis Dams and Alexis Jacoby
University of Antwerp, Belgium

francis.dams@uantwerpen.be
alexis.jacoby@uantwerpen.be

Abstract: Entrepreneurship is important in many ways. On many occasions, researchers have stressed the importance of entrepreneurship for economic growth. As a result, entrepreneurship is stimulated and supported by many initiatives in order to increase the number of entrepreneurs and to increase the success rate of these starting firms. Prior research mentions the drivers and the barriers for individuals to start a self employed career. Among the drivers the need for independency and the opportunities for a higher income gain the upper hand. On the barrier's side risks and uncertainty prevail. In the group of barriers for starting an enterprise two aspects are important: the need to find a proper business idea and the need to find complementary competences in one or more co-founders. This paper proposes a research-by-design approach tackling these two important barriers for entrepreneurship. Through the design of a product-service system the potential field of opportunities is scanned and mapped in order to find solutions for the most important gaps, which are -in turn- being evaluated by the process stakeholders. The research-by-design project follows a human-centered approach, integrating divergent and convergent thinking in the early development stages, in which we focus on the user's needs throughout the process of starting a business. The resulting product-service focuses on high potential entrepreneurs with a lot of experience in corporate business, having the skills for entrepreneurship but to whom the final step for a career switch is too big. The solution integrates 4 important aspects: finding complementary competences, developing and enriching business ideas, designing the business and formalizing the cooperation between co-founders. It also differentiates on required speed in the start-up process and the status of the business idea at that point. Both the research-by-design process and the resulting solution build on the product development methodology in the front-end of innovation in which analysis and synthesis alternate, in order to propose validated solutions for a specific need.

Keywords: research-by-design, entrepreneurship, cofounder, innovation

1. Introduction

Entrepreneurship is commonly accepted to be an important driver for economic growth. Prior research reveals that entrepreneurship has some positive effects on innovation, employment creation and economic growth (Van Praag & Versloot, 2007). The number of entrepreneurs in a certain region is a measure for the economic prosperity of that region. In her 2020 plan, the European commission focuses on the stimulation of entrepreneurship (European Commission, 2013) by funding relevant projects.

Stimulation of entrepreneurship suggests that the focus is on entrepreneurs to be. Ashcroft et al. (2009) make a difference between latent and potential entrepreneurs, both referring to not self-employed persons with a preference to be self-employed of which the first holds no specific business idea and the latter does. Both show a certain propensity towards entrepreneurship.

This research focuses on the barriers for entrepreneurship on an individual level and the way to overcome these barriers, in the specific context of Flanders, Belgium. Existing measures, taken locally by governmental organizations in order to support entrepreneurship (VLAIO, 2018) work in two directions. Firstly, a part of the initiatives focuses on individual propensity towards entrepreneurship with the intention to make potential entrepreneurs take the step into entrepreneurship. A second movement aims at increasing the personal capabilities of the starting entrepreneur in order to support him or her with the required knowledge, attitudes and skills for successful entrepreneurship (Dams, 2018). Our approach, however, focuses on potential entrepreneurs for which the barriers to entrepreneurship are not related to personal capabilities nor the lack of propensity towards entrepreneurship. The research digs deeper in the remaining barriers, offering both insights and practical solutions.

The project is conducted as a master thesis project in integrated product development at the University of Antwerp. The objective of this course, for the student, is to generate new innovative concepts for products or services or the combination of both, and to validate the novel concept with regard to desirability, viability and feasibility, which are seen as the cornerstones of any design thinking project (Brown, 2009). This way, the

project serves a double function: to generate an innovative concept for a problem and to add new knowledge to the knowledge base regarding the barriers for entrepreneurship.

2. Methodology

This research project follows a design inclusive approach. Horvath (2008) makes the difference between research in design context, focusing on research in design related phenomena and design inclusive research. The latter refers to research activities integrating the design practice and thus, making use of the knowledge constructing power of creative actions. The purpose of a design inclusive research is to generate both new theoretical understandings and practical solutions to multidimensional problems. The design inclusive approach is appropriate for relative complex problems to be addressed in the real world, in collaboration with practitioners, in order to yield plausible solutions. These solutions, then, can be refined through reflective inquiry (Kennedy-Clark, 2013).

The design inclusive approach combines analytical research methods and constructive design methods. The methodology comprises three major phases (Horváth, 2008):

- The phase of explorative research actions, including the analysis of the current understanding of the phenomenon and the formulation of research questions and design problems.
- The phase of creative design actions, in order to solve the design challenge.
- The phase of evaluative research actions, including the verification and validation of the design outcome.

The design phase itself, described by Horváth (2008), is limited to the sequential phases of conception, design and prototyping,. The approach during this project follows a more elaborate flow according to the design methodology used in the department of product design and development at the University of Antwerp (Braet & Verhaert, 2007; Jacoby, 2016). The design process consists of a process that runs through 5 elaborated phases:

- The phase of opportunity scouting and need detection consists of the exploration of existing problems and future opportunities with regard to market trends, users and technologies.
- The phase of idea generation, in order to find a multitude of possible options for innovation challenges.
- The phase of product and service definition, including the multidisciplinary analysis that leads to full requirements and specifications and a product or service architecture.
- The phase of system design solutions, integrating and solving the most critical aspects of the design challenge.
- The phase of product or service concept solutions, leading to the final validated concept in which all potential criticalities have been tackled.

Despite the fact that the 5 phases are defined as design phases leading to solutions, every phase consists of both analytical and synthesizing activities, alternating between divergent and convergent thinking and between design and verification.

2.1 Explorative research actions

The first part of the design inclusive research process concentrates on the definition of the new challenge.

Entrepreneurship is considered a very broad theme so the subject is narrowed to the specific case in which potential entrepreneurs with a propensity towards self-employment are confronted with barriers in order to actually take the step into entrepreneurship. This way the target group of the project is defined and the research actions focus on gaining insights in the specific needs of the target groups within the actual context.
The early analysis comprises three elements:

- Analysis of the target group, by means of expert interviews
- Analysis of the decision-making process, using a Customer Journey Mapping tool (Stickdorn & Schneider, 2012)

- Analysis of the context, including the stakeholders and the existing solutions in the market, using a context-mapping tool. Also, the freedom to operate within the law is checked.

2.2 Creative design actions

The creative design actions include the actual design process in which two major questions have to be answered: what is the future product or service (or combination of both) that could answer the needs and opportunities, and how should it be designed in order to meet the specific context and requirements. The phase consists of sequential analysis-synthesis cycles in which firstly different needs are formulated and selected. Secondly, a myriad of ideas are generated and selected in order to come forth with the idea with the largest innovative potential. In a third phase, the full definition is compiled and verified.

As from there the pre-development phases of the innovation design cycle are finished (Braet & Verhaert, 2007) and the project moves on to the actual product or service development in which solutions are formulated for the key partial problems and integrated in a coherent principle solution that meets all the requirements.

2.3 Evaluative research actions

Although the specific needs haven been validated throughout the process, it is important to verify whether or not the overall proposed solution meets the requirements.

The evaluative research actions consist of the validation of the design proposal through both feedback by means of expert interviews as through a proof of concept. In view of the fact that the design solution consist of a product-service combination, the first validation concentrates on the service part during a pilot event with both potential and latent entrepreneurs: the co-founder night.

2.4 Data collection

Throughout the process, expert interviews have been used for data collection for both exploration and validation. In the first phase, the explorative research actions, 15 expert interviews have been held within different categories (table 1). In the evaluation of the proposals, 8 interviews have been held with entrepreneurs and organizations that support starting entrepreneurs in Flanders, Belgium (table 1).

Data collection was performed through semi-structured interviews with a wide range of diverse stakeholders. The approach can be seen as a grounded theory approach since the data collected was used to conceptualize, new ideas based on the concerns of the stakeholders in order to determine the variables that affect the propensity towards entrepreneurship.

Table 1: expert interviews

Explorative research actions	**Category of experts**	**# interviews**
	Start-up owners	3
	Latent entrepreneurs	5
	Organizations	7
Evaluative research actions		
	Start-up owners	5
	Organizations	3

The interviews were analysed without full transcriptions. During the explorative research actions, analysis was based on collecting and comparing relevant statements regarding the barriers and incentives towards entrepreneurship. In the evaluative research phase, statements were collected regarding the proposed concept. In both situations, the rich information was necessary to understand the conditions for which the statements were relevant (Hutjes & van Buuren, 1992).

Although the research approach suggests a clear division between the three main phases, some of the evaluative research actions have been performed in close iteration with the creative design actions, thus leading to an efficient interaction between ideation and verification.

3. The design challenge definition

The exploration into the field op potential and latent entrepreneurs leads to the definition of the design challenge or the opportunity for which a design solution could be the answer. During the explorative research actions, following base opportunities emerged:

- How to provide the right trigger or incentive for latent and potential entrepreneurs to actually take the step into entrepreneurship?
- How to support latent entrepreneurs by defining and selecting the right business opportunity to start with?
- How to overcome the perceived risks and uncertainties associated with entrepreneurship?

In order to define the related decision making process, 5 customer journey maps (Stickdorn & Schneider, 2012) were composed with 5 respondents in order to define which stimuli, motives and barriers they encountered in their specific journey from an employed to a self-employed career as entrepreneur. The results of the customer journey analysis provide deeper insights in potential triggers for entrepreneurship. While the unavailability of the right business idea is a potential barrier for taking the step into entrepreneurship, the possibility to act together with a co-founder, having a business idea but not all the required skills, opens opportunities for incentives into entrepreneurship.

Since the opportunities are related to the context in which they might be solved, a context and stakeholder mapping analysis was conducted to in order to detect all factors that might influence the relation between the future user and the product-service (Sanders & Stappers, 2012) and thus, leading to boundary conditions for the eventual solution.

The market for supporting entrepreneurship in Flanders consists of a wide range of initiatives. Some of them are private, some of them are supported by the Flemish government. However, by analysing which opportunities were covered by one or more initiatives in the market, it was possible to detect the gaps regarding the above-mentioned opportunities:

- Smart matchmaking with possible co-founders
- Support for development of business ideas, taking into account the actual status of the emerging ideas

4. The design solution

Matchmaking with possible co-founders and developing new business ideas are the starting point for the ideation process. The design challenge was stretched with the additional driver to connect both opportunities. In an ideal situation the product-service to develop should integrate both aspects in order to create efficiency and effectiveness throughout the process. Developing business opportunities together is potentially a good way to interact with future co-founders.

The design process consists of different ideation phases in order to determine and evaluate a wide range of options. Since there are no stand-alone criteria to argue whether or not an idea is a good one, evaluation by comparing different ideas is the most appropriate option.

4.1 Ideation

In a first round of brainstorms, conducted in a small workshop with generic creative minds, the design brief was challenged against triggering concepts such as ‘engagement’, ‘inspiration’ and ‘information’. The quantity of ideas, in this round, is more important than the idea quality (Adañez, 2005). The main purpose of this session is to trigger new ideas and this way, extending the base of actual options. The brainstorm participants were asked to assess the different ideas against feasibility, impact, relevance and novelty.

4.2 Idea enrichment

The roughness of the ideas doesn’t permit to actually decide on the final idea to continue with. An idea enrichment phase was introduced to elaborate on the highest ranked ideas and to conceptualize first scenario’s associated with these ideas.

1. The first idea is an online inspiration platform that could inspire people to find business ideas. The scenario describes how ideas are gathered and posted, how potential entrepreneurs can reserve specific challenges and how they are inspired with tips and tools to actually deal with these challenges.
2. The second idea is an online matchmaking platform that supports to link potential entrepreneurs having business ideas to potential entrepreneurs lacking business ideas but having complementary skills. The platform focuses on automated profiling and matchmaking but supports the next step by providing tools and approaches to collaborate on the business ideas in order to actually connect and create an understanding.
3. The third idea is a pop-up environment that focuses on short triggers, mini evaluations and coaching on-the-spot, to stimulate entrepreneurship. It is a concept that lowers the first barriers for entrepreneurship by actually visiting the potential target groups within their proper context.
4. The fourth idea is a personal assistant concept, in which very personal support is alternated with group coaching sessions with fellow potential entrepreneurs. Through an extensive profiling, it is possible to find the gaps that need to be filled in individually.

For each idea, in this stage, was also assessed which potential business models could make these ideas viable in a private or a subsidized market.

Five respondents were asked to provide feedback through a semi-structured interview. They could score the enriched ideas on the predefined criteria of viability, feasibility, relevance, impact, novelty and potential interest. Additionally, they were able to comment on the specific details of the ideas, in order to determine boundary conditions or requirements related to these ideas.

4.3 Idea variations, product architectures and product definition

The prior phase has led to a ranking of ideas and additional information on how to optimize the different concept directions. Two ideas withstand the evaluation and again, they are enriched through the definition of alternative architectures. Product service architectures determine the functions of an idea and the way these functions interact with each other (Ulrich & Eppinger, 2008). The definition of the system borders actually determines which functions are included in the proposition and to which external functions it can be linked.

Through redefinition of the system borders, alternative architectures can be proposed, leading to alternative solutions (Braet & Verhaert, 2007) for the product service system.

With regard to the matchmaking platform, the alternative architectures show how additional features can be added to the service, ranging from an extended facilitation of possible co-founders, to the facilitating of individual advice and the information on formal aspects of the co-founding trajectory (Fig. 1). The architecture also provides the first options for the underlying business model, showing which parts of the service are free and which involve payment.

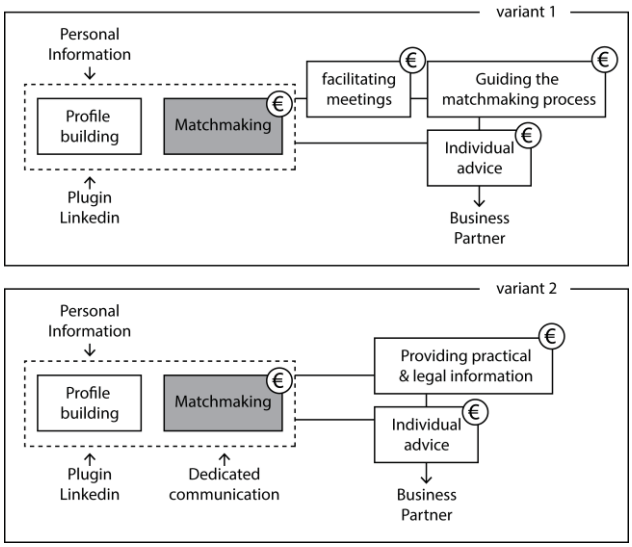

Figure 1: alternative product-service architectures for idea 1

With regard to the inspiration platform, the alternative architectures show different additional functions, related to the base function of providing latent entrepreneurs with business opportunities (Fig. 2). The main difference relates to the fact whether or not facilitating the further development of the business idea is included in the service. A personal guidance trajectory for further development makes part of the service. Those additional features open possibilities for revenues.

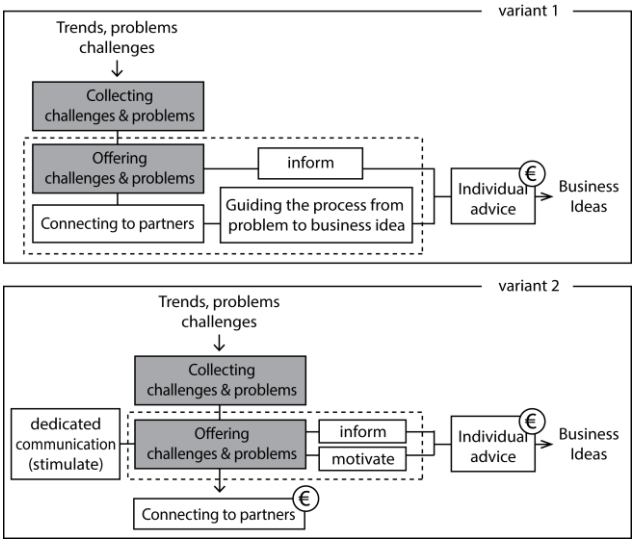

Figure 2: alternative product-service architectures for idea 2

Building on the alternative product architectures, the most important requirements for development are considered. They describe which qualities should be reached in the way the different functions - profiling, matchmaking, facilitation of potential co-founders, guiding the interpersonal connections - are solved. For the inspiration platform requirements are drawn for collecting business ideas and challenges, the way these challenges are translated to the potential entrepreneurs, the communication, the way entrepreneurs can connect with the specific business cases, and the way the entrepreneurs can be supported with the further development of the business idea.

4.4 Product service solution

Previous phases have answered the question why a solutions is required and what the answer should be to the needs detected. In the solution phase, the question turns to 'how?'. Despite the fact that ideas have been generated and defined in a certain direction, the actual result evolves to a new integrated solution. Expert interviews with potential users of the service (Table1) favour certain requirements and specifications but do reject others. As a first step to the actual solution, the product service idea is altered in favour of a combined solution, providing both possibilities to connect with potential co-founders but also, in course of this process, take a firm step forward in the actual development of the business idea.

An essential element, however, in the development of business ideas is the fact that the starting point of business ideas differs to a great extent between cases. Some business ideas are defined as an observed need, some business ideas are defined as a dedicated opportunity and some are defined as a real solution. Starting from a different entrance point, the process for further development requires an adapted approach to those different needs. As such, an essential element of the concept is to differentiate between business idea level, taking into consideration to which extent the idea is actually defined.

A second essential element to the solution is the fact that participants have a different time frame in mind. The expert interviews show that some potential entrepreneurs start slowly. They are only interested to take the step towards entrepreneurship if they find the business idea and the potential co-founder that suits their interest. They are exploring the option but there is no strong urge to take the step. The second group of potential entrepreneurs is beyond this point. They have taken a decision and feel a strong urge to develop their business idea and to find the additional competences needed for their start-up. The product-service solution should take into account these requirements.

4.4.1 Concept description

The final product service concept is a service in which potential entrepreneurs are brought together to connect with potential co-founders. Throughout this process they are encouraged to get known each other and, at the same time, further develop the new business idea one of the co-founders brought into the potential partnership.

The service provides a platform in which potential entrepreneurs can complete their profile. Based on these profiles and potential matches, co-founder nights are organized in which the participants meet with potential partners based on both profile matching and individual choice. The co-founder nights are organized in a way that an innovative mind-set is created towards the business ideas by providing tools and knowledge that can be used to enrich emerging business ideas.

When the co-founder nights lead to specific matches, the potential co-founders have the option to start a stand-alone co-founder process programme focussing on 4 targets:

- Developing and enriching the business idea, broadening the solution space and looking into alternative solutions for the same need or opportunity.
- Developing the business design and business plan
- Considering and deciding on the formal aspects of the partnership
- Learning about the values and drivers of the potential partners.

The programme is supported by a co-founder kit providing the approaches and tools for attaining the above mentioned targets. The co-founder kits have different content for both partners in order to reduce the possibility that they wouldn't work together on the issues. The kit includes both adapted and existing tools and even consultancy options from specific Flemish organizations providing a specific value in this process. Other tools are adapted to suit the specific needs of the co-founder challenge. Figure 3 gives an overview of the entire product-service.

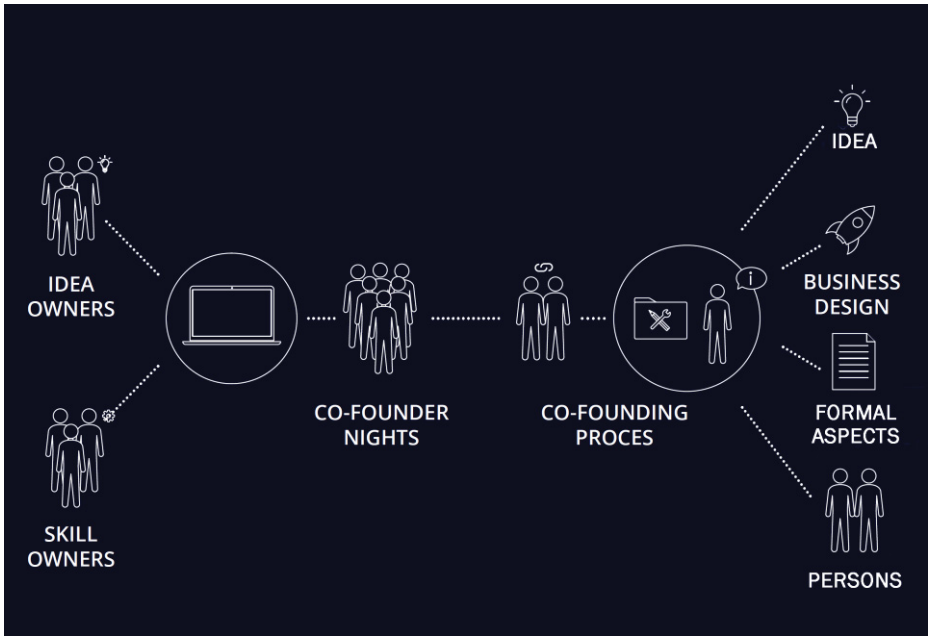

Figure 3: Product-service concept

4.4.2 Business Model

During the definition phase of the design trajectory, a business model is set-up simultaneously in order to define the viability of the product-service. Compliant with a design approach including divergent and convergent thinking, multiple options for viability have been compared in order to define a final viable model.

The proposed business model includes both a basic and a premium membership. The basic membership model targets latent entrepreneurs exploring the possibilities for entrepreneurship without having a concrete

deadline in mind. Linking to the platform is free but a limited fee is paid for every co-founder night they attend. The revenues are related to the active participation during the events. The premium membership targets potential entrepreneurs with an urgent need for co-founders. They pay a high fee as from the start of the programme but can fully access the database, attend all co-founder events and additional supporting events during a certain period of time.

5. Pilot event

In order to validate the first part of the product-service solution a pilot event was organized for co-founders to attend. Through the network of the chambers of commerce of Antwerp, potential entrepreneurs were addressed to join this co-founder event. 48 persons answered positively to this call and filled in the online questionnaire to provide full information regarding their personal offer and needs. 18 profiles were selected to actually join the pilot event. Profiles were selected based on the potential matches between participants and the potential market segments they intend to work in.
The pilot event was organized as follows:

1. Welcome and possibility to look into profile cards attached to the wall
2. Short speed dating with 5 potential co-founders
3. Short break - preparing connections for the next step
4. Joined exercise between two participants
5. Free networking

The different tools for the joined exercise were tested in a preliminary test setting with 12 participants. Six pairs of people, related to each other by the fact that they work for the same employer without knowing each other, were asked to test 2 of the exercises each and to provide feedback on the process of the exercise and the way it serves its purpose: obtaining better insights on potential collaboration with the other party.

The feedback was used to refine the specific exercises.

5.1 Profile cards

During the welcome drink, participants could walk around and look into detail into the profile cards of all other participants which were linked to the personal LinkedIn profiles online. This way, participants could gather extra information regarding the careers of the other participants.

5.2 Speed dating

Based on their potential profile matches, every participant could have a short conversation with 5 other participants. The short speed dates took 5 minutes each. The participants could use a card set with generic but atypical questions in order to dig deeper into the values and characteristics of the conversation partners. After the sessions, candidates could mark their potential matches.

5.3 Short break

The short break was meant for the organizers to actually match potential co-founders for the next step. Meanwhile participants could have a drink, get informed and have informal chats.

5.4 Joined exercise

All participants were matched to a potential co-founder. Every pair received an assignment to work on for half an hour. The assignment combined existing tools used in business definition and innovation workshops but were adapted in order to learn about the tools but also about each other. The tools triggered intense collaboration providing insights on the way the other deals with creative challenges.

5.5 Free networking

The evening was closed with a free networking moment where participants could informally meet and talk. All participants were asked to assess the co-founder event in detail.

The results of the assessment provide no validation of the fact that co-founders events actually work but do provide valuable insights regarding the way this co-founder event was designed. Overall, most of the participants were happy with the event and indicated their willingness to participate once again if the possibility would occur.

The specific programme was perceived positively by most participants although a difference could be seen between the participants seeking a very supported approach for meeting potential co-founders and those, seeking a very open, unstructured approach for meeting people, without the supporting tools to actually connect with others.

6. Conclusions and recommendations

Our research contributes in two ways. The design inclusive research reveals a new product-service system that supports both the first steps into entrepreneurship and the development of new business ideas along the way.

Secondly, it shows that the design inclusive research approach is a valuable approach in order to formulate novel solutions for existing needs. The design itself, but mainly the verification of the underlying principles of the design solution, provides better insights in the way potential entrepreneurs want to be supported in their journey towards entrepreneurship. Although the number of respondents related to the exploration and validation research actions is limited, their feedback provides valuable insights in the way an eventual solution could add value to the process of lowering the barriers to potential entrepreneurship.

The research by design approach follows a path that gradually defines a product-service idea and convert it in a validated product-service concept. Although the way to the solution is not rectilinear, every step taken leads to the right direction and creates a better understanding of the actual problem and narrows down the potential fields of solutions.

Our research definitely points to the need for supporting the process of finding complementary competences in co-founders and, along the way, develop business ideas and decide and agree on formal aspects of future partnerships. The novelty of this concept is to be found in the way partial solutions for several barriers are integrated into one integrated product-service and the way the solution takes into consideration a differentiated entrance point for both skill owners and idea owners.

Our research pointed out that the actual status of the business ideas, together with the diverse intentions and characters of potential entrepreneurs are the most important aspects to anticipate on. A one-size-fits-all solution provides no answer for the diversity of the needs.

It is our recommendation for future research to actually roll-out this product-service concept on a larger scale and to detect in which way this solution enables potential entrepreneurs to overcome existing or perceived barriers. Due to the fact that the service part of the product-service is highly adaptable, real-life testing provides the best opportunities for improvement.

The Role of Family Firm on the Relationship between KMP and Innovation

Ana M. Serrano-Bedia, M. Concepción López-Fernández, Gema García-Piqueres and Maria Obeso

maria.obeso@unican.es

Abstract: Given the central role of knowledge management practices (KMP) in fostering innovation, besides the distinctive characteristics of family firms (FF) regarding their innovative behaviour and results, this paper addresses two main objectives. Firstly, it deepens in the study of the relationship between five KMP -acquisition, creation, storage, transfer and application- and innovation. Secondly, we explore whether being a FF moderates the KMP- innovation relationship, a question that, to our knowledge, has not been explored to date. The empirical study to test these relationships uses data from 238 Spanish SMEs and is based on a linear regression by OLS over the dependent variable. Our results show that, consistent with the extant research, creation and storage KMP have a positive and significant effect on firm innovation whereas, contrary to previous research, no significant effect of acquisition, application and transfer KMP on firm innovation has been found. This study also finds the effect of investing in the creation and storage of new knowledge on innovation is less positive, or even negative, among FF, a result coherent with the lower level on R&D investment among FF reported by previous literature. We also found that being a FF positively moderates the negative, non-significant, link between transfer KMP and innovation, pointing to a higher efficiency of family firms in transforming knowledge transfer in innovation.

Keywords: Knowledge management practices, innovation, family firm, knowledge management, innovation performance

1. Introduction

At present time, knowledge management is considered as a strategic tool in order to obtain competitive advantages in enterprises (Oliva, 2014). Following Del Giudicce & Maggioni (2014) globalization supposes a challenge, and the creation of new knowledge and learning promotion are essential to organization´s success. Within this general context, family firms (FF) are widely recognized as important contributors to both employment and wealth creation for economies around the world (IEF, 2015; Botero, Cruz, De Massis & Nordqvist, 2015; Memili, Fang, Chrisman & De Massis, 2015).

In this scenario, this paper provides evidences about knowledge management practices (KMP) and their influence on the innovation activity in enterprises. Regarding this objective, the main research question is:

How do KMP –acquisition, creation, storage, transfer and application- influence the innovation activity in enterprises?

In addition, related to the FF highlights, the moderating influence of this characteristic in the KMP-innovation link is analysed. In this sense, considering FF´s particularities as the relationships among their members facilitate knowledge sharing, the following question is considered:

Do FF moderate the relationship between KMP and innovation?

This paper is structured as follows: first, a literature review section about KMP, innovation and FF is presented. Then, in the third section, the theoretical model is proposed. Fourth section includes the methodology used. Later the results and the discussion are presented, where the main findings and implications are identified.

2. Literature review

2.1 Knowledge Management Practices and innovation

According to the knowledge-based view of the firm (Leonard-Barton, 1992), knowledge is the most important resource for organizations to develop sustainable competitive advantages (Grant, 1996; Mustafa et al., 2016)

and obtain superior organisational performance and success (Spender, 1996; Andreeva & Kianto, 2012; Oliva, 2014). Thus, knowledge management (KM), defined as the processes and practices that enable firms to manage their intellectual assets and to achieve knowledge-based competitive advantages (Nonaka & Takeuchi, 1995) has become a key organizational activity.

Knowledge management (KM), and specifically knowledge management practices (KMP) defined as the set of management activities aiming to improve the effectiveness and efficiency of organisational knowledge resources (Lee & Choi, 2003; Andreeva & Kianto, 2012), are very relevant in fostering innovation (Lee et al., 2013; Yusr et al., 2017). This is because innovation consists of the successful exploitation of new ideas (Amabile et al., 1996) and is therefore associated with the creation and use of knowledge. Owing to knowledge, companies can innovate, create organisational routines, be sustainable and obtain competitive advantages (Chen & Huang, 2009). Innovation is usually considered a direct outcome of KM effectiveness (Du Plessis, 2007), for this reason managers aiming to improve firms´ innovative activity and results should establish the ideal contextual conditions to propel and optimize the organization's use of KMP (Donate & Sanchez de Pablo 2015). However, KMP design and implementation is a difficult task for managers conditioned by the characteristics of the firm and the members involved in it (Bojica et al., 2017).

The literature that analyses the KMP-innovation relationship has explored the direct effect of one (Li et al., 2009), two (Chen et al., 2010, Alegre et al, 2013, Stanovcic et al., 2015, Donate & Guadamillas, 2015), three (Lee et al., 2013), four (Andreeva & Kianto, 2011, Donate & Sanchez de Pablo, 2015, Yusr et al., 2017) seven (Kianto et al., 2014) or even ten (Inkinen et al., 2015) KMPs on innovation, finding a positive relationship. Despite this general result, several important issues have been under-researched in the literature, such as: (1) with very few exceptions, most of previous KM studies -especially in research exploring KM in FF- have either considered only one or a few KMP. For this reason, we aim to provide additional empirical evidence by proposing, in line with the existing research, a direct and positive relationship between five KMP -acquisition, creation, storage, transfer and application- and innovation; 2) with very few exceptions (Serrano-Bedia, Lopez-Fernandez & Garcia-Piqueres, 2016; Kallmuenzer & Scholl-Grissemann, 2017) none of the studies exploring KM in FF analyse their effects on firm innovation.

2.2 Family businesses

Research on innovation management in family firms (FF) shows that these firms have peculiar features and different innovation behaviours based on their risk preferences, wealth concentration, resource endowments, and family objectives (Chrisman & Patel, 2012; Kellermanns, Eddleston, Sarathy & Murphy, 2012; Chrisman, Chua, Pearson, & Barnett, 2012; De Massis, Frattini & Lichtenhaler, 2013; Classen, Carrée, Van Gils & Peters, 2014; Patel & Chrisman, 2014; De Massis, Frattini, Pizzurno & Cassia, 2015; De Massis, Frattini, Kotlar, Messeni & Wright, 2016). All of these create both advantages and disadvantages in certain dimensions of the innovation process (Konig, Kammerlander & Enders, 2013; Lichtenhaler & Muethel, 2012). More specifically, FF exhibit specific innovation behaviours and results -e.g., they invest less in innovation but have an increased conversion rate of investment into innovation and actually a higher innovation output than non-FF (Duran et al., 2016)-. They also share certain characteristics, such as the close relationships among their members that facilitates knowledge sharing (Zahra et al., 2007), but their homogeneity and preference for cohesion may prevent a deep learning (Zahra, 2012), a circumstance that could influence their innovation behaviour and/or results differently from non-family firms.

Considering the unique innovative behaviours of FF, and following the call for further research by Duran et al. (2016), this paper tries to extend our knowledge of the mechanisms that lead to/hinder superior conversion rate and higher innovation output in FF different of the internal and institutional factors these authors explored in their meta-analysis, such as KM. Research exploring KM in family firms (FF) is still scarce and partial. We are aware of works that explore some KM processes such as knowledge sharing (Zahra et al., 2007; Cunningham et al., 2016) knowledge integration/combination (Chirico & Salvato, 2008; Patel & Fiet, 2011), or knowledge transfer and its effects on the successor's Innovativeness (Letonja and Duh, 2016); but none of them explore their effects on firm innovation. Our literature review has revealed only one paper reporting a negative moderating effect of family characteristics –namely CEO tenure, CEO-founder duality and family involvement- on the positive relationship between the use of various types of knowledge sources and innovation performance (Serrano-Bedia, Lopez_Fernandez and Garcia-Piqueres, 2016). Another second study investigates the effect of knowledge internalization and external knowledge on technological and management innovation of family businesses (Kallmuenzer & Scholl-Grissemann, 2017). For this reason, this

paper aims to contribute to the FF literature by analysing the moderating role of FF on the relationships between KMP and innovation, a question that, to our knowledge, is practically absent in the literature to date.

3. Methods

3.1 Data Source

We surveyed 238 Spanish SMEs in December 2017. We developed a questionnaire based upon an extensive literature review, exploring a wide range of issues relating to family characteristics, KMP and innovation. CEOs were used as key informants (Kumar, Stern, & Anderson, 1993), since they receive information from a wide range of departments and, therefore, are a very valuable source for evaluating the different variables of the organization.

3.2 Measurement and variables

The scales used for the construction of multi-item variables were subjected to validity and reliability by using principal component analysis and by calculating the Cronbach's alpha for each scale. The results supported the validity of these scales, as indicated by the amount of variance explained and loading factors of all items within each scale -exceeding 0.5 in both cases (Hair et al., 1998)- and the Cronbach's alpha for the scales -surpassing the threshold point of 0.7 or quite close to it (Nunnally, 1978)-. The existence of multicollinearity was analysed by using the Variance Inflation Factor together with the condition indexes. The resulting variance inflation factors (all smaller than 2.927) and highest condition index (4.039) suggested multicollinearity was not a concern.

All constructs were measured using Likert-type scale with a five-point response ranging from "totally disagree" to "totally agree". The description of the variables is as follows:

Dependent variable: innovation is based upon two different innovation types: product and process innovation, in line with the Oslo Manual's definition of innovation.

Independent variables: We employ the measure of four KMP (creation, storage, transfer and application) employed by Donate & Sánchez de Pablo (2015). We introduce an additional KMP: acquisition, following Kianto et al. (2016).

Moderator variable: The family nature of the firm is taken as a moderator variable. We identified family firms through a subjective criterion: we asked the SMEs' CEOs whether or not they perceived their firm as a family business (e.g., Cooper et al., 2005), which allowed us to capture the essence of the family firm (Chua et al., 1999). Following this criterion, 181 firms in our sample were identified as FF and 58 as non-FF.

Control variables: Past performance, Size, CEO tenure, Environmental dynamism, Industry dummies (manufacturers and construction), International orientation of the firms, and Cooperation with universities and other firms.

3.3 Methodology

In order to estimate the effect of different KMP on innovation as well as the moderator effect of family nature of the firm on this relationship, we carry out linear regression by OLS over the dependent variable. Four models were developed: Model 1 (includes the control variables); Model 2 (includes also the independent variables –KMP-); Model 3 (also the moderator variables –family firm-); Model 4 (also the interaction variables between family and the five KMP).

4. Results

The results of the empirical analysis (see table) show that, in Model 1, three of the control variables were significant: Environmental dynamism, International and Cooperation with universities. In model 2, a significant increase in R2 can be observed and two of the independent variables have also a significant and positive effect on innovation: creation and application. In Model 3 not significant change regarding R2 is observed, with the same variables remaining significant compared to model 2. In Model 4 a significant increase in R2 is observed and the same control variables remain significant as in previous models. However, in this case the KMP that exert a significant effect on innovation are creation and storage.

Table 1: Results of OLS regression for innovation

Levels of significance: *** p<0.001; ** p<0.01; * p<0.05; t p<0.1

Finally, regarding the moderating effects, the results show a negative moderating effect of FF on creation and storage-innovation relationship, and a positive moderation for transfer (see Figures 1, 2, 3).

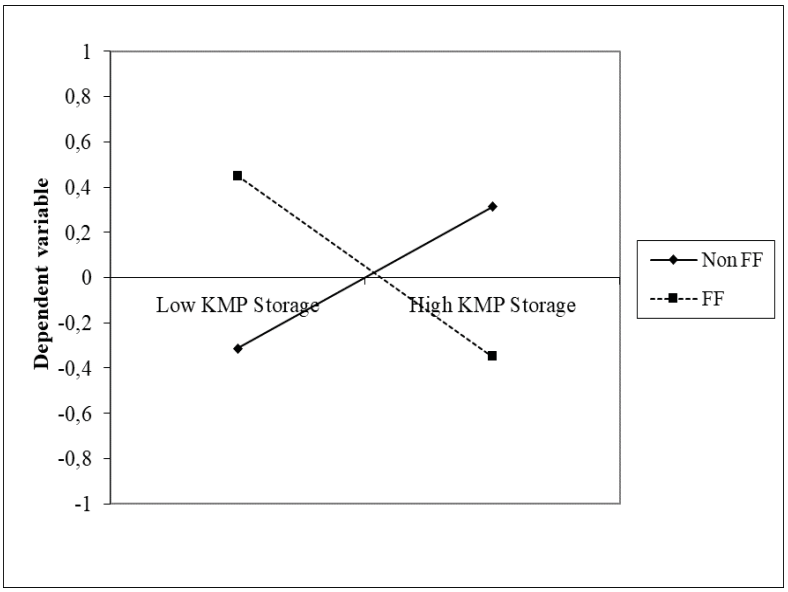

Figure 2: Moderating effects of FF on knowledge storage practice-innovation relationship

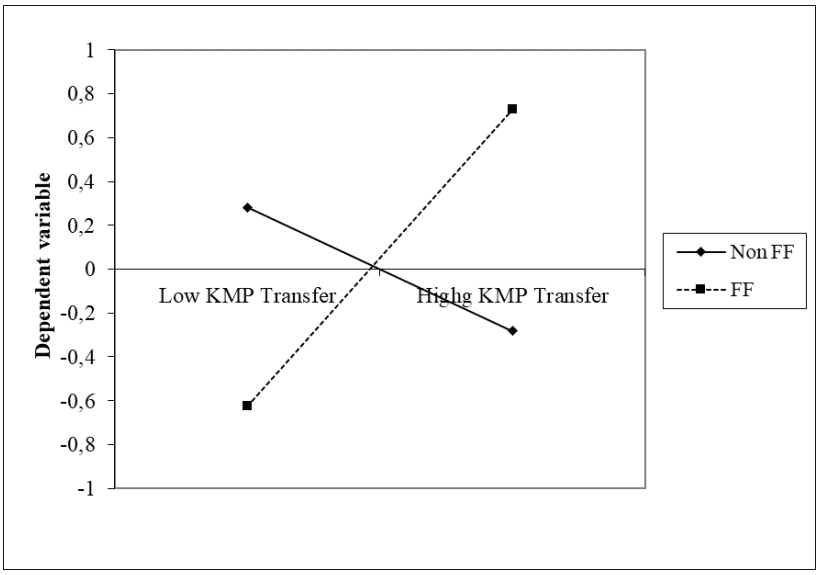

Figure 3: Moderating effects of FF on knowledge transfer practice-innovation relationship

5. Discussion, implications and research limitations.

This research contributes to the knowledge-based view of the firm and the innovation management literatures by demonstrating the impact of KMP as a managerial tool for advancing innovation. More precisely our results show that, on the one hand, and consistent with the extant research (Alegre et al, 2013; Lee et al, 2013; Andreeva & Kianto, 2011; Chen et al, 2010; Donate & Sanchez de Pablo, 2015), creation and storage KMP have a positive and significant effect on firm innovation. On the other hand, and contrary to the previous research mentioned, no significant effect of acquisition, application and transfer KMP on firm innovation has been found.

In this sense, this paper confirms that those enterprises interested on innovation activity should focus their efforts on creation and storage KMP. On the one hand, knowledge management creation is related to the new knowledge development inside the organizations, tacit as well as explicit knowledge. This creation is linked to the new ideas and with the workers in the organizations. On the other hand, storage like a KMP includes all activities dedicated to the storage knowledge inside the enterprises, like structures, documentation, database or procedures, between others. Therefore, as previous studies note, those enterprises keen on innovation activity should focus their efforts on create new knowledge and storage tools.

However, the results related to the acquisition, application and transfer KMP contrast to previous studies because they show these practices haven´t influence on innovation. KM transfer is linked to the activities carried out to knowledge sharing like, for example, mediation rooms. KM application includes all activities connected to the practical knowledge and knowledge implementation. And, finally, KM acquisition is about enterprise´s capacity to identify and acquire external knowledge (knowledge in the market).

Nevertheless, following previous publications like Jian et al. (2016) “knowledge acquisition is a precursor to knowledge creation, which helps to uncover the relationships between different types of knowledge management practices” (2016, p. 112). This statement seems conflicting with the result, thus in this way a new future research possibility could be analysed: what about these practices and the innovation process?

This study also contributes to the FF literature by providing, for the first time, empirical evidence on the moderating influence that being a FF exert on the KMP-innovation relationship, finding relevant results. Namely, we found that being a family firm negatively moderates the positive link between creation and storage of new knowledge and innovation. Put differently, in family firms the increase in these two KMP do not generate more innovation. These results are coherent with the lower level on R&D investment among FF reported by previous literature. Besides, we also found that being a family firm positively moderates the negative (but non-significant) link between transfer KMP and innovation. This result points to a higher efficiency of family firms in transforming knowledge transfer in innovation, opening the door for further exploration of the causes and size of this effect.

These findings have also valuable managerial implications because, by adding to a better understanding of the most effective KM practices that are likely to have an effect on firm innovation, this study serves as a guideline for the managers aiming to reinforce innovative behaviour and results. The study's potential limitations are its cross-sectional design and the use of subjective measures. In addition, this research is limited to one country under investigation (Spain), and in a context of internationalization and globalization as we are today, organizations can offer different answers to the same problem depending on the cultural factors that surround them. Hence, to extend our research to other countries and cultural contexts would enrich our results. Finally, the generalizability of our findings is also limited by the nature of sample used in this study, and it remains for future studies to determine whether these results will hold for larger companies.

Capturing of Entrepreneurial Opportunities Deriving from Crowdsourcing Practices and Additive Manufacturing Technologies

Dmitry K. Shaytan and Georgy D. Laptev
Lomonosov Moscow State University, Russia
dshaytan@gmail.com
glaptev@econ.msu.ru

Abstract: Our research explore entrepreneurs' willingness and readiness to utilize advancements in additive manufacturing/prototyping technologies (AT) in combination with managerial advancements in crowdsourcing practices for the purpose to extend application of agile management practices in their business processes. Growing number of online market places like Amazon Mechanical Turk, CloudFactory, Odesk, InnoCentive, Treadless, etc. allow entrepreneurs to apply crowdsourcing management practices for more and more type of tasks leading to a more like market type of a firm that contract services and production by on-line calls to crowd-labor communities. This strategy of business processes arrangement gives entrepreneurs more flexibility and improves implementation of agile and lean startup management approaches. At the same time development of technologies for additive manufacturing/prototyping makes agile project management methodologies more relevant for "hard" engineering projects and manufacturing beyond just design input/requirements and development planning. Both crowdsourcing managerial technologies and additive technologies are developing steadily from small scale (laboratory) emerging ones to those that already effect and will radically affect business practices in multiple industries. Combination of rapid developments in these fields, uncertainties related sometimes even to hypes boosted by media around these technologies, lack of application statistics, and promises of these technologies to improve agile and lean management practices create an interesting mix for researchers in entrepreneurial management. In the research through interviews and questionnaires we explore how currently entrepreneurs and business men/women perceive utilization of these managerial and technical innovations for their business development strategies, how discrepancies in perception of these technologies and these technologies capabilities generate entrepreneurial opportunities. The research results are done for Eurasian Customs Union region so far. They show steadily growing communities that possess additive technology equipment and master its utilization. This is regarded as strong basis for development of online market places (IT platforms for crowdsourcing of additive technology product/services). At the same time research results show barriers for these technologies application in business practices. The findings are of interest for practitioners.

Keywords entrepreneurial management, agile management, additive manufacturing, crowdsourcing, crowd-labor

1. Conceptual foundations for the research identification

The idea of the research was ignited by curiosity how entrepreneurs can transform business process by utilizing technological advancements at additive manufacturing/prototyping technologies (AT) in combination with utilization of managerial advancements at crowdsourcing practices.

For better understanding of issues of the article we would like to introduce concepts describing entrepreneurship and agile management, additive technologies, and crowdsourcing.

1.1 Entrepreneurship, lean-startup, and agile management.

Conceptualizations of entrepreneurship refer to concepts of "value" and "opportunity". For example, according to (Timmons, 1994): "Entrepreneurship is creating and building value from practically nothing. . . . Entrepreneurship involves the definition, creation, and distribution of value and benefits to individuals, groups, organizations and society"; according to (Stevenson, 1983) entrepreneurship defined as: "The pursuit of opportunity beyond the tangible resources that you currently control."

The significant breakthrough in conceptualizing entrepreneur activities was done by Steve Blank (Blank, 2012) and Eric Rice's (Rice, 2011) by introducing the startup concept, and its stages, tasks and objectives. S. Blank concept "startup is a laboratory" very distinctly differentiated startup management practices from small business ones.

The "startup is a laboratory" concepts have several stage concepts inside (Blank, 2012): "customer discovery", "customer validation", "customer creation", and "customer building". The former two relates to company growth: execution and business development.

The "lean startup concept" (Rice, 2011) states that lean management is a must to follow in entrepreneurial management especially for the "customer discovery" and "customer validation" stages of a startup. Moreover in entrepreneurial management there is high correlation between lean management strategy and agile methodologies of management.

Agile management approach refers to iterative and incremental types of managing design and product building in software development, consulting services and other business areas that allow acting in a highly flexible and interactive manner, following the principles of the Manifesto for Agile Software Development (Williams, 2012). Availability of technologies and other market factors can facilitate implementation of agile methods in particular project management, business area, or become a barrier in agile methods application. If these factors allow implementing agile methodology than the value for a company could be a product or service that higher valued in the eye of a client but without the company over commitment of resources to its development and production – higher value with more flexibility. However, agile practices can be inefficient in vast number of business activities (Larman, 2009). If agile software development methodologies are too extreme in particular case than it is possible to implement Hybrid approaches that blend elements of agile management and plan-driven approaches (Barlow, 2011).

The agile came from the process of development of managerial solution addressing problems in software engineering in 1970s. In software development projects there are standardization practices and compatibility of technological platforms that allow to use iterative and incremental steps in building software products enabling technically to move development along application (software) layers, vertical and horizontal slices back and forth, that is to say, minimizing risks of starting "new building" from the new basement constriction and favoring reduction of burdens of hard planning and perfect documents development. In contrast when ones try to build new building in the hard ware world than agile implementation in the areas beyond planning and prototyping is questionable. Issues of relative impossibility to modify "physical" product design in manufacturing process with an ease of software new feature release scare away managers from using agile approach. Perfect planning and documentation are still essential in most engineering projects. However, Agile is "welcome" in those cases where it could be applied.

1.2 Additive technologies, manufacturing, and prototyping

Advancements in additive manufacturing technologies expand cases of agile management application in engineering projects. Additive technologies allow direct manufacturing from CAD models without use of cutting tools, injection molds, and etc ones used in materials treatment. These bring modification of prototypes and manufacturing products or its components closer to how software new features can be released. However, what is important, this doesn't mean that additive technologies exclude or not compatible with those technologies in manufacturing or prototyping technological process.

Additive manufacturing is not just making close technological connection of virtual CAD models to its manufactured physical analogues but also transforming management of engineering projects and manufacturing business process. Affected by values of direct printing from CAD models this transformation is rapid in aerospace, medical implants, dentistry, jewelry and a few other industrial applications sensitive to AM values like geometry freedom and its change with minimal additional costs, materials scrap reduction. The other industrial applications more sensitive to additive manufacturing disadvantages of AM equipment cost, materials cost for AM and their limited variety, speed of manufacturing including AM equipment preparation for the next production cycle, required quality of surface and internal structure. Some industrial applications hedge disadvantages by combining additive manufacturing technologies with casting and cutting, for example, by using additive manufacturing for tools like molds for casting, or combining ultrasonic additive manufacturing technology with CNC milling in one hybrid machine. The additive technology in these cases is not direct CAD model printing of the final product but just one dependent technique in the manufacturing technology process.

The above examples show the constant additive technology developments towards extension of areas of its business applications by the AM technology improvements, or by improving efficiency of its integration with "traditional" technologies, or by business process reengineering. This tendency of extending areas of AM business applications leads to extension of business areas where agile project management approach can be implemented. Areas of engineering and manufacturing of hard-ware components/products get the enabling technology to follow Agile manifest principals.

However, there are several impeding factors in additive manufacturing application beside AM equipment cost, materials costs for AM and their limited variety, speed of manufacturing including AM equipment preparation for the next production cycle, required quality of surface and internal structure. They refer to lack of industrial standards in AM, and lack of skilled additive technologists for employment.

The solution for diminishing these impeding factors could be found in a field of utilizing crowd and outsourcing capacities available on the market.

1.3 Crowdsourcing and crowd-labor

New practices that outsource functions, performed before inside organizations, to network of people (crowd) by open calls for proposals are relatively new phenomena of business process arrangement or even new business-models creation. Those cases of managerial innovations could be called crowdsourcing systems, and provide opportunities for entrepreneurs to reduce classical way of business process arrangement in the form of a firm by hiring employees.

"Crowdsourcing" is a modern concept that covers many activities among communities and companies where community can even be defined, for example, as the company employees, and some company as a political party that outsource micro-tasks from volunteers or its members.

The name crowdsourcing is formed from two words, crowd, making reference to the people who participate in the initiatives, and the word sourcing, which refers to a number of procurement practices aimed at finding, evaluating, and engaging suppliers of goods and services.

While there is an evidence that crowdsourcing was utilized as an activity long ago in civilization history, for example, cathedral building in the 15th century (Boudreau & Lakhani, 2011) the term "crowdsourcing" was originally coined by (Howe, 2006) "...a sourcing model in which organizations use predominantly advanced internet technologies to harness the efforts of a virtual crowd to perform specific organizational tasks".

The crowdsourcing as an outsourcing market capacity developed slowly through history from an amateur type of freelancing to a serious, widely distributed workforce of professionals (Brabham, 2012, Leimeister, 2009).

ITC technologies are platforms that boosted e-markets formation and commoditization of outsourcing services. Crowd-labor, also known as cloud labor, is the e-market that can be used by companies for services outsourcing. The available ICT platforms allow to build cost effective management structures with decentralization of decisions and labor, and the same time in combination with automation software reduce gaps between professionals and amateurs. For example, automation in photo and video editing, graphical design services perfectly illustrate this transformation.

Analyzing these examples we found that businesses can increase their flexibility and "agilability" in sectors where crowd-labor e-markets are formed through enabling amateurs and hobbyists by automated digitalized means of production. In its turn additive technologies could be also regarded as enabling mean of production for armatures and hobbyists that are foundation for AM crowd-labor e-market emergence.

2. Research methodology

Our research goal was to analyze is there an entrepreneurial opportunity mix in Eurasian Customs Union (ECU) region from:

1. Crowd-labor pool of amateurs/hobbyists empowered with additive technologies means of production that could be a basis for the e-market platform building;
2. Contractors pool of entrepreneurs and small enterprises that regard AM as a way for business process transformation to get more flexibility, and sustainability through lean and agile approaches implementation.

Systematic literature analysis identifying the research topic didn't provide evidence of any research that examine possibility of transforming business processes by launching or utilizing existing crowd/cloud-labor e-markets in additive manufacturing or prototyping in Eurasian Custom Union region. Why we make this geographical boundary or attribute scale for the sample? According to (Roland, 1937) beside price there are

transactional costs while obtaining goods or services on a market like search and supporting information obtaining costs, bargaining costs, enforcement costs, transaction costs, and etc. He suggested that: "firms will arise when they can arrange to produce what they need internally and somehow avoid these costs". As business practice show there are legal barriers related to Custom Service and financial transaction costs that lead to blocking costs for benefits of crowdsourcing AM services beyond Eurasian Customs Union.

1. The crowd-labor of 362 respondents was formed from social networks and databases from event management companies. The selection criteria were ownership or free access to the additive technology equipment (for example, public universities laboratories or body shops). Segmentation inside the research pool sample for potential freelancers at the e-market as amateurs or professionals was made on nominal values of attributes of respondent education background, special knowledge/skills in understanding additive technology physics, chemistry, and mechanics. These attributes assume respondents' capabilities to provide quality services regardless of the level or automated features of the equipment or software enabling amateurs to act as professionals. This reference research pool sample has knowledge, skills, and enabling equipment to become part of the AM crowd-labor e-market.
2. The contractors-pool sample of 354 respondents was formed from client databases of design and engineering studios that provide services in 3D scanning, 3D modeling, 3D printing. The professional design and engineering companies were interested in the research results to estimate threats and compulsory transformation in case of crowd-labor e-markets emergence in AM industry and distributed questionnaires. This type of respondents was selected to eliminate survey errors in exposing extempore/unprepared respondents to questions about specific technical and business areas. Answers of entrepreneurs and managers that didn't have previous experience in additive technologies utilization could be regarded as invalid and survey result unreliable. Also this research pool sample are definitely first contract-pool of users or potential beneficiaries of exploiting a new crowd-labor e-market advantages.

In the survey we used pre-coded data of ordinal values for the attributes 4 = Strongly Agree; 3 = Agree; 2 = Disagree; 1 = Strongly Disagree and "not applicable" variant if the question is irrelevant to measure perception of:

- willingness in the both pools to be the part of the AM crowd-labor e-market,
- readiness to contract and provide services at the e-market,

Also for the contractors-pool sample we measured sense of agency in using agile management approach in business process incorporating AM and the e-market contracting. Sense of agency refers to the feeling of control over actions and their consequences (Synofzik, 2008).

1. The crowd-labor pool sample is regarded as representation of core basis/foundation for the potential formation of the AM crowd-labor e-market on the freelance/supplier side.

Their willingness to serve the potential demand at the e-market was measured through correlation with job satisfaction according to (Kalleberg, 1977; and Brayfield, 1951). Job satisfaction is regarded of being affected by the level of income and its change, and by non-income factors. According to Minnesota Satisfaction questionnaire (2011) these non-income factors could be: "I meet very good friends in my job, it gives me a high level of satisfaction as it is socially important, I spend my time very pleasantly during working hours, and it is a pleasure to work with our team". For the crowdsourcing e-platforms no-income variables are the most important motivations to be present there, and it is integral part of a member self-identity (Fedorenko, 2017).

These four non-income variables addressing level of satisfaction were presented in the survey as:

- "AM crowd-labor is a good community/crowd for me to be/work with",
- "be part of the AM crowd-labor community is socially important for me",
- "it is a pleasant time for me to work on orders via the AM crowd-sourcing platform".

The income satisfaction from the crowd-labor e-market platform can be measured as:

- "freelance work is important for me to reach required or desired (please, underline here only one the most correct definition for you) income level".

The readiness to provide services was measured through assessment of their ability to design and to print: "I can take order for 3D printing today" (with variations of using additive manufacturing technology FDM, SL, MJP, SLS, or binder jetting), "I have more than one year of experience in 3d printing", "I serve orders in 3D printing as freelancer".

1. The contractors-pool sample represents the core basis for the potential formation of the AM crowd-labor e-market on the companies/demand side.

Their willingness and readiness to make orders through the AM crowd-labor e-market platform were assessed through common practices, values, risks, and sense of agency associated with required managerial decisions to be made. Typical questions with the pre-coded data scale were:

- Group 1. "I used crowd-labor e-market platforms like www.freelance.ru, www.www.upwork.com or any similar one at least once", "I was fully satisfied with this experience";
- Group 2. "I regard those and alike platforms as a good alternative to employ people/specialists; I regard those and alike platforms as a good alternative to direct contracting from suppliers; I regard those and alike platforms as a good supplementary alternative to direct contracting from suppliers.
- Group3. "I regularly outsource through crowd-sourcing e-market micro-tasks; I regularly outsource through crowd-sourcing e-market macro-tasks; I regularly outsource through crowd-sourcing e-market simple projects; I regularly outsource through crowd-sourcing e-market complex projects". Definitions were provided to respondents what were regarded as micro-tasks, macro-tasks, simple projects, and complex projects, please, see below.
- Group 4. "The crowd-sourcing is a high value solution for the current business process optimization in terms of direct costs per each item; same question for the overhead costs".
- Group 5. "The crowd-sourcing is a high value potential solution for the transformation of business process optimization in terms of reduction of direct costs per each item produced; same question for the overhead costs".
- Group 6. "The crowd-sourcing is a high value potential solution to hedge market risks influence on my business (the business I represent) contributing to quick adaptation or flexibility".
- Group 7. "I know what is Agile; I use Agile management practices in my (the business I represent) business process; Agile management approach is highly valuable and I want to expand its application, I feel unsatisfied with the current status of hybridization of Agile with Plan-driven approach".
- Group 8. "I outsource AM technologies to produce components for the product; I outsource AM technologies to produce components for prototypes only, I'm ready to outsource AM operations through crowd-sourcing platforms like freelancer.ru if there will be that opportunity".
- Group 9. "If I place an order at a AM crowd-labor platform there is no feeling of uncertainty or danger"; I will definitely feel confident to order through AM crowd-sourcing platform if there are track records of freelances metrics of orders/contracts served before, I will definitely make orders at the platform if there are commoditization of product/services, like the Uber e-market"
- Group 10. "AM technologies are of value to benefit from Agile management application extension in my business (the business I represent), AM crowd-labor market development is a great chance/opportunity for integration of AM technologies into business process of my business (the business I represent)".

Micro-tasks are regarded as small tasks that could be provided by any contractor and have a minimal level of complexity. The average time to accomplish a micro-task is up-to one hour. Macro-tasks are regarded as medium size tasks that could be provided by contractors with specialization and have a low level of complexity. The average time to accomplish a macro-task is up-to one working day (~ 8 hours). Simple projects – are regarded as projects that could be provided by contractors with specialization and have a medium level of complexity. The average time to accomplish a simple project is up-to one week. Complex projects are regarded as projects that could be provided by contractors with deep expertise and experience and are complex. The average time to accomplish a complex project is more than a week.

There was a simple survey data structure with the data from a single-round survey. Some questions were overlapping to highlight anomalies in responses and follow-up by phone for clarification. Any unqualified inconsistencies were exempt from the collected data.

The measured perception of the statements of the ordinary scale from strong positive 2 to strong negative -2 were multiplied by weights. This made presentation of the research data more accessible/usable in this paper and also the research data interpretation for entrepreneurial opportunities recognition derived from blending crowdsourcing practices and additive manufacturing technologies.

3. The research results

Results of the research analysis are presented on Table 1 below.

Table 1

Type or category of the research sample	Willingness to be part of AM crowd-labor e-market	Readiness to be part of AM crowd-labor e-market
Crowd-labor pool	11.8 (moderate and close to extra)	5.6 (moderate)
Contractors pool	41.4 (moderate and close to negative)	13.8 (negative)
Contractors' pool segment of direct printing of products/components	34.5 (negative and close to moderate)	11.2 (negative)
Contractors' pool segment of tools printing	48.3 (moderate and close to extra)	16.4 (moderate and close to extra)

1. The crowd-labor research sample willingness to provide services has the following measurement criteria:
- Extra willingness score from 12 to 16;
- Moderate willingness score from 9 up-to 12;
- Negative willingness score below 9;

2. The crowd-labor research sample readiness to provide services has the following measurement criteria:
- Extra readiness score from 6 to 8;
- Moderate readiness score from 5 and below 6;
- Negative readiness score below 5;

3. The contract-pool research sample willingness to contract AM services has the following measurement criteria:
- Extra willingness score from 50 to 60;
- Moderate willingness score from 40 and below 50;
- Negative willingness score below 40;

4. The contract-pool research sample readiness to provide services has the following measurement criteria:
- Extra readiness score from 17 to 20;
- Moderate readiness score from 14 and below 17;
- Negative readiness score below 14;

The average numbers of the research results show that there are moderate but close to extra willingness and readiness of armatures and hobbyists to serve orders through a hypothetical AM crowd-labor e-platform. They perceive themselves as skilled enough to meet requirements of contractors and possess necessary AT means of production.

On the other side of the potential AM crowd-labor e-market there are two segments of contractors.
One segment of those that print directly end products/components has negative willingness but not exclude trials to investigate the opportunity.
The other segment that use AT as a mean for tools using them in final products manufacturing process is more open and perceive values from the crowd-labor market. Their willingness and readiness are moderate but close to the extra scale range.

4. Conclusions

The conceptual foundations of the research identification show that there is a firm relation among level of automation of means of production, level of their adoption by amateurs/hobbyists, and transformation of labor markets towards crowd based (freelance) type of relations. At the industry of additive technology means of production we see the same trends as exits before in photo, video and graphic design industries where automation and the wide adoption of this means by amateurs transformed labor and structure of supply.

The empirical part of the research reviled disproportions in today's situation between supply and demand sides of the potential additive manufacturing labor-cloud e-market.

The supply side has foundation pool of the enabled amateurs and freelance professionals that are willing and ready to form additive manufacturing labor-cloud e-market.

The demand side for the crowdsourcing (crowd-labor) is represented by two major segments. One use additive technologies to produce tools for manufacturing (non direct production of products and components by AM) and the other segment use additive technologies for the direct production. The former segment is willing to develop supply side on the market by labor-cloud platforms for their benefits as they have sense and methods of the factory gate product quality control. This segment has already opportunity to benefit from extension of agile management application in manufacturing with less commitment into in-house infrastructure, employment, contracting, and keep risks acceptable at the same time in compare with the other demand side segment.

We think that the segment of "direct printing of products or their components" will become more open overtime for outsourcing at AM crowd-labor e-markets along with this markets development by automation of AT means of production and establishment of the mature AM crowdsourcing market with customer reviews and ratings as it happened in digital product industries. Follow-on research is planned to verify this preliminary inference.

Abstract: This paper describes the development process and the pilot use of an ethnography-inspired analysis method to investigate group reflection in group discussions. Reflection is the process of thinking, acting, experiencing, evaluating and analyzing alone or together tied to the surrounding social reality or context. Social relationships are an inherent feature of a group; these relationships refer to group dynamics, i.e. interpersonal processes in and between groups over time. The method is piloted on three lightly moderated microentrepreneur network meetings in Finland. The meetings provide microentrepreneurs with a forum where they get into social interaction with other entrepreneurs. Each meeting provides a single case with a different starting topic. The method development was an inductive and data-driven process. We adapted the double stimulation tool by Vygotsky to the situated event of this study by adding two further steps: analysis of the group reflection and finally the symbolic visualization of the group reflection path. Each case discussions provided a unique road related visualization that symbolizes the discussion flow, directions and process. The main finding of this study is that each case meeting formed a unique group reflection path. The analysis of what, how and why entrepreneurs are talking about topics related to business creates an understanding of how they construct the meaning of entrepreneurship and related factors as part of their culture.

Keywords: group reflection; group dynamics; method development; micro-entrepreneurship; network

1. Introduction

Entrepreneurs are deeply embedded in the society in which they operate (Granovetter, 1985), and the social structure is an intrinsic part of the entrepreneurial process (Dodd & Anderson, 2007). We adopt a practice-based research framework towards the social processes which help entrepreneurs to produce and reproduce the entrepreneurial action (Goss, 2005). The aim of this study is to describe the development process for a novel analysis method to investigate features of group reflection in network group meetings among microentrepreneurs. We do this through an ethnography-inspired analysis of the structure of entrepreneur-centered network meetings, group dynamics in the meetings, and symbolic visualization of the group reflection paths.

The promise of ethnography is increasingly recognized in entrepreneurship studies (Jack & Anderson, 2002; Johnstone, 2007). Ethnography is well suited to capture the ways in which micro-level behavior—including entrepreneurial behaviour—is embedded in the context. We regard networking as an entrepreneurial action (Engel et al, 2017) that can provide a significant source of social support and increase the likelihood of business success (Brüderl & Preisendörfer, 1998). To investigate the everydayness of entrepreneurship action (Steyaert, 2004) in the context of network meetings, the focus of this study is on an ethnographic analysis of the communicative habits of entrepreneurs. The communicative events analyzed are micro entrepreneurs' network meetings in Northern Finland, and these meetings constitute a particular situated event in the macro-context of microentrepreneurship (Figure 1.).

Ethnographic research is aimed at finding out things that are often not seen as important but belong to the implicit structures of people's life. The priorities of the ethnographic research strategy vary (Genzuk, 2003).

The ontology of ethnography implies that language is context itself, and thus part of social structure and social relations. In ethnographic research, language is approached as something that has a certain relevance to humans, and humans' existence is tightly linked, conditioned or determined by society, community, the group and culture (Blommaert & Jie, 2010). Of the several possible factors to be identified in an analysis of communicative events according to the famous ethnographic methodologist Hymes (1964), we chose to focus on the topics and comments that a message may be about, and the events and their characters as wholes. In this study, we followed the ethnographic view of data-driven approach and chose to follow the data that

suggested us a particular theoretical framework, namely the Vygotsky's double stimulation (1978) to be used as an analysis tool.

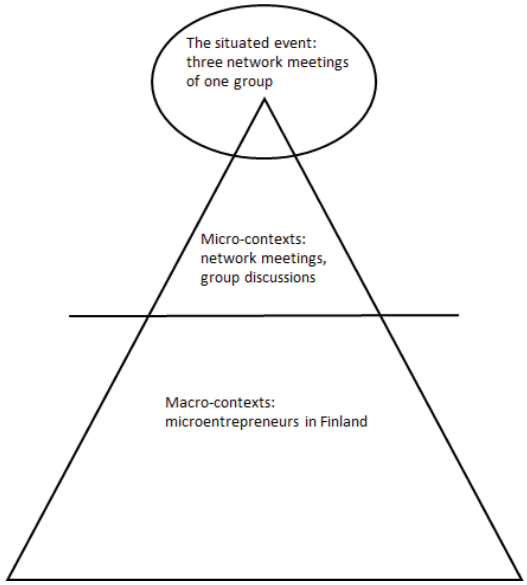

Figure 1: The contextual layers of the present study (modified after Blommaert & Jie, 2010, p. 18)

2. Theoretical framework

The basis of our theoretical framework is related to group reflection and group dynamics. Reflection is the process of thinking, acting, experiencing, evaluating and analyzing alone or together tied to the surrounding social reality or context (Fernandez et al., 2012), and so-called meta-competency (Cheetham & Chivers, 1998) which enables one to reflect and evaluate one's own activities. Seibert (1996) stated that self-evaluation, critical review, analyzing, and learning through experiences are the significant considerations of genuine and realistic self-reflection. In addition, self-reflection helps to increase awareness, understanding, and renewal of various phenomena (Argyris & Schön, 1996; Boud et al., 2006). Kemmis (1985) refers to the communality of reflective action, which is conditioned by the use of language, social interaction and cultural affiliation. In addition, the surrounding environment or context has to be taken into account during reflection (Fernandez et al., 2012).

Moon (2002) argues that reflection is like a mental activity, which creates distance from different tasks, situations and events, and it offers a view to be more objective. Thus, reflection can be seen and utilized as a process, which enables an individual to use his/her, experiences and determine competencies. Further, it is possible to detect new activities and features to promote better and useful decision-making. Reflection can be seen as the opposite to authority-guided and routine activities, which are like barriers to development. Thus, reflection offers a way to observe experiences and to look at them from a removed perspective (Slotte, 2003).

In addition, reflection can be considered as a tool for creating new knowledge, which combines information, emotions and action (Ståhle & Grönroos, 2000).

To understand group reflection, one needs to be aware of group dynamics and group as a social unit. As Forsyth (2018) explains, to capture the many nuances of the word 'group' is not possible with one definition. Even so, he describes the group as "two or more individuals who are connected by and within social relationships". This is in line with what Levi (2014) says of people in groups having a connection of some kind with each other. He also states that there is a reason and a goal for a group to exist.

Forsyth (2018) provides a categorization of different varieties of groups ranging from primary groups to social groups and collectives. However, the one that seems most applicable in this study is a social category, i.e. a grouping of people assumed to be similar in some ways but different in one or more ways. The formation of groups can be either planned or emergent (Forsyth, 2018). In addition to this feature, the group formation

model by Arrow et al. (2000) also includes the dimension of external vs. internal forces as the initiators of the group.

By definition, social relationships are an inherent feature of a group; these relationships refer to group dynamics, i.e. interpersonal processes in and between groups over time (Forsyth, 2018). Forsyth (2018) reviews the processes by naming five different interpersonal processes possible in the context of groups: 1) formative, i.e. interpersonal and personal processes making a group of strangers into a true group, 2) influence, i.e. interpersonally effective forces aiming at transforming individuals into a socially coordinated collective, 3) performance, i.e. achieving the goal of the group by uniting members' efforts, 4) conflict, a natural feature of a group, and 5) contextual, i.e. influences of the social and environmental contexts on groups.

3. Data and method

3.1 Microentrepreneurs' peer-to-peer network meetings

The analysis is based on audiotaped group discussions of a microentrepreneur peer-to-peer network with regular meetings in northern Finland. The network provides microentrepreneurs with a forum where they get into social interaction with other entrepreneurs, and find new solutions to the development challenges of their businesses. The implementation of the network events takes place as follows: the network is coordinated, and the research team at the host company's premises facilitates the meetings (Hänninen, Jokela, Kotavaara, Saarela, & Muhos, 2017). The host entrepreneur chooses the starting topic of the event. In addition, representatives from public business advisory services are invited to the meetings. Free discussion and exchange of experiences around the selected topic is the most important part of the event. The main goal of the concept is to provide the entrepreneurs with new ideas and help them find new ways to develop their own businesses. From the viewpoint of research, these entrepreneur-centric and lightly moderated entrepreneur meetings provide a unique access to naturally occurring data on the discursive practices of entrepreneurial processes, which is hard to access as a researcher.

A total of 23 individual entrepreneurs, six business advisors, four researchers and one journalist participated in three different meetings over a three-month period (Table 1). Only one entrepreneur participated in all three meetings.

Table 1: Individual participants in each meeting

3.2 Method development process

The number of scientific methods has increased and at the same time their boundaries have been blurred. Blurring is related to cultural research that has brought looseness to empirical research and interpretations of various data (Matikainen 2008). Thus, Feyerabend (1978) and Eskola (2003) emphasize the openness to various ways of obtaining data, developing methods and doing research. We approached group reflection with an open mind and from a fresh perspective. In line with the ethnographic approach, the analysis was initiated inductively without any fixed preconceptions about theoretical frames.

The authors re-read the transcribed group discussions several times. We started the analysis by identifying the main topic of the meeting. Then we followed the path of discussion by identifying the consequential topics.

Quite soon, we noticed that the paths could be visualized as symbols such as different kinds of roads. At this stage, we found that double stimulation, an analytical tool developed by Vygotsky (1978) appeared to be applicable to this context. The tool has previously been applied to learning, management and organizational development. The original tool is based on two interrelated stimuli. The task (or learning challenge) acts as the first stimulus and solving it is the second stimulus. In the context of the present study, the first stimulus (Step 1) is the topic of the meeting that the participants reflect individually prior to the meeting based on their personal experiences and expectations (see Figure 2). The host entrepreneur has chosen the starting topic and the participants are informed of the topic beforehand. Thus, the participants do not necessarily have any personal experience related to the topic and they start reflecting it first by themselves prior to the meeting and deepen the reflection while discussing in the group. The second stimulus (Step 2) is the reflective group discussion where new topics are introduced and the discussion flows from the starting topic onwards depending on the group dynamics, preconceptions of the participants, and introduction of new topics. The double stimulation tool is based on interaction between the first and second stimulation. Participant may have ideas and images on the topic beforehand. During the discussion and group reflection topics may remain unchanged or change; the participant continues invisible dialogue with him/herself and with the group.

The two first steps are regarded as the reflection stage where the reflection path remains invisible (latent) to the participants. To progress towards the manifest presentation of group reflection path, we adapted the tool to the situated event of this study by adding two further steps: analysis of the group reflection (Step 3) and symbolic visualization of the group reflection path (Step 4). In Step 3, the researcher analytically follows the discussion and observes whether the discussion proceeds with the starting topic or whether the flow moves to other topics, or if the discussion is glued around (a) certain topic(s). The symbolic visualizations of three group discussions are presented in the Findings section.

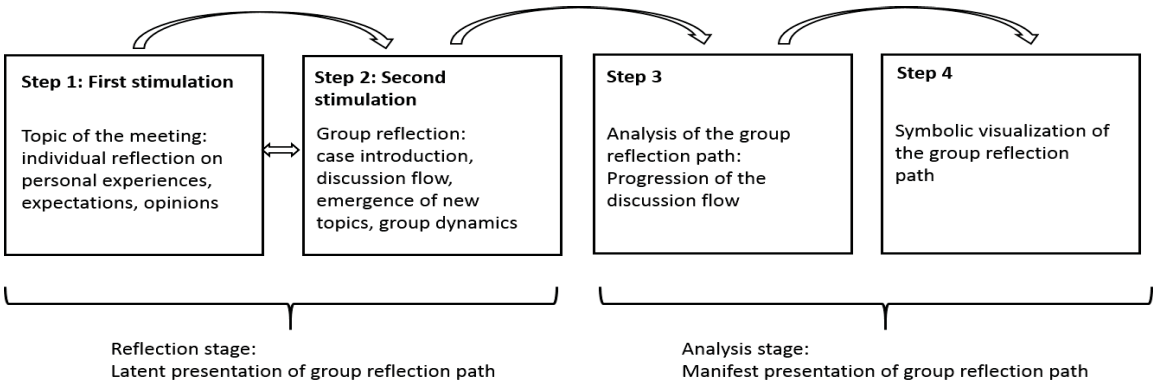

Figure 2: Four steps of the group reflection path analysis inspired by Vygotsk's (1978) double stimulation

4. Findings

4.1 Case 1: Active sales and staff commitment

First stimulation: Case meeting 1 took place in December 2015. Eleven entrepreneurs, two business advisors and four researchers (facilitators) participated in the meeting. The topic chosen by the host entrepreneur was "Active sales and staff commitment". The group had gathered to their first meeting approximately half a year earlier, so at least some of the participants had met each other before.

Second stimulation: The meeting was started by introducing the topic of the evening. As can be expected, there were two principal topics in the evening; active sales and staff commitment. For the most part, these were discussed from the perspective of the host company. Numerous dimensions came up in relation to the topic of sales such as sellers, means of making the company known, methods of marketing and ways to simplify the sales process. Additionally, the host company has an unconventional company structure, as the employees jointly own the company. This was discussed at length, and it was seen as one way to enhance the employees' commitment to the company. Apart from these two topics, a couple of others were briefly covered. These include for instance projects from the viewpoint of companies, entrepreneurs' well-being and products of the host company.

Analysis of the group reflection path: The discussion began with the host company presentation and proceeded to three major topics. The flow was not straightforward but the path zigzagged between a couple of topics several times. Later the discussion returned back to the host company, and at the end of the meeting, the discussion flew more freely in a small talk manner.

Symbolic visualization: The form of the discussion in Case 1 is symbolized as "a main road". There are a limited number of minor crossing roads where the discussion from time to time turns but returns back to the main road of sales and employee commitment. The width of the road is moderate as crossings to the side roads prevents a very deep reflection process.

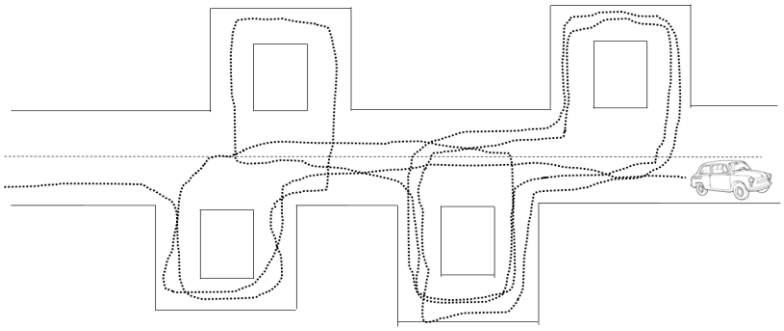

Figure 3: Symbolic presentation of the group reflection path in case 1: Main road

4.2 Case 2: How to find professional workforce?

First stimulus: Case 2 took place in January 2016. Seven entrepreneurs, three business advisors and three researchers participated in the meeting. Two of the entrepreneurs also participated in case 1. The topic was "How to find professional workforce?"

Second stimulus: The discussion was tightly focused on the host company's needs. Participants tried to solve the host company's problems together. The approach was problem-based and it led to a discussion that circulated around the host company. The host company was given many advice and anecdotal examples of participants' personal experiences.

Analysis of the group reflection path: The form of the discussion could be symbolized as urban streets. The discussion circulated around the host company during the whole meeting and the discussion never actually reached a deeper conversation level. During the discussion, many short openings were made to lead the discussion towards a new track but very soon the focus was back on the host company.

Symbolic visualization: The symbol of the group reflection is “urban streets”. The discussion rotated several times around the same topic and the host company. The reflection paths form a zigzag-like pattern that follows the same streets several times and does not really proceed far from the starting point. The streets are narrower than in case 1, because the reflection remains rather case-specific.

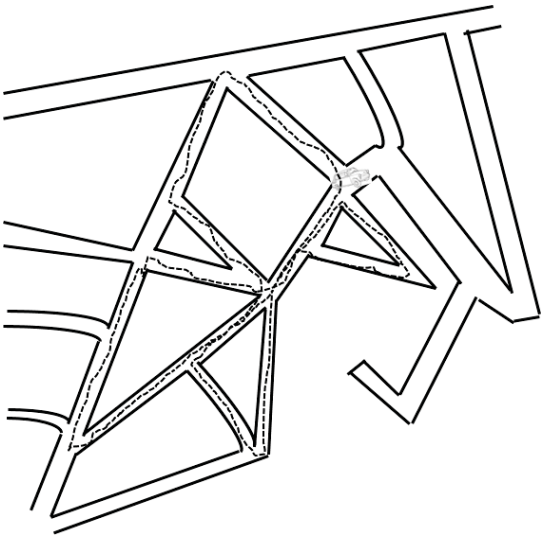

Figure 4: Symbolic presentation of the group reflection path in case 2: Urban streets

4.3 Case 3: Co-operating with media

First stimulus: The topic of the group meeting was ´cooperating with media´ (meaning mainly cooperation with newspapers and journalists). Besides the host entrepreneur, there were eleven other entrepreneurs, four business advisors, three researchers and one journalist. The meeting took time two hours and the location was the host entrepreneur´s company.

Second stimulus: Firstly, the conversation spins on company affairs and its media visibility. The company had previously been involved in a TV format and the participants wanted to know how the role played on the TV had affected the company's business. The next phase of group discussion can be described like reading a yellow press in highway´s service station; the conversation was like small talk with humor overwhelmed. The topic of evening was not posted at all. The third and last phase followed a smooth process.

Analysis of the group reflection path: The group had a multidimensional and profound discussion, and it proceeded fluently like a process from one topic to another, but they profoundly covered the theme of the evening.

Symbolic visualization: The symbol is a highway where the route is straight with very few crossing streets. The symbol refers to a long road, giving a relatively fast connection between two places. The road is wide symbolizing the depth of reflection.

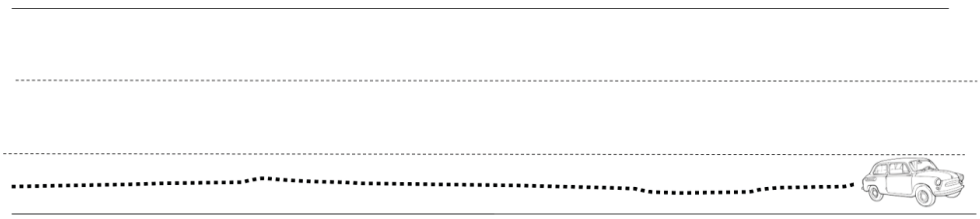

Figure 5: Symbolic presentation of group reflection path in case 3: Highway

5. Discussion

Developing a novel research method is challenging and takes time. However, it is justified if the methods developed earlier do not provide enough scientific answers to the phenomenon to study. In our case, we recognized the need for an analysis tool that could be used to analyze and visualize the process of reflection in

group meetings. After the ethnography inspired inductive data-driven analysis phase, the double stimulation tool of Vygotsky (1978) felt applicable as the theoretical framework for the development of a novel approach to analysis.

The symbolic visualization shows that the group reflection paths in the three case meetings were different. Case 3 was quite straightforward and processual from the starting topic towards a deeper reflection ("highway"). The majority of the participants were active in the discussion and our impression is that the discussion helped entrepreneurs to reflect the topic more thoroughly. On the other hand, cases 1 and 2 were more meandering and the conversation zigzagged between the main topic, host company, and other topics.

The discussion never really proceeded from the starting topic and the host company, but returned or rotated around it throughout the meeting. As opposed to the original purpose of the meeting concept, the discussion was not raised to a more generalizable level, which the majority of the participants could relate to and use it as part their business development. Our impression is that the general depth of reflection remained lower in cases 2 and 3 than in the "highway" structured case 1 where the discussion progressed from the starting topic towards a deepened reflection.

This study indicates that although the meeting concept and its principles are the same in all meetings, the group reflection can be very different in various occasions. As Cheetham & Chivers (1998) point out, reflection is working when individual has ability to reflect his/her thoughts and actions as well as to combine them to the context and the surrounding environment (see also Fernandez el al., 2012). For example, in case 3 the meeting flows like a planned process and as Kemmis (1985) argues, the social interaction and cultural affiliation play a significant role in the group reflection and the sense of community. On the other hand, the two other cases straggle and flow back and forth without any clear process. This could partly depend on the first stimulus, namely the topic of the meeting. In particular, the starting topic in Case 3 is very limited and clear. Since the reflection was visualized as a highway, the participants got further from their preconceptions during the discussion. In case 1, the starting topic was a mix of two loosely linked topics. The reflection did not really proceed but rotated around the starting topics and other topics back and forth. To summarize the findings, the group reflection was richest in case 3 because the discussion was very deep and it offered a way to learn (Moon, 2002; Ruohotie, 2002). If the discussion only circulates around the case company and its operations, the group reflection remains vaguer than if the topic is common and recognizable to everyone.

The group in this study is the same but the individuals in each meeting vary. The number of entrepreneurs in meetings varied from seven to twelve. Only one entrepreneur participated in all meetings. Our analysis is purely based on the transcribed discussions and not on entrepreneurs' own perceptions so we can only speculate about the reasons. In all likelihood, one explanation is the long distances which can be up to almost 100 km between the meeting locations. Still, the chosen topic is also important. As an individual's work and work-related topics are guided by a person's interests, activity, understanding, and professionalism (Cheetham & Chivers, 1998) as well as opinions and principles (Rampersad, 2004), personal interest towards the starting topic is likely to play a role in how engaged entrepreneurs are in each meeting.

In any group, there are interpersonal forces, which influence the members' actions. The group dynamic polarized clearly in the case meetings: in the course of discussions, there were noticeable followings of other participants when participants concentrated on a certain topic for a longer time. Although agreeing comments dominated the discussions, occasionally some participants even challenged other entrepreneurs' views. The tendency for conflict processes is a natural feature of a group (Forsyth, 2018). Although the concept of the case group can be regarded as a mutually supportive group (Forsyth, 2018), the questions posed to others were mainly technical and company-specific and did not relate to emotions or more general views on entrepreneurship. It seems that the group was still on the forming stage: the participants did not know each other very well and thus the trust had not yet reached a level where they would raise matters that are more personal.

6. Implications

6.1 Practical implications

According to Blommaert and Jie (2010), most cultural and social behavior is performed without active reflection or awareness; consequently, people cannot necessarily put it in words if being asked about it. The

analysis of what, how and why entrepreneurs are talking about creates an understanding of how they construct the meaning of entrepreneurship and related factors as part of their culture (Selden & Fletcher, 2015). We argue that this language-based analysis method is useful in gaining an understanding on how entrepreneurs internalize topics related to business. The main finding of this study is that each case meeting formed a unique group reflection path. Group facilitators cannot assume that each evening follows a certain structure although the concept and principles are the same. Setting the topic starts the individual reflection process, but ideally, the reflection is deepened in the group during the discussion. Meeting facilitators should be trained beforehand in order to consider this and ensure that all participants are involved in the reflection. In addition, from the perspective of group dynamics and trust formation, discussion about other issues than strictly the topic of the event can be important in a new group.

6.2 Research implications

In ethnographic research, theory is the outcome of theorization of the data. The three cases presented in this pilot study are a part of a large database. After analyzing more cases, we will be able to state whether it is possible to identify some recurring symbolic representations in the reflection paths or whether they are all unique. We will also combine the group reflection paths with more content-focused analysis to investigate how entrepreneurs reflect various topics, how microentrepreneurs identify themselves in relation to larger companies, and what entrepreneurs perceive as the special characteristics of microenterprises. We are also curious to see how group reflection and group dynamics change over time when the participants learn to trust each other.

7. Conclusions

The process of method development led to the preliminary adoption of the tool in three cases of microentrepreneurs' group discussions. The group reflection visualization method is a useful tool to analyze how entrepreneurs reflect selected topics in a regularly meeting peer-to-peer network group. The symbolic visualization can later be combined with a more content-focused analysis of how entrepreneurs reflect these topics.

What Happens when Kids Become Part of the Design Process? Kidz Design Lab Makes Products by Kids for Kids

Tale Skjølsvik[1] and Sverre Steensen[1,2]
[1]Oslo Metropolitan University, Norway
[2]Unikia.com
tale.skjolsvik@oslomet.no
sverre@unikia.com

Abstract: The Kidz Design Lab (KDL) offers a unique way of enabling customers to take part in the design process. It is a lab, a methodology and a brand where kids develop products for kids, which illustrates the inclusion of end users as designers. As the customers themselves develop the product, the methodology emphasizes embedding the customer into the particular setting of the product rather than emphatizing, as emphasized by design thinking. Additionally, the methodology of the KDL extends the scope of the design process and incorporates the development of a business case, packaging design and marketing as well as negotiation with producers and distributors. In particular, the products are sold based on a presentation of the prototypes to distributors, rather than the final product. This enables KDL to severely reduce risk for the owner of the product as well as shorten the process from an initial idea until the product is in the store. Based on the documentation of the design process using a television crew, KDL enables storytelling and personification. The holistic thinking of the KDL has important implications for practitioners in that it shows the benefit of integrating different stakeholders related to product development. It also illustrates the benefit of product developers to develop their process facilitation skills in order to enable involvement of customers. As the product is sold before production, KDL allows for extensive risk reduction compared to traditional product development processes.

1. Introduction

As cost advantages are being eroded, innovation stands out as a key source of competitive advantage for most companies and industries. In service industries, customers are often active co-creators, while for physical products they have mostly played a passive role as participants in focus groups. Customers have largely been central in defining needs and problems, which form a basis for new products and services, and in testing. This paper explores how customers can be co-creators in the entire development and launch process related to a physical product. In particular, Kidzdesignlab.com takes a fresh perspective on the involvement of kids in the development of real products. It is a lab, a methodology and a brand where kids develop products for kids.

Thus, this paper presents the methodology and a case analysis of what happens when the end user becomes the designer.

The purpose of this paper is to present the lab and explore its design methodology. In particular, documentary material is analyzed, the case described and the KDL methodology distilled. The paper presents an overview of the concept of the Kidzdesignlab.com, relates the concept to design thinking, and aims to show how the design methodology used in the lab adds to our current understanding and conceptualization of design practice from a design thinking point of view.

2. Theoretical background

Design thinking came out the design company IDEO (Brown, 2008, 2009) and has over the last 10 years developed into a key perspective in innovation and management theory – and gained interest in education (Johansson-Sköldberg, Woodilla, and Çetinkaya, 2013; Benson and Dresdow, 2014). Design thinking takes a human centered design ethos, which includes "a thorough understanding, through direct observation, of what people want and need in their lives and what they like or dislike about the way particular products are made, packaged, marketed, sold, and supported [Brown, 2008: p. 87]. It assumes that design should be involved in the big picture of society, that the design process is a collaborative effort spread among diverse participating stakeholders, and that ideas need to be "prototyped," and tried out early in the design process. Design thinking typically involves 3 main stages: inspiration, where information is collected, ideation where ideas are developed and implementation where solutions are tested and evaluated.

Design thinking forms an important basis for the education at Stanford University (Johansson-Sköldberg et al., 2013)[i], where they have developed the methodology into 5 steps to detail the process: Emphatize, define, ideate, prototype and test. In emphatizing it is about doing interviews, shadowing and developing a non-judgemental understanding of the problem, product or service at hand. In working on the defining phase, personas – typical persons from the understanding of interviews and shadowing - is developed. Key issues that are treated are role objectives, decisions, challenges and pain points. As a last stage of ideation, priorities and selections are made. As the ideas have been prioritized, mock-ups and storyboards are developed. The point is to fail and iterate fast. Finally, testing is done to see what works and not, and adjust. These steps are not linear and might take an iterative form depending on the insights gained as one moves along the path of the design process.

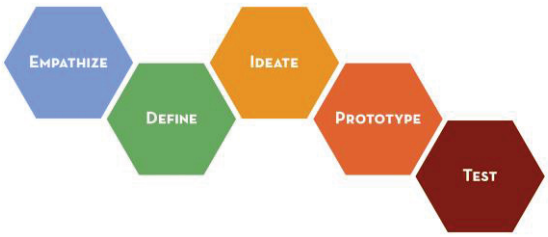

Figure 1: Overview of Design Thinking process, Stanford University Design School.

The key assumption in design thinking is that the designer owns the process, collects the data and is in charge. Limited research has been done to integrate the customers further and let them be in charge of the process, with the support of the designers. This paper takes such a position and develops a complementary perspective on design thinking. In particular, the paper asks: *What does the design process look like and what is the role of the customer under conditions of high customer involvement?*

3. Methodology

To develop an understanding of a case of high customer involvement in a design process, an inductive, qualitative research approach was used (Glaser and Strauss, 1967; Langley, 1999). In particular, a single extreme exemplar case study was used (Eisenhardt, 2007; Yin, 2017). The research was done based on the case of the Kidz Design Lab (www.kidzdesignlab.com) in Norway. The Kidz Design Lab (KDL) is a concept where kids between the ages 8 til 13 years old develop products for kids with the help of professional product designers (PPDs). The concept was developed in 2016 by a serial entrepreneur[1]. The main idea of the KDL is to involve kids in the whole product design process – from a decision to target a product category - until the product is present in the shelves of a distributor. The concept has been run for three different product segments during 2016 and 2017: kitchen, school and cleaning. In each of these segments, 6-7 product categories have been reinvented based on the perspective of the kids. For example, within the kitchen segment, the following products were targeted: frying pan, casserole, mixing bowl, knives, stool and heat gloves[2]. The process through which the products were made was filmed in full and an edited version is available online at https://www.facebook.com/kidzdesignlab/.

Each round of the KDL starts with the establishment of a co-operative partner, and the invitation of 50-60 kids to register for an audition. 6-7 kids are then selected to be part of the product development process. The remaining kids are included as test pilots that test prototypes and the final products. The kids selected for the lab find or are given a problem or product to work on. In turn - with extensive support from the PPDs that are part of the lab – the kids come up with ideas and prototypes. The prototypes are in turn developed into products that are sold to distributors, and launched to end customers within 40 weeks of the first audition.

Kidzdesignlab.com is now in its third season and more than 15 products have been developed, of which 10+ products have been launched into the market.

[1] The second author on this paper.
[2] Details on the products can be found here: https://kidzdesignlab.com/collections/all

All the work that has been done in KDL has been documented by Monster, a reputable and well known production and television company in Norway[3]. For each of the three series, Monster had a total of approximately 100 hours of footage. This documentation has been edited and made into a series of short films (5-10 minutes) that has been used as data. This data has been used to map out the design process and the role of the kids in each stage of the process. Additionally, interviews have been done with 3 of the kids, the entrepreneur and the key product designer involved in the series. The interviews were transcribed in full.

The data was analyzed in three phases, following the process of Gioa, Corley, and Hamilton (2013). In particular, in the first phase, all the films were seen through for familization by the first author. Secondly, an informant-centric approach was taken to understand the process and the role of the kids across the different phases of the process based on the participants descriptions. The outcome of this work was the write-up of a process description. As a final phase, a research-centric approach was taken, where the process was compared to the process described in design thinking to look for similarities and differences. The initial analysis was done by the first author, and this process was in turn reviewed and validated by the second author, which has first-hand knowledge of the case.

4. Findings

The design method of the KDL can be described in 9 main phases. Each of these phases are described below and summarized in Table 1. While not part of the design process as such, KDL is initiated based on an audition. During the audition, the kids test the products and try to understand what the limitations are for them as kids, when they are using products typically designed for adults. Thus, all the kids functioned as a focus group, and the insights from all the kids were leveraged to develop ideas for new products.

In the ideation phase, the kids primarily developed prototypes as a way to capture their thoughts. A traditional ideation phase did not seem suitable for the kids. Rather, going straight to the physical material and building prototypes seemed much more effective. Thus, the kids were testing and ideating at the same time. The prototypes were developed by the kids with the support from the professional product developers (PPDs).

After the prototypes were developed, the kids that came for the audition and wanted to were brought in as test pilots, offering their reactions and advice related to the products. In this stage, the kids took center stage and revised the products based on the comments that they got. In turn, the PPDs developed final prototypes in co-operation with potential factories. The kids were not involved in this more technical process.

After this technical process, the business developers related to the KDL developed a business case for each of the products, in some cases in discussion with the kids. In turn, the kids had to present their product and key numbers related to the business case to the board. The board then decided if the product would be accepted. All products were accepted, and this was more of a learning experience for the kids, than a real decision gate. Still, the kids did not know this, were nervous and prepared hard for the presentation.

After getting their products accepted by the board, the kids had to negotiate and discuss each product with the selected factory. This was also for the major part a learning experience and facilitated by the business developer at Kidz Design Lab.

Having done the presentation to the factories, the process was taken back to an ideation stage to work on the packaging of the product. This was done through a workshop facilitated by PPDs. The kids developed their own packaging solution in practice with the support of the professional. In turn, the packaging was prototyped and tested by the professional.

Before putting the product into production, the kids had to sell the products to the distributers, which was an important to enable distribution and for marketing. The business developer had arranged the meetings, but the kids themselves were presenting each of their products for the distributor to evaluate. Again, this was done more as a learning experience, but the meeting was realistic, and the kids worked hard to get their product into the assortment of the distributor.

Table 1: Overview of the design process of Kidz Design Lab

Quote	Phase name	Description	Role of kids	Phase in design thinking	Added insight
"My arm was hurting – I think I can make something better that make it easier for kids to do it." Selma, 9 years old	1) Testing of existing products	Understanding strengths and weaknesses	Primary actor	(Emp-hatize)	Actual kids as personas. No shadowing needed. Embedding over emphatizing.
"If you see that plasticine – It is to make the edges smoother and to make it easier to get into the frying pan." Emma, 10 years old	2) Proto-typing	Developing ideas; Prototyping and doing 3D design	Primary actor; 3D modelling done by professionals	Ideation, Proto-typing and testing	The kids easily developed crude prototypes. That was their way of ideating.
"You need some rubber on the handle of the knife so it does not fall down." Camilla, Test-pilot, 9 years old.	3) Testing	Testing of prototypes by a panel of kids	Primary actors	Testing	The kids on the test panel had massive amounts of insights that enabled further development of the products.
"Now, we will work with the producers and develop the product somewhat more so it can be presented to the board." Tom, Designer	4) Final prototyping	Final prototypes and 3D models developed by professional product designer (PPD).	Kids help summarize results from testing.	Proto-typing	There is no need to involve the customers in the technicalities of the product.
"The board has decided to invest in this product – we believe in you and the product". Sverre, Chairman of the Board, Kidz Design Lab	5) Business case	Business case for the product developed by professional business developer (PBD)	Kids present the product to a board	Imple-men-tation	The kids as enthusiastic promoters of the products.
"We think the price for the products is a little high. How can we reduce that?" June, 11 years old.	6) Negotiation	Negotiation with factories	Telephone call to factories; facilitated by PBD		Kids as protector of ethics in factories. Strong negotiators.
"…here there is a hole for the egg-cracker so it does not hurt the packaging." Hellek, 13 years old.	7) Packaging design	Developing a great packaging design.	Participation in workshop. Co-creation with a PPD	Ideation	Packaging expert as facilitator. Packaging as separate design process.
"If we are to take in your product something else that we has in our store needs to be taken out." Representative, distributor.	8) Marketing	Developing a PR and marketing strategy/sell product to distributors	Kids presented to distributors; facilitated by PBD	Imple-mentaton	The kids as primary persons representing the products.
"*The answer to what we [Norway] are to live off after the Oil is just what you have been part of right now."* Thorbjørn Røe Isaksen, Norwegian Minister of Knowledge at Launch.	9) Launch and post introduction initiatives	Formal launch of the product; Visit shops that sell the products/ communicate with end users	Primary actor; Facilitated by all stakeholders of the Kids Design Lab		Kids as owners of ideas and products.

The final part of the process was the launch of the product into the market, which included a launch party as well as a presentation of the products to end users in store of the distributers selling the products. In this phase, the kids were shown as the designers of the product.

5. Discussion

Kidz Design Lab (KDL) offers a new perspective on design, which is more comprehensive compared to existing conceptualizations following a design thinking perspective on design theory. Figure 2 gives an overview of the identified process. Building on this process, The KDL offers 5 key additions and insights compared to existing design thinking:

1. The scope of the process is broader than what is assumed in existing design thinking;
2. the involvement of the customer is more extensive then proposed by existing processes;
3. a separate ideation phase is offered for packaging;
4. products are sold before they are produced; and

5. the documentation and communication of the process represents a key part of the marketing – which is also part of the process.

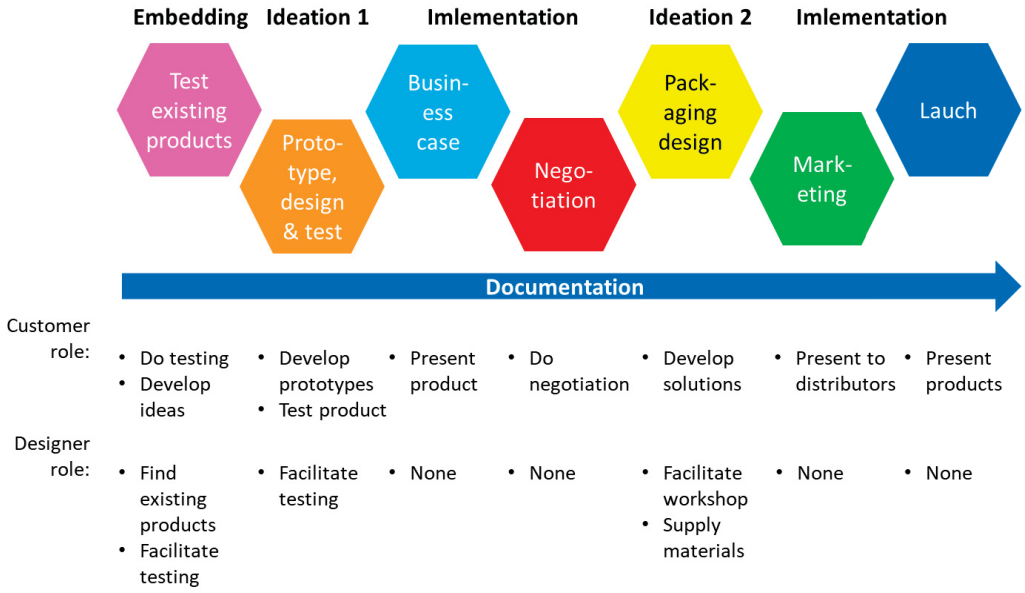

Figure 2: Kids Design Lab Process Overview

Design thinking involves a relatively narrow design process in which the key focus has been on development of a product or service [1], and much less emphasis has been put on the related initiatives that needs to be put in place to enable a product to be used and valued by customers. KDL offers such a broader perspective – including a number of activities that integrates the customer perspective more in depth. An overview of these additional process steps are shown in Figure 3 on the next page as adjacent bubbles beyond the traditional process of design thinking.

The KDL Methodology involves potential customers into the whole design process. While design thinking emphasizes developing empathy for the user to understand their problems (Brown, 2008), the KDL moves the customer to the centre of the product development process. As shown in figure 2 the customer in fact does more of the job related to the product compared to the designers. In every step of the process, the safety and wellbeing of the kids were however a top priority. The kids only worked with materials and methods appropriate for their age, and under strict supervision by the professional product designers.

The relevance, importance and functionality of packaging is recognized in the methodology and given special attention after a prototype of the product has been developed. In particular, the process reverts to the ideation phase for packaging after prototyping.

An interesting insight from the process is that the products are sold before they are actually produced. In particular, the products are sold based on a presentation of the prototypes rather than the final product. This enables KDL to reduce product risk and the need for financing during the product development process. Additionally, it enables a shorter time span from a product development initiative is initiated until a product is in the store.

Finally, the KDL enabled the development of the story related to every developer. Through documenting the process through film, the story becomes a key feature of the product. Thus, it enables storytelling and personification, which is often difficult to achieve for physical products. This story forms the foundation for the marketing of the product.

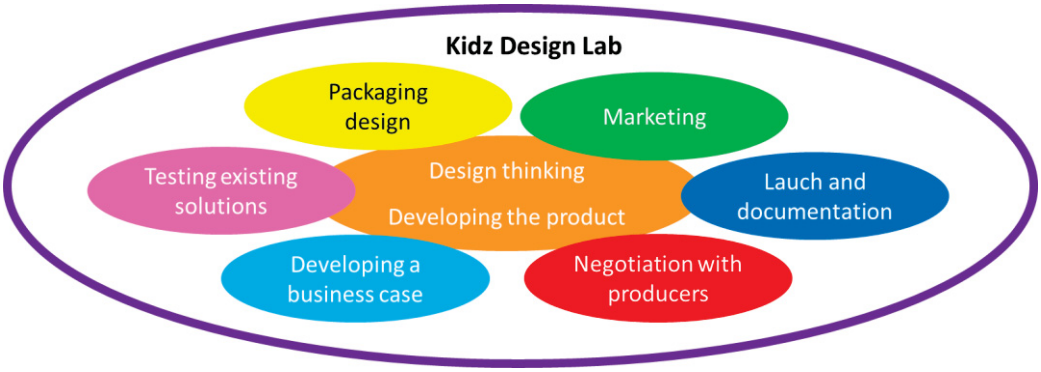

Figure 3: The scope of Kidz Design Lab

6. Conclusion

The KDL methodology represents a new perspective on user oriented product development. Key characteristics of the process concerns the cross-disciplinary approach, the extended scope, the pre-mature product sales and the integration of the design and marketing in the documentation and use of social media.

The holistic thinking of KDL has important implications for practitioners in that it shows the benefit of integrating different initiatives and stakeholders related to any product initiative. It also illustrates the potential for product developers to develop their process facilitation skills in order to enable true involvement of customers. Based on the sales of the product before production, the methodology offers potential for extensive risk reduction and cost cutting. Further, KDL offers interesting opportunities in developing education within product design, innovation and entrepreneurship.

Human Capital, Knowledge and Innovation in the European Union: A Cross-Country Analysis

Iwona Skrodzka
University of Bialystok, Poland
i.skrodzka@uwb.edu.pl

Abstract: Innovation is a subject of great importance for economic growth in developed countries. Researchers throughout the world are studying innovation in great detail, trying to determine the different parameters that influence its levels. Institutions, industry, academia, and governments, along with factors such as R&D, funding, infrastructure, markets, and businesses, have all been identified as crucial to innovation. However, it is human capital that is the most important source of innovation. Not only is human capital the carrier of knowledge but, what is more, it promotes the creation of new knowledge, as well as the adoption of new knowledge. The purpose of this paper is to examine relationships between human capital, the stock of knowledge, and the level of innovation in the EU countries. Research into this kind of dependencies is extremely difficult since the phenomena involved in them are intangible and requires advanced methods from the field of multidimensional analysis. The first part of the paper presents theoretical assumptions about human capital, knowledge and innovative processes. Then, empirical studies are conducted into the construction and estimation of a model describing the relationships between human capital, knowledge, and the level of innovation. The research uses the method of soft modelling developed by Herman Wold. Soft modelling allows users to examine links between variables which are not directly observable (latent variables). The conducted research has demonstrated that human capital and knowledge were important factors of innovation of the EU countries. The obtained results also made it possible to create rankings of the examined countries according to the stock of human capital, the stock of knowledge, and the level of innovation.

Keywords: human capital, knowledge, innovation, soft modelling, European Union

1. Introduction

Innovation is a subject of great importance for economic growth in developed countries. Researchers across the world are studying innovation in great detail, trying to determine the different parameters that influence its levels. Institutions, industry, academia and government, along with factors such as R&D, funding, infrastructure, markets, and businesses, have all been identified as crucial to innovation. However, the most important sources of innovation include human capital and the stock of knowledge available in a given country. The significance of human capital and knowledge for economic growth and development, including innovation-based growth, has been widely discussed by such authors as: Nelson and Phelps (1966), Lucas (1988), Romer (1989), Mankiw, Romer and Weil (1992), Benhabib and Spiegel (1994), Grossman and Helpman (1994), Jones (1995), Benhabib and Spiegel (2005).

The impact of human capital on economic growth is interpreted in two different ways. Firstly, human capital can be introduced as an additional input in an otherwise standard production function, linking aggregate output to the stocks of productive inputs (employment and physical capital) and to an index of total factor productivity. Secondly, human capital can be seen as a determinant of the rate of technological progress, through its interaction with the stock of technological knowledge. This involves specifying a total factor productivity function, which includes both variables related to human capital and R&D stock and an interaction term for these two variables (Teixeira and Fortuna, 2004).

In the Nelson and Phelps' model (Nelson and Phelps, 1966), where human capital and technology frontier analysis was introduced, economic growth is based on the level of human capital as well as on the level of technology improvisation. Countries that are far from technological frontiers could sustain their growth by adapting innovations. However, the speed of adaptation depends on the level of human capital in these countries. Countries that are close to technological frontiers could grow only by introducing innovations and this process is related to the level of human capital. In this model, human capital acts indirectly by increasing the level of technology used, thereby raising productivity (Aleknavičiūtė, Skvarciany and Survilaitė, 2016). More recent studies (in relation to Nelson's and Phel's research) claim that the closer a country is to the technological frontier, the greater the importance of innovation processes for their economic growth and that investment in human capital is more significant for the development of domestic innovations (Vandenbussche, Aghion and Meghir, 2006; Aghion and Darlauf 2009).

The purpose of this paper is to examine the relationships between human capital, the stock of knowledge and the level of innovation in the EU countries. Since the phenomena involved in this kind of dependencies are intangible, research into them is extremely difficult and requires advanced methods from the field of multidimensional analysis. Among such methods is Herman Wold's soft modelling. The method makes it possible to investigate those relationships between variables which are not directly observable (latent variables). The values of such variables cannot be gauged in a straightforward manner because of the lack of a widely accepted definition or a uniform method of their measurement.

This paper proposes the following research hypotheses:

H1a: Human capital is positively associated with the level of innovation in the EU countries.
H1b: The stock of knowledge is positively associated with the level of innovation in the EU countries.
H1c: Human capital is positively associated with the level of knowledge in the EU countries.

The obtained results allowed the author to realise the research objective and verify the proposed research hypotheses.

2. Research method

The soft modelling method (in the literature also referred to as PLS Structural Equation Modelling, PLS-SEM) was developed by Herman Wold (1980). The soft model consists of two sub-models: an internal one (structural model) and an external one (measurement model). The internal sub-model depicts the relationships between the latent variables on the basis of the assumed theoretical description. The external sub-model defines latent variables by means of observable variables (indicators). Indicators permit direct observation of latent variables and are selected according to the assumed theory or the intuition of the researcher. A latent variable can either be defined inductively (with the use of indicators): this approach is based on the assumption that the indicators make up latent variables (formative indicators), or deductively: when it is assumed that indicators reflect the respective theoretical notions (reflective indicators). Under the deductive approach, the latent variable, as a theoretical notion, is a starting point for a search of empirical data (the variable is primary to a given indicator). In the inductive approach, it is the indicators that are primary to the latent variable which they comprise. Both the approaches use latent variables that are estimated as the weighted sums of their indicators. However, depending on the definition, indicators should be characterized by different statistical properties – no correlation in the case of inductive definition and high correlation in the deductive one (Rogowski, 1990).

Estimation of the parameters of the soft model is performed by means of the partial least squares method (PLS). The description of the method can be found in: Boardman, Hui and Wold (1981), Lohmöller (1988), Westland (2005).

The quality of the model is assessed with the use of determination coefficients (R^2), established for each equation of the internal sub-model. The significance of the parameters is verified by means of standard deviations calculated with the Tukey's cut method ('2s' rule: a parameter significantly differs from zero if double standard deviation does not exceed the value of the estimator of this parameter). Also, in the case of the external sub-model, the estimators of factor loadings can be treated as the degree in which the indicators match the latent variable that they define. The prognostic property of the model can be evaluated by means of the Stone-Geisser test, which measures the accuracy of the forecast obtained as a result of the model's application as compared with a trivial forecast. The test statistics take values from the range $<-\infty,1>$. In the ideal model, the value of the test equals 1 (the forecasts are perfectly accurate in comparison with trivial forecasts). When the value of the test equals zero, the quality of the model's forecast and the trivial forecast tend to be identical.

Negative values indicate a low quality of the model – its weak predictive usefulness compared with a trivial forecast (Rogowski 1990).

Using the partial least squares method, it is possible to obtain the estimated values of latent variables, which can be regarded as the values of synthetic measures. They can be employed for linear ordering of the examined objects. These values depend not only on the external relationships, but also on the relationships be-

tween the latent variables which are assumed for the internal model. This means that the cognitive process hinges not merely on the definition of a given notion, but also on its theoretical description.

3. Specification of soft model

The model consisted of the following two equations:

$$INN = \alpha_{11} \cdot HC + \alpha_{12} \cdot KNOW + \alpha_{10} + \xi_1, \quad (1)$$

$$KNOW = \alpha_{21} \cdot HC + \alpha_{20} + \xi_2, \quad (2)$$

where *INN* – level of innovation, *HC* – human capital, *KNOW* – stock of knowledge, α_{ij} – structural parameters of the model (i = 1,2 and j = 0 ,1, ,2), ξ_i – random component.

The latent variables were defined by means of observable variables on the basis of the deductive approach, i.e. the latent variable, as a theoretical concept, serves as a starting point to identify empirical data. The statistical data come from the Eurostat, OECD, and European Innovation Scoreboard (EIS) databases. The indicators for the model were selected based on criteria of substantive and statistical nature. Using the available domestic and international literature, primary sets of indicators were developed. The methodologies used included, among others, "Knowledge Assessment Methodology" (Chen and Dahlman, 2005) and "European Innovation Scoreboard Methodology" (European Commission, 2017). Selection of the research period (2015) was determined by the availability of statistical data. The developed database was checked in terms of missing data. Data shortages were overcome by using naive prognosis, consisting in replacing lacking values with the values for the previous year.

From the statistical point of view, the following considerations were taken into account: variability of indicator values (coefficient of variation above 10 %) and analysis of the quality of the estimated model (ex post analysis). The indicators which passed substantive and statistical verification are presented in Table 1.

The latent variable *HC* is defined by seven indicators. Five of them regard education among population (potential human capital) and the education of employees (effective human capital), and in particular its level (*HC*1, *HC*2, *HC*3, *HC*4) and quality (*HC*5). The indicator *HC*7 refers to health, while *HC*6 reflects the problem of underutilization/wasting of human capital. The latent variable *KNOW* is defined by four indicators. The first one (*KNOW*1) reflects specialist knowledge embodied in the employed population. The second (*KNOW*2) indicates assessment of knowledge quality by external entities (high level of knowledge-based services proves that the assessment of the quality of these services is high, which also shows that the level of knowledge in a given country is assessed positively). The two remaining indicators (*KNOW*3 and *KNOW*4) reflect the quality and efficiency of the knowledge sector. The latent variable *INN* is defined by six indicators. Three of them (*INN*1, *INN*2, *INN*3) reflect the potential and efficiency of innovators, two (*INN*4 and *INN*6) concern cooperation among innovating entities. The indicator *INN5* reflects the inventive and technological achievements of a given country.

Three of the indicators which define the variable *HC* (*HC*5, *HC*6, *HC*7) are destimulants – the lower their values, the lower the level of the latent variable, i.e. the lower the stocks of human capital in a given country. All the other indicators of latent variables are stimulants – the higher their values, the higher the level of the latent variable.

Table 1: Indicators of latent variables

Symbol of latent variable	Symbol of indicator	Description of indicator	Type of indicator	Source of data
HC	*HC*1	Percentage of population aged 15-64 having completed tertiary education (%).	Stimulant	Eurostat
	*HC*2	Percentage of population aged 25-64 participating in education and training (%).	Stimulant	Eurostat
	*HC*3	Percentage of employees aged 15-64 having completed tertiary education (%).	Stimulant	Eurostat
	*HC*4	Percentage of employees aged 25-64 participating in education and training (%).	Stimulant	Eurostat
	*HC*5	Underachievement in reading, maths or science (% of 15-year-old students).	Destimulant	OECD

Symbol of latent variable	Symbol of indicator	Description of indicator	Type of indicator	Source of data
	*HC*6	Young people neither in employment nor in education and training (% of population aged 15 to 29).	Destimulant	Eurostat
	*HC*7	Death rate due to chronic diseases (number per 100 000 persons aged less than 65).	Destimulant	Eurostat
KNOW	*KNOW*1	Employment in knowledge-intensive activities (% of total employment).	Stimulant	EIS
	*KNOW*2	Knowledge-intensive services exports (% of total services exports).	Stimulant	EIS
	*KNOW*3	Scientific publications among the top 10% most cited publications worldwide (percentage of total scientific publications of the country).	Stimulant	EIS
	*KNOW*4	International scientific co-publications (per million population).	Stimulant	EIS
INN	*INN*1	SMEs introducing product or process innovations (% of SMEs).	Stimulant	EIS
	*INN*2	SMEs introducing marketing or organisational innovations (% of SMEs).	Stimulant	EIS
	*INN*3	SMEs innovating in-house (% of SMEs).	Stimulant	EIS
	*INN*4	Innovative SMEs collaborating with others (% of SMEs).	Stimulant	EIS
	*INN*5	PCT patent applications (per billion GDP in PPS).	Stimulant	EIS
	*INN*6	Public-private co-publications (per million population).	Stimulant	EIS

The model was estimated using the PLS method, which enables simultaneous estimation of the external model parameters (weights and factor loadings) and the internal model parameters (structural parameters). The estimation was conducted with the help of PLS software. The software was developed by Prof. J. Rogowski from the Faculty of Economics and Management, University of Białystok and is free of charge.

4. Results of soft model estimation

The results of the estimation of the external model are presented in Table 2. Each weight represents the relative share of a given indicator's value in the estimated value of a latent variable. Factor loadings are coefficients of correlation between indicators and latent variables, thus indicating the degree and direction in which the variability of an indicator reflects the variability of a latent variable. The ordering of indicators according to weights is performed when a latent variable is defined inductively. In the deductive approach, which was applied in this research, it is the factor loadings that are interpreted. The following interpretation of the r_{ij} factor loading was assumed (: $|\pi_{ij}| < 0.2$ – no correlation, $0.2 \leq |\pi_{ij}| < 0.4$ – weak correlation, $0.4 \leq |\pi_{ij}| < 0.7$ – moderate correlation, $0.7 \leq |\pi_{ij}| < 0.9$ – strong correlation, $|\pi_{ij}| \geq 0.9$ – very strong correlation.

In terms of the signs of the estimated parameters, the results are consistent with the expectations. Stimulants have positive estimations of weights and factor loadings and destimulants have negative ones. Moreover, all the parameters are statistically significant, in accordance with the "2s" rule (see table 2, column "Standard deviation").

Table 2: Estimations of external relationships of soft model

Symbol of latent variable	Symbol of indicator	Weight	Standard deviation	Factor loading	Standard deviation
HC	*HC*1	0.1872	0.0032	0.7589	0.0038
	*HC*2	0.2270	0.0020	0.9036	0.0009
	*HC*3	0.1330	0.0037	0.5740	0.0045
	*HC*4	0.2219	0.0017	0.9004	0.0008
	*HC*5	-0.1443	0.0012	-0.6535	0.0011
	*HC*6	-0.1680	0.0023	-0.7077	0.0005
	*HC*7	-0.2382	0.0072	-0.6866	0.0042
KNOW	*KNOW*1	0.2580	0.0007	0.8989	0.0004
	*KNOW*2	0.2351	0.0026	0.8657	0.0012
	*KNOW*3	0.2981	0.0029	0.9376	0.0005
	*KNOW*4	0.3161	0.0058	0.9018	0.0015
INN	*INN*1	0.2043	0.0223	0.9285	0.0470
	*INN*2	0.2083	0.0236	0.8408	0.0252
	*INN*3	0.1922	0.0232	0.9001	0.0381
	*INN*4	0.1735	0.0142	0.7914	0.0164
	*INN*5	0.2026	0.0130	0.7747	0.0237
	*INN*6	0.2074	0.0153	0.8099	0.0204

The latent variable *HC* proved to be very strongly associated with two indicators related to population (*HC*2: 0.9036) and employees (*HC*4: 0.9004) participating in education and training. Apart from this, the variable was strongly reflected by the indicators: "Percentage of population aged 15-64 having completed tertiary education" (*HC*1: 0.7589) and "Young people neither in employment nor in education and training" (*HC*6: -0.7077). Three indicators were moderately correlated with the variable *HC*. The latent variable *KNOW* was very strongly correlated with two indicators reflecting the efficiency of the knowledge sector (*KNOW*3: 0.9376, *KNOW*4: 0.9018). Two remaining indicators were strongly associated with the variable. The latent variable *INN* was at least strongly reflected by its defining indicators.

The outcomes of the internal model estimation are illustrated by the following equation:

$$\hat{INN} = 0{,}2403 \cdot HC + 0.6284 \cdot KNOW + 0.2191 \qquad R^2 = 0.71 \qquad (3) \text{ and}$$
$$(0.0826) \quad (0.0710) \qquad (0.1422)$$

$$\hat{KNOW} = 0.8546 \cdot HC + 2.6909 \qquad R^2 = 0.73 \qquad (4).$$
$$(0.0008) \quad (0.0521)$$

The brackets contain standard deviations calculated by means of the Tukey's test. The structural parameters are statistically significant ("2s" rule). The values of the coefficients of determination R^2 justify the conclusion that, to a high extent, the independent variables determine the variability of the dependent variables. The values of the Stone-Geisser test, which verifies the soft model in terms of its predictive usefulness (see Table 3) are positive, which proves the model's high prognostic quality.

Table 3: Values of the Stone-Geisser test

Symbol of indicator	Value of S-G test
*INN*1	0.4628
*INN*2	0.4478
*INN*3	0.3894
*INN*4	0.3317
*INN*5	0.4138
*INN*6	0.4399
General value	0.4178

The equation (3) indicates a positive and statistically significant impact of both human capital and the stock of knowledge on the level of innovation in the EU countries in 2015. This means that those countries which reported higher stocks of human capital also had higher levels of innovation. Moreover, countries with higher stocks of knowledge had higher levels of innovation in that year. The impact of knowledge was more than 2.5 times stronger than the impact of human capital. The equation (4) shows that human capital had a positive, statistically significant impact on the stock of knowledge in the EU countries in 2015. This means that those countries which reported higher stocks of human capital also had higher stocks of knowledge in that year.

Basing on the synthetic measures of the variables *HC*, *KNOW*, and *INN* which were obtained during modelling, three rankings of the studied countries were created. The results are shown in Table 4.

Table 4: Rankings of EU countries according to the stock of human capital, the stock of knowledge, and the level o innovation in 2015

Country	*HC*	*KNOW*	*INN*
Austria	8	11	5
Belgium	13	7	1
Bulgaria	27	26	25
Croatia	25	25	20
Cyprus	14	9	16
Czech Republic	19	20	18
Denmark	2	2	4
Estonia	9	16	22
Finland	3	8	3
France	7	12	10
Germany	15	10	7
Greece	22	19	13
Hungary	24	21	24
Ireland	10	5	8

Country	*HC*	*KNOW*	*INN*
Italy	23	13	14
Latvia	21	22	26
Lithuania	17	28	17
Luxembourg	4	1	11
Malta	18	14	19
Netherlands	5	4	6
Poland	20	24	27
Portugal	16	18	15
Romania	28	27	28
Slovakia	26	23	23
Slovenia	11	15	12
Spain	12	17	21
Sweden	1	3	2
United Kingdom	6	6	9

The next step consisted in dividing the countries into typological groups according to the stock of human capital, the stock of knowledge, and the level of innovation. Countries classified into a given typological group were characterized by a similar level of the studied phenomenon. The results of the grouping are presented in Figures 2, 3, and 4. The boundaries between the groups were established on the basis of the arithmetic mean and standard deviation of the synthetic measure z_i (equal to 0 and 1, respectively, for each of the latent variables). The groups are as follows: group I (very high level of latent variable): $z_i \geq 1$, group II (high level of latent variable): $0 < z_i \leq 1$, group III (medium and low level of latent variable): $-1 < z_i \leq 0$, group IV (very low level of latent variable): $z_i \leq -1$.

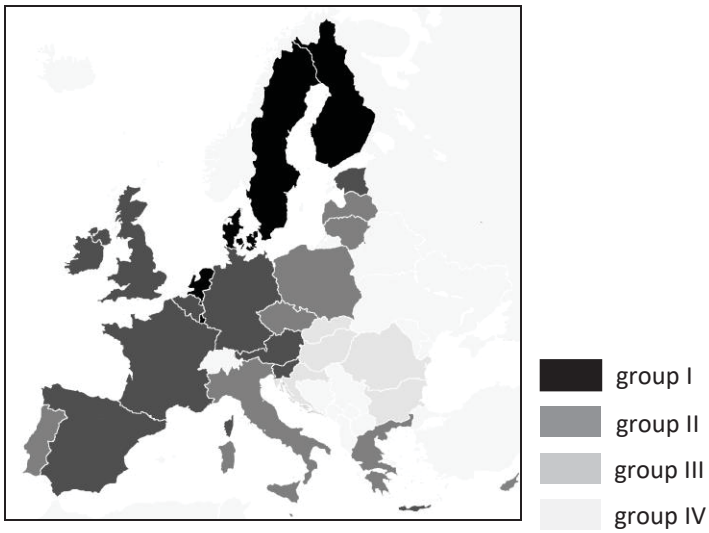

Figure 2: The EU countries according to stock of human capital in 2015

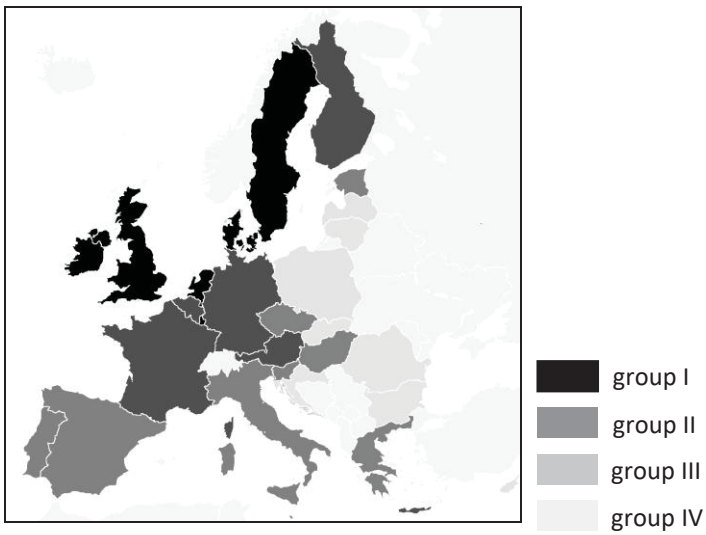

Figure 3: EU countries according to stock of knowledge in 2015

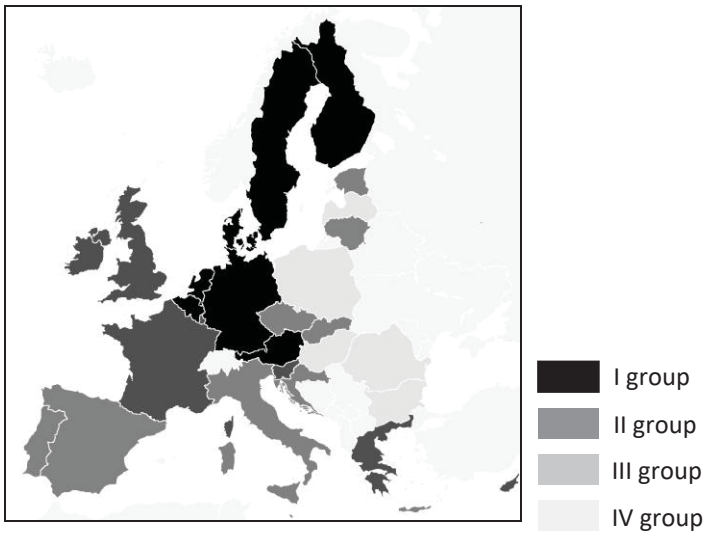

Figure 4: EU countries according to level of innovation in 2015

5. Conclusion

The conducted research leads to the following conclusions. Both human capital and the stocks of knowledge had a positive, statistically significant influence on the level of innovation in the EU countries. Although knowledge was the more important factor, human capital was a very strong determinant of the size of the stock of knowledge. Therefore, human capital also had an indirect impact on the innovativeness of the EU countries as a vehicle of knowledge and an indispensable link in creation and absorption of new knowledge.

This conclustions are consistent with the results of other empirical studies: Dakhli and De Clercq (2007), Aleknavičiūtė, Skvarciany and Survilaitė (2016).

The results of external sub-model showed that education and training were the most important components of human capital. The quality and efficiency of the knowledge sector turned out to be the factor that the most strongly determined the stock of knowledge in a given country. The level of innovation was strongly related to the potential and efficiency of innovators, cooperation among innovating entities and the inventive and technological achievements of a given country. The conclusions formulated above can be used in practice by governmental institutions, for example for planning the economy policy as well as innovation policy of countries.

The obtained results also made it possible to create rankings of the examined countries according to the stock of human capital, the stock of knowledge, as well as the level of innovation. In all of them, the highest ranked countries included: Sweden (*HC*: 1st position, *KNOW*: 3rd position, *INN*: 2nd position) and Denmark (*HC*: 2nd position, *KNOW*: 2nd position, *INN*: 4th position). The countries with the lowest rankings were Romania (*HC*: 28th position, *KNOW*: 27th position, *INN*: 28th position) and Bulgaria (*HC*: 27th position, *KNOW*: 26th position, *INN*: 25th position). The leading position of Belgium in the ranking of innovativeness stemmed from the fact that all the indicators which defined the latent variable *INN* had high values in that country (e.g. *INN*1 and *INN*4 – the highest values, *INN*3 – 2nd value). The results of the level of innovation ranking present very high compliance with the EIS ranking (European Commission, 2017) and high compliance with the Global Innovative Index ranking (Cornell University, INSEAD and WIPO, 2016). Spearman's rank correlation coefficients are 0.89 and 0.77 respectively.

Very high stocks of human capital were observed in the following countries: Sweden, Denmark, Finland, Luxembourg, and Netherlands. The group with high stocks of human capital comprised nine countries: United Kingdom, France, Austria, Estonia, Ireland, Slovenia, Spain, Belgium, and Cyprus. Nine countries were classified as economies with medium and low stocks of human capital: Germany, Portugal, Lithuania, Malta, Czech Republic, Poland, Latvia, Greece, and Italy. Five countries were characterised by very low stocks of human capital: Hungary, Croatia, Slovakia, Bulgaria, and Romania.

Six countries proved to be economies with very high stocks of knowledge: Luxembourg, Denmark, Sweden, Netherlands, Ireland, and United Kingdom. The group with high stocks of knowledge comprised: Belgium, Finland, Cyprus, Germany, Austria, and France. Group III – countries with medium and low stocks of knowledge – consisted of: Italy, Malta, Slovenia, Estonia, Spain, Portugal, Greece, Czech Republic, and Hungary. Low stocks of knowledge were reported by Latvia, Slovakia, Poland, Croatia, Bulgaria, Romania, and Lithuania.

Seven countries made up the group with a very high level of innovation: Belgium, Sweden, Finland, Denmark, Austria, Netherlands, and Germany. The group of countries with high levels of innovation included: Ireland, United Kingdom, France, Luxembourg, Slovenia, and Greece. The third group of medium- and low-level of innovation was comprised of: Italy, Portugal, Cyprus, Lithuania, Czech Republic, Malta, Croatia, Spain, Estonia, and Slovakia. Very low levels of smart growth were recorded in: Hungary, Bulgaria, Latvia, Poland, and Romania.

The Impact of Crowdfunding on Entrepreneurial Value Creation: Differences between Social, Cultural and Commercial-Oriented Projects

Cristina Sousa and Mónica Azevedo
University Portucalense, REMIT, Oporto, Portugal

monicaa@upt.pt

Abstract: The aim of this study is to analyse the impact of crowdfunding in the development of innovative projects related to entrepreneurial value creation in Portugal. Although the literature on crowdfunding is growing, our knowledge in this area is still incipient regarding its impacts on the value creation and on the differences between projects of different nature, namely between social-oriented, cultural-oriented and business/commercial-oriented projects. In this analysis, the divide between social- cultural- and commercial-oriented projects is considered. The empirical research covered the identification and characterisation of the oldest crowdfunding platform operating in Portugal and an in-depth analysis of the entrepreneurial projects successfully funded from the creation of the platforms until 31th December 2016. The results from this study show that the concept of crowdfunding is still little explored in the country, specifically for entrepreneurial commercial-oriented value creation. They also highlight that commercial-oriented projects tend to exceed the target investment in a more marked way compared to the other types of projects.

Keywords: Crowdfunding, social-oriented projects, commercial-oriented projects, cultural oriented projects.

1. Introduction

The concept of crowdfunding has evolved from the broader idea of crowdsourcing, i.e. a decentralized problem-solving and production model, where the online crowd is used to obtain services, ideas, feedback and solutions to develop corporate activities (Howe 2008; Kleeman et al. 2008; Belleflamme et al. 2013).

In the particular case of crowdfunding, the objective is to obtain financing for a project or a venture without resorting to standard financial intermediaries by using online communities, where each individual can participate with a small contribution of the total funding amount (Belleflamme et al. 2013).

Although some authors consider crowdfunding as a relatively new concept (Banhatti 2016; Golić 2014), others recognize that the notion of crowdfunding is not new, going back, at least, to the 19th century (Attuel-Mendes 2014; Beck et al. 2016). Nonetheless this divide, scholars agree on the fact that its usage has intensified in the past ten years or so, namely after the signature of the JOBS Act (Jumpstart Our Business Startup), in 2012 in the USA, that regulates equity-based crowdfunding. Crowdfunding has become effective and available worldwide, and it is increasing rapidly in the last years (Banhatti 2016).

The literature on crowdfunding has also increased in the last years, both in terms of published academic papers and in reports by different types of agencies and associations.

Scholars show that this type of funding can fill the gap in accessing to capital in the early stage creation of an innovative project, when capital needs are higher and traditional funding sources are less receptive (Deffains-Crapsky & Sudolska 2014; Manchanda & Muralidharan 2014).

Despite the growth of knowledge on the process and types of crowdfunding, as well on its role in financing new ideas and projects, there is still a need to go deeper in the understanding of crowdfunding impact on the value creation and on the differences between projects of different nature, namely between social-oriented, cultural-oriented and business/commercial-oriented projects (Bruton et al. 2015; Moritz & Block 2016).

This paper targets this gap, by studying the use of a Portuguese crowdfunding platform – PPL. It analysis the successful campaigns until 2016 and assesses differences between social-oriented, cultural-oriented and commercial-oriented projects.

2. Conceptual background

2.1 Crowdfunding: concept and types

It is possible to find several definitions of crowdfunding in the literature. Golić (2014) considers that crowdfunding is a way of raising money from a quite large number of investors via the Internet and using an open call, so that the entrepreneurs can collect funds to sponsor their projects. Lehner (2013) defines crowdfunding as a procedure of supporting new and original projects. Hooghiemstra and De Buysere (2016: 136) consider that "crowdfunding can be defined as a collective effort from a large number of individuals, who support individual projects and businesses with small contributions initiated by entrepreneurs (SMEs) or organisations".

Medeiros (2015) calls our attention to the fact that the crowdfunding definition can change according to two different sides – the supporter and the promoter. Ordanini et al. (2011) focus on crowd side, by considering that crowdfunding can be described as a phenomenon, in which diverse consumers gather, often by the Internet, in order to finance other people and organisations' projects. By the other hand, Belleflame et al. (2014: 588) highlight the promoters' side, considering that "crowdfunding involves an open call, mostly through the Internet, for the provision of financial resources either in the form of donation or in exchange for the future product or some form of reward to support initiatives for specific purposes".

Regardless of these differences, scholars recognize the growing interest in this kind of financing, as an alternative to the more common sources of finance (Gierczak et al. 2016; Moritz & Block 2016). For example, Banhatti (2016) agrees that crowdfunding is growing as a powerful instrument used by common people to find a different way of sponsoring their new and original ventures outside standard systems. To Mollick and Robb (2016) crowdfunding enables access to financial resources to exploit and disseminate innovative projects to everyone.

Relatively to crowdfunding types, multiple contributions have emerged. Gierczak et al. (2016) consider that crowdfunding types rely on some kind of benefit provided for the sponsors' finance. In fact, some authors underline that one of the most important motivations in crowdfunding is the expected returns that crowdfunders get in exchange for their finance (Hemer 2011; Thürridl & Kamleitner 2016). These returns can be of different types. De Buyser et al. (2012) distinguish three types of returns: social, financial and material.

On the other hand, Hemer (2011) identifies seven types: donation, sponsoring, pre-ordering, membership fees, crediting, lending, and profit-sharing.

According to the type of return, it is possible to classify the type of crowdfunding. Lehner et al. (2015) stress that crowdfunding varies from a simple way of pre-financing to full grown debt or equity investments although they are usually small guarantees that can developed into exorbitant amount of money. Belleflamme et al. (2014) establish two poles: pre-ordering and profit-sharing. However, most authors tend to distinguish four type of crowdfunding: donation-based (crowddonation), reward-based (subsuming rewards and pre-ordering, usually the rewards are a tangible product related to the campaign), capital-based (equity crowdfunding or crowdinvesting) and credit-debt-based (crowdlending) (Belleflame et al., 2015; De Buyser et al., 2012; Gajda & Walton, 2013). Recently, Banhatti (2016) not only considers the existence of these four main models but also highlights the emergence of hybrid models, which combine basic models. In most cases, crowdfunding platforms tend to rely on a single model, but some platforms exploit several models. The most common combination is the reward and donation models on a single platform. Scholars tend to agree that reward-based crowdfunding is the most common, and the most famous platforms, like Kickstarter and IndieGogo, belong to this type.

2.2 Crowdfunding as an instrument to fund innovative projects

Business ideas with a particularly innovative nature have difficulties in access to funding, and therefore face a financing gap, which is due mainly to the existence of market failures. These failures are related to the existence of information asymmetry that complicates the measurement of risk, both for the projects promoters and for the project. Issues of adverse selection and moral hazard arise, which normally represent a greater difficulty in obtaining funding and/or the payment of higher interest rates (Hall & Lerner, 2010). This gap is particularly wide in the case of SMEs (Müller & Zimmermann 2006).

Crowdfunding is a possible solution for reducing this gap. Deffains-Crapsky and Sudolska (2014) found a positive relationship between innovation and crowdfunding. The authors put the emphasis on the funding of radical innovations, which, due to the high degree of uncertainty and the high costs of R&D, face difficulties in financing through traditional financial intermediaries. The authors suggest that the capital-based crowdfunding could be used in a consumer-investor perspective, where the "crowdfunders" analyse the project first in a consumer optics and then decide to invest or not, giving a prediction on the possibility of success of the project. This concept would help to reduce the risk of investment, due to the degree of acceptance that the project could get in the "crowd" and attract future investors.

Manchanda and Muralidharan (2014) argue that enterprises in the start-up phase, when the capital requirements are greater, can largely benefit from crowdfunding. They consider that venture capital institutions, which are very selective, cease to invest in many innovative ideas. Venture capitalist can also profit from the growth of crowdfunding, notably in terms of finding promising start-ups and of accessing all the information that the "crowd" might provide. These authors add that some venture capitalists already invest in crowdfunding platforms or create their own, concluding that the two forms of funding, in the future, will "go hand in hand".

Also Agrawal et al. (2013) claim that crowdfunding is causing a change in the way of raising capital and increases the total amount of funding available for new innovative ventures. As an example of success, they refer to the innovative design of the "Pebble" Watch, which through the crowdfunding managed to raise in just 2 hours 100,000 dollars and closed the campaign 37 days later with more than 10 million dollars, collected from almost 70 thousand people, being considered one of the major successes in the history of Kickstarter.

The difficulty of obtaining funding for innovative projects tends to be higher when the project has a social nature. As social projects prioritize social change above private wealth creation, this can create tension in the application of resources: being economically viable while in pursuit of a social mission can impose tension on the available resources (Doherty et al. 2014). Therefore, access to funding can be a higher challenge, when compared to business/commercial-oriented projects.

Projects targeting social innovation envisage “novel ideas that create value which are social in both their ends and their means” (Murray et al. 2010: 3). Social innovations can be defined as new products, services and models that have been developed to meet social needs (Mulgan et al. 2007). These projects can have a major impact to communities and societies, by adopting business models to offer creative solutions to complex and persistent social problems (Zahra et al. 2009).

Thus, social-oriented project are often related to social entrepreneurship or social enterprises. Even though there is no single agreed upon definition of social entrepreneurship, one key ingredient is present in all of the definitions: the striving for societal goals (Austin et al. 2006). Social entrepreneurs have an ambition that goes beyond pure economic reasoning. They look for societal value-added and combine societal goals with entrepreneurial attitude.

Still the benefits of crowdfunding go beyond the access to financial resources, and include aspects like: use the campaign as a marketing tool, attract attention to the project even after the campaign’s conclusion, obtain genuine feedback on the idea and improve it during the process, advertise "niche ideas", and turn investors into loyal clients (Manchanda & Muralidharan 2014).

2.3 Factors affecting the success of a crowdfunding campaign

Crowdfunding platforms are online sites linking project promoters/fundraisers and project supporters/funders. The promoters are those who, through a campaign, intend to obtain funding and the funders are those who invest financial resources in the project (Gerber & Hui 2013). The fact that any person or entity can easily become a funder but specially a promoter has allowed the rapid mediatisation and growing of this type of funding.

To obtain the necessary funding, and therefore to have a successful campaign, the promoters, through the platforms, publish the idea/project/experience, describing the objective, a short history, how the investment will be applied, among other information. In this sense, the campaigns made available by promoters are similar to products/services/experiences. In the case of reward-based crowdfunding, the campaign is

successful when it reaches the goal. Usually reward-based platforms use an "all-or-nothing" mechanism, meaning that the promoter must pay back all the money if the campaign fails, but the total funding can exceed the initial goal.

Mollick (2014) identifies some success factors of crowdfunding campaigns based on the analysis of donations and reward platforms. The results of the study indicate that the quality, the geography and meeting deadlines are decisive factors of success, as well as the social relations of the promoters. The author also considers that the project's innovative component of value creation will increase the interest of investors, to the extent that this represents a quality factor. In this way, innovative projects are most likely to be successful in attracting the interest of the crowd and in obtaining financing.

Previous studies have found mixed evidence regarding the relation between the number of supporters and the success of the project. While Kim et al. (2015) found no significant relation between the two variables, Robertson and Wooster (2015) found a negative impact of supporters in the first day of the campaign on its success. This last study also found a positive impact of the number of Facebook shares on the campaign success.

Medeiros (2015) identifies the success factors of crowdfunding campaigns in Portugal, stressing the role of campaign quality, platforms effort and supporters' encouragement as essential to achieve the success. Then, based on information available in platforms, the author lists the following factors as the means to guarantee a well-succeeded campaign: transparency, divulgation, presentation, enthusiasm, monitoring, personalization and counterparts.

3. Empirical setting and data

3.1 Crowdfunding in Portugal

Crowdfunding arrived to Portugal in 2011, through the creation of four different platforms: PPL, Massivemov, Redebiz and Zarpante. In 2012, three new platforms have appeared in the country: Novo Banco Crowdfunding, Olmo, and Crowdfunding Networks. The difficulty faced by firms in getting initial funding for projects (namely start-ups) and the financial crisis may have played a crucial role to crowdfunding market expansion (Medeiros, 2015; Brüntje & Gajda, 2016).

Notwithstanding the creation of several platforms in 2011 and 2012, crowdfunding did not grow in Portugal as fast as in other countries and some platforms cessed their activity. The PPL and Novo Banco platforms continue to operate (see Table 1) and its activity is similar to the large global platforms like Kickstarter or Indiegogo, based in the reward-type of crowdfunding. Novo Banco is only dedicated to social projects and covers reward and donation types.

More recently, other types of crowdfunding platforms have been created. One of these platforms is Raize that, despite the start of activity in 2014, only recently was noted by the amount raised in campaigns - more than 11 million euros. Based on Crowdinvesting, more specifically lending crowdfunding, Raize is dedicated to loan to SMEs and to start-ups. Companies request a financial loan of a specified amount and investors present proposals for partial or total loans with associated interest rates. Companies can accept or reject the investors' proposals.

Besides the Raize platform, the Housers platform is also active in Portugal, dedicated to the Crowdinvesting, but in the property (Equity) type. It has begun its activity in Spain and currently it is also present in Italy.

Housers is devoted to investing in real estate by means of lease, construction, reconstruction or works of art. In this case, the financiers acquire property titles corresponding to a part thereof and depending on the purpose of the project. The investor obtains the monthly income (lease), at the end of the period (in the sale of the property) or even for the sale of the titles.

Table 1: Active Crowdfunding platforms in Portugal

Platform	Starting year	Type	Amount raised (€)	Successful Campaigns	Success rate
PPL	2011	Reward	2 647 531	810	45%
Novo Banco	2012	Donation & Reward	433 000	104	59%

Platform	Starting year	Type	Amount raised (€)	Successful Campaigns	Success rate
Raize	2014	Loan	11 213 000	578	-
Housers a)	2016	Property	42 628 255	103	-

a) Housers ' data reflects the entire activity spanning the 3 countries where it operates (Portugal, Spain and Italy)

The crowdfunding activity (collaborative funding) only began to be regulated in Portugal in 2015 (Pereira, 2016). In 2013, the Socialist Party formulated the first project approving the juridical regime of crowdfunding in Portugal. Two years later, the Law No. 102/2015 (August 2015) was published regulating collaborative financing. However, crowdfunding based on capital or loan was only regulated in 2016 when, such as specified by Law No. 102/2015, the Portuguese Securities Market Commission (CMVM) approved the regulation of legal regime of crowdfunding (Regulation CMVM No. 1/2016, signed on 5th May 2016 and published in Diário da República on 25th May 2016).

Due to the growing activity in Portugal, the Portuguese Government felt the need to approve the new Law No. 3/2018 on collaborative financing, amending Law No. 102/2015. This new law, in addition to clearly dividing the Crowdsponsoring from the Crowdinvesting, adds a sanctioning regime to the activity of crowdfunding.

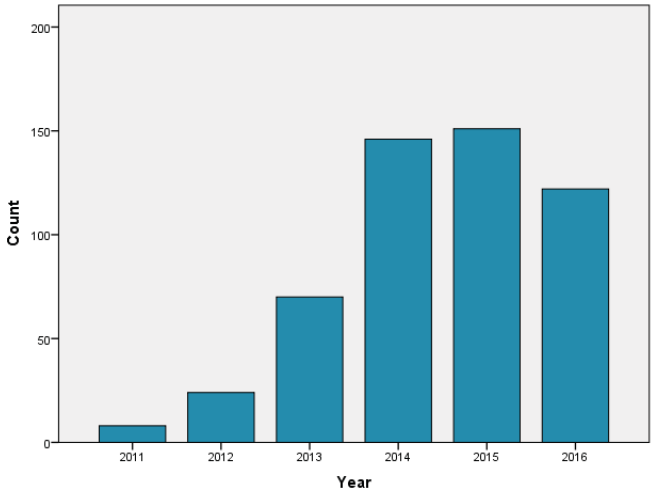
Previously, all crowdfunding activity was regulated and supervised by CMVM but with this new law, Crowdfunding's activities regarding donations and rewards become Regulated by the Food and Economic Security Authority (ASAE) and the activities associated with capital and loan continue to be regulated by the CMVM. The sanctioning regime strengthening the image of the Crowdfunding making it more regulated, more reliable and controlled. But, from the point of view of some experts and politicians, it removes the practical and simple image that characterized the Crowdfunding making it a more bureaucratic process.

3.2 Data

This research analyses the successful campaigns of the PPL platform that targets the reward-based type of crowdfunding. This platform was chosen because it encompasses both commercial, cultural and social projects, enabling to uncover differences between them. It is also the oldest and one of the most dynamic platforms in Portugal. Since 2011, the platform has raised more than 2.6 million euros, with a success rate of 45%. The platform uses the “all-or-nothing” mechanism.

The study uses data extracted from the PPL in 31th March 2017. At that time, since 2011, 1486 campaigns were launched and 623 were successfully completed. In the analysis, we only consider these successful campaigns, designated as projects hereafter. Figure 1 shows the evolution of the number of projects.

Figure 1: Evolution of the number of projects



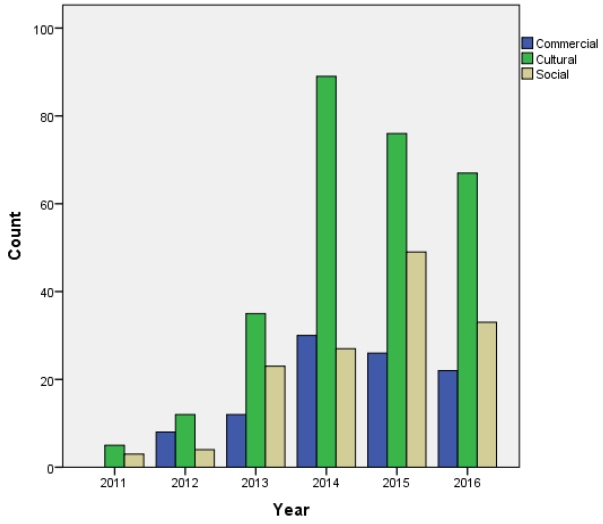
The projects were classified according to their nature. In order to perform this classification the full description of each project was analysed and three categories were created: social, commercial and cultural projects. In this process, 102 projects were excluded because they could not be considered in one of these three categories – they fit better in the donation category and were targeting support for an individual cause.

The classification of the projects obeyed the following criteria:

- Social projects – projects focusing on collective action and on the solution of social problems (poverty, social exclusion, citizenship, human rights, rehabilitation public spaces, education, health, animal protection); 139 projects were classified in this category.
- Commercial projects – projects focusing the launching of products or services, or raising investments for commercial activities (e.g. equipment modernization); 98 projects were classified in this category.
- Cultural projects – projects focusing the promotion of cultural events and products, including books, exhibitions and shows; 284 projects were classified in this category.

Figure 2 shows the evolution of the projects by type. It is possible to see that cultural projects predominate in every year. It is also possible to see that in 2014 commercial projects were more frequent than social ones.

Figure 2: Evolution of the projects by type



4. Results

As mention above, the paper sets out to analyse the successful crowdfunding campaigns and to assess differences between social-oriented, cultural-oriented and commercial oriented projects. In order to analyse the differences, several variables, related to the success of the campaign, were considered: the target investment in euros (goal), the raised investment in euros, the number of backers (investors), the average investment in euros (investment per investor), the target fulfilment (total raised divided by target times 100), the number of comments, the number of shared images and the number of views. Table 2 shows the descriptive statistics of these variables.

Table 2: Descriptive statistics

	Minimum	Maximum	Mean	Std. Deviation
Target	500	25000	2336,11	2264,96
Raised	500	25165	2669,14	2642,29
Backers	1	1122	67,26	76,21
Average Investment	4	1000	54,18	64,21
Target fulfilment	100,00	415,75	116,5969	32,59
Comments	0	73	2,01	5,15
Images	1	10	5,49	2,88
Views	934	45876	6404,67	5368,31

There is a positive and significant correlation (Table 3) between the number of views of the campaign and the investment (both target and raised) and the number of investors. This indicates that the most successful projects have more views in the platform, and therefore that promoters need to invest in the visibility of the campaign. Comments and images seem to have a lower correlation to those success variables.

Table 3: Pearson correlation coefficients

	Target	Raised	Backers	Average Investment	Target Fulfillment	Comments	Images	Views
Target	1	,942**	,437**	,228**	-,074	,076	,163**	,412**
Raised	,942**	1	,528**	,186**	,165**	,102*	,123**	,467**
Backers	,437**	,528**	1	-,200**	,292**	,208**	,040	,591**

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

In order to test the differences between the types of projects (social, cultural, commercial) we used the ANOVA analysis. The results of ANOVA are reported in Table 4. It is possible to conclude that significant differences between groups were only present in the variable target fulfilment. Commercial projects exhibit the higher investment fulfilment ratio, while cultural projects exhibit the lower (Figure 3).

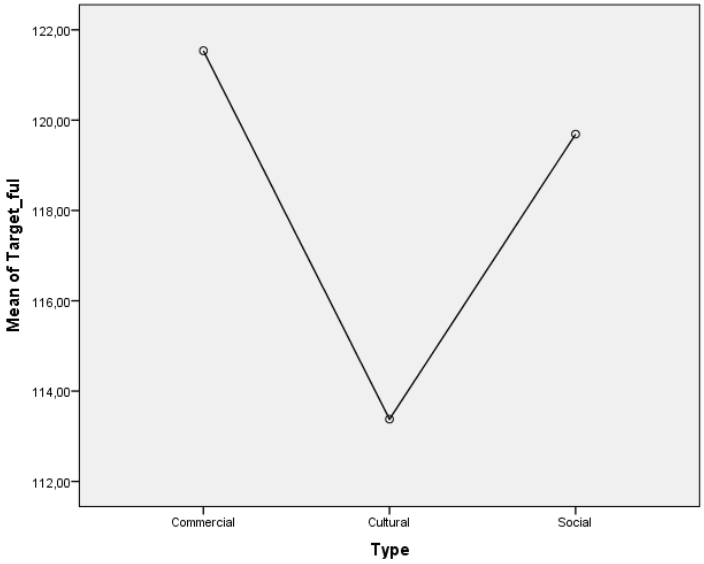
Figure 3: ANOVA Mean Plot



5. Conclusion

Crowdfunding is a new and complementary form to finance innovative projects, particularly for project start-up, that otherwise would not be able to raise the necessary capital. The paper sets out to analyse the successful crowdfunding campaigns and to assess differences between social-oriented, cultural-oriented and commercial-oriented projects.

Results show that most successful projects have a cultural or a social oriented nature. This can be related with the fact that we are considering a reward-based type of crowdfunding and with the still incipient use of crowdfunding to finance commercial oriented innovations in Portugal (Medeiros, 2015).

Our results also show that the number of views achieved by a campaign is significantly and positively related to the success of the campaign, being the correlation stronger than the number of comments and the number of images. This suggests that is vital to spread the word to a vast public in order to have a successful campaign, regardless of the type of project.

Despite the different nature and challenges face by the three different type of projects – commercial, social and cultural – when it comes to the crowdfunding campaign success this research only found significant differences in terms of the investment fulfilment ratio: commercial-oriented tend to exceed the target investment in a more marked way compared to the other types of project, namely the cultural-oriented.

Aligning Innovation Practices with Trajectories of Development of Leanness and Agility Capabilities

Inga Stankevice, Mantas Vilkas and Jurga Duobiene

Abstract: In times of smart businesses, digital factories and data-driven services, competitive enterprises are expected to be lean and agile. There is no consensus about how leanness and agility are achieved, but it is common to concentrate on four competitive priorities – quality, delivery, flexibility, and cost. Now, in facet of increasing dynamism of Industry 4.0, many authors express the need to include innovation into the discussion of leanness and agility too. In the paper, we propose an integrated theoretical framework that links together different innovation practices with low performing, lean and agile enterprises, including their transitional stances. In assessing changes towards leanness and agility performance dimensions, innovation practices play a major role. Moreover, according to a cumulative capabilities model, the transition from a low performer to a lean or agile one happens in a certain way. However, the traditional sequence of competitive capabilities development has been questioned by a number of authors who proved that a considerable number of enterprises did not follow this sequence. So, in the paper, alternative capabilities development trajectories are proposed. They are dependent on innovation practices onto which enterprises embark. Thus, the paper aligns innovation practices with enterprises' capabilities development trajectories towards leanness and agility and conceptualises an integrated theoretical framework of innovation-based capability development sequences. The major arguments are deducted from our previous research findings based on the analysis of Community Innovation Survey longitudinal data starting from 2006 and supplemented with the empirical evidence of other researchers who also performed statistical analyses: exploratory factor analysis, confirmatory factor analysis, cluster analysis, regression, and structural equation modelling predominantly. The paper contributes to better understanding of competitive capabilities development trajectories and performance of enterprises in dynamic environments, especially in the field of operations management which has insufficiently focused on such important elements of strategic management as innovation strategy.

Keywords: agile manufacturing, capabilities development trajectory, enterprise performance, innovation practice, lean manufacturing

1. Introduction

Both strategic management and operations strategy receive considerable attention in the scientific literature. However, the attention is rather individual. Whilst strategic management scholars aimed at innovation decades ago, in the field of operations strategy it had long remained in the shade of such competitive priorities as quality, delivery, flexibility and cost. In facet of increasing dynamism of Industry 4.0, authors attempt to include innovation into the discussion of leanness and agility too (Nair, Boulton 2008; Hallgren, Olhager 2009; Klingenberg et al 2013; Shin et al 2015; Edison et al 2018).

In the paper, we answer a question why innovation plays a key role in capabilities development and demonstrate that innovation is not only an additional competitive priority, but it is the springhead of any competitive priority. In addition, it is not clear which innovations lead to either leanness or agility, or both at a time, or which innovations dominate in low, lean or agile performers. Furthermore, new evidence shows that over 30% of enterprises do not follow the traditional sequence of developing competitive capabilities (Schroeder, Shah, Peng 2011). So, the paper proposes alternative trajectories towards leanness and agility. In doing so, the questions are: which innovation practices correlate with capabilities development trajectories towards leanness and agility; how do different innovation practices alter these trajectories? Hence, the paper aims to propose a theoretical framework aligning innovation practices with enterprises' capabilities development trajectories towards leanness and agility.

1.1 Main concepts and their relationships

Leanness and agility are two main concepts commonly applied in manufacturing (Narasimhan, Swink, Kim 2006; Hallgren, Olhagen, 2009; Soltan, Mostafa, 2015) with later application in supply chain management and its integration with manufacturing to the system of production (Naylor, Naim, Berry 1999; Goldsby, Griffis, Roath 2006; Lotfi, Saghiri 2018). They are applied variously, e.g. as supply chain strategies (Naylor, Naim, Berry 1999), thinking concepts (Eltawy, Gallear 2017), operations characteristics (Hallgren and Olhager, 2009),

manufacturing paradigms or performance capabilities (Narasimhan, Swink, Kim 2006; Lofti, Saghiri 2018). Both leanness and agility are recognized for going beyond a traditional application area and might be applied successfully in different industries and business conditions (Eltawy, Gallear 2017).

The concept of leanness describes the system that is used for eliminating any type of waste as a core feature (Narasimhan, Swink, Kim, 2006). Strategic intent of applying leanness is waste reduction or "less of everything" (Eltawy, Gallear 2017, p. 157), but ensuring product quality, delivery, flexibility and cost for meeting customer needs as market responsiveness. Based on the empirical research, Narasimhan, Swink and Kim (2006) characterise lean performers by cost efficiency followed by the quality of conformance and design. Hallgren and Olhagen (2009) indicate that lean performers operate in stable environment and are represented by repetitive production, daily schedule adherence, and flow oriented layout.

Agility reflects the same competitive priorities, but it emphasises different elements (Narasimhan, Swink, Kim 2006). In case of agility, market responsiveness comes as the first and main component that is supplemented by waste reduction (Soltan, Mostafa 2015). According to Narasimhan, Swink and Kim (2006), agile performers do not emphasise cost efficiency so much as lean performers. Agile performers are similar to them by the quality of conformance and design, but scored higher in flexibility (new product and process) and delivery (speed and reliability), representing the feature of rapid reconfiguration. According to Hallgren and Olhagen (2009), they have high customisation capability, handle efficiently variety, and have new product agility.

Another difference between leanness and agility is in competitive strategy. Hallgren and Olhager (2009) claim that agile manufacturing is related negatively with cost leadership strategy that corresponds to the findings of Narasimhan, Swink and Kim (2006). While leanness in operations fits well for implementing cost leadership strategy, agility fits well for differentiation strategy. Moreover, the results of Hallgren and Olhager (2009) contribute to previous description of leanness and agility by showing that they both affect significantly such operational outcomes as quality and delivery.

The integration of leanness and agility in one supply chain is based on the combination of waste efficiency and market responsiveness and called leagility. Naylor, Naim and Berry (1999) claim that the need for leagility as a combination of leanness and agility depends on the strategy of total supply chain. Although, leanness and agility complement each other if the correct supply chain strategy is applied. Agile manufacturing satisfies a fluctuating demand and lean manufacturing follows a level schedule (Naylor, Naim, Berry 1999). They can be applied into one supply chain according to demand direction at a decoupling point. If the demand is smooth and goes upstream, lean manufacturing can be applied. If the demand varies and goes downstream, agile manufacturing can be applied for product differentiation. Actually, leagility is an explanation how the integration of leanness and agility may serve to the market needs (Kisperska-Moron, de Haan 2011).

Discussed differences and similarities of leanness and agility turn back to three clusters of performers which have been analysed by Narasimhan, Swink and Kim (2006). The analysis of low, lean and agile performers reveals a considerable overlap between manufacturing concepts according to the perspective of practice, but from the perspective of performance leanness is a predecessor of agility. Narasimhan, Swink and Kim (2006) claim that the performance perspective ensures a strategic view for setting priorities what should be done.

1.2 Trajectories of operations capabilities

The discussion on how organisations should develop their capabilities for lean or agile manufacturing follows between two main models of trade-off and cumulative capabilities. Classical trade-off model is described by strategic choices in selecting a competitive dimension to emphasize at the expense of other dimensions (Rosenzweig, Easton 2010). Competitive dimensions reflect to operation capabilities by Narasimhan, Swink and Kim (2006) and consist of quality, delivery, flexibility and cost. Although, Rosenzweig and Easton (2010) claim that mentioned capabilities do not necessarily conflict with each other and emphasise the simultaneous outperformance on all four capabilities of Japanese manufacturers to North American and European counterparts.

Meanwhile, cumulative capabilities model is known as the sand cone model and describes the sequence how these capabilities are acquired. The quality is obtained first, followed by delivery, flexibility and finalised with cost. Empirical evidence on sand cone model is still lacking (Hallgren, Olhager, Schroeder 2011) or contradicting (Flynn, Flynn 2004). Although, the results of empirical testing by Narasimhan and Schoenherr

(2013) and Boon-itt and Wong (2016) confirm the sand cone sequence. However, Narasimhan and Schoenherr (2013) draw the attention to observed similar or better results on other sequences. Alternative trajectories reflect the split of sequence after delivery. Empirical results of Hallgren, Olhager and Schroeder (2011) research show that flexibility and cost are developed simultaneously, not sequentially. Moreover, they claim that there is no link between cost and flexibility. In linking cost and flexibility to leanness and agility, it might be hypothesised that the trajectory to cost reflects leanness and the trajectory to flexibility reflects agility.

Researchers reveal other models in addition to trade-off and sand cone ones. Schroeder, Shah and Peng (2011) have found a high variance of sequences instead of a single one of sand cone. As they claim, there might be many of alternative ways to the high performance and it depends on chosen strategies. Alternative models like 'threshold model', average model', 'non-competitive model', and 'multiple model' have been also tested by Singh et al (2015). Although they have not tested the sequence, empirical results have confirmed the threshold model when one capability is high and others are at the average levels as well as the average model with all average capabilities. The non-competitive model where all capabilities are low has been also confirmed by small but significant proportion of researched plants. The multiple models with various combinations of capabilities have got a strong support from empirical data, therefore calling for the further investigation of alternative trajectories of operational capabilities and their drivers.

1.3 Innovation practices

Narasimhan and Schoenherr (2013) provoke future researcher with additional capability that must be added to the common sequence of quality, delivery, flexibility and cost, i.e. innovation. In particular, they emphasise the impact of innovations in cost reduction by eliminating defects, in shortening manufacturing time, in contribution to quality and delivery performance. The stronger relationship has been identified between innovations and quality, delivery, flexibility, cost than the interrelation between these four capabilities (Singh et al 2015). Furthermore, Nair and Boulton (2008) argue that innovation should be included into general sequence of sand cone model with competitive priority for proactive adaptation of operation strategy to fulfil the requirements of changing environment.

However, in operations strategy literature, dimensions underlying the complex concept of innovation are more limited than those which authors from the field of strategic management analyse. Thus, Nair and Boulton (2008) characterize innovation according to three dimensions. Klingenberg et al (2013) focus on operational innovation (i.e. process innovation) only. Similarly, Shin et al (2015) analyse collaborative innovation as one of four pillars underlying agility, where collaborative innovation refers to all the relevant activities of process innovation. In practice, different innovations and innovation activities are usually implemented together and form bundles which therefore are referred to as innovation modes, innovation strategies, innovation regimes, innovation routines, or innovation practices (Stankevice 2015). It is the latter denotation to which the aforementioned innovation bundles are referred to in this paper.

2. Methodology for aligning innovation practices with leanness and agility profiles

What lets us to relate operations management literature on agility/leanness and strategic management literature on innovation is enterprise performance. In the field of operations management, it is common to measure performance of types or intensity of leanness and agility (Narasimhan, Swink, Kim 2006; Hallgren, Olhager 2009; Klingenberg et al 2013; Singh et al 2015). Likewise, in the field of strategic management, different innovation practices are also associated with different levels of performance (Frenz, Lambert 2012; Prajogo 2016). Hereby enterprise performance serves as a binding element between agility/leanness and innovation practices.

For certain performance levels and types of leanness/agility, we rely mostly on nearly classical differentiation between agile, lean and low performers (Narasimhan, Swink, Kim 2006). We also focus on the recent refinement of capabilities development model proposed by Singh et al (2015) where they analysed innovation as the fifth competitive priority along with quality, delivery, flexibility and cost. From the strategic management side, we use the previously analysed typology of innovation practices (Stankevice 2015) as it is much in line with others researchers' (Frenz, Lambert 2012; Prajogo 2016) findings and is based on solid Community Innovation Survey data. This typology includes six innovation practices emerged as the result of exploratory factor analysis (Table 1). One innovation practice was dismissed in this paper because it does not represent manufacturing sufficiently (see 3.1).

Table 1: General characteristics of innovation practices

	Marketing laggard	Process modernisation	Organisational support	Marketing leader	Networked value creation
Products new-to-market over new-to-firm	No	No	No	Yes	Yes
Performance	Low	Average		High	
Corresponding types of industrial enterprises	Low performers	Lean performers		Agile performers	

While some components of these practices represent quality, delivery, flexibility and cost, other components (e.g. sources of knowledge for innovation, etc.) can hardly be classified as competitive priorities typical of agility/leanness discussion, so these components were not analysed further in the paper. The rest of the components are presented in Table 2 together with competitive capabilities equivalent to the components which emerged as the elements of statistical factors.

Table 2: Elements of innovation practices as competitive priorities of leanness and agility

Competitive capabilities	Elements of innovation practices	Innovation practices to which elements belong
Cost	• Labour cost reduction	• Organisational support *(correlates significantly with networked value creation)*
Delivery	• New/improved logistic, delivery or distribution system (can also be classified as process innovation)	• Process modernisation
Flexibility	• To improve production capacity • To improve production flexibility	• Organisational support *(capacity correlates significantly with marketing leader)*
	• To increase range of goods and services	• Marketing laggard
	• To improve ability to develop new products or processes	• Process modernisation
Innovation	• Continuous engagement in intramural R&D • Improved communication and information sharing	• Networked value creation *(communication and information sharing correlates significantly with organisational support)*
	• New methods for product placement • New methods of pricing	• Marketing leader
	• New media techniques • Training for innovative activities	• Marketing laggard
	• New business practices	• Organisational support *(correlates significantly with process modernisation)*
	• Acquisition of external knowledge • Acquisition of machinery, equipment and software	• Process modernisation
Quality	• To improve quality	• Marketing laggard *(correlates significantly with organisational support)*

Based on the correlations of innovation practices with enterprise performance, and on the factor components, the innovation practices were aligned with agility/leanness profiles proposed by Narasimhan, Swink and Kim (2006) and Singh et al (2015). In doing so, trade-off model was not considered because none out of 1438 plants examined by Singh et al (2015) followed it. Ultimately, an integrated theoretical framework for reaching leanness and agility by means of innovation practices was conceptualised.

3. Innovation practices and capabilities development trajectories

If to compare agility/leanness profiles with the previously emerged innovation practices (Stankevice 2015) by enterprise performance, there is a parallel. As Narasimhan, Swink and Kim (2006) distinguished between three performance-based types of leanness and agility, so six innovation practices were also classified into three groups based on their contribution to better or worse firm performance.

3.1 Low performers: non-competitive operations strategy

Low performers (Narasimhan, Swink, Kim 2006) can be aligned with two innovation practices, namely, marketing laggards and service providers. However, service providers represent mostly financial, insurance, information and communication sectors and their auxiliary activities (Stankevice 2015), but not manufacturing. Thus, in manufacturing, it is marketing laggard practice that can help us to establish links between innovation practices and low performers.

The essence of the marketing laggard innovation practice is to introduce new techniques for product promotion (e.g. a new advertising media, a new brand image, or an introduction of loyalty cards) to replace outdated products and processes in the first instance. Innovations of marketing laggards are typically new at an enterprise level, but not in their markets. Since current innovation practices of marketing laggards help to keep up, but not to develop, other innovation practices are needed to vitalize competitive capabilities and bring them up to a higher performance level. Therefore, enterprises engage into training for innovative activities.

The major obstacles for the enterprises embarking onto this innovation practice to become leaders is that they lack a wider range and better quality of goods, and not always timely replace outdated products and processes. In this way, marketing laggards can be classified as low performers in terms of quality and flexibility (Narasimhan, Swink, Kim 2006). Other studies suggest also that enterprises which embark onto innovation practices similar to the said one are constrained financially (Stankevice 2015) to implement more advanced innovations. So, on the cost dimension marketing laggards are also concomitant with the cluster of low performers.

However, the aforementioned innovation practice has no implications for delivery, so there is no clear evidence that its level is low. Presumably, low performers are able to start their capability development sequence with satisfactory delivery. In leanness/agility typology presented by Singh et al (2015), such enterprises would correspond to non-competitive model of operations strategy with all low or four low (innovation, cost, quality, flexibility) and one average (delivery) capability.

3.2 Lean performers: average and threshold operations strategies

Two innovation practices are associated with average enterprise performance, namely, process modernisation and organisational support (Stankevice 2015). The essence of the first innovation practice is to improve the ability to develop new products or processes (i.e. to improve product flexibility in Narasimhan's et al (2006) words) through the acquisition of external knowledge, machinery, equipment and software. In fact, process modernisers are generally good at utilizing innovations originally developed by others and acquiring relevant knowledge disseminated by others, so their product flexibility is at an average level and corresponds to that of lean performers. More than a half of these enterprises have already introduced new logistic, delivery or distribution systems, thus indicating present process innovations and that delivery's as a competitive priority's level is average or high.

Interestingly, none of the internal components of this innovation practice has any implications for cost or quality. However, other studies indicated that process modernisation focuses on developing standardized products and reducing costs through routinizing process improvements (Zuniga, Crespi 2013), and this is how it limits the impact of its innovations to products which can be mass-produced within standardized routines. So, cost as a competitive priority is at a high level in this case and corresponds to that of lean performers. In Singh's et al (2015) typology process modernisers follow threshold operations strategy with two high (delivery, cost) and three average capabilities (innovation, flexibility, quality) or one high (cost) and four average capabilities (delivery, innovation, quality, flexibility). The only competitive priority which is not fully empirically verified by the process modernisation innovation practice is quality.

Another innovation practice with the average performance (i.e. organisational support) includes such objectives as reduction of labour costs, improvement of production flexibility and capacity, and improvement of quality. Information about delivery is lacking, but average performance and the wish to improve all the other capabilities aligns the said innovation practice to average operations strategy in Singh's et al (2015) typology, i.e. with all average capabilities (allows for four average and one low capability). Enterprises that embark onto the organisational support innovation practice do so to increase market share or, more rarely, enter new markets. To reach the set goals, the enterprises establish new business practices, such as knowledge management, supply chain management, business re-engineering, lean production, quality management, etc., and they also improve communication and information sharing (Stankevice 2015), i.e. they implement a number of well-sequenced organisational innovations.

3.3 Agile performers: cumulative operations strategy

Two innovation practices associated with the highest enterprise performance are based on marketing leadership and networked value creation, accordingly (Stankevice 2015). The latter innovation practice, due to the continuous intramural R&D, high value technological innovations and close collaboration with research institutes, demonstrates the greatest correlation with new product creation. Hereby, networked value creators can be characterized as having the highest product flexibility. So, from this perspective, networked value creation innovation practice falls under the category of agile performers. Another feature of agile enterprises is that cost is typically the only capability where agile performers yield to lean ones (Narasimhan, Swink, Kim 2006; Singh et al 2015). Precisely, about a half of networked value creators assume reduction of labour costs is important. Hereby this finding fits for agile performers as well. However, such capabilities of networked value creators as quality and delivery did not emerge as the factor components and need better empirical evidence.

Marketing leaders also showed slightly higher correlations with new-to-market products than with new-to-firm ones (Stankevice 2015). As Drechsler, Natter and Leeflang (2013) demonstrated, "both marketing research quality and the ability to translate customer needs into product characteristics serve to increase marketing's influence on NPD [new product development – authors' remark]. This increased influence, in turn, positively contributes to overall firm innovation performance." (p. 298). Marketing leaders combine advanced (e.g. new pricing, new discount systems) marketing innovations with the non-advanced ones (e.g. loyalty cards) and with organisational innovations (e.g. teamwork, new systems of responsibilities, etc.). So, we can deduct that both innovations and product flexibility are at a high level in such enterprises. Similarly to the networked value creation, the factor components do not have any implications for quality or delivery, but the fact that marketing leaders aim aggressively at new markets, coupled with pretty high performance, lets us assume that high quality and well established delivery are present.

So, both networked value creation and marketing leader innovation practices correspond to cumulative operations strategy in Singh's et al (2015) typology with five high or four high and one average capability. In case of networked value creation, the average-level capability is cost, and in case of marketing leaders, the average-level capability is volume flexibility which is related to marketing leaders' expansion into new markets and consequent challenges, such as the need to increase production capacity.

4. Innovation-based trajectory towards leanness and agility

In practice, it is likely that different enterprises have varied capabilities development trajectories. The discussion presented above has also shown differences in the trajectories of low, lean and agile performers, including differences within a same performance cluster. However, in the highly dynamic and digitalized environment of Industry 4.0, enterprises often need to combine leanness and agility, so it is advantageous to propose a way of doing so by applying right innovation practices at right stages.

Thus, training for innovative activities and successful installation of new delivery, distribution or logistic systems helps to lift performance up and approximate leanness. To increase cost efficiency, it is common to acquire external knowledge, as well as new software, equipment and/or machinery. These changes are typically accompanied by organisational innovations, such as supply chain management, business re-engineering, lean production, quality management, teamwork, etc.

To approach agility closer, enterprises engage into continuous R&D, collaboration with research institutes and higher education institutions; thus, they also need to improve communication and information sharing. Heavy R&D, more often than not, causes decreased cost efficiency, but helps to reach excellence in all the other competitive capabilities. It is also worth mentioning that alongside R&D, complex marketing innovations contribute to verging agility too. Figure 1 illustrates the innovation based trajectories towards leanness and agility.

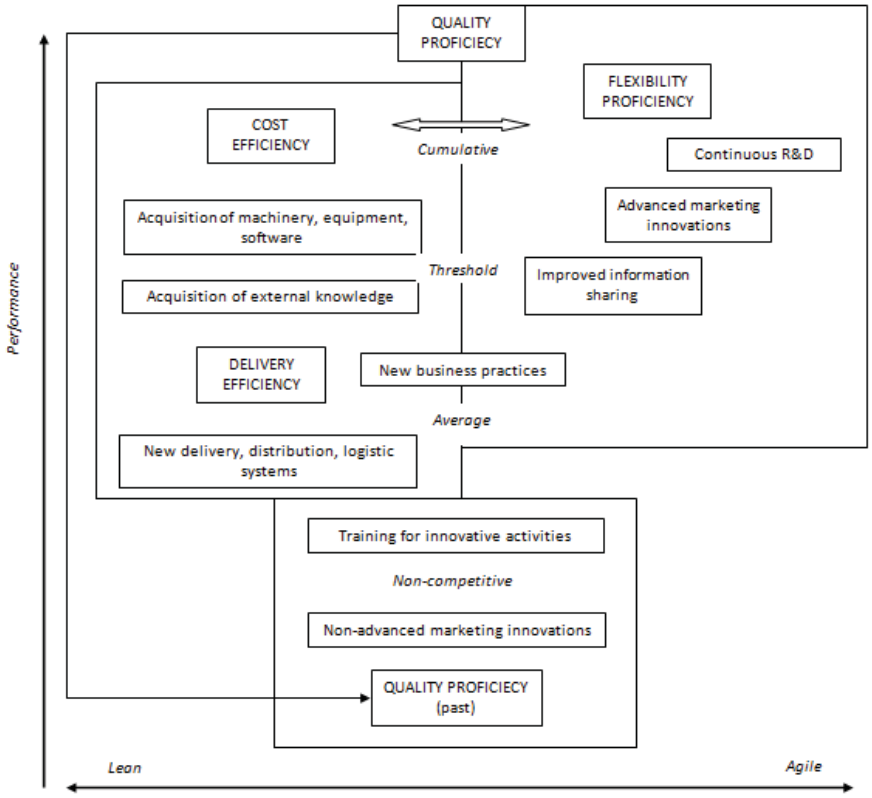

Figure 1: Innovation-based trajectories towards leanness and agility

In the framework above, capabilities development is seen as a cyclic and continuous process. It is demonstrated in various studies that capabilities development is environmentally dependent and goes through different development cycles, especially when innovation is considered (Nair, Boulton 2008; Hallgren, Olhager 2009; Bottani 2010; Schroeder, Shah, Peng 2011; Gligor, Esmark, Holcomb 2016). In the alignment of innovation practices with leanness/agility, no proof was found for quality being the first or the last capability in the performance development trajectory. Hereby we rely on the most popular sequence starting with quality, even though alternative sequences may exist (Schroeder, Shah, Peng 2011). However, quality, as well as other capabilities, needs to constantly be revisited. Similarly, advanced marketing innovations at some point of time become obsolete, new delivery systems become outdated, new knowledge becomes irrelevant. Hereby, the process of capabilities development is cyclic.

Another important aspect of the framework is the two-way path between leanness and agility. Research shows that there may not be a single sequence in which capabilities are built (Narasimhan, Schoenherr 2013), e.g. capabilities may be developed not sequentially, but in parallel. Thus, cost and flexibility can be developed simultaneously (Hallgren, Olhager, Schroeder 2011). Another insight is provided by Gligor, Esmark and Holcomb (2016) who proved that agile strategies are more efficient in highly uncertain environments, and lean strategies fit better for stable environment. Similarly, Prajogo (2016) proved that competitive environments weaken the effect of product innovation on performance, but strengthen process innovation. So, these arguments and evidence from previous aforementioned studies are convincing enough to enable the mutual transformation and convergence of leanness and agility in the framework.

5. Conclusion

There is an increasing support for the idea to include innovation into competitive capabilities development trajectories. In the paper, innovation is not only an additional competitive capability, but its role is critical on enterprises' way towards leanness and agility. Innovation bundles, or innovation practices, may alter capabilities development trajectories, and they may also serve as a means to lift competitive capabilities up to a higher performance level in a cyclic way. However, the deducted trajectories towards leanness and agility have some limitations. First, the data on which the trajectories were built relate to varied industrial sectors, thus meaning that other patterns may appear if to extract manufacturing only. Second, the trajectories do not

specify sequences of competitive capabilities. So, the paper provokes further research to investigate the deficient aspects.

Entrepreneurial Mindset as a Driver for Digital Transformation – A Novel Educational Approach from University-Industry Interactions

Audrey Stolze, Klaus Sailer and Herbert Gillig
Strascheg Center for Entrepreneurship, Munich University of Applied Sciences, Germany
audrey.stolze@sce.de
klaus.sailer@sce.de
herbert.gillig@sce.de

Abstract: A major challenge faced by organisations today is how to adopt and leverage new digital technologies (NDT), as it requires organizations and its leaders to embrace different mindsets and skill-sets in order to develop digital transformation strategies. In this scenario, how can universities support the formation of organisations' digital mindset? How to educate students to be (digital) transformational agents? And how to produce value for all stakeholders in the process? The Triple Helix (TH) of University-Industry-Government enables a sustainable innovation ecosystem and promotes regional development. The entrepreneurial university (EUni) supports the transition from a society based on physical artefacts to a knowledge-based society. The EUni model includes increased university autonomy and greater involvement of external stakeholders. At the same time, Entrepreneurship Education (EE) at EUnis has expanded and evolved significantly in the past decades. In 2006 a European Commission report on how to build a knowledge-society, added EE as one of eight key competences for life-long learning, due to the transferability of the entrepreneurial mindset to other branches of one's professional and personal life. Based on learnings from project-based EE programs with industry partners in different contexts (e.g., local/international, classroom-only/virtual-component), a novel educational concept that deep dives into the topics Entrepreneurship & Digital Transformation is being developed through co-creation, as an attempt to answer the presented questions. A specific evaluation framework assesses the experiment, by collecting qualitative and quantitative data throughout the development process, while in parallel an empirical research is aggregating findings from past and current EE programmes. Initial findings presented in this paper illustrate the need of Triple Helix (TH) interactions to co-create programs that produce value for all stakeholders, allowing the conceptualization of a novel approach for EE development, which might enable technology transfer, emergence of start-ups/spin-offs and foster an entrepreneurial mindset.

Keywords: Entrepreneurial Mindset, Digital Transformation, Triple Helix, Entrepreneurial Universities

1. Introduction & Background

A major challenge faced by organisations today is how to adopt and leverage NDT – as the ability to promote digital transformation is in large part determined by a clear digital strategy enabled by a culture of change, risk-taking and innovation, supported by its leaders. The path to digitalization requires organizations to embrace a digital mindset, as NDT demand different mindsets and skill-sets than previous waves of transformative technologies (Fitzgerald *et al.*, 2007; Kaufman and Horton, 2014; Kane *et al.*, 2015).

Effectively developing and communicating a strategy is a difficult task, which design techniques and processes can support. Design Thinking (DT) is proposed as a suitable framework for the development of strategies, products, services, and new businesses, i.e. a model for value innovation and transformation. The person or team to pursue this endeavour should be "T-shaped", that means someone that has a principal skill, e.g. software engineering, that describes the vertical leg of the T; and also, has empathy to branch out into other skills, the width arm of the T (Brown, 2005; Brown and Katz, 2011). At the same time, it is argued that teaching entrepreneurship as a method requires going beyond understanding, knowing, and talking; it requires using, applying, and acting (Neck and Greene, 2011) and the key concepts of DT add value to EE, as it provides educators with a process that facilitate multidisciplinary learning (Huber *et al.*, 2016).

Studies suggest that taking entrepreneurship courses influences students' entrepreneurial intentions (Lange *et al.*, 2011). Ensuring that a broader segment of the population possesses entrepreneurial knowledge seems to positively affect start-up rates and subsequent job creation (Kuckertz, 2013). Since 2006, the European Commission (EC) has included entrepreneurship education as one of eight key competences for life-long learning. Further EC directives have been released since, including a framework for teaching entrepreneurship competences with a respective progression model and learning outcomes (European Council, 2006; Bacigalupo *et al.*, 2016). However, EE by itself may not directly produce entrepreneurship outcomes, its impact is rather indirectly through mediating mechanisms, as personal characteristics, networks and self-efficacy (Rideout and Gray, 2010). The personality traits of innovativeness, pro-activity and self-efficacy strongly correlate with

entrepreneurial behaviour (Rauch and Frese, 2007). From a human capital perspective, knowledge/skills relate higher with entrepreneurial success, than education/experiences (Unger *et al.*, 2011). In this context, entrepreneurial mindset encompasses knowledge, skills and attitudes. Hence the assessment of EE is possible by focusing on the impact of EE measured as the evolution of students' mindset, rather than number of businesses created (Fayolle, Gailly and Lassas-Clerc, 2006). However, beyond the student perspective, the assessment of EE programmes should be stakeholder-driven, i.e. it needs to involve all stakeholders in the process to validate the added value from all perspectives: administrators, faculties, government bodies and donors, external partner firms, etc. (Duval-Couetil, 2013).

In what regards universities, the digital transformation causes dramatically changes in distributing knowledge. Universities will no longer own the traditional monopoly in knowledge creation. Private sector and civil society institutions now provide different education pathways enabling practical knowledge generation and its transfer into society. Moreover today's societies face complex challenges and changes that can only be tackled and resolved peacefully by bundling expert knowledge and finding responsible solutions.

Hence, the future role of universities will be to handle large volumes of information and to integrate the ever-growing diversity of mass communication into sensible contexts of teaching so that applicable knowledge and competences are nurtured and created in both, local and virtual communities. Although bits of information are continuously generated and saved (Big Data), their relational contexts often remain in closed forums or are being discussed on exclusive panels only.

At the same time, knowledge sharing to resolve specific and individual needs and challenges becomes ever more relevant for accessing information, in not only local communities, but also increasingly through virtual communities across the globe.

These circumstances pushes universities to re-define their role and shifting their education mission from pure knowledge transfer towards educating entrepreneurial minds that understand the entire spectrum of societal challenges and new digital technologies, students that are willing and capable to live up to these challenges on a daily basis. The universities have to convert themselves in an entrepreneurial university (EUni), as described by the EC (Hannon, 2013).

The EUni, which adds entrepreneurship as a third mission, in parallel to teach and research, is a key driver for society's transition from being based on classical industries towards being knowledge-based and contributes to regional and national development. The EUni-model includes increased university autonomy and greater involvement of external stakeholders (Etzkowitz and Leydesdorff, 2000; Etzkowitz, 2014). Accepting this new role, universities have to get an emancipated part of the society. Instead of living in knowledge silos, separated by the different disciplines, they have to interconnect with relevant stakeholders from the commercial and public sectors, as well as politics – the so-called Triple Helix – and civil society institutions (Quadruple Helix).

Such University-Industry-Government-Civil Society collaboration enables a sustainable innovation ecosystem and promotes regional development. Nevertheless, it is important to highlight that civil society is a broader democratic format than are institutional spheres, not being a parallel sphere to academia-industry-government and hence the concept of a fourth helix is disputed in literature (Leydesdorff, 2012; Etzkowitz, 2016; Etzkowitz and Zhou, 2018).

The introduction of EUnis new role face barriers due to university-wide cultural issues and gaps between faculties that need to cooperate often restrain the emergence of an institution-wide entrepreneurial culture and due some professors' view of Entrepreneurship as a non-academic discipline. To overcome these barriers a long-term perspective is necessary (Janssen and Bacq, 2010; Kuckertz, 2013).

In this context, hybrid organizations (HOs), e.g. entrepreneurship centers, play an important role, as a key micro-component of TH interactions. HOs allow different practices and experimentations, which eventually help to overcome cultural barriers between stakeholders in a regional entrepreneurial ecosystem (REE) (Etzkowitz and Leydesdorff, 2000; Etzkowitz, 2016; Champenois and Etzkowitz, 2017; Leydesdorff *et al.*, 2017).

The analysis of TH interactions in a REE should take into account relevant elements, as the capacities of the firms, the existing informal relationships between stakeholders and the kind of knowledge that is in exchange

between a university and their surrounding firms. Current research on the status quo of TH interactions show that those are often weak or non-existent in many regions and only a small amount of academics follow the EUni model (Philpott *et al.*, 2011; Fernandez-Esquinas, Merchan-Hernandez and Valmaseda-Andia, 2016).

Furthermore, contextual factors for REE success are elusive (Etzkowitz and Zhou, 2018) and their performance should not be evaluated by simple metrics (e.g. number of startups or spin-offs created), as the emergence and growth of such a complex ecosystem and its ability to produce certain (entrepreneurial) behaviours may require metrics that capture the depth and breadth of those interactions. The use of mix-methods approaches and specifically qualitative comparative analysis (QCA) and interpretivist qualitative research are more appropriate methods to capture the multi-faceted and temporally unfolding characteristics of REE (Roundy, Bradshaw and Brockman, 2018).

2. The Case of MUAS/SCE

The Munich University of Applied Sciences (MUAS) is one of the largest university of applied sciences in Germany with around 18 thousand students across 14 faculties, including a faculty for General and Interdisciplinary studies. The university has adopted entrepreneurship as one of its three guiding principles (together with internationalization and sustainability) and has a long-term commitment to promote an entrepreneurial mindset among faculty staff and students. Affiliated to MUAS is the Strascheg Center for Entrepreneurship (SCE), a hub for entrepreneurial activities within the university and the REE. Founded in 2002, SCE offers startup support and EE programmes across faculties and beyond the university environment and network. The collective efforts of MUAS and SCE have contributed to the emergence of a lively entrepreneurial ecosystem in Bavaria, specifically in its capital, Munich. MUAS had been ranked as the number 1 entrepreneurial university in Germany (Stifterverband and Heinz Nixdorf Stiftung, 2016). An analysis of the development path of entrepreneurship support at MUAS/SCE between 2002 and 2012 showed that internal factors, that is, people involved in the support activities, students, and university governance, were more influential than external factors to SCEs development. However, external factors in the form of private sector influence, public funding and strategic partnerships, were dominant in two dimensions: (i) internal organisation and external collaboration, and (ii) financial resources (Gillig, Hofer and Sailer, 2012).

Throughout the years, learnings from EE programmes developed locally or as part of international consortiums have allowed MUAS/SCE to build expertise, aiming to position the institutions as Thought Leaders in EE nationally and across Europe. A summary of educational approaches and key learnings from four selected programmes (table 1) provide an overview of the background that led to the conceptualization of a novel educational approach in entrepreneurship for digital transformation.

Table 1: Summary of educational formats and learnings from selected MUAS/SCE EE Programmes

Selected EE Programmes	Short Description	Key Learnings
Real Projects (RP)	Cross faculty format available since 2011, in which a SCE facilitator co-teaches a regular course with a professor during a semester, by applying a RP method consisting of: impulse, problem analysis, ideation, implementation, and presentation to the class. There are special editions in collaboration with industry partners, who provide the initial impulse (i.e. innovation challenge). RP has been introduced into the curricula of multiple degree programs of most MUAS faculties. The evaluation is conducted based on the ASTEE assessment tool, which assess EE based on evolution of students' entrepreneurial mindset	The need to combine desired EE learning outcomes (knowledge, skills and attitudes), with the learning goals of each specific course; The need to understand entrepreneurship education as a transdisciplinary method that enables interdisciplinary team work; Not all university professors think and act entrepreneurially, requiring train-the-trainer initiatives in experiential pedagogy; The need of an evaluation tool that measures desired learning outcomes The need to coordinate and organize efforts between SCE and Faculties/Professors: Since 2014 MUAS established Thursdays as a "Project Day" facilitating this process. (Turgut-dao *et al.*, 2015)

Selected EE Programmes	Short Description	Key Learnings
Academic Program in Entrepreneurship (APE)	Facultative advanced program, open to students and participants beyond MUAS, since 2008. It consists of 2 semesters (10 months): one in which participants form teams, ideate and develop their own startup idea around a proposed impulse topic and another where the teams go through a design thinking-enabled process to tackle an innovation challenge from an industry partner. In between, the participants take part in an intensive international APE Bootcamp, in which they work in English with guest participants from around the world (i.e. one week summer school format). APE assessment is based on ASTEE tool and qualitative research efforts.	Design thinking concepts facilitate multidisciplinary learning and provide educators with a number of important concepts, tools and methods that may be directly integrated into existing courses; Enabling an international setting support the development of intercultural and communication skills; Training students in an entrepreneurial as well as intrapreneurial settings allows for multi-faceted career trajectories; More than 30% of APE graduates start a successful startup within five years of graduation; (Huber et al., 2016; Huber, Sailer and Peisl, 2017)

Selected EE Programmes	Short Description	Key Learnings
EU-XCEL	Funded by the Horizon 2020 scheme, EU-XCEL was executed by an international consortium of six partner universities between 2015-2017 engaging with over 400 participants. The aim was to enable the formation of "Born European" ICT startups and train them to be "incubator-ready". The program had 2 editions, each consisted of a one-week workshop, ran by each partner university, in which students and recent graduates from all over Europe immersed in the entrepreneurial journey and formed interdisciplinary international startup teams. Afterwards the teams went through a 12-14 weeks virtual acceleration, enabled by remote work and virtual coaching support. At the end, the 12 best performing teams of each edition met for a final competitive pitching event. In 2017 EU-XCEL was extended for 6 months to enable a "Momentum Workshop" with active teams from both editions to provide further support and mentoring on launching/scaling up (www.euxcel.eu) Extensive empirical research was conducted by partners and included the ASTEE tool.	EU-XCEL demonstrated that creating cross-border collaboration is an achievable policy objective; 95% of participants completed the programme, which indicates that virtual component in EE is feasible – critical success factors seem to be the establishment of structured roadmap with milestones and assignment of a coach; 86% of participants improved their entrepreneurial skillset during the program; 79% indicated greater confidence in their knowledge of start-up development with a European-wide team; And 70% of participants felt their international entrepreneurial network improved due to EU-XCEL; Identified pitfalls for cross-national startup projects were associated with the lack of a roadmap to market readiness in international settings, an adequate international support network including technical support and dedicated mentoring (O'Flaherty *et al.*, 2017)
Bavaria-Israel Partnership Accelerator (BIPA)	A bi-national program funded by the Bavarian Ministry for Economics and the Israeli Consulate in Bavaria aiming to promote exchange between the Israeli and German innovation cultures. At BIPA, SME partners propose innovation challenges, which are tackled by bi-national interdisciplinary teams formed by students and recent graduates. The program already had 82 participants and 20 SME partners and is currently in its 5th edition, each consisting of: A kick-off workshop either in Munich or Israel, followed by a virtual acceleration, in which the teams work remotely and are virtually coached by 2 coaches (one Israeli and one German) and report to the SME partner in milestones. After 8-10 weeks, the teams present the conceptualized solution (www.bip-accelerator.com). Assessment is conducted via ASTEE tool and further empirical research efforts (unpublished).	Bilateral EE promote an enriching intercultural and entrepreneurial experience that bring together both innovation cultures and add value to all stakeholders involved; SME partners that are more involved in the process and interact more with teams seem to be perceived more added value, as they are able to internalize innovation process knowledge and skills, besides receiving the final conceptualized solution; SMEs readiness to engage in such TH-enabled EE program needs to be improved and specific training to this stakeholder seems required; There are short-comes in virtual acceleration related to participants engagement level, coordination of remote work and intercultural communication; Short-term project may not promptly produce startups and spin-offs, though knowledge transfer seem possible;

3. Development Process for a Novel Educational Approach

The development of a new EE program focusing on Digital Transformation was based on the conceptual framework for the design and assessment of entrepreneurship education programs (Figure 1) proposed by (Valliere, Gedeon and Wise, 2014). This framework is based on the causal implications of the Theory of Planned Behavior, the contextual influences of ontology and environment, and additional perspectives offered by Stakeholder Theory. Although the framework is supported mainly by entirely theoretical arguments, it has been previously applied by MUAS/SCE in the curriculum development of RP, EU-XCEL and BIPA. The framework

provides a structured and comprehensive overview of contextual factors and interdependencies effects of the many aspects concerning the design the of the new EE program, enabling a more effective co-creation process.

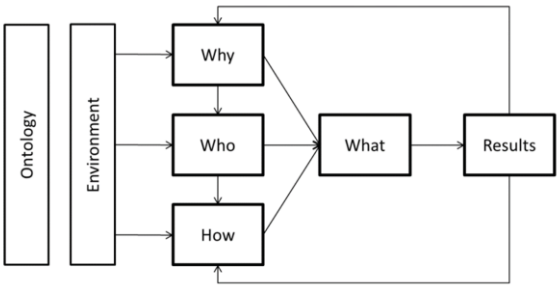

Figure 1: Framework for the development of EE programmes (Valliere, Gedeon and Wise, 2014)

The first step in the co-creation process was to conduct discussion between MUAS/SCE leaders and a series of relevant stakeholders (e.g. professors, faculty deans, and industrial and technology partners) through individual meetings and a larger workshop to formulate the requirements and guidelines for future training in the field of Entrepreneurship and Digitalization. The main insights of this step were:

- The different actors of society (i.e. students from different faculties, teachers, external actors from industry, entrepreneurs, politicians, etc.) play an active, context-related role, which results from the multi-faced interaction of these actors;
- Working on specific projects in small, interdisciplinary groups does not contradict social embedding, but presupposes it. In such a context, one-dimensional instructions in teaching and learning are no longer applicable; rather, continuous reflective experience, coordination and negotiation in direct exchange in both physical and virtual space are essential;
- The more intensively different professional and personal learning areas are trained and experienced in context, the better competencies and personality in the sense of "T-shaped People" can develop;
- Entrepreneurship in conjunction with the involvement of external partners can provide a preferred, holistic learning framework that optimally combines specific professional, personal, interdisciplinary, systemic and cooperative elements;
- Individual learning space can serve different goals, such as working on a real project or further academic education;
- The transition from learning to lifelong learning should be encouraged;
- In the dynamic field of digital transformation and entrepreneurship training, the university sees itself more and more as an initiator, co-designer and enabler, giving students and motivated innovators from industry a holistic, project-specific access to knowledge, experience and practice. In this way, participants can implement their strengths, ideas and visions and develop into responsible, entrepreneurial leaders in the long term.

The resulting outcome, after several feedback-loops, was summarized in the form of a grant proposal for a novel educational approach towards further developments in university education. The so-called DEEP DIVE programme (DDP) is an intensive full-time educational offer at master level, which combines the promotion of professional competences in the field of digital transformation with the development of an entrepreneurial mindset. Hence, DDP should include the following characteristics:

- The university works together with strong external technology and application partners from the REE to meet the demands for a leading international program. Well-regarded organizations have signed letters-of-intent to cooperate;
- DDP intends to support real entrepreneurial projects in small groups individually and according to their needs, through a flexible individualized curriculum, rather than a standard cohort curriculum;
- DDP combines work on a real project in the field of digital transformation with further academic education, being open to both bachelor students and motivated professionals, who see the new challenges of digital transformation as an opportunity and wish to further educate themselves;
- DDP should be inter- and transdisciplinary in its composition of participants and faculty engagement;

- DDP supports projects in different areas of digital transformation through coaching and support by experts and mentors according to their needs;
- DDP is open to international participants and hence, offered in English;
- DDP novel educational approach is to be constantly further developed through continuous evaluation with regard to students' development (entrepreneurial mindset), real projects output and value added to main stakeholders. The evaluation shall be empirically pursued using mix-methods and should include the ASTEE assessment tool, in order to enable comparative analyses with other MUAS/SCE formats;

An overview of DDP format is present on Figure 2. It comprises a four-week preparation phase (Online Immersion Modul, i.e. MOOC) in which a broad target group is prepared for the current challenges of digital transformation and possible entrepreneurial activity via curated online modules. These modules form individual independent learning units with a time expenditure of about five hours each. Topics on current trends and challenges in digital transformation are paired with a reflection on corresponding entrepreneurship concepts.

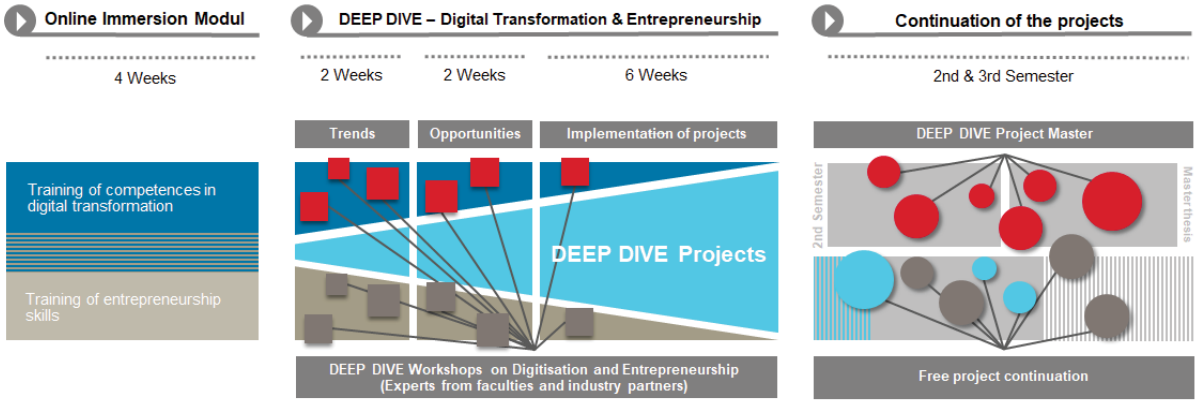

Figure 2: Structure and procedure of the DEEP DIVE program

The master programme is divided in 3 semesters awarding 90 ECTS. In the first semester, DDP selects students with diverse discipline backgrounds (e.g. business, engineering, education and design) to intensively immerse them in current topics and confronted with real complex tasks of digital transformation and entrepreneurship, over a period of one semester (full-time). This measure is designed to identify and intensively promote young, well-trained and above all highly motivated pioneers of digital transformation. At this stage, students should define a project idea to pursue which can be submitted by themselves, industry partners or professors. The development of student projects is enabled through intensive DDP workshops, guided by experts from MUAS, SCE, as well as external partners from the REE.

After completion of DDP first semester participants receive a Certificate and have the possibility to continue for two further semesters to pursue their project as a master thesis, while immersing themselves on specific topics by selecting existing courses from different faculties at MUAS or an international partner university to acquire the necessary ECTS points to obtain a qualified Master's degree.

Moreover, the continuation of projects beyond the DDP format should also be enabled and encouraged, through e.g. cooperation with the industry partner internally or via spin-off format; or by setting up a start-up, which the MUAS incubator start-up consultancy provides valuable support and advice through its proven processes.

Beyond the DDP structure, another key aspect of its development is the decision to create a Joint Commission (JC) to oversee the program, rather than attach it to a specific faculty. This format is enabled by Art. 19 (6) of the Bavarian Higher Education Act in conjunction with § 34 of the Ground rules of the Munich University of Applied Sciences. The JC (figure 3) is formed by a number of faculties and aims to enable an effective interdisciplinary format, overcoming possible regulation barriers of single faculties. The JC is responsible for organizing the study program in coordination with the participating faculties, by for example: Developing the

joint study and examination regulations; Approving adjustments to study content and plans; and Coordinating the access process of new faculty members.

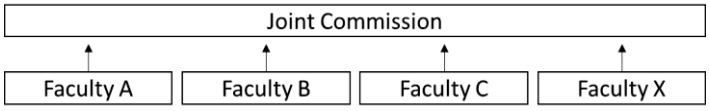

Figure 3: Proposed Program Joint Commission Structure

4. Discussion & Implications

To live up expectations regarding the future role of EUnis, universities will need to drive innovative ways of teaching. Knowledge provision surely remains important (through e.g. research journals). However, EUnis need also to add value to society, by developing and driving new approaches of knowledge generation through decentralized, inter- and transdisciplinary formats. This shift of self-understanding purpose shall be essential to resolve urgent problems and challenges in the field of digital technologies. Teaching formats and research results shall be integrated “real-time“ into the “real-world“ making sure user perspectives and dependencies to other areas of life stay in focus to produce value and advance society.

For this approach to succeed, universities must re-structure, starting with a mindset change – away from “admin-thinking“ towards an “entrepreneurial mindset“ by recognizing opportunities, demonstrating the ability to act quickly and precisely, agile developing new concepts, and enabling a flexible and supportive infrastructure.

In this scenario, transdisciplinary-learning environments in EUnis should not depend on faculties; rather REE stakeholders should be included in co-creation to think, tinker and tackle challenges that are rising in particular fields of society and/or having impact on specific regional areas. In-house EUnis infrastructure would pride itself with a flexible architecture and open access points so that stakeholders connect and communicate easily (e.g. living labs and creative spaces).

This paper presented the development process of a novel interdisciplinary educational approach, regarding the possibility to combine the implementation of an entrepreneurial idea with the acquisition of a Master's degree. This approach shifts away from short-term EE formats to a more long-term continuous approach that deep dive into a topic, while supporting the continuous development of a real project from idea to solution to market. Hence, the expectation is that DDP graduates actively shape the future of digital transformation through entrepreneurial thinking and action in the REE.

Theoretical implications of this paper regard advancements in understanding and shaping EUnis future within in a REE, through the case DDP development by MUAS/SCE. The DDP implementation will also contribute to shed light on which drivers towards a more entrepreneurial mindset are best affected through different educational approaches.

Practical implications are threefold: First, DPP impact and strengthens Munich’s REE by skilling-up future workforce and founders, while knitting ties between REE stakeholders tighter. Second, DPP offer industry partners access to a rich EE teaching experience. Third, DDP shall enable life-long learning opportunities to participants.

Overtime, the DDP continuous evaluation shall empirically establish the value added to all stakeholders involved and shed light into the feasibility, desirability and viability of such educational format.

Competence-Related Challenges for Micro-Enterprises Entering the Field of Servitization

Kyllikki Taipale-Erävala and Matti Muhos
MicroENTRE, University of Oulu, Finland
kyllikki.taipale-eravala@oulu.fi
matti.muhos@oulu.fi

Abstract: The purpose of this study was to examine the competencies that micro-enterprises (micros) need in order to enter the field of servitization. Servitization is a great business opportunity for micros, but it is important to know what competencies a firm needs when targeting the longer and more profitable customer relationships that servitization may offer. Micros possess limited human resources and thus competencies, and it is crucial for them to understand competence-related challenges in order to operate successfully. This empirical study was conducted by employing a qualitative research approach in order to enrich the collected data and the findings. The multiple case strategy used here allowed for an extensive examination of the phenomenon of interest. Data were collected by means of interviews in eight Finnish subcontracting micros in the fields of forestry and mining in order to produce new information about the competence-related challenges faced by micros entering the field of servitization. The results show that micros face competence-related challenges in servitization in terms of entrepreneurship, functioning under change and financing. Entrepreneurial competencies are strongly linked to recognising opportunities and envisioning future business opportunities. There is also a need for change competencies, both for micros and customers, including the ability and willingness to change by renewing employees' skills and methods of working. Financial difficulties and a lack of understanding regarding future economic responsibilities were highlighted as challenges. This competence-based approach to studying micros in the context of limited human resources allowed us to identify the competence-related challenges that micros face in the industrial mega-trend of servitization. In addition, this study addressed academic and practical application gaps in the study of micros.

Keywords: micro-enterprises, competencies, servitization, case study, Finland

1. Introduction

This paper concerns the competence-related challenges that micro-enterprises (micros) face when entering the field of servitization. Servitization means enhancing the capabilities and renewing the processes of a company in order to create mutual value for the company and its customers. This process occurs by shaping a firm's offering from traditional products to product–service entities (Baines et al., 2009).

Micros employ 1–9 people and have a turnover ≤ € 2 M€ or a balance sheet total ≤ € 2 M€ (European Commission, 2018). Micros represent over 95% of European enterprises (Muller et al., 2016) and are considered a driver of the European Union's economy. There is a lack of academic research on micros (Kelliher & Reinl, 2009) and a considerable gap in the literature regarding micros (Samujh, 2011). It is widely acknowledged that micros experience resource scarcity, which forces them to operate under financial and expertise constraints (Kelliher & Reinl, 2009). Human resources are limited, and, therefore, competencies are limited as well.

Micros are largely influenced by their owners and managers (Burns, 2010). Predominantly, a micro's culture is an extension of the owner's personality, as the owner plays a pivotal role in an organisation's focus and success (Kelliher & Reinl, 2009; Burns, 2010). When a micro-entrepreneur faces challenges, unexpected changes or crises, he or she must usually solve them alone. Entering the field of servitization may challenge a micro's competencies, and it is crucial for micros to evaluate their limited competencies proactively before entering the servitization field. In addition, to acquire competitive advances in business with limited human resources, Barney, Wright & Kechen (2001) stated that, for small firms, '[. . .] much of the focus of RBV [resource-based view] research has been on larger firms, yet smaller firms also face the need to acquire critical resources to create a sustainable competitive advantage' (p. 634).

Servitization has a great impact on customer value in terms of co-operation and individualisation (Carsten Carsten, Müller-Stewens & Zimmermann, 2017). For micros, servitization is a great business opportunity, but it is important to know what competencies a firm needs when targeting the longer and more profitable customer relationships that servitization may offer.

To study competence-related challenges in micros, the research questions of this study were as follows:

1. What competence-related challenges do micros face when entering the field of servitization?
2. How do limited human resources influence micros entering the field of servitization?

The current paper, being qualitative in nature, examines competence-related challenges from various perspectives and focuses on defining the phenomenon in terms of micros with limited resources. Generally, competence literature concentrates on large business units (Barney et al., 2001) with people who have special competencies that enable them to perform different tasks in a company. However, in a small firm, everybody must perform several tasks (Taipale-Erävala, 2015); thus, the current competence literature cannot be applied micros. This study narrowed a discovered gap in qualitative case study research on management development and training in the context of micro-business entrepreneurship and micros (Devins et al., 2005). Qualitative research and face-to-face interviews are informative and may offer wider understanding of a phenomenon; thus, interviews were conducted. Furthermore, this study obtained new knowledge related to servitization.

Although many academic studies have been conducted on this topic, research on servitization seems to concentrate on existing knowledge in the study of manufacturing industries (Kowalkowski, Gebauer & Oliva, 2017). Micros generally act as subcontractors in various industries and offer a rich platform for research as a result.

2. Previous Research

There are few competence-related studies on micros. Kelleher and Reinl (2009) studied the competencies and competitive advantages of micros, concluding that 'there is an assumption that knowledge must be used optimally within the micro-firm by developing the analytical and critical skills of individuals, groups and the entire organisation so as to sustain and grow these firms' competitive advantage'. Micros employ between one and nine people, so studying competence is partly individual and partly organisational.

Before diving into the previous literature, it is important define *competence*, as it is a fuzzy concept (Delamare-LeDeist & Winterton, 2005) due to its similarity to *competencies* (van der Klink & Boon, 2003). Sanghi (2007) explained that competence is skill-based (i.e., what a person can do), while a competency is behaviour-based, (i.e., how to do it). Many definitions of *competence* and *competencies* exist in the literature (e.g., Biemans et al., 2004; Brockmann, Clarke & Winch, 2008; Spencer & Spencer, 1993). In this study, we define competencies as human features, abilities, attitudes, capabilities, skills, experiences and other traits that influence a firm's operations. According to Klemp (1980), a competency is 'an underlying characteristic of a person which results in effective and/or superior performance on the job' (p. 21).

A business begins when an individual discovers an opportunity, executes an idea into profitable innovation and establishes an enterprise, becoming an entrepreneur (Shane, 2003). The act of discovering an idea, exploiting it and executing it requires entrepreneurial competencies. Entrepreneurial competencies focus on scanning the future business environment, generating ideas and identifying new business opportunities (Mitchelmore & Rowley, 2010). Chandler and Jansen (1992) explained that entrepreneurial competencies include entrepreneurial skills, managerial skills and technical skills. Micros are small; thus, an entrepreneur who exploits and executes an idea often acts as a manager and requires managerial competencies.

Managerial competencies are crucial for firms to develop other competencies (Lado, Boyd & Wright, 1992), including financial and human resource management, marketing and commercial activities and leadership skills (Loué & Baronet, 2012). Thus, an entrepreneur orchestrates physical, human and monetary resources and business performance using managerial competencies. When starting a business, an entrepreneur focuses on physical and monetary resources and then on human resources. Human resources in micros are usually limited. In Europe, micro-, small- and medium-sized enterprises employ at least four people (Lukacs, 2005), forming an organisation with organisational competencies. According to Teece, Pisano & Shuen (1997), organisational competencies are firm-specific assets formed by individuals and groups to facilitate firms' performances. Similar to organisational competencies are network competencies (Ferrer et al., 2009), which focus on inter-organisational networking and co-operation (Lambert & Cooper, 2000). Organisational competencies are built on top of individual competencies (Nurach, Thawesaengskulthai & Chandrachai, 2012).

Overall, individual competencies create a basis for a firm's expertise; therefore, the effect of employees' skills and competencies on any firm's performance is significant. Job competency (i.e., how an individual benefits a micro) is an underlying characteristic of an individual that results in superior and effective performance in a job (Boyatzis, 1982; Klemp, 1980). In order to achieve competitive advantages, both employee- and organisational-level competencies are important (Hitt, Ireland & Hoskisson, 2005). The business environment changes constantly; thus, individuals and originations must be willing to change. Change competencies allow firms to survive through various business changes, such as renewing skills and work mannerisms and having a proactive attitude towards change (Taipale-Erävala, 2015). When a business environment changes, change competencies are required. Servitization, as a modern trend, is a challenge to many companies, including micros.

Servitization is an action where a 'firm offers bundles of customer-focused combinations of products, services, support, self-service and knowledge' (Vandermerwe & Rada, 1988) to enhance competitive advantages (Wise & Baumgarter, 1999; Neely, 2007; Baines et al., 2009a). Over the years, product–service combinations have increasingly shifted from selling a product to customers to leasing, hiring, pooling and paying for availability or performance (Spring & Araujo, 2009). Thus, the boundary between products and services is now obscure (Ren & Gregory, 2007; Baines et al., 2009b).

3. Research methods, data collection methods and data analysis

This study is a cross-sectional multiple-case study (Saunders et al., 2009; Yin, 2009). Case study research produces detailed and holistic knowledge based on the analysis of multiple empirical, context-rich sources (Tellis, 1997). It is commonly used in business research as a method to improve the knowledge of individual, group-level, organisational and social phenomena (Yin, 2009). Case studies can produce rich descriptions of every-day life (Stake, 1995); in this study, this refers to the beliefs, opinions and views of micro-enterprise managers regarding the competence-related challenges of entering the field of servitization. A case may be a unique or special, operating according to a pattern (Stake, 1995). Micros and the competence-related challenges related to servitization are special cases because of their novelty in business.

The data collection used herein involved individual, focused interviews. In a focused interview, the aim is to collect data by interviewing a person or people for a short period of time (Yin, 2009). The data were collected from eight Finnish micros using semi-structured interviews to ensure that rich and focused information was collected (Merriam, 2009). A qualitative approach was selected for this study in order to obtain a better understanding of the context within which decisions are made and actions are performed (Myers, 2009). The researchers interviewed the representatives of the micros. In this study, the firms were chosen based on industry, size and location. The case companies represent Finnish micros functioning in process industry. The interviews were conducted between 24 April 2017 and 22 August 2017. Table 1 summarises the studied micros and interviews.

Table 1: Descriptions of the interviewees and their interviews

Case number	Industry in which the firm operates	Number of employees	Interviewee(s)	Length of interview
1.	Forestry	2–3	Managing director	1 h
2.	Mining and delivering comprehensive ICT services and solutions	5	Managing director, Marketing manager	1 h 18 min
3.	Machining, subcontracting	5	Managing director, Chief financial officer	1 h
4.	Supplying electrical devices and equipment for mining and community infrastructure building	2	Managing director	1 h 16 min
5.	Maintenance services in the mining industry	8	Managing director	59 min
6.	Manufacturing high-speed electronics for mining, the steel industry, pharmacies and bio-pharmacies	6	Managing director, Marketing manager	1 h 11 min
7.	Diving and underwater works for industries, municipalities and ports	1	Managing director	1 h 2 min
8.	Installing equipment for the forestry, mining, energy and steel industries, including maintenance and welding	4, temporary staff when needed	Managing director	1 h 8 min

Before the interviews, all interviewees received a semi-structured questionnaire to familiarise themselves with the topics. During each interview, the order of the topics varied. Interviewer allowed each interviewee to discuss the topics freely, as a relaxing atmosphere allows people to talk openly about their opinions, beliefs and experiences. The questions were clarified and repeated if necessary in order to ensure the interviewees' comprehension. The central themes covered by the interview were; (1) customer, (2) offerings, (3) value proposition, (4) sales structure, and (5) present and future challenges. Before each interview, the researcher explored the publicly available secondary data pertaining to each micro.

A modified grounded theory-based process (Easterby-Smith, Thorpe & Lowe, 1991) was used to conceptualise the framework through the classification of data related to the research questions (Merton & Kendal, 1957). The interviews were first coded based on the research questions, and after that the main coded items were grouped and categorised based of their similarities.

4. Findings

The findings are presented separately related to the research questions RQ1 and RQ2. First, the analysis of the data related to the first research question RQ1 revealed the following competence categories: entrepreneurial and managerial competencies, individual competencies related to an entrepreneur, individual competencies related to an employee, financial competencies and change competencies. Table 2 presents the competence categories classifying the first phase of the coding with examples taken directly from the interviews. Second, the analysis of the data related to the second research question RQ2 revealed that limited human resources are a major challenge for micros entering the field of servitization.

4.1 Competence-related challenges for micro-enterprises entering the field of servitization

The competence-related challenges are categorized in the Table 2 below divided in Entrepreneurial and managerial competencies, Individual competencies of an entrepreneur and an employee, Financial competencies and Change competencies.

Table 2: Competence-related challenges for micros entering the field of servitization

Competence category	Examples	Quotations
Entrepreneurial and managerial competence	A lack of entrepreneurial competencies (case 3) Not actively looking for new business opportunities (case 3) A lack of managerial competence needed to clarify business plans (case 4)	'We need to search for longer customerships and partnerships, but we have not achieved them, and this is our challenge in the field of marketing' (case 3) 'The [business plan] needs to be cleared up because our resources will not last long' (case 4)
Individual competence (entrepreneur)	A lack of language proficiency, which is an obstacle to increasing international trade (case 1) In a network, a single entrepreneur is able to conduct more work; however, in a network, not all possess network competencies (case 7)	'My language proficiency is limited. I had to choose either technology or language. I chose technology' (case 1) 'I could find a partner and get together a packet, but it has failed to happen' (case 7)
Individual competence (employee)	Availability of competent, permanent employees (case 1) Shortage of experienced, skilled, multi-tasking personnel (case 4)	'I have trained about 10 guys, and, when they are skilled, they put their papers [job applications] elsewhere' (case 1) 'We have to recruit, but it is terribly difficult to find employees. This is a special field; it takes time for a person to learn' (case 4)
Financial competence	No observations about cost effects (case 6) Understands variable costs, but not the influence of fixed expenses (case 7)	'It [servitization] may be a goal in the future, but it demands resources from the company and the organisation. We do not possess such resources at the moment' (case 6) 'Goodness, insurance is the greatest nuisance' (case 7)
Change competence	An entrepreneur understands the risk of one supplier shutting down a mine but clings to the past (case 5) Field-specific unwillingness of customers to develop new solutions (case 2) Do-it-yourself attitude prevents new sales (case 1)	'It is kind of difficult to experiment away from here, because the work there remains undone and work here remains undone' (case 5) 'The culture [in mining] is such that people want to do things that they have done before in the same way' (case 2) 'You [the customer] can get the best profit using new skills' (case 1)

4.2 Competence-related challenges for micro-enterprises entering the field of servitization

Herein, entrepreneurial and managerial competencies were treated together, because, in a micro, the entrepreneur acts as the manager as well. Entrepreneurial competencies include searching for new business possibilities by scanning the business environment and developing new business ideas. It is possible to exploit servitization in order to search for new business possibilities, for example, by increasing digitisation or increasing the number of services instead of delivering products. Passiveness is a competence-related challenge in searching for new businesses, as noted in case 3 with the following statement: '*We need to search for longer customerships and partnerships, but we have not achieved them, and this is our challenge in the field of marketing'*. Another challenge is clarifying scattered business plans, as noted in case 4: '*The [business plan] needs to be cleared up because our resources will not last long'*.

Individual competencies were treated from the point of views of entrepreneurs and employees, as micros with few employees may be competent and successful by networking or acquiring other competencies. This study revealed a lack of language proficiency to be a challenge, as noted in case 1: '*My language proficiency is limited. I had to choose either technology or language. I chose technology'*, as well as the need for networking, as noted in case 7*: 'I could find a partner and get together a packet, but it has failed to happen'*. Micros have challenges in terms of the unavailability of professional and permanent personnel. As such, they must train employees to obtain the skills the micro needs, as noted in cases 1 and 4: *'I have trained about 10 guys, and, when they are skilled, they put their papers [job applications] elsewhere' and 'We have to recruit, but it is terribly difficult to find employees'* (case 1) and *'This is a special field; it takes time for a person to learn'* (case 4).

Financial issues and competencies are important for micros to secure financial capital and ensure low turnover. Servitization is a novel issue, and observations on its financial effects on business operations are scarce. In a start-up, *'it [servitization] may be a goal in the future, but it demands resources from the company and the organisation. We do not possess such resources at the moment'* (case 6). In the interviews, insurance came up unexpectedly. When asked about the financial considerations when entering the field of servitization, the interviewee stated, *'Goodness, insurance is the greatest nuisance'* (case 7).

When entering the field of servitization, business operations change; thus, change competencies are required, including a proactive attitude towards change, the ability to tolerate uncertainty and the willingness to renew skills and work mannerisms (Taipale-Erävala, 2015). Change is difficult to implement, as entrepreneurs may cling to the past, as seen in case 5: *'It is kind of difficult to experiment away from here, because the work there remains undone and work here remains undone'*. In addition, customers or industries may avoid novel business solutions and want to proceed as usual, which interferes with servitization, as seen in case 2: *'The culture [in mining] is such that people want to do things that they have done before in the same way'*. In addition, customers' do-it-yourself attitude prevents new sales, as noted in case 1: *'You [the customer] can get the best profit from your forest using new skills'*.

4.3 Limitations of human resources for micros entering the field of servitization

Servitization requires planning. When a micro considers providing advanced services, it may face a lack of time, challenges in increasing business operations, challenges in changing employees' individual attitudes and challenges in recruiting skilled and motivated personnel. These challenges are presented in Table 3.

Table 3: Limitations of human resources for micros entering the field of servitization

Limitation	Quotations
Lack of time	'We do not have the time or human resources to acquire knowledge of the conditions of international business' (case 1) 'No time to invest in marketing and minor human resources in marketing' (case 3)
Challenges in increasing business operations	'We do not have any resources for servitization yet' (case 6) 'The servitization business in the industry is too big for a small firm, so small firms remain small' (case 8)
Employees' individual attitudes and conditions	'We have difficulties getting personnel to work long-distance jobs' (case 5) 'It is a challenge to recruit personnel to work long-distance jobs' (case 8)
Difficulties in recruiting skilled and motivated personnel	'You cannot operate in servitization at a large scale because of the unavailability of competent personnel' (case 1) 'Challenges in recruiting competent staff. Young people are not interested in the field [mining]' (case 5)

A lack of time is a common challenge for small firms, as confirmed in this study. The research question targeted the influences of limited human resources, which were manifested as slight actions in marketing (case 3) and a need for familiarisation with servitization (case 1). Based on the research, servitization seems to be connected to international business, which naturally depends on the industry of the micro.

Overall, micros lack resources for servitization (case 6), which may also mean limited physical or financial resources. In addition, servitization seems to be a big issue for micros (case 8). Servitization refers to certain actions, such as taking care of devices. Thus, employees must work outside of the micro's premises. The study revealed that employees are unwilling to work far away from their normal living areas (cases 5 and 8), which makes entering servitization challenging.

In addition, recruiting challenges hinder micros from entering the field of servitization. Although micros want to offer advanced services to their customers, the unavailability of competent personnel (cases 1 and 5) prevents this. Moreover, attractiveness varies by industry, in that young people are generally not interested in working in some industries (case 5).

5. Discussion and conclusion

The study focused on examining the competencies that micros need in order to enter the field of servitization using empirical and qualitative methods, specifically targeting the competence-related challenges that a micro may face, especially those caused by limited human resources. The findings highlight that servitization is quite novel and unfamiliar to micros. All the interviewed firms operate within large companies in the forestry and mining industries, where servitization has been used for years. Although some micros operate in industries where servitization is used, they might not recognise it as a new trend but rather through the lens of the status quo. However, micros will face servitization eventually; thus, the sooner that enterprises familiarise themselves with the basic issues of implementing servitization, the sooner these firms may benefit from the business obtained by providing advanced services.

A business begins when an individual discovers an opportunity, executes an idea into profitable innovation and establishes an enterprise, becoming an entrepreneur (Shane, 2003). Entrepreneurial competencies focus on scanning the future business environment, generating ideas and identifying new business opportunities (Mitchelmore & Rowley, 2010). This study indicated that micros desire long customerships in order to stabilise business fervency but do not see servitization as a solution. In addition, micros possess unclear business plans due to their limited resources, which can be solved by achieving proper entrepreneurial and managerial competencies (Chandler & Jansen, 1992).

In terms of managerial competencies (Loué & Baronet, 2012), marketing and financial issues are challenges. Actions of marketing focus on acquiring more customers and orders but neglect financial issues, which can deeply harm small businesses. Thus, servitization seems to challenge the financial ability and economic knowledge of micros. Advanced services may produce high revenue for micros, which also means higher costs in terms of increased investments. According to this study, micros experience variable costs, especially insurance costs, to be the biggest challenge, although fixed costs may cause bigger challenges.

Individual competencies refer to all human features, including abilities, attitudes, capabilities, skills and experiences, all of which can affect job performance (Boyatzis, 1982; Klemp, 1980). Both employee- and organisational-level competencies are important (Hitt et al., 2005). This study indicated a lack of individual competencies (e.g., language proficiency and insufficiency to achieve the desired goal) and frustration surrounding the need to train competent employees and then losing them. The unavailability of skilled and competent personnel is a challenge that relates first to the individual competencies of employees and second to entrepreneurial and managerial competencies, as entrepreneurs are in charge of recruiting employees. Discovering the reasons for employee turnover will allow entrepreneurs to enhance their managerial and entrepreneurial competencies.

Servitization is a huge change in manufacturing industries that demands change competencies, such as a proactive attitude towards change, the ability to tolerate uncertainty and the willingness to renew skills and working mannerisms (Taipale-Erävala, 2015). This study revealed that change competencies are required, and entrepreneurs cannot cling to the past. They must put effort towards looking for new customers or business

ideas. Long customerships with only one customer endanger a micro's business continuity if the entrepreneur does not change his or her attitude towards change. The research highlighted that customers hinder change and want to operate in the same way as always. Thus, the progress of servitization depends both on micros and on their customers.

The study found that limited human resources are caused by a lack of time. Acquiring knowledge and familiarising oneself with servitization takes time from entrepreneurs and employees, but small firms can lower the threshold by networking. Sharing resources and building trust with partners in a network broadens human resources and enables efficient, flexible, high-quality and time-based operations (Ferrer et al., 2009). Using network co-operation had not been considered by micros but can be done to broaden human and other resources in the future.

In addition, the quality of personnel limits micros from entering the field of servitization. Employees' individual attitudes and conditions influence new business outputs. The unwillingness to work outside the premises and ambitiousness both indicate the personal valuation of work circumstances and institutional and social appreciations, all of which a micro may find difficult to change.

In conclusion, this study determined competence-related challenges for small enterprises, including a lack of time and the unavailability of personnel, both of which are connected to limited human resources. This may be eased by networking and co-operation with other small enterprises. This study also identified the importance of entrepreneurial competencies, focusing on discovering new businesses and exploiting possibilities for servitization. In addition, this study found that financial competencies challenge micros through the increased consciousness of investments and costs, which may fall on a supplier instead of a subcontractor. Finally, this study found that servitization changes the business environment. Overall, through change competencies, it is easy for a micro to enter the field of servitization.

First, this study is limited to competence-related challenges of micro-enterprises entering the field of servitization in manufacturing industries. In order to have broader view of competence-related challenges in micros, we encourage further research in other industries. Second, the data is collected in Finnish context. To study attitudinal and other competence-related challenges, we recommend opening the phenomenon in other contexts (different countries, regions, cultures, business ecosystems etc.). It may open new perspectives; e.g. if cultural items influence willingness to work outside the local business ecosystem, and other personal valuations of work circumstances. Moreover, in addition to studying the phenomenon in the context of micro-sized enterprises opened in this study, we encourage opening the competence-related challenges of small and medium-sized as well as large enterprises entering the field of servitization.

Acknowledgements

This study was funded by the European Union program Interreg V A Nord project entitled *Business Model Innovation and Internalization of Process Industry SMEs (ProcessSME)*. The European Union program Interreg V A Nord is supporting cross-border cooperation in order to strengthen the economic and social development. The areas included in the program are north Norway, north Finland, north Sweden and Sápmi (which spreads over all three countries). The main objective of ProcessSME project is to improve the competitiveness of SMEs whose customers are found within the process/mining/energy/oil/gas industries.

t.maswera@shu.ac.uk

Abstract: Knowledge transfer is often seen as a mechanism to support innovation of this sort, and in this paper, we describe work aimed at developing an understanding of such collaborations. Within this setting we believe that the adoption of digital technologies can lead companies on a path that can take them into new and challenging territories. Our work focuses upon support for digital innovation for Small to Medium Enterprises (SMEs) aiming to identify alternatives/strategies for establishing effective knowledge transfer based innovation. We analysed existing digital innovation models and instruments in order to develop an understanding of the factors valued in characterising digital innovation. Our findings show that although existing approaches have a useful role in digital innovation, they are however inappropriate for SMEs, who have probably not been involved in such a transformation. In addition, this paper reports on the early instrument developed to identify potential for digital innovation based on collaborative knowledge transfer between SMEs and universities. This study provides a better understanding of the makeup and effectiveness of some of the existing digital innovation models and frameworks.

Keywords: Knowledge Transfer, Digital Technology, Knowledge Exchange, Innovation.

1. Introduction

The aim to innovate is commonly proposed as a good means of supporting commercial growth within industry as well as presenting opportunities (Arbell et al., 2016). It normally offers the prospect of moving beyond incremental changes to business models and processes improvements; enabling steep changes through developing new products and services, and also revisions to tried and tested models of operation and distribution. This research is based upon the assumption that there are a number of characteristics of digital technology that make its general role in innovation and commercial growth interesting while also often being poorly understood.

> *"… computing devices are no longer isolated but connected by increasingly ubiquitous communication networks. Mobile devices and pervasive applications link their users to networked applications and to other people almost permanently. The nascent 'Internet of things' and digital/material 'hybrid' objects are beginning to link what we have to come to think of as distinct 'virtual' reality to the reality of everyday material objects."* (Walker et al., 2012)

Digital-based innovation is dominant in many aspects of business transformations and developments. This ranges from operational innovation of realising and developing in-house digital capability, through to the innovative application of novel technology within a specific sector, or market. However, there are two main drivers: technological feasibility and market readiness. These often enable operational transformations resulting from: smaller, faster, more secure, more accessible (geographically and temporally), intelligent and/or automated products and services. While enabling operational improvements at the point of implementation, their potential to be disruptive within a market is high and often the innovation is in terms of business models and processes.

Despite these opportunities, there are significant challenges about how to make the best of digital innovations within business, including technological, financial, organisational and regulatory (Ramilo et al., 2014). As Berkhout and Duin (2004) put it: merely investing in product development does not suffice in a competitive digital industry.

- Our research and assessment is driven by two perspectives concerning governmental and strategic support for company innovation:
-
- *Third party innovators* – This refers to the role adopted often by agencies and consultants, by explicitly bringing innovation to a company. Although this can appear naïve, it has the benefit of being a way of

managing, monitoring and resourcing interventions aimed at supporting innovation. Hence, it is especially relevant to governmental programmes aimed at driving innovation. It should be noted that in terms of management of innovation, value comes from collaborations (such as joint-ventures), as opposed to the transactional perspective offered by third party innovators (BSi, 2008). The third party we focus upon, in this paper, is that of University expertise (sometimes termed a "knowledge provider"). Unlike consultants and professional agencies, Universities provide a level of access to expert knowledge and insight, and thus have an interest in ensuring that their own knowledge and research expertise are employed. Hence, they are not simply facilitators but also actively transfer or apply knowledge.

- *SMEs and Innovation* – SME's are of specific interest for a number of reasons based on their strategic economic relevance (Higón, 2011). Broadly speaking they are opportunistic and flexible and while often valuing innovation they are commonly not in a position de-risk an innovation process (Auzzir et al., 2018; Beck & Demirgruc-Kunt, 2006; Garcia-Perez-de-Lema et al., 2017; Liang et al., 2017; Ramilo et al., 2014). Specifically, in our experience for digital innovative products and services "speed to market" is often prioritised by SMEs in the digital sector.

Given this setting, the problem we wish to address is from the perspective of a "third party innovator" aimed at serving and supporting SMEs:

How can companies be helped to identify opportunities for innovation with digital technologies?

There are many facets to this problem beyond specific technologies. All companies will be at different stages of creating, developing and deploying innovations, hence the current "innovation maturity" of a company needs to be understood. More specifically, innovation may be enabled or inhibited by organisational and operational factors. Naturally, linking these in the business context will normally be motivating or justifying innovation. For a third party to effectively engage and contribute, clearly these facets are all relevant.

In order to gain a deeper understanding of this problem, we have focused upon developing an instrument to assist with scoping and assessing the potential for collaborative innovation. Since our institution is actively engaged as a third party innovator for SMEs, the instrument should be useful in itself. However, its design, development and refinement will provide key insights in to the problem of helping identify quality innovation opportunities.

In this paper, we discuss different innovation models and related instruments for understanding and managing innovation. This has fed into the creation of an initial version of our instrument, which has then been critically reviewed in collaboration with knowledge transfer professionals. We conclude the paper by summarising on our early findings and plans regarding the development of the instrument.

1.1 Knowledge transfer in the context of Higher Education in the UK

Interdisciplinary work and the exchange of knowledge between participants is central to innovation (Wehn & Montalvo, 2018; Lin & Wei, 2018). Within the context of higher education, perspectives are shaped by academic disciplines and objectives. In the broadest sense, it can range from research dissemination to public and professional courses (continuing professional development - CPD), through to an academic-based contribution to business and industry, and commercialisation of intellectual property. In the UK, there have been numerous governmental reviews of how an academic knowledge base could best interact with industry needs (see Wilson 2012, Witty 2013, Dowling 2015). In the context of this work, we focus upon the value of academic collaboration with industry that has relevance for one or both parties:

- There is a strategic and sometimes financial value for academia to realise the benefits of applying their knowledge and expertise in a commercial setting. The classical view being that of arrow projects (Witty 2013), where a discovery or insight forms the core basis for a future product, patent or service. The same value is recognised through the concept of research impact - a core element of UK research excellence framework (Stern 2016, REF 2017).
- There is a pedagogic value to knowledge transfer activity for academia in that it strengthens academic awareness of contemporary practice in industry that can underpin, inform and direct pedagogic objectives and practice. Strong academia-firm interactions have positive impact on innovativeness of SMEs (Jones & Corral de Zubielqui, 2017).

- There is an industrial value to being able to access expertise and knowledge in specific domains. Academic awareness of state of the art practice has the potential to contribute to product and process improvement and growth.

While this is not an exhaustive list of opportunities, it characterises some key cases. It is important to note that the different perspectives do not necessarily align. For example, the academic desire to publish research findings is at odds with an industrial desire to gain commercial advantage from the same insights.

1.2 Concepts of Digital Innovation

Digital innovation has over the years presented companies with a competitive edge in many respects. Numerous examples exist in e-commerce and, less directly, social media. It is hard to characterise such innovations, though we can pick some common features:

- The dissolution of traditional boundaries regarding: location, distance, scale and timeframes.
- The improved automation of processes (i.e. dissolution of boundaries of skills, ability and agency)
- Access to more data (quantity and quality) and the potential for greater transparency and/or insight.

Smart products which are data driven have been emerging to complement the traditional physical products both in homes and industry (Schwab, 2015). Digital innovation impacts also upon organisations' products and services that have been digitised – such as media production and publishing (for example, see Roast, et al., 2011).

These points concur with Nylen & Holmstrom (2014) who highlight that research in digital innovation has not progressed as much as innovation research in other fields, mainly because managers lack knowledge about digital technology and its potential. Hence, there is the potential that digital innovation opportunities need to be managed differently. Two significant challenges presented by digital innovation:

- The pace of digital innovation processes is judged to be different to that of traditional innovation. This is predominantly attributable to the fact that production processes differ and that the quality and integrity of digital products is largely inaccessible and only indirectly understood. This encourages a prioritisation of speed-to-market within digital technology companies and also means they need to keep technically up to date to maintain their competitive advantage.
- Once available, a digital innovation's impact is not easily managed. Digital is present in, and core to, so many processes that innovations have the potential to skew the very business assumptions and context on which the initial concept was based. The wide reach and accessibility of digital technology underpins this disruptive influence, and cascaded innovations. The reach of digital innovation is such that it impinges on many non-digital details (see UBER Rulings - Chapman, 2017).

While these factors are not new in innovation, we'd claim their relevance and velocity is distinctive in the domain of digital innovation.

2. Review of frameworks for understanding Business Innovation with Digital technology

In our research we analysed existing digital innovation frameworks, identifying those that were diagnostic in nature and explicitly relevant to digital innovation (Barbieri & Teixeira Álvares, 2016; Berkhout and Duin, 2004; Binz and Trufer, 2017; Carayannis et al., 2018; Chanaron, 2016; Chen et al, 2018; Gkypali et al., 2018; İzadi et al. 2013; Nylen and Holmstrom, 2014; Scaringella and Silviana, 2018;).

Berkhout and Duin (2004), BSi (2007), and Nylen and Holmstrom (2014) each present a different perspective: technology-cyclic, innovation management, and components of digital innovation. These different frameworks were critically reviewed by the authors and then insights and observations compared. The resulting assessments are summarised below, for each we identify their core features relevant to formulating a comprehensive approach to understanding digital innovation.

2.1 Cyclic Innovation model

The cyclic innovation model (Berkhout and Duin, 2004) is motivated by the fast-paced technological and market developments in the telecommunications industry and how they have continually influenced the way

companies innovate. However, with the advent of technological convergence across many business sectors it can be argued that its scope is not limited to telecommunications. The cyclic view is contrasted with the traditional linear model, where innovation is represented by a pipeline of sequential processes that starts at pure scientific research and ends with commercial applications. The cyclic account captures refinements that take into consideration the feedback from the market, and three other domains, linking changes in science, business, and technology. This gives four interacting "cycles of change" (Figure 1), intending to reflect the complex, contemporary cross-boundary innovation processes.

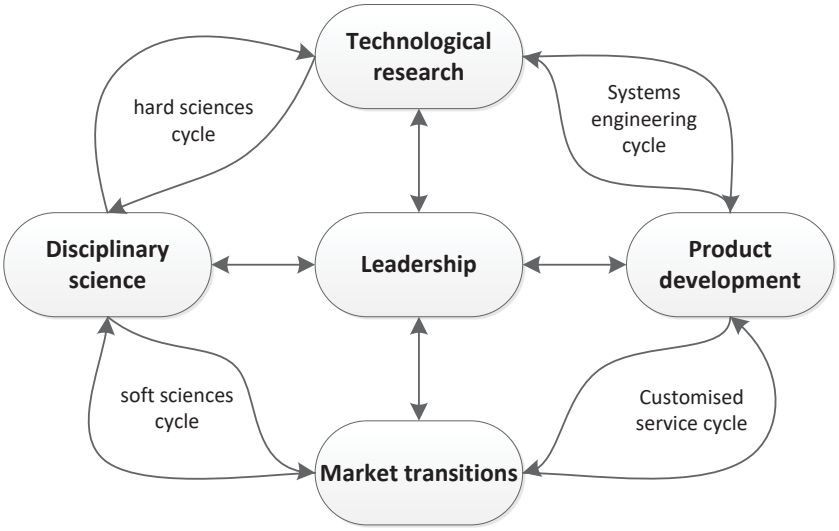

Figure 1: The Cyclic Innovation Model (Berkhout & Duin, 2004).

The model was used to analyse the introduction of a mobile data service into the Dutch telecommunication market. Berkhout and Duin (2004) discuss the complex nature of this specific venture, where a number of stakeholders contributed to the design and implementation of the service. In their analysis, they ascertain that the *Science and Technology* domain had not played any significant role in the new digital service - i.e. new science and technology components were not required to develop the new data service. While the *Market* domain played a vital role in that much attention was needed to understand the emerging business requirements and market potential during the early stages of the project. Subsequently, the understanding of the market allowed the establishment of a number of *Product* requirements (both functional and non-functional). In turn, those requirements specified the technological capabilities of the partners required in the project - i.e. software development, mobile device specs and telecommunications infrastructure.

In this example, innovation happened through the "Customised service cycle" and the "Systems engineering cycle" iteratively. Which illustrates that different innovation processes, will comprise different domain and different cycles of the model. The other cycles in the model clearly reflect viable innovation processes. However, timescales and velocity of each vary and thus shape the manner in which they may interact.

Although this model has not been used extensively, it is of value in that it is inclusive in the sense of recognising innovation drivers from a variety of stakeholders. The validity of this perspective can be found in many digital examples. From a digital focus, *Science and Technology* largely predicates innovations that are closely allied to *Market* transitions through customer engagement (and customer/market creation). Examples, such as UBER and many others illustrate this point - the technological infrastructure used has not purposefully driven the innovation. That said, the model also entertains a "reverse" flow from product concept to technological and scientific research. Some digital examples where product need has driven technological advances might be evident in Internet of Thing (IoT) development and cyber security.

In terms of our research aims, the model substantiates the view that innovation engages many facets of value that are not purely led by technology, or themselves digital. As we have observed above, the model also supports the point that digital results in innovations can gain their value in many "non-digital" contexts (principally business and market contexts). One question it does pose is whether any of the four domain and cycles represent necessary activities.

This model presents an interesting challenge for University based innovation under the auspices of KT, since it suggests that innovation in digital technology is not driving innovation within digitised markets - contrary to the notion of arrow projects. A more positive point is that the model indicates that innovation may benefit multidisciplinary knowledge transfer that Universities could easily support.

2.2 BS 7000-1:2008 Design Management Systems. Guide to managing innovation

BS 7000-1:2008 Design management systems (BSi, 2008), sits in contrast to the process view of the cyclic model, its primary perspective is organisational and focusing upon strategy, managerial structures, features and mechanisms that support innovation. Also, unlike more rigorous notions of a 'standard', it takes the form of guidance and recommendations for supporting innovation that are to be used selectively and adaptively to suit the needs of an organisation. Despite this, the dominant philosophy is that innovation should not be approached half-heartedly. It is not necessarily an individually-driven activity or linked to specific projects or programmes of work, it is something that needs to be practiced as an organisation - an overall philosophy that will reap benefits that will not be immediately measurable or causally related to specific initiatives.

The benefits of managing innovation effectively are those common to knowledge management in general, it supports a better understanding across an organisation, sharing of experience and reduces the risk of innovation 'drying-up'. This managerial perspective means that innovating within a company is not in itself innovative; it also resists the third party innovator model -especially where the innovator has no formal interest in a project.

The framework positions itself mainly in terms of innovation as a means of identifying and meeting customer needs or drawing in new customers in a competitive market. Hence, there is a strong customer focus/drive behind innovation. This emphasis on the domains of *Product* and *Market* means that, while *Science and Technology* are clearly relevant, an innovation without *Product* and *Market* relevance is unlikely to be supported.

As a rather management heavy perspective the standard is not ideal for small enterprises, and enterprises with light management. However, the tools and techniques provided have a greater potential value. Many of the innovation techniques collated are techniques widely adopted in many digital SMEs, especially those working in the B2C context. In addition, the standard offers a number of checklists and diagnostics for assessing innovation within a company, and these are likely to be of relevance within SMEs. This offers pointers towards evidence of innovation maturity within an enterprise with long term relevance, since the practice encouraged that are likely to enable sustained and successful innovation.

2.3 Managing Digital Innovation

Nylen and Holmstrom (2014) devised a framework not only to encourage innovation in organisations but also to help them keep track of their digital innovation ventures. The framework is a product of research examining the innovation processes and the challenges and demands of new technologies. In order to be able to properly manage uncertainties brought about by innovation driven by digital technologies three dimensions were identified: the digital *products/service*; the digital *environment* and characteristics of the *organisation*. Within these, five areas were proposed as being of importance to managing digital innovation:

- User experience (in Product/Service) - The focus of products should not just focus on usability but also on engagement and aesthetics as users are affected and influenced by what the product looks like. It was argued the focus on aesthetic properties by Apple has led to its dominance in the PC market. Within the innovation management processes, the relevance of the users voice and values is also recognised though not prioritise as here.
- Value proposition (in Product/Service) - Organisations need to clearly define the value proposition of the new product or service. The framework evaluates value proposition by assessing customer segmentation. The framework analyses the target market in an effort to ensure that the product is accessible to everyone. The information from the analysis of customers will be used to determine how to customise the product for each customer segment. Value proposition also assesses the revenue from the digital product or service which goes to distribution networks.
- Digital evolution scanning (in Environment) - As digital technology evolves, firms need to continuously look at how they can take advantage of the new technologies to improve goods and services. This is done by gathering information about new and upcoming digital technologies. Firms also need to

explore emerging distribution channels and how users react to them. This relates closely to one of the innovation tactics "horizon scanning" endorsed in the BSi document.

- Skills (in Organisation) - The rapid pace at which the digital innovation process occurs needs to be matched by the skills available within a firm. The framework evaluates this process by looking at ways in which learning is supported and promoted. The learning will have to be continuous to ensure a better understanding of the unique properties of the digital technologies. Companies are encouraged to take note of staff who come up with unprompted initiatives and then put them in roles that will enable them to experiment further with these technologies. Again, this aligns closely to some of the best practices encourage by the BSi document.
- Improvisation (in Organisation) - Traditional ways of designing and developing new products and services will not work because of the pervasive nature of digital technologies. This framework promotes innovation through improvisation. It is recommended that staff be given time and space to explore emerging technologies in an effort to promote creativity and ability to innovate.

Nylen and Holmstrom (2014) devised a diagnostic tool based on these key areas. The tool is "oriented" in the sense that it each element contributes directly to a score of digital innovation readiness. The tool is also not a standalone in that it is proposed as being basis for workshops and discussions about how to support digital innovation - starting with the lowest scoring areas of the framework.

This approach has been developed for the purposes of internal review of innovation practice within companies developing digital media. While our focus is on KT and SMEs in a wider range of industries, the dimensions proposed and their components can be repurposed on a wider context.

3. Developing an Instrument

Bringing together our findings and observations we have developed a pilot diagnostic instrument. This combines ideas from the three frameworks with the aim of helping to address our initial question. Specific attributes of the pilot instrument are: conciseness (for enabling engagement); generality (to cover the diversity of innovation contexts involving digital technology); digital relevance.

The instrument comprises a series of statements aiming at ascertaining a company's business strategy, and their approach to innovation and product/service development and value proposition. Also, company's understanding of their: market, segments and customer expectations; attitude to digital horizon scanning; and approach to the development of knowledge and skills among staff.

To date, the pilot instrument has been collaboratively assessed by nine KT professionals, ranging from 2 to 25+ years of experience in KT and Innovation roles. The full analysis of feedback and refinement of the pilot instrument is currently being conducted. However, on the whole, feedback has been positive with most critical elements concerning operational specifics regarding how it would be used in practice. Other points raised concern: the difficulties of keeping a digital focus (when an innovation may not involve an intrinsically digital advance); the extent to which companies have clear goals; and the importance of managing company expectations of KT, among others.

4. Conclusion and Future work

Our analysis shows that existing innovation frameworks have got a useful role to play in understanding innovation. However the distinctive nature of digital innovation is not easily identified, thus these frameworks may not be suited to companies with limited resources, light management structures, and no specific or explicit innovation goal. The three models reviewed represent different perspectives upon innovation, ranging from managerial to digital solutions. Nylen and Holmstrom (2014) is the closest to the diagnostic instrument we believe will enable to assist companies identify potential for innovation. However, in general, evidence backing their validity is limited.

Our original research interest is: How can companies be helped to identify opportunities for innovation with digital technologies? The three areas of interest shaping our work are: the distinctiveness of digitally based innovation; the role of knowledge transfer principally via third party innovators, and supporting SMEs. Only the first of these is addressed by the previous work of Nylen and Holmstrom (2014), while the second is discouraged by the British Standards Institution (2007).

Following a review, features of the models and frameworks analysed have been used to develop our own pilot instrument for address our original question. The next stage of this project is additional to the formative validation work, prior to applying the instrument within digital innovation opportunities coming from a "live" innovation programme for supporting SMEs.

The differentiation of digital and other technologies in innovation partly reflects the fact that digital is still novel in many respects. As such the authors are conscious that there are on-going legislative and regulatory changes that do, and will, impact upon digital services and their use of data (Government UK, 2017). Hence, while digital can view as presenting extensive new opportunities, it is worth noting that some innovations may be constrained.

A Study on the Growth of Millennial Entrepreneurs in India

Shaili Vadera
Amity University Uttar Pradesh, India
svadera@amity.edu

Abstract: India is among the top five countries globally in terms of recent millennial start-up revolution. According to the survey by Deloitte, millennial entrepreneurs are taking the lead in creating new start-ups in emerging markets. Six emerging markets economies like Vietnam, Philippines, Thailand, Malaysia, Peru and Indonesia show higher millennial entrepreneurship rates for women than men. In developing countries there has been a gradual increase in the number of millennial entrepreneurs in the last three years in contrast to United States where millennial entrepreneurship rates have fallen more than 70 percent since 1990s. The yearly percentage change is however projected to decrease from 1.07% in 2020 to 0.28% in 2050. The fact that there are such wide variations between entrepreneurial activity in different countries, distinction between necessity-based and opportunity-driven entrepreneurs is difficult. Millennial Entrepreneurs are important for sustainable development of emerging economies like India. Bengaluru has emerged as the prime destination for IoT (Internet of Things) start-ups to set up base, as it accounts for 55% of the total IoT start-ups in India followed by Delhi NCR with 13%, Mumbai 10%, Hyderabad 4.5%, Chennai 3%, and others together accounting for 18%. India still has a long way to go as compared to global entrepreneurial startup ecosystem. Total number of startups in US is 84,000 whereas India has only 10,000 startups. Technology based startups in US are 49,000 whereas India has only 4,300 tech-based startups. US has 35,100 non-tech based startups whereas India has only 5,700. The potential economic gains could be realised through India's increasing "demographic dividend", as county's working age population becomes larger than the dependent population. In India the median age is forecasted to be between 27 years to 40 years from 2020 to 2050.

Keywords: Millennials, Innovation, Motivation, Entrepreneurship, Economic Development

1. Introduction

Entrepreneurship has received much attention across the world over the last 20 years (Davidsson, 2008).

According to Kobia and Sikalieh (2010), entrepreneurship is relatively a young field of research study. The millennial entrepreneurs are known for their approach towards creative thinking and risk-taking. There are many challenges to starting and operating a new business (Bhuiyan, 2012). The entrepreneurship ecosystem is strongest in the innovation-driven economies. According to Global Entrepreneurship Monitor Report, top five Countries in Global startup ecosystem in 2017 were United States, United Kingdom, Canada, Israel, and Germany. Total number of startups in US is around 84,500 whereas India has only 10,500 startups. Technology based startups in US are 49,500 whereas India has only 4,400 tech-based startups. US has 35,200 non-tech based startups whereas India has only 5,800. Five out of six world's leading firms are U.S. tech companies with investments in artificial intelligence, Internet of things, robotics and automation.

Table 1: Comparison of Global Entrepreneurial Startup Ecosystem

Details of startups	India	China	Isreal	U.S.
Total number of startups	10,500	10,500	4,750	84,500
Tech-based startups	4,400	3,400	4000	49,500
Non-tech based startups	5,800	6,600	750	35,200
Ease of doing business (Days)	30-60	30	13	4
Corporate tax rate	34%	25%	26%	39%
Bank-lending rate	10.30%	5.60%	3.90%	3.30%

Source: World Bank, news article 2017-18

The main reason behind the success of US entrepreneurial stint is easy access to mature venture capital industry. Also, United States startups follow Lean approach in building the right product for the right target market for creating unique customer experience.

Millennial entrepreneurship is important for sustainable development of emerging economies like India. The potential economic gains could be realized through India's increasing "demographic dividend", as county's working age population becomes larger than the dependent population. In India the median age is forecasted

to be between 25 years to 40 years between 2020 to 2050. Currently, India has the highest youth population in the world. Millennial entrepreneurs are likely to create more than 1 million new employment opportunities by 2019-2020. Already, India has jumped 30 positions to become the top 100th country in terms of ease of doing business ranking in 2018 as announced by the World Bank.

2. Literature Review:

The entrepreneurship is the creation of new organizations (Gartner 1985). The Identification, screening and evaluation of business opportunities represents the beginning of the entrepreneurial process (Baron, 2010).

As per Caree 2005, Entrepreneurship is a multidimensional term that is difficult to define. Currently, there is not a single accepted definition of "entrepreneur" that has been uniformly accepted in the literature (Carlock 1994). Generally, the term "entrepreneur" is applied to the founder of a new business, or a person "who started a new business where there was none before" (Gartner 1985). The term has been used to indicate a range of activities from creation, founding, adapting to managing a venture (Cunningham & Lischeron). Peter Drucker in 1965 observed that despite inflation, recessions and major job losses in certain industries and government, there had been huge jobs growth in America. According to him, 40 million have not been created by large corporations or government, but mostly by small and medium sized businesses.

Kirzner (1985) defined entrepreneur as one who perceives market opportunities. According to Hisrich (1990) entrepreneur is a creative thinker who accepts risk and failure. According to Astebro et al (2003), there is a negative correlation between bank loan and business survival and positive relation between non-banking loan and business survival. As per Zara et al 2002, entrepreneurship is a relatively young academic field in the early stages of its developmental cycle. Howard Stevenson "added an element of resourcefulness to the opportunity-oriented definition. There is direct co-relation between marketing efforts and entrepreneurship (Hills et al., 1989-2009). Marketing orientation is central to the creation and sustainability of new ventures (Hunt, 2003), particularly during the opportunity recognition stage. Millennials have been portrayed as less willing to devote themselves to jobs, preferring a balanced lifestyle (Myers 2010). According to Holland's (1997) theory, people are attracted to work environments that conform to their personality orientation. Entrepreneurship is the engine fueling innovation, creativity, opportunity identification, employment generation, better standard of living, regional development contributing to economic growth and development of the country and society at large.

3. Motivational factors for rise of Millennial Entrepreneurs in India

1. Entrepreneurial Intent:

Gird (2008), found that attitude towards entrepreneurship is the strongest predictor in terms of entrepreneurial intent. Entrepreneurial intent plays a major role in entrepreneurship and innovation.

Schweitzer and Lyons (2010) used a large survey sample to determine the career goals, priorities and expectations of the millennial generation. Wang discussed that attitude, funding, family business, experience and education significantly impact millennials' entrepreneurial intention. Entrepreneurship activities are intentional based (Krueger et al., 2000). In other words, millennials will not adopt entrepreneurship without external or internal triggers and most importantly motivation.

According to Ajzen (1991), intention is directly affected by three factors, (i) attitude; (ii) subjective norm and; (iii) perceived behavioral control. According to Ajzen (1991), Attitude is considered as one of the important determinants of intention. Prahalad et al (2010) performed a study to investigate the motivational effects of attitude on students' entrepreneurial intention and found that attitude towards change, money and entrepreneurship were indeed some good predictors of entrepreneurial intention.

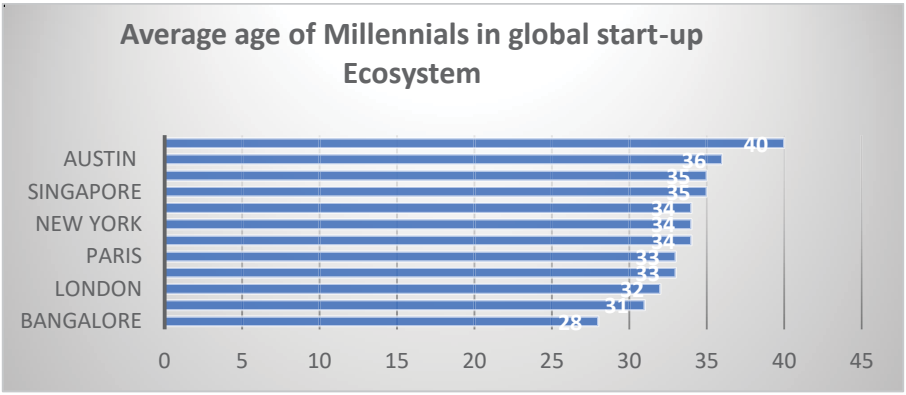
According to Global Entrepreneurship Monitor Report 2016-2017, the following motivational factors influencing millennial entrepreneurs in India were identified:

		H Value	DF	Significance
1.	Passion to become an entrepreneur	17.691	10.00	0.061
2.	Desire to be independent	3.796	4.0	0.435
3.	Funding	3.272	4.0	0.009**
4.	Previous experiences	19.138	4.0	0.008**

5.	Family Business	14.028	4.0	0.007**
6.	Attitude	1.972	1.0	0.006**
7.	Entrepreneurial intent	17.692	4.0	0.003**

The table clearly indicates that the following 5 factors viz., funding (0.009**), previous experience (0.008**), family business (0.007**), attitude (0.006**) and entrepreneurial intent (0.003**) are the key motivational factors contributing in the rise of millennial entrepreneurs in India. Entrepreneurial intention has been extensively researched in the West, Carr and Sequeira (2007). Findings on determinants predicting entrepreneurial intention varies across countries and cultures (Boulton and Turner, 2005).

Graph 1: Comparison of average age of Millennials in Global start-up Ecosystem



Bangalore is India's top city for startups and ranked 15 in the Global Startup Ecosystem Index. Bangalore has the youngest millennial entrepreneurs with an average age of 28S years compared to Silicon Valley's 36.2 years. The country is home to over more than 3,500 startups, making it among the top startup hubs in the world. The National Investment Fund is set to be established with an annual flow of INR 20,500 crore which will fuel entrepreneurship across Tier II and Tier III cities.

3.1 Millennial Startup Ecosystem in India

Chell (2008) suggests that personality traits of entrepreneurs may be important for millennial entrepreneurship. Shepherd et al., (2009) assumes that personality traits of the entrepreneur may explain entrepreneurial failure. Zhao et al., 2010) points out that personality traits have a direct effect on entrepreneurial performance. In India, millennial entrepreneurship has gained significant importance in last five years as a way of boosting economic development and promoting holistic regional development. Millennials are people born between 1980 and 2000 who believe in innovation, have positive mindset, risk-takers, seek opportunities, socially responsible and maintain work-life balance (Lloyd et al 2013). Millennial entrepreneurs are setting up their own businesses as early as 25 years compared to baby boomers that set up most of their first businesses at the age of 35 years.

According to BNP Paribas Global, while baby boomers were opening four companies, millennials were opening nearly eight companies in 2017. Private startups like Flipkart, Ola and PayTM having an equity of more than $1 billion, which has managed to motivate the next generation entrepreneurs. Millennipreneurs are targeting larger gross profit margins of almost 70% compared to 40% by baby boomers.

Table 2: Technology-based millennial start-ups in 2017- 2018

Sector	% share
Technology based E-commerce	34%
B2B	25%
Consumer Internet	14%
SaaS	7%
Other	10%

Source: NASSCOM Startup Report 2018

Share of Technology based start-ups in India were 34% followed by business to business at 25%. The digital economy is growing at a very high rate. Cooey, SenseGiz, PlaySolar, Altiux, iBot, Locanix, Entrib, GetActive,

Retsense, and Leaf wearables are few technology based start-ups which have emerged from the Indian IoT ecosystem.

3.2 India is home to Frugal Innovation

For much of the 20th century, innovation was the largely practiced by more advanced economies of North America, Western Europe and Japan and china (Ahlstrom, 2014; McCloskey, 2010). Millennials thrive on new challenges, innovation and creativity and expect responsibility early on in their careers (Severt et. al. 2009).

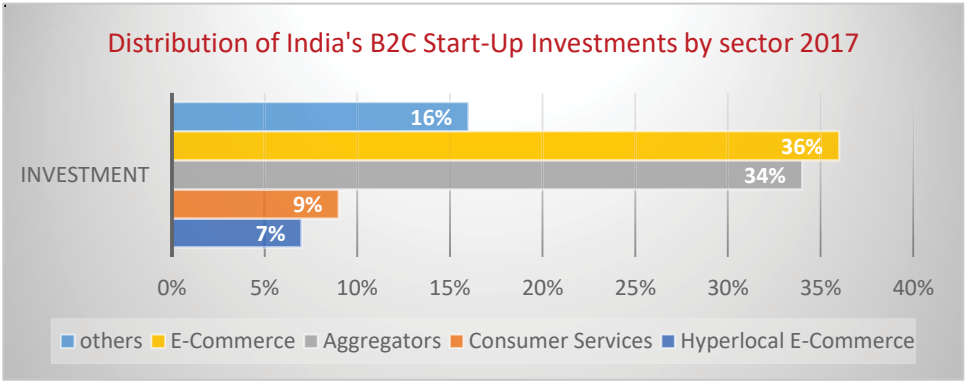
Innovation is critical for growth of millennial startups. Personality traits of entrepreneurs may have a different effect on firm performance in case the firms are innovative (Zhao et al., 2010).

Since 21st Century, much innovation has shifted to the large emerging economies of China, India and Brazil (Ramani & Szirmai, 2014). Also, a significant amount of the innovation taking place in emerging countries can appropriately be characterized as frugal, flexible and inclusive. Emerging markets account for some 86 percent of the global population under 30. Hart and Christensen (2003) explored how generating disruptive and frugal innovations for bottom-of-the-pyramid (BOP) markets represent a significant opportunity for millennial entrepreneurs. 80% of millennial entrepreneurs believe they are major source of technology innovation in India.

84 percent of millennial entrepreneurs are optimistic that entrepreneurial innovation will further rise in the next two years. India has been at the forefront of frugal innovation. Millennials entrepreneurs have vast opportunity related to frugal innovation tailored to meet the needs of emerging markets like India. There are several examples related to frugal innovation in India like a “smart plug” developed to help lower, middle and upper-middle class consumers manage their energy consumption more effectively. Mitticool, a biodegradable low-cost clay fridge has been developed which does not require electricity specially designed for rural population (Radjou, Prabhu & Ahuja, 2012). A similar approach to innovation called “the Swach,” a low-end water filter that does not require electricity and utilizes waste (such as rice husks) (Ahlstrom, 2010). General Electric has also designed ultra-low cost ECG machine to name a few.

3.3 Role of Incubators, Angel Investors, Venture Capitalists and Government in promoting millennial entrepreneurship in India.

India is 3rd largest start-up hub where percentage share of tech-based start-ups is 45% whereas non-tech based is around 55%. India is also home to many unicorns as well. More than 470 active Venture capitalists, private equity and angel investors participated for $5.5 billion funding in 2017. Average number of new tech startups have increased from 495 in 2010 to 940 in 2016 which is further expected to increase to 2,500 by 2020.



E-commerce sector received highest Investments followed by service aggregators at 34%. Till date there are 11,500 technology based new start-ups viz-a-viz 5,700 non-tech based start-ups in India. The average age of startup founders in India is around 26-28 years out of which 9.5% of total new start-ups are founded by women. The total number of incubators has grown by 45% to 115 during 2016-17. Approximately 70% of new jobs were created by MSMEs during 1993-2017. A lot of startups in India have entered the industry either unearthing an entirely new market or through gaps in existing markets or product line for example Housing.com, Zivame, AdPushup, Paytm, Uber, Redbus, InMobi, Chaayos etc.

Following is the list of start-ups and funding received in 2017-2018 from investors.

Table: 4 Top Millennial Start-Ups with Funding

Start-Up	Sector	Funding (USD Million)
Flipkart	E-Commerce	$3,200
Snapdeal	E-commerce	$1,700
Ola Cabs	Taxi services	$1,230
Paytm	Fin Tech	$936
Big Basket	Grocery E- Commerce	$ 249
OYO Rooms	Hotel network	$230
Zomato	Food Tech	$ 234
Practo	Med Tech	$179
Grofers	Logistics	$ 165
Pepperfry	Furniture	$ 128
Mobikwik	Fin Tech	$ 126

Source: Tracxn 2017

Flipkart, Snapdeal and Ola cabs were the three major start-ups which received funding from top investors. With a 57 percent of B2C, 36 percent of B2B, and 5 percent of B2C/ B2B startups, this ecosystem has a lot of ground to cover in terms of funding.

Under the non-technology based start-ups Engineering sector has 18% share followed by construction at 13%, agri-products at 10%, textile at 8% etc.

Table 5: Non-tech startups in India

Sector	**% share**
Engineering	18%
Construction	13%
Agri products	10%
Textile	8%
Printing & packaging	7%
Transport & logistics	6%
Outsourcing & support	5%
Other	33%

Source: NASSCOM Startup Report 2017

Manufacturing startups are driving innovation and widening the frontiers of industry for growth. Startup India is a flagship initiative by the Government for nurturing innovation and design in manufacturing startups in India. The intent of the campaign is to attract foreign investments and encourage reverse innovation to transform India into a manufacturing hub.

E-Commerce companies in India are planning to break into India's rural market as a part of the government's Digital India initiative. By 2020, a projected 11,500 tech-startups are going to emloy around 250,000 people.

Digital India aims to provide thrust in the following nine sectors including Broadband highways, universal access to mobile connectivity, public internet access programme, e-Governance, reforming Government through technology, electronic delivery services, Information for All, e-manufacturing, IT for jobs, and early harvest programmes. Government of India has also introduced expedited services for patent registration.

Large number of educational institutions have also started incubation centers to promote entrepreneurship among aspiring student entrepreneurs. Amity Innovation Incubator helps entrepreneurs realize their startup journeys through range of world class infrastructure facilities including incubation support, business advisory, mentoring, financial services and nurturing creation of university spin-off companies. Amity Innovation Incubator Startups' have been on the top of the innovation curve recognized on platforms like 'The power of ideas', Tata NEN, NASSCOM Innovation Awards, Red Herring Global awards to name a few. It has also launched virtual incubation in 17 cities like Mumbai, Ahmedabad, Kolkata, Hyderabad, Chennai, Kochi etc.

4. Impact of millennial entrepreneurs on growth of Indian Economy

Baron and Shane 2008, discussed about the role entrepreneurs play in bringing economic changes and advancements to a country's economy. According to (Martin and Osberg 2007) entrepreneurship is the product of a combination of three elements, opportunity identification, set of personal traits and the capacity to materialize the opportunity, by transforming it into results. For the Millennials, the most defining experience has been the growth of the Internet and technology (Joshi, Dencker, Gentz, & Martocchio, 2010).

The Indian startup ecosystem is driven by an extremely diverse and inclusive entrepreneurial workforce. India's millennial population is expected to expand to more than 25 percent of the global labor force by 2027, up from 18.5 percent this year. The number of people in China aged 15 to 64 will drop by 20 million to 979 million. In India, this number is expected to exceed more than one billion which provides an opportunity for the country's workforce to adopt entrepreneurship. Out of 500 workers surveyed in India, 60 percent considered quitting their jobs to start their own business." This was the highest percentage globally and the survey was held across 33 countries. Few of the leading millennial start-ups include Flipkart, Oyo Rooms, Paytm, Redbus, Zomato, Chaayos, Ola cabs, Zivame, Limeroad, Quikr, Cardekho, Justdial, Pepperfry, Practo, Urban ladder, Grofers, Shopclues, Nearbuy,Voonik, Inmobi, Yepme, Mobikwik, Bigbasket, Caratlane, Paperboat, Gojavas, Craftsvilla, Roposo, Nykaa, Hopscotch, Bluestone etc. India needs 10.5 million jobs a year and global data shows that it is start-ups that create net new jobs in any country. With over $7 billion worth investment in 2018, India has paved its way to secure the third position in the world in terms of the number of start-ups. India's current youth population is expected to serve for the country at least for the next 3 to 4 decades. India will become the world's youngest country by year 2020, with an average age of 29 years, and account for around 28% of the world's workforce. India will be experiencing a period of "demographic bonus," where the growth rate of the working age population would exceed that of the total population, which is certainly an added advantage.

5. Conclusion

Startup ecosystem in India has risen to a next level. Startup incubators share both tangible and intangible resources such as equipment, office space, services such as accounting, computing and legal services. They also assist startups in raising startup capital and perform various networking activities to reduce the financial burdens and resource issue. Educational institutions are creating centers of excellence to train professionals in the area of entrepreneurship to create a pool of resource persons in guiding and motivating the youth to take up entrepreneurship as a career option and promote research and development required for creating university spin-off companies. Incubators help entrepreneurs in building sustainable business environment while benefitting the broader corporate communities. Pro-reforms measures are therefore required to provide much needed impetus to brand India as a Startup nation.

paa1380@gmail.com

Abstract: Despite the laws and employment programs and support for people with disabilities, the employment rate for disabled people remains less supportive than non-disabled people. Studies show that disabled people unemployment rate accelerate 63 percent and the clients' unemployment rate is over 48 percent in the society. Accordingly, it causes a high material and spiritual costs for disabled and clients' families as well as the society and supportive organizations. The aim of this study is to explain and codify the Welfare Organization' disabled people employment in region four of the country. This research is descriptive correlational. The participants were all people with disabilities under Welfare Organization in State Welfare Organization of Region Four of the Iran. The sample consisted of 376 people selected using stratified sampling. A researcher-made questionnaire used for data collection. The validity of the questionnaire determined through Factor analysis and academic experts review and Cronbach's Alpha used to enhance reliability. To analyze the data, confirmatory factor analysis and structural equation modeling used. Standard coefficient between variables of financial, personal, governmental, family, and job seeking factors, respectively on disabled people tendency to create business are .46, .86, .55, .70, and .36, which represents the strength and direction of impact is the independent and dependent variable. This ratio indicates that a unit change in these variables disabled people trends in order to create business respectively 46, 86, 55, 70,and 36 percent rise positively. Overall results indicate that individual, family, governmental, financial and job seeking factors of entrepreneurial have a positive and meaningful impact on the business tendency of disabled people. However, belief variable at 95% significance level does not have a meaningful impact on disabled people business tendency. The studies also shown in the development of entrepreneurship in this area should be more reviewed and considered, one of them is to receive and transmit experiences of adults with disabilities, and other changes due to the attitude of employers with disabilities to understand the specific capabilities of people with disabilities.

Keywords: Entrepreneurship, Disabilities, Self-employment, Employment, State Welfare Organization, Iran.

1. Introduction

Work has always been considered as an important aspect of human life throughout history (Sandys, 2000). In today's world, men's new approach and attitude towards life is mostly based on competition and considerable changes in different parts like, economic, politic and socio-cultural. These new approaches have brought about different forms of issues and problems different to that of the past. Among these, one of the challenges is the issue of job and earning especially for the young generation. With regard to increase and change in population, shortage of sources, bankruptcy in business, continual economic stagnation, change in taste and interest and customers' expectation ect. These issues, have formed move intricate question then other social problems (Nahid & Ghanbari, 2010). In addition, disabled people one offer jobs and asking for fair income to that of others, no matter how small the job might which could be in accordance to their capabilities (McConkey and Mezza, 2001, Reid & Bray, 1998; Riches & Green, Schwaman, 1986).

Though physical in capabilities of the person may cause major challenges in finding a job. There are however, many jobs that disabled can have as decent jobs. These jobs can be in accordance to disabled physical and mental abilities and be different. For example, jobs in workshops, home business, self-employment and supportive activities and among the many jobs these people can have. Educational supportive workshops have been designed in a way that a disabled adult with basic professional skills and physical abilities can be employed. The purpose of such workshops is to develop working skills of the disabled in a way that it enables then to have a better chance of getting a job (Siporin & Lysack, 2004). The recommendation letter issued by international work organization has mentioned job opportunities for disabled, such as, supportive employment, way of getting rid of physical barriers. It is worth mentionir that, in developing countries disabled people do not have the same opportunities and access to facilities available for ordinary citizens like, sanitary

services, education, skill programs, employment services etc. (Mirkhani, 2006). In other words, illiteracy, unemployment, poverty, hunger, not a good level of education and health care and proper living condition due to poverty and socio-economic situations are among problems that can affect life and among problems that can effect life and working condition of such group of people to a great extent. It is obvious that by improving the structure of socio-economic condition, helping in poverty and sanitation and medical services and other measures one can to a large extent help to decrease the in capabilities of the disabled (Mohammadi, 2006). In spite of what employers believe in being fair in treating capable and incapable employees in workshops, at least attempts have been taken for the success and improvement of incapable people in their workshops (Dixon, Kruse & Van & Horn, 2003).

What is important in the employment of the disabled is that not only the person himself, but also his family and society can all benefit from it. Therefore, self-employment can be one of the most important solutions for employment for this specific group of people in the society. So, this study attempts to effect in making a tendency for start-up a business in distinct four of State Welfare Organization (SWO) including provinces like, Gilan, Semnan, North Khorasan and Golestan. Explanation will make it clear as to way and for what reasons people in their decisions for self-employment and running an independent business choose home as their starting point of their activity.in this study, the researcher is often finding the dimensions and indecencies that can not only help to explore the impact items in creating self-employment, but also helping in job security and satisfaction. Therefore, the aim of this study is to find out empirically analysis of factors affecting entrepreneurship and employment of disabled in state welfare organization of region four of the Iran. In this case, the next section explains the theoretical framework of the study and methodology used in measuring entrepreneurship. The forth section finds out the data analysis processing entrepreneurship in state welfare organization of region four of the Iran. The last section is the conclusion.

2. Theoretical background

The phenomena of disability gets it's meaning with regards to its kind, causes and the interpretation the society offer, in a way that one cause of it could be social happenings like, war and natural disasters. Other happening could be the effect and many social consequences it could bring about. For example, a person's disorder in making communication with his or her souranding environment. This can in turn, decrease the social economical activities and finding a job for the disabled (Adam et al. 1998). Creating job for the disabled has special importance, which can be done after evaluation stage, professional and educational guidance and general services based on evaluation. The employment of the disabled is based on three aspects of knowing the disabled person, knowing the job and analyzing the suitability of the job with the disabled (Bozorgnia.. 2007). In initiating a business there are usually different kinds of motivations. The existence of an opportunity and entrepreneurial idea. Monetary incentives and willingness of being one's own boss and employer and other motivations the person decides for his/her entrepreneurial. These motivations and affected by means of a person's characterize especially sex (Walker et al. 2008). These kind of motivations in this type of people, even causes them to move towards the activities of pink color staff (Service activities needing low skills) and not willing to develop one's own business (Thompson, 223, 2009).

Risk aversionis another reason which moves people towards self-employment and entrepreneurship. Though, written works and research about different dangers among disabled and non-disabled people are different, what is certain is that, home business can reduce the risk seeking of initiating a business since it needs less capital in comparison with other businesses (Walker and Webster, 406,2004).

2.1 Disabled person

With regard to world health organization, a disabled is a person who has lost part of his/her body either temporary or perm natty due to genetic reasons, accidents or old age, which intern, has reduced his/her independency for learning or working (Ismalinasab, 2003). Also, world health organization in 1981 has defined disabled as creating relation between one's self and environment.

2.2 A disabled person under the support of State Welfare Organization service

According to the definition by health organization, disabled person is referred to as someone whose disability has been recognized and confirmed by medical committee and receive continual or non-continual supportive services offered by state welfare.

2.3 Feeling of being more effective

Irvine and Lupart (2008) had an interview with ten disabled people while working. The results showed experienced a sense of being purposeful as well as experiencing a better social life. Cram et al. (2009) in their study showed that doing some sort of business can help to increase the independency and interaction of the disabled.

2.4 Behavioral benefits

Stephens, Collins, and Dodder (2005) in their study on 2760 adult disabled showed that an increase in Adaptive Behavior like, personal skills, social interaction, group worked, self-control have a positive relation. The advantage of understanding social groups is that unemployed, the disable have no interaction and lose the chance of being with others. Unemployed, they are secluded and have little chance of interaction (Hutchison et l. 2009). Earning money, is another advantage with in which such people can satisfy their necessary needs (Siporin & Lysack, 2004). Reid and Bray (1998), found that the disabled and keen to have control of their life's and make their own decisions. Decisions like, shopping, sharing a living and independency in presenting his/her ideas. Looking at different aspects of life. It is obvious that been with a job is very advantages, though beside these advantages there are some obstacles.

The physical intensity of the disabled has an effect in helping him to final proper job, so inability itself is considered as an important obsticale for an adult with developmental disabled in finding a kind of job (Dusseljee, et al., 2001). According to Cioffi, and Yovanoff (1998), the level of physical disability can seriously effect job experience. Ghoord, Dennin and Hall (1984) believe that the lack of social skill and proper personal ability in making interaction with co-workers makes employment period shorter. Also, the lack of proper facilities and movable goods are among other problems in getting a job (Lemaire & Mallik, 2008). Ford et al., also believe that support of family, friends and institutions the disabled are not capable of keeping one's job.

Although, the relations and supportive believe independency of the disabled at certain time. Proper support at work for the disabled is necessary in being successful at their work (Jahuda et al. 2009; Lengnick-Hall, Gaunt, & Kulkarni, 2008). Although, the severity of disability on high education is effective, but studies show that the higher the degree the disabled hold the better chances they have in getting a job (Achterberg, et al. 2009; Lengnick-Hall, Gaunt, & Kulkarni, 2008). Even the receving benefits in the disabled is increased depending on the intensity of their inability (Ford et al. 1984). In addition, the discriminative view towards the disabled has brought about less chances for employment and in some cases losing their jobs (Schmidt and Smith, 2007).

Based on what has been said so far, the review of literature, information data and statistical reports all are indications of finding ways to employ adult disabled. However, with respect to economic stagnation, Medias of the give reports of employment problems and the related factors which is indication of a more serious situation than it looks like. Therefor this study is to offer some solutions the develop and path the way for employing these group of people in society. It is however true that research is based on the sample studies of the four districts of state welfare organization with in the country on which analysis have been made. In should, however, be mentioned that based on theoretical studies, research findings and conclusions obtained by authors and researchers the effect of some factors considered as strategies can be of some help in developing employment for the disabled these include: financial factors, ideological factors, job seeking factors, family factors, governmental and personal which are taken as independent factors. The effect of these factors which can help in developing employment for the disabled which come under the little of dependent variables are analysis and studies.

Table 1: Summery of Indicators

Alternative	Norm	Reference
Financial factors	Low risk, low initial capital home-based business, you need to come in second, not the cost of renting or buying a place to work, reduce travel costs	Agehi, Naghibegi, & Mirakzadeh, 2014; Yaghobi, Vahdat Moadab & Latifi,2013; Khenfir, Ahmadiazarm, & Zamanifar, 2010; Valker, Vang & Redmond, 2008
Job seeking	The desire to be president and his employer, lack of job opportunities tailored to individual expertise, hatred of unemployment	Khenfir, Ahmadiazarm, & Zamanifar, 2010
Ideological F.	Failing values and beliefs of individual working environment	Khenfir, Ahmadiazarm, & Zamanifar, 2010
Personal F.	The planning, the effort and perseverance, expertise, skills and experience, public relations and social high, having free time, successful experience at home jobs	Agehi, Naghibegi, & Mirakzadeh, 2014; Sadi, Jalilian & Yaghobi, 2014; Golabi, et al., 2011; Najafi &Safa,2014

Alternative	Norm	Reference
Family F.	Flexibility home business, being with family and earning at the same time, participate in and benefit from the support of their family, work and life balance	Agehi, Naghibegi, & Mirakzadeh, 2014; Yaghobi, Vahdat Moadab & Latifi,2013; Khenfir, Ahmadiazarm, & Zamanifar, 2010
Governmental F.	There are proper market, hold on workshops and classes from organizations, get insurance, the availability of tourism and tourism, the domestic Career Fair	Yaghobi & Jalilian, 2015; Milotfi, Alavizadeh & Badakhsh, 2014; Yaghobi & Vahdatmoadab, 2014; Najafi &Safa,2014; nikelson, 2010

3. IV Methodology

The present study by means of its goals is practical and in terms of data collection research is descriptive and correlational. , which is done for the purpose of identifying the effective factors in developing employment for the disable SWO as well as offering strategies for such our purpose. In doing so, a questionnaire was designed which included Demographic and specific items. The validity of its content were analyised by experts and Construct validity was evaluated by confirmatory factor analysis. The population include all patients of SWO in adult disabled section from 5 province of Iran. The number of population is 224599. With regard to the number of sampling and respect to Structural Equation Modeling (SEM) the following formula is used;

$$5Q \leq n \leq 15Q$$

Hence, at least 376 sample is selected using stratified sampling. In a way that each province chosen as one category and then from each province with regard to its obtained percentage based on Table 1 was done.

Table 1: Population and sample size

	Central P.	Tehran	North Khorasan	Mazanderan	Semnan
Population	31988	154469	21195	52471	14476
Sample size	45	211	30	71	19

As well as to validation, among a sampling of 30 people a pretest was done in which consisted that Cronbach's α coefficient for each factor was higher than 0.7 Indicating the validity of the survey as shown in Table 2.

Table 2: Results of Cronbach's α coefficient

Index	Number of Question	α coefficient
Financial factors	5	0.792
Ideological F.	1	0.901
Job seeking	3	0.818
Personal F.	6	0.755
Family F.	4	0.777
Governmental F.	6	0.745

To analyze data, descriptive statistics, inferential statistics at the beginning of the factor analysis was used for the validity of questioner. Then, Structural equation modeling to study the impact and the intensity of the relationship between independent and dependent variables using LISREL software has been used.

4. V Empirical Results

The descriptive statistics show that the most number of sample are from Tehran with 56% the other Province are respectively; Mazanderan 19%, Central 12%, North Khorasan 8% and Semnan 5%. In case of sex results show that 75% of respondent's men and 25% were female and 77 % of the respondents were married. Also, about 73% of respondent's were unemployed and 27% were employed. Regarding education, about 32% have is high school, 30% had associate degree, 20% bachelor, 12% had M.A and 2% PhD and 4% had primary school.

About age of respondent's, about 16% were age between 20 to 29, less than 8% below 20 years old and Most people in the age category 30 to 39 years, 33% were in the 40 to 49 floors and 6% were more than 50 years old. Confirmatory factor analysis was used to determine the validity of questionnaire. Factor analysis indicated that all sub-criteria factors effective on disabled entrepreneur from the values of t (> 1.96) and load factor (>0.3) accepted, are to evaluate disabled entrepreneur variable sub-criteria are appropriate. In addition, the standard estimates and significant results indicates the fitness of the model. With regard to the LISREL output, χ^2 value divided by the df., equal to 1.93, that is acceptable and appropriate (<3); low levels of this indicator showed little difference between conceptual models with observed data research. Also outputs, the RMSEA =

0.067 for the show. In addition, χ^2, whatever the RMSEA is less than 0.08, indicating that the model is a better fit.

4.1 Second order confirmatory factor analysis for each of the criteria in initiating a business in distinct on disabled of SWO

In the table 3 of second order confirmatory factor analysis shown that all the factors loadings and significant numbers of model parameters, with the exception of ideological factor that are obtained lower than 1.96, Ideally other factors that fit the criteria of the relevant variables are favourable measurement model. Also, $\chi^2/_{df}$, equal to 1.90 and >3 is allowed and RMSEA is also 0.076. . In addition, χ^2, whatever the RMSEA is >0.08, indicating that the model is a goodness fit. Consistency ratio the matrix of paired comparisons was calculated as 0.044, which indicates that the results of paired comparisons are acceptable and valid. In addition, the conceptual model is tested. Therefore, structural equation modelling and LISREL software has been used.

Table 4 represents the coefficients of the variables is standard. These coefficients show the strength and direction of the relationship between variables. In other words, larger values indicate greater impact of independent variable on the dependent.

But when this factor is significant that significant coefficients corresponding to each of the standardized coefficients are also significant. Output from significant coefficient presented in Table 3. The coefficients that are significant when outside of ±1.96. In other words, when standardized coefficients are outside of this limit, standard coefficient of the research variables are significant.

Table 4: Standard and significant coefficients among the variables

Factors	Standard coefficients	Significant coefficients	Hypothesis
Financial Factor	.046	5.32	Is confirmed
Personal Factor	0.86	11.94	Is confirmed
Governmental Factor	0.55	6.24	Is confirmed
Family Factor	0.70	2.36	Is confirmed
Job Seeking Factor	0.36	3.12	Is confirmed
Ideological Factor	0.22	1.8	Is Rejected

As shown in Table 3, for example, the standard coefficient among variables in financial factors is bringing about tendency for start-up a business in distinct four SWO for the disabled is 0.46. The coefficient indicate that if the financial factor 1 unit increase then disabled tendency to create business will rise 46%. Significant coefficient is 5.32, which is out of ±1.96, so, at 95 percent, financial factor has a significant impact on disabled tendency to create business. Hence, the first research hypothesis is confirmed. Furthermore, the Significant coefficient among variables in ideological factor regarding tendency to start-up a business for the disabled is 1.80, which is within of ±1.96, so, at 95 percent, ideological factor has not significant impact on disabled tendency to create business. Hence, the research hypothesis is not confirmed.

Goodness Fit the model: The results show that χ2 has become significant (P>0.05). When this statistic becomes significant indication of unsuitable fit model with data. Though, this statistic is sensitive to the value of sample and in large samples this statistic usually becomes significant, because complete fit model with data in practice is not in accordance with reality. For this reason, usually $\chi^2/_{df}$ is used. Which has an acceptance domain of <3 for this index. The achieved value for study model is 1.78 which is an indication of a fit with data. The other index is GFI. This index is also in a >0.9 which is acceptable for 0.96 model which is obtained. Thus, this index rest upon the acceptable domain and is accepted. The third index used for studding fit model was AGFI. The acceptable domain for this index was >0.9 and the obtained amount for the study was 0.91 and so the model is fit. RMSEA was the next used index for studying fit. The value obtained for the model is 0.011 and the acceptable domain for this index is <0.05. Therefore, the value obtained for the model is within the acceptable domain. The next two indexes are CFI and RMR. The acceptable domain is >0.9 and <0.1 respectively. The value related to these two indexes are equal to 0.97 and .056 respectively. Both indexes used the acceptable domain. With regard to the indexes used for fitting model, it can be said that, the model is fit and consistence with data. The following Table 4 show that the goodness fit the structural model.

Table 4: Goodness fit the structural model

Fitness Index	$\chi^2/_{df}$	GFI	AGFI	RMSE	CFI	RMR
Acceptable values	<3	>0.9	>0.9	<0.05	>0.9	<0.1
Calculated values	1.78	0.96	0.91	0.011	0.97	0.056

5. VI Discussion and Conclusion

The study is based on employment and tendency for start-up a business in distinct four SWO. The collected data was done by binge present at the disabled's workplace and SWO and by means of interviewing and a questioner was completed. The results of the study showed that the designing model of structural equation model for enabling the disabled is the refection of a goodness fit and to a level of expectancy. Also, the results of factor Analysis shown that the most effective factor for having tendency in start-up a business is personal factor. In addition, the most important variable is related to the personal factor is perseverance and attempt. This factor supported by Satarafza (2010); Pishvaie (2014); Najafi & Safa (2014); Golabi et al. (2011); Tagbigi, Agehi, & Mirakzadeh (2014).

The second effective factor was family factor and the most important variable for having tendency in start-up a business is a balance between work and life. This factor supported by Yaghobi, Vahdat moadab, and latifi (2013), who believed that the six factors including; socio-cultural, Infrastructureand financial, personality, supportive, family and educational are the barrier for start-up a business. Furthermore, Mirghafori, et al. (2009) believe that the Lack of financial and spiritual support from the family is the barrier. Also, the finding of Walker et al. (2008) is alignment.

Governmental factor with the variable of insurance supported by; Tagbigi, Agehi, & Mirakzadeh (2014); Mirlotfi, Alavizadeh, & Badakhsh (2014); & Nicholson (2010). Financial factor with creat a business is alignment with Yaghobi, Vahdat moadab, and latifi (2013); Khenifer, Ahmadi, & Zamanifar (2010), and Mirghafori et al (2009) believed that the variable of Infrastructure and financial are the motivator and stimulator to start-up a business. The fifth factor, job seeking, with the lack of appropriate job relating to disabled education was the effective variable that is alignment with the study of Khenifer, Ahmadi, & Zamanifar (2010).

6. Suggestion

Based on the financial factor, financial support has an important role in developing a business for the disabled. So it seems that, it is essential to make financial support by loans and other financial methods to create and develop a new business.

It seems that the public sector should prepare what is necessary for create a new business for disabled. In addition, one of the most important factor in this area is to develop a market for output from products. So, it is suggested that public sector can be make a link between large firms and disabled business. Also, expansion and development of fairs, (internal & external) supported by public sector is another suggestions.

University–Company Collaboration in the National Innovation System from the Perspectives of Micro-Entrepreneurs

Kati Vehmas and Martti Saarela
University of Oulu, Finland
kati.vehmas@oulu.fi
martti.saarela@oulu.fi

Abstract: The way we view collaborative projects influences how project practices are built. According to the National Innovation System (NIS), the innovative process is organized into projects. In most research, collaboration has been approached and analyzed by examining, for example, the innovations, interactions, and actions of the collaborators. However, prior to the present study, university–company collaboration has not been examined through the lens of project management in the NIS. The perspectives of companies and especially micro-enterprises in the NIS are under researched. The role of micro-enterprises in university–company collaboration is growing, although there are many challenges. National systems of innovation tend to be rigid and bureaucratic, especially for the agile innovations of micro-enterprises. The background is influenced by different projects approaches whose significance for practices and innovation is not recognized. This empirical study approaches university–company collaboration from the perspectives of companies, focusing on micro-entrepreneurs that are willing to grow and develop. Data was gathered through interviews with big companies and micro-entrepreneurs who have participated in university-company collaboration project in Finland. Data has been analyzed by using content analysis. The framework for the micro-enterprises data analysis derives from an earlier study on companies' point of and project approach in NIS. A strong understanding of project management is essential for organizations engaging in collaborative projects, as it will help them develop the innovative processes in their projects and at the micro-enterprise level.

Keywords: innovation, project management, micro-entrepreneurs, innovation systems, project practices

1. Introduction

An increasing number of collaborative projects between universities and companies have become subject to measurement and improvement (Bruneel et al, 2010), which is important to the organization of innovative processes in the NIS (Lundvall, 1992; Nelson, 1993; Cooke et al, 1997; Caloghirou et al, 2001; Cohen et al, 2002; Perkmann and Walsh, 2007). There are many challenges involved in collaboration, the most important of which are related to processes, outdated structures, and system inefficiencies (Bruneel et al, 2010; Uudistuva Suomi 2015–2020, 2014). Innovation is not even considered possible in rigid and bureaucratic structures (Dougherty, 2006). Too often, collaboration is examined separately from the context in which it takes place, such as the forms of organizations involved (Fagerberg et al, 2005). University–company collaboration has not been studied through the lens of project management, despite the special features of "projectification" that affect the content of the collaboration (Packendorff, 1993).

The NIS has been experiencing a paradigm shift over the last 10 years, particularly in Finland (Viljamaa et al, 2009; Pekkarinen and Harmaakorpi, 2011). The NIS is an institutional, political environment consisting of economic and societal actors and linked to economic and educational policies (Nelson, 1993; Lundvall et al, 2002; Sharif, 2006; Lundvall, 2010). The central task of the NIS is to produce knowledge for commercial use and combine education with the economy (Sharif, 2006). However, the system is transforming into an innovative environment of networks in which the interest is shifting from the products to the processes (Miettinen et al, 1999; Lundvall et al, 2002; Sharif 2006; Löppönen et al, 2009; Viljamaa et al, 2009).

The links between universities and industries are multifaceted (Geisler and Rubenstein, 1989; Perkmann and Walsh, 2007; Ankrah and Al-Tabbaa, 2015). Perkmann and Walsh (2007) described three levels of university–industry connections. The lowest level includes weak interactions, such as the commercialization of intellectual properties, publications, and conferences. The middle level is comprised of mobility, such as human-resource transfer and academic entrepreneurship. The highest level consists of research services and research partnerships. The present study concentrates on research partnerships as high-level interactions between universities and companies. University–company collaboration involves a variety of interactions, not only knowledge transfer, as has been traditionally attributed to such partnerships (Bakhshi et al, 2008).

University–company collaboration is typically utilized by large companies (Laursen and Salter, 2004). Small and medium-sized enterprises (SMEs) or micro-enterprises have traditionally found it very difficult to participate in university–company collaboration, at least in Finland (Uudistuva Suomi 2015–2020, 2014). Last year, the role of SMEs and micro-enterprises in the NIS has grown. For example, Business Finland, national business developing company, reported that 77% of companies funded in 2016 have been SMEs and micro-enterprises (Härmälä, 2017).

The clear majority of SMEs are micro-enterprises, which account for about 93% of all enterprises in the European Union (Muller et al, 2016). Micro-enterprises refer to a type of firm that employs fewer than 10 people and whose annual turnover and/or annual balance sheet does not exceed 2 million euros (Reid, 1995; European Commission, 2003). Micro-enterprises are a significant source of economic growth and play an important role in innovation and the economy in general (Storey, 1994; Fielden et al, 2000). Empirical research has shown that small firms create a higher proportion of new jobs than large firms (Carree et al, 2015). In the European Union, net job-creation rates decrease with each increase in firm size (de Wit and de Kok, 2014), and micro-enterprises accounted for 37% of total employment growth in 2015 (Muller et al, 2016). Compared to larger firms, micro-enterprises are intrinsically different in terms of organizational characteristics and approaches to challenges and obstacles (O'Dwyer and Ryan, 2000; Kelliher and Henderson, 2006).

There is a notable lack of academic studies on university–company collaboration. This phenomenon has largely been examined from a normative point of view (see Pertuze et al, 2010; Perkmann and Salter, 2012), and research partnerships have been studied through the lens of the NIS (see Caloghirou et al, 2001; Cohen et al, 2002; Carayol, 2003; Fagerberg et al, 2005; van Beers et al, 2008; Lundvall, 2010; Nieminen et al, 2011). It is also popular to analyze university–industry relations in general (see Perkmann et al, 2013; Ankrah and Al-Tabbaa, 2015) or define the barriers to collaboration (see Bruneel et al, 2010). Several studies have investigated the role of universities in research partnerships and the differences in corporate culture between the educational and industrial sectors (Gibbons et al, 1994; Etzkowitz and Leydesdorff, 2000; Etzkowitz, 2003).

Although the financier point of view is well represented in previous research, few academic studies focus on the perspectives of companies, especially micro-enterprises, in university–company collaboration (Fagerberg et al, 2005). The innovation practices of micro-enterprises is significantly under researched as well (Faherty and Stephens, 2016).

University–company collaboration typically takes the form of a research project, but there is a gap in the literature concerning project management in this context. Projects as a specific form of organization has not identified, yet project management is seen as one of many issues in university–company collaboration (Kapsali, 2011; Ankrah and Al-Tabbaa, 2015). Understanding the nature of projects and the way in which a project is seen has thus far been relegated to the periphery (see Engwall et al, 2003; Perkmann et al, 2013; Ankrah and Al-Tabbaa, 2015). The present study analyzes these concepts from the perspectives of micro-enterprises involved in collaborative projects with universities.

2. Theoretical background

The ways in which a project is seen affects how it is managed (Packendorff, 1993; Lundin and Midler, 1998; Söderlund, 2004b). Project research is key to understanding and developing modern organizations (Söderlund, 2004b). In knowledge-intensive work and rapidly changing environments, where complex products and services are developed, projects are the preferred working mode (Hodgson and Cicmil, 2007; Hoverfält 2012, p. 11). Projects are considered part of the shift from permanent to temporary structures and functions (Engwall et al, 2003).

Projects are rooted in major industrial processes, which are controlled through engineering (Morris, 1994). They are considered the most effective way to achieve a goal (Lundin and Midler, 1998). Mainstream project-management theories are based on the Project Management Institute's (PMI) classic definition of projects (Packendorff, 1995; Engwall et al, 2003). According to this definition, the project is seen as an effective, task-oriented method for fulfilling unique goals and needs, and the main steps include planning, controlling, and evaluating (Packendorff, 1995; Hoverfält, 2012, p. 12). However, classic project studies are narrow and overly project-centric, as projects are seen only as tools without context (Shenhar and Dvir, 1996; Engwall et al, 2003; Hoverfält, 2012).

Today, the use of projects as a working mode has been increasing and becoming more complex, which must be considered in the project research field (Söderlund, 2013). Along with the classic project approach, an organizational view has emerged in this field, called the "temporary organization" (Engwall et al, 2003).

Temporary organizations are based on descriptive, practice-centered ontology, while the classic approach is based on positive ontology (Geraldi and Söderlund, 2017). As the present study aims to identify the project approaches used in university–company collaboration from the perspectives of micro-entrepreneurs, the differences in the project practices of permanent and temporary organizations will also be studied (see Lundin and Söderholm, 2013).

Although projects are not merely twofold (i.e., permanent vs. temporary), the principles of provisional organization are usually presented in the classic project approach (see Engwall et al, 2003; Hoverfält, 2012), the intention behind the temporary organization is to expand into the mainstream (Engwall et al, 2003).

Temporary organizations concentrate on the relationship between the project and the "parent organization," not on defining the project itself (Engwall et al, 2003; Söderlund, 2004).

According to Enwall et al (2003), the four pillars of a temporary organization include:

- the social construction of project boundaries,
- natural uncertainty in project missions,
- a high degree of embeddedness in project management, and
- the expectations and mission-driven patterns of its projects.

The social construction of project boundaries refers to the idea that a project is not a given entity, as it is seen in the classic approach (Engwall, 2003). As such, project boundaries are compromises that are constructed over the duration of the project. A team is formed around a task, but its members have other "homes" outside the temporary organization (Lundin and Söderholm, 1995). Mainstream projects are based on planning and specification, which are executed by specific practitioners (Engwall et al, 2003, pp. 118–119).

The classic project approach underlines the need to remove uncertainty, as it is highly undesirable (Engwall et al, 2003). In contrast, the temporary-organization approach views uncertainty as a natural part of projects. Temporary organizations also consider the parent organization, as well as the time before and after a project. The project is not an island; it is in close contact with the surrounding organization and reality (Engwall et al, 2003, pp. 111–112).

3. Data and methods

The present study is empirical, and the data consists of interview responses by five micro-entrepreneurs who have participated in collaborative projects with universities. The data will be compared with previous data consisting of eight interviews with ten interviewees from large companies. The initial interviews were carried out in December 2007 and November 2008, with additional rounds in 2010. The previous data illustrates the aforementioned paradigm shift in the NIS. The signs of a new paradigm are reflected in the present material, but this phenomenon is only beginning to emerge in the literature. The interviews thus represent the first phase of the phenomenon (Viljamaa et al, 2009).

The data is constructed in interaction with researcher. Reseacher is interpreter throughout the process, not just a passive finder (Alvesson & Kärreman 2007; Gherardi 2000). The purpose of the data is to give a meaningful theoretical interpretation for the university-company –collaboration from the companies point of view.

3.1 Research sample

The micro-entrepreneurs operate in different industries, including travel and leisure, information and communication technology, and more traditional industries. They all have experience in university–company collaboration and have participated in one or more projects. Three of the micro-entrepreneurs have employees, while the remaining two are solo entrepreneurs.

The previous sample consists of interviewees from large companies who are experts in university–industry collaboration. They are responsible for deciding whether their companies participate in such projects and have many years of experience working in collaborative projects (Welch et al, 2002). Among the interviewees are experts in technology, design, sociology, marketing, and sales. They have worked in R&D-related managerial positions at various companies in the mobile telecommunications sector, the printing industry, traditional industries, and innovative technological industries. This has been attempted to seek scope and diversity, as well as time coverage for building a business perspective.

3.2 Data collection

The first interviews are non-structured with experts. The content included predetermined topics intended to guide the discussion, so the interviews sought to achieve a broad understanding of the interviewees' experiences and ideas regarding the collaborative projects. The four topics addressed in the interviews include: a) experiences and practices before the project started, b) experiences during the project, C) experiences regarding the project results, and d) achievements and practices after the project ended (Engwall 2003, p. 791).

In the present study, the interviews were conducted by phone and lasted from 30 minutes to 1 hour, during which the interviewees discussed their own experiences of the collaborative projects. In the previous study, the duration of the interviews ranged from 45 to 90 minutes and were recorded and subsequently transcribed verbatim for analysis.

3.3 Data analysis

The interviews were analyzed using content analysis (Strauss & Gorbin, 1998; Miles & Hubermann 1994; Erikson & Kovalainen 2008). The stages of analysis included coding, categorization, and thematic definition (Strauss & Gorbin 1998; Saldana 2013). Atlas.Ti and Nvivo has been used as an analyzing tools.

Open coding based on grounded theory, and it has been a lead setting in the first interview analysis (Strauss & Gorbin 1998). Process has been spiral, and included two rounds of coding. After coding categories has constructed based on conzeptualization, and to find differencies and similarities (Erikson and Kovalainen, 2008). Last stage of analysis has been making four descriptive themes (Saldana 2013).

Analysinz the second data, micro-entrepreneur interviews, the firs coding stages has been similar. The categories have since become goal-oriented; that is, they have been arranged by the contextual practices and issues emerging from the interviews (Kivinen and Ristelä, 2000; Luomanen, 2010; Ruusuvuori et al, 2010). The analysis based on conzeptualizing of first data. This technique is not purely data-based, nor is it theory-based (Erikson and Kovalainen, 2008; Strauss & Gorbin 1998). The contents of the interviews therefore do not reflect reality as if it is an object that can be found; rather, a contextual view of collaborative projects from the company perspective is formed through analysis (see Gherardi, 2000; Gherardi and Nicolini, 2001; Pihlström, 2007, p. 160).

4. Findings

4.1 The classic project approach: before the paradigm shift

Projects are key to the inner workings of an organization. Defining the project implicitly also defines the regular activities of its parent company (Johansson et al, 2000; Lundin and Steinhòrsson, 2003). According to the data collected, the concept of the project has changed alongside an emerging paradigm shift in the NIS.

The NIS currently consists of two project approaches that focus on the perspectives of large companies, which generate structures that define the existence and function of a project (Pekkarinen and Harmaakorpi, 2011).

The classic project approach emphasizes design, the goals remaining, predefined working methods, and the importance of reporting (Packendorff, 1993), which the company views as an image of the project produced by the NIS. This is contrary to the fact that design, control, and reporting are seen in the literature as atypical for innovation (Dougherty, 2006; Lovio, 2009).

4.1.1 Project planning

Generally, in the NIS, funding for a research partnership project between a university and a company is based on the project's plan. When examining a cross-section of the innovation paradigm, the significance of project planning is highly evident, as the project's success is largely monitored in relation to its plan and mission (Cooke et al, 1995; Edquist, 1997; Innovaatiotoiminnan vaikutukset, 2008). From a company perspective, project planning must also meet strict goals in content creation, not just project management.

> *"And even in Tekes, there is, unfortunately, the spirit that when you read the project plan, then you have to do it, even if it is quite unattractive."* (Interview 3, research director)

According to the NIS, the starting point of a project consists of the implementation of an approved plan (Cooke et al, 1997; Cooke, 2001); however, project plans are often drafted up to a couple of years before the start of the project. During this time, the company may experience extensive changes in operation, and the plan may no longer be feasible.

"That is a bad project, which is really stiff and where you have to commit to the plan for four years, which you have written three years before the start of the project, after which the business goals have changed and the priorities are, and still, it is obligatory to do what it will be time to do." (Interview 12, micro-entrepreneur)

Defining content in advance is an atypical innovation activity, as the primary goal is to create new content (Dougherty, 2006). In the classic project approach, however, designing and planning are key starting points for a project, which form the prerequisites for success as well as the project's metrics (Packendorff, 1995; Hoverfält 2012, pp. 10–13). These practices hamper innovation and prevent the project from developing new content (Dougherty, 2006).

4.1.2 Working methods

The NIS paradigm initially emphasized a linear model of innovation (Enquist, 1997; Cooke, 2001; Pekkarinen and Harmaakorpi, 2011). The literature describes the practices of the NIS and the linear model (Lundvall et al, 2002). However, such formal structures create challenges for companies. In most cases, the progress of a project is measured through project meetings between the collaborators. All of this is intended to eliminate uncertainties in the process (Viljamaa et al, 2009); however, securing a linear process will lead to weak innovations. According to evaluations of collaborative projects between universities and companies, their impacts appear to be weak (Uudistuva Suomi, 2015–2020, 2014). In the literature, predefined actions are seen as challenges in collaboration. Uncertainty and cyclical activities are, according to the present study, the basis of innovation (Koski, 2001; Lundvall et al, 2002; Pavitt, 2005).

> *"…Then also responsible for the company that the results are really going ahead, not just drinking coffee and knocking it off, whether it's a good research. But that's why you should know that you do not..."* (Interview 11, business development director)

Following the linear innovation model, the NIS emphasizes the transfer of knowledge, and its practices have been built around enhancing this activity (Brown and Duguid, 2001; Hautamäki, 2008, p. 66). The forum for the official launch of a project consists of a management team with pre-appointed personnel. The content of the project is formed elsewhere, and there is no need for a practical interface.

4.1.3 Project reporting

> *"And then, when it is practically revealed that it is something concrete to be able to see and build, of course in cooperation with others, then it is quite a challenging thing."* (Interview 4, development director)

There are few opportunities for companies to make use of the information generated in collaborative projects (Kaufmann and Tödtling, 2001; Bruneel et al, 2010). The transfer of information by various means is ineffective. The challenges lie not only in the quality of the results or how they correlate with the plan, but also in their exploitation. The results are not expected to be ground-breaking and can hardly be utilized commercially (see Kankaala et al, 2007, pp. 73–75). Companies must therefore adapt the project results to fit their own needs, because the results are born outside their practices.

> *"So that I can double the page report, or even the five-page report in Word format, so I can throw it into the garbage from the point of utilization."* (Interview 3, research director)

Collaborative projects are like external organizations, so the results must be transferred from one organization to another. The NIS directs the transfer of information in very traditional ways: via reports and presentations. This is seen as very problematic and contributes to poor results (Cohen and Levinthal, 1990; Kaufmann and Tödtling, 2001).

4.2 University–company collaboration from the approach of establishing a temporary organization

The concept of a project is based on concrete practices (Gherardi and Nicolini, 2000; Gomez et al, 2003). In part, those involved in a project will rebuild the practices produced by the system, which broadens the concept of collaborative projects between universities and companies.

The previous data shows a transformation in the NIS, from a linear innovation model toward a network model (Miettinen et al, 1999; Lundvall et al, 2002; Sharif, 2006; Löppönen et al, 2009; Viljamaa et al, 2009). According to the data, the linear innovation model is linked to the classic project approach; however, companies are trying to shape their practices into modes that are more appropriate and productive for university–company collaboration. In doing so, these companies follow a project approach that differs from the mainstream; they are establishing temporary organizations.

4.2.1 The importance of interaction

Innovation is largely based on advances in technology. The introduction of new technology has led to innovations that follow a very straightforward path from one organization to another (Chesborough, 2006).

Despite the fact that the innovative process is more complex than a simple linear model, the phase-out concept has continued to dominate collaborative projects, and the phases were seen to end and come next, although they could repeat the process (Cooke, 2001; Lundvall et al, 2002; Chesborough, 2006). The underlying concept of information has also remained unchanged, as information is considered to move from one stage to the next (Gherardi and Nicolini, 2000).

> *"Well, actually, at least I have to take advantage of such a project of ways, which suits me. I do not know whether it has changed in culture as a whole, or is it just that it has been the case that such practices work."* (Interview 5, research manager)

In collaborative projects, companies typically develop practices rather than content. According to the interview data, the development of innovative processes is not essential, but challenges in the project practices are considered very important. Interaction and situated learning are emphasized in the innovative process, and experiment-driven innovation is an effective way to develop this process (Nooteboom, 2000; Lovio, 2009). The development of such practices has deepened the nature of collaboration, from the simple procurement of services to a true research partnership (Geisler and Rubenstein, 1989; Perkmann and Walsh, 2007).

> *"But through the projects, it has been learned that, okay, there are some opportunities to do something and it is understood that the stoics are now much better than in history. And it has revealed the challenges and other things that it has."* (Interview 3, development manager)

Companies are learning how to carry out collaborative projects via their experiences. Project managers are developing ways to obtain the most use out of a project and the organizations involved. The innovative process is gradually shifting from the traditional transfer of knowledge toward the interactions between collaborators and the modes of action. The change builds the transformation of the paradigm of the innovation system described (Viljamaa et al, 2009). This phenomenon is especially emphasized in the micro-entrepreneurs' responses, which indicates that their participation and interactions in the project are very important.

> *"So it's nothing like sparring and peer support, and then there's information going to change and that hey, I could do it like you're not doing. That's the way it is, though. If you are participating and active. That it requires it to do something to get it*." (Interview 12, micro-entrepreneur)

4.2.2 The social construction of project boundaries

With these gradually changing practices, the project's boundaries will also be restructured (Engwall, 2003). Collaborators other than those who were initially assigned will become involved in the project. This extends the concept of the project into the temporary-organization approach.

> *"And then usually in the way that the end result is presented in such a way that the audience is that the audience is as wide as possible. For example, if my team were so responsive, it was a person in the project, so the whole team was able to listen to the results."* (Interview 5, research manager)

The aim is to integrate the results into the company's daily operation and practices by involving as many employees as possible in the project, at least in its progression. Information is thereby constructed contextually (Lave and Wenger, 1991; Yanow, 2000). Nooteboom (2000, p. 54) also discussed this point while emphasizing the attitude of the adoptive person, who re-invents and associates information with organizational routines and structures. However, the traditional structure of the NIS has prevented this, as it removes information from its context and forces it into its own objective entity, report, or transferable pre-information packet.

4.2.3 The natural uncertainty of projects

> *"…Especially projects should be…more like extensive, and they should be like…you don't know the result in advance, or it is not necessarily known whether the result is as useful or not. …Companies can specifically try. Not so much money to go but in the future I can really produce a lot. If in a way they dare to get enough."* (Interview 6, chief specialist)

Companies see innovation as a creative, searching process that needs space to evolve (Koski, 2001). According to the data, the goals set in collaborative projects are limiting or somewhat unnecessary, which may not be as planned. This perspective has also been raised in the literature regarding the NIS; that is, the cause and effect of research, technology, and innovation does not produce innovations, and the effectiveness of this approach has come under question (Lundvall et al, 2002; Harmaakorpi and Melkas, 2008). It is now understood that networking and interaction are key elements of innovation (Lundvall et al, 2002).

> *"...I see very important the importance of raising my people's competence and general education and knowledge in the area. That it has such a function. …On a personal level, I would like to be great, so it is, I think it is of great importance because people look at things from a different point of view, ventilate their ideas, network with new people, try new methods."* Interview 5, Research manager

According to the data, participation, interaction, and personal relationships are highly sought in university–company collaboration, in addition to the official project results (Kanunda et al, 2007). The challenges of achieving the official results are compensated by the situated learning and development of individuals.

> *"...You have not come to a surprise in the negative direction that has come, there have been many boys who did not initially even think that it could be born."* (Interview 3, development manager)

In practice, the preconditions for innovation (i.e., insecurity, interaction, and complexity) have created challenges in the innovative process (Dougherty, 2006; Bruneel et al, 2010). Company attitudes toward innovation have gradually become more flexible, which has incited changes in the prevailing paradigm. The systematic and gradual nature of the innovative process is being questioned (Mutanen and Parjanen, 2008).

From the company perspective, the importance of the results has decreased, while the importance of the process has increased (Viljamaa et al, 2009).

5. Discussion

The present study provides data extracted from interviews with micro-entrepreneurs who have experience in university–company collaboration, along with a description of the changes that have taken place in the NIS of Finland over the past 10 years (Viljamaa et al, 2009; Pekkarinen and Harmaakorpi, 2011). These changes indicate that the rigid structure of the NIS has been ineffective, even to the point of inhibiting innovation (Chesborough, 2003; Chanal, 2004; Fagerberg, 2005). The foundation of a collaborative project should be practice and innovation, not bureaucracy (Dougherty, 2006; Hautamäki, 2008).

University–company collaboration projects, having special projects features that also affect the content of the activity, like one such feature is the emergence of innovations (Packendorff, 1997). According to the data, companies construct their own innovation-supporting practices instead of relying on those defined by the NIS.

This paradigm shift mirrors the differences between the classic project approach and the establishment of temporary organizations (Engwall et al, 2003). Understanding these differences in the context of university–company collaboration will help us parse the emerging challenges to project flexibility, openness, and process orientation (see Table 1).

Table 1: Factors that inhibit/support innovation activities and project approaches

Inhibit	Support
Bureaucratic planning	Natural uncertainty
Closed structure	Open structure
Results-oriented	Process-oriented
Classic project approach	Temporary organizations

The formal structure of the NIS is based on the classic project approach, which emphasizes project planning, a closed structure regarding the project and its assigned participants, and the importance of the results and their evaluation through the realization of the project's objectives. The classic project aims to enhance and control its participants in the border region, as well as prioritize a strict adherence to the objectives and practices of the project (Blomquist and Packendorff, 1998; Engwall et al, 2003).

Based on a preliminary analysis, micro-enterprises emphasize a casual attitude toward process-oriented and uncertainty in university–company collaboration. In practice, this means that the companies emphasize interaction between the project participants. Interaction appears as concrete meetings and shared practices and peer support for different ways. Throughout the shared practices situated learning, or learning through action is constructed (Gherardi and Nicolini, 2001).

In addition to this, natural uncertainty is underlined by micro-entrepreneurs. Natural uncertainty is, above all, flexibility with regard to objectives and plans of projects. The plans and aims should update during the project process from the micro-entrepreneurs point of view. Keeping originally plans and implement the project without reflection and interaction, appears really irrational for the companies. Here is a conflict between NIS official project approach and companies way to view projects.

The NIS therefore creates a different field of operation for collaborative projects between universities and companies. According to the data, the formal, bureaucratic structure of the NIS has been partially constrained in such projects, which have been actively pursued through practical measures. The factors emerging from this paradigm shift are linked to differences in the classic project approach and the temporary-organization approach. During the transition, both aspects are present, which causes much of the challenges in collaborative projects. The project approach offers a conzeptualization and way to improve NIS from the micro-entrepreneurs point of view.

anaaaisa94@gmail.com

Abstract: In the current economic context of great complexity, entrepreneurship is perceived as an alternative to create employment and reduce uncertainty, and allows the transformation of an innovative idea into a company. Entrepreneurship is a concept with many peculiarities. It is not an exact science to be implanted, but a way of thinking to be developed. It emphasizes opportunities rather than threats and obstacles, and its ability to identify opportunities requires first and foremost the study of entrepreneurial intentions of individuals (Krueger et al., 2000). What determines individual's decision to create their own business? Variables such as personal characteristics, family influence, social background, self-efficacy and others have been pointed out, but the understanding of the different motivations for someone to undertake has revealed a dynamic and complex area of study. According to Theory of Planned Behaviour (Ajzen, 1991), individuals engage in an activity (such as starting a business) as a deliberate action which is reflected on their intention to this behaviour. The aim of the investigation is to measure and compare the entrepreneurial intentions of engineering and management students. The paper presents the results of a survey, named EMPREENDE 2017, which included 436 Portuguese students from the University of Minho. The sample focused on students from the 1st to the 3rd year of different courses at the Engineering School and the Management School at the university, divided into engineering students (49.08%) and management students (50.92%). The study does not identify differences in the entrepreneurial experience of parents but identifies differences in attitude, subjective norms, perceived control, and entrepreneurial intention of the two groups of students.

Keywords: Entrepreneurial intentions; university students; engineering and management students; University of Minho, Portugal; survey

1. Introduction

Entrepreneurship is seen as a mechanism to promote employment in a country and, as a result, to accelerate the development of the respective economy (Bryson et al, 2017; Baptista, Escára and Madruga, 2008; Van Stel, Carree and Thurik, 2005). This is why members of the Organization for Economic Co-operation and Development (OECD) give priority to entrepreneurship as an alternative to counteract the effects of the economic crisis that is still felt in several countries (OECD, 2009). By recognizing new and innovative business opportunities and taking risks, it is possible to reverse the current situation by increasing competitiveness and adjusting markets (Rahman, Ahmad and Taghizadeh, 2016, Hisrich, Peters and Shepherd, 2014, Oosterbeek, Van Praag and Ijsselstein, 2010, Sarkar, 2010).

One of the recommendations to increase entrepreneurship is for universities to take an active formative role. Universities must prepare their students for entrepreneurship by taking a more active position in transmitting technical and theoretical knowledge and providing them with the indispensable tools to start and maintain their own business (Duval-Couetil, Shartrand and Reed, 2016; Souitaris, Zerbinati and Al-Laham, 2007).

Starting from the premise that technical and academic knowledge are important for the creation of an entrepreneur, engineering students have more technological and industrial knowledge, and may be perceived as having greater ability to detect new business opportunities. In turn, students of socio-economic sciences, given their training, are perceived as having greater affinity with issues related to the economic viability of a business. Although they do not all have the same competencies, these two groups of students are considered the most capable individuals to create successful companies that promote economic growth (Maresch et al, 2016). Both have the necessary knowledge to undertake, yet is their predisposition and entrepreneurial intent the same?

The paper is structured as follows. Section 2 defines an entrepreneur. Section 3 presents the conceptual background of entrepreneurship intention. In the Section 4 is presented the results of a survey to engineering

and management students to measure and compare their entrepreneurial intentions. Finally, in Section 5, are presented the main conclusions.

2. What defines an entrepreneur

Like the concept of entrepreneurship, also the concept of entrepreneur has been the subject of discussion by some authors. Between the nineteenth century and the twentieth century the entrepreneur is seen as an individual capable of forming and managing a company in the face of uncertainty, which accounts for expenses and manages to make a profit by the end of the year. Also the ability to "invent" is added to the idea of entrepreneur, that is, the entrepreneur is someone who can innovate through invention or the reinvention of a product or a process (Hisrich, Peters and Shepherd, 2014). Schumpeter, in 1951, was the first author to defend this image of the entrepreneur as an innovator, who has the skills to create new services, products and technologies. This is seen as an individual who has a set of characteristics and skills that enable him to manage, organize and deal with his own business risk (Sarkar, 2010).

The GEM declares the entrepreneur as an individual who is entrepreneurially active in implementing a business or managing an existing one (Reynolds et al, 2005). According to this report the entrepreneur is defined "as those who capture good opportunities to start a business, as well as those who believe they have the required skills, are the potential entrepreneurs of society." (Global Entrepreneurship Research Association, 2017, p.19).

Currently, an entrepreneur is considered to be the one who has technical knowledge and experience, as well has a set of genetic and psychological characteristics that contribute to his predisposition to undertake (Belás and Kljucnikov, 2016; Honjo, 2015; Raijman, 2001). The family and the previous experiences of the individual can influence his decision to start a business. For instance, the contact with the entrepreneurial example of the parents can result in a greater appreciation of the autonomy and independence of a business of its own (Laspita et al, 2012; Wyrwich, 2015). One of the most salient psychological characteristics is leadership, that is, the individual's ability to lead the business, the organization, and the individuals around him. Entrepreneurs, apart from being ambitious, are also passionate about what they are developing and trusting in themselves and their abilities. Another characteristic trait of the entrepreneur, equally important, is constant learning from the analysis of other businesses, both the successful and the failed. This attribute promotes two other features, namely, problem-solving and decision-making (Belas and Ključnikov, 2016; Hisrich, Peters and Shepherd, 2014).

For this there are two approaches to entrepreneurship programs. De Jorge-Moreno, Laborda Castillo and Sanz Triguero (2012), Duval-Couetil, Shartrand and Reed (2016), Liñán (2004) and Souitaris, Zerbinati and Al-Laham (2007) advocate an approach that consists in alerting students to the importance and impact of entrepreneurship in the country's economy, personal life and how the creation of one's own business can become a professional career. The other approach has a more practical approach, such as providing all the necessary tools and promoting academic contact with work reality, for example through networking or mentors in some successful activities or potential funders.

3. Entrepreneurship: from intention to action

Many researchers have studied entrepreneurship including the identification and study of explanatory factors for entrepreneurial behaviour. In the literature of psychology, it has been demonstrated the explanatory power of intention as an important predictor of behaviour. Ajzen (1991) developed the Theory of Planned Behaviour, which explains one's intention to behaviour as the result of three antecedents: 1) the positive or negative attitude with which he faces this behaviour, 2) the opinion that others have of this same behaviour (subjective norms) and 3) the perceived control of the same.

Entrepreneurial intention can be seen as a precise predictor of planned behaviour towards starting a new business. The Theory of Planned Behaviour developed by Ajzen (1991), when applied to the entrepreneurial behaviour (to create the own business), can also explain the entrepreneurial intention of the individuals. In the specific case of entrepreneurship, the attitude towards the behaviour is the reflection of the degree of familiarity that the individual has with entrepreneurship, i.e., whether she/he has a positive or negative attitude towards entrepreneurship, and whether or not she/he can identify benefits in entrepreneurship. The subjective norm translates whether individuals feel influenced by others in the sense of becoming

entrepreneurs, namely the impact that the opinion of others exerts on decision making, especially the opinion of those who are close to them or who are seen as a following example. Finally, the perceived behaviour control measures the ease of acquisition of a particular behaviour, in this specific case the entrepreneurial behaviour (Ajzen, 1991; Carr and Sequeira, 2007; Fretschner, 2014; Küttim et al, 2014; Lee et al, 2011; Liñán, Rodríguez-Cohard and Guzmán, 2011; Liñán and Fayolle, 2015; Maes, Leroy and Sels, 2014; Obschonka, Silbereisen and Schmitt-Rodermund, 2010; Peterman and Kennedy, 2003; Souitaris, Zerbinati and Al-Laham, 2007; Zhang, Duysters and Cloodt, 2014).

Krueger, Reilly and Carsrud (2000) and Shapero and Sokol (1982) suggest that the entrepreneurial intention of an individual is also influenced by two other components, which intertwine with subjective norm and personal attitude: the perceived desire and perceived capacity. The first one reflects how attractive the individual feels that behaviour is (in this case entrepreneurial behaviour), and the second refers to the capacity recognized by the individual to undertake. Perceived capacity is also related to the level of self-confidence of the individual, which consequently influences the perception of perceived control.

The family has an influence on the development of entrepreneurial intentions of an individual. Laspita et al (2012) and Bhandari (2012) argue that the exposition to a family business can propensity offspring's entrepreneurial intentions by increasing their perceptions that self-employment is a meaningful career option and it is possible to obtain highest entrepreneurial rents.

4. Data collection and analysis

This paper presents the preliminary results from a survey designed to measure and compare the entrepreneurial intentions of engineering and management students. Engineering students have a vast technological and industrial background, which eases the recognition of new business opportunities, and management students are familiar with the contents and tools of the economic viability of the business.

Although they have different skills, they are considered as the set of individuals most suitable to create successful companies that promote economic growth (Maresch et al, 2016).

The survey, named by EMPREENDE 2017, was applied to students of engineering and management courses from University of Minho who were approached in their classes and asked to participate in the research. Our sample has a total of 436 respondents, divided into engineering students (49.08%) or management students (50.92%). The gender distribution reflects the female domain among engineering and management students (65.37% females and 34.63% males). From the three analysed years it was verified that 39.68% of the respondents are first year students, followed by 35.32% of the third year and 25.00% of the second year (see Table 1).

Table 1: Respondents' profile

Characteristic		Percentage (%)	Total
Gender	Male	34.63	151
	Female	65.37	285
	Total	100.00	436
School	Engineering	49.08	214
	Management	50.92	222
	Total	100.00	436
Academic year	1º	39.68	173
	2º	25.00	109
	3º	35.32	154
	Total	100.00	436

Age ranges from 18 to 37 years (amplitude 19), with a mean of 19.96 years and a standard deviation of 2.432 years (with mode and median equal to 20 years).

4.1 Entrepreneurial behaviour of students' parents

The study begins by asking the respondents about the entrepreneurial behaviour of their parents: "Have you grown up in an entrepreneurial family? Do you have a father and / or a mother with their own business?" (Adapted from Laspita et al (2012)). Table 2 presents answers: 58.49% of respondents admit that their parents were never entrepreneurs against 41.51% who reported that parents have or have had a business (32.80% of

respondents indicate that the business is still active, 5.28% that has been over for more than five years and 3.44% that the business has ended but still was active until 5 years ago), which represents a significant percentage of entrepreneurs parents.

Table 2: Entrepreneurial behaviour of students' parents

"Have you grown up in an entrepreneurial family? Do you have a father and/or mother with their own business?"	**Total**		**Engineering School**		**Management School**	
	n	**%**	**N**	**%**	**n**	**%**
a. Yes, their business is still active	143	32.80%	65	30.37%	78	35.14%
b. Yes, but it still worked at least until 5 years ago	15	3.44%	6	2.80%	9	4.05%
c. Yes, but their business ended more than 5 years ago.	23	5.28%	12	5.61%	11	4.95%
d. No, my parents were never entrepreneurs	255	58.49%	131	61.21%	124	55.86%
Total	**436**	**100.00%**	**214**	**100.00%**	**222**	**100.00%**

In Table 2, the analysis by also can be seen that 61.21% of engineering students choose the option "No, my parents were never entrepreneurs" against 55.86% of management students with no entrepreneur parents.

The percentage of students whose parents have a business still active is 30.37% for engineering students and 35.14% for management students, respectively.

A chi square test was conducted to determine whether there was an association between school and entrepreneurial behaviour of students' parents. A non-significant relationship was present (χ^2= 1.871 (3), p=0.600).

4.2 Entrepreneurship: attitude, subjective norms and perceived behaviour control

The Theory of Planned Behaviour (Ajzen, 1991) defines that the intention of a given behaviour is based on attitude, subjective norms and perceived behaviour control. In order to explore the differences between the two groups of students under study (engineering students vs management students), the questionnaire included questions to measure their attitude towards entrepreneurship, their perception of the subjective norms for entrepreneurship and their perceived behaviour control in entrepreneurship. Since scales were adapted from previous studies (see Table 3), to refine the scale adaptation process to Portuguese, a back translation and back translation review were implemented (the scales were translated into Portuguese and then translated back into the original English and the versions were compared with the original).

Table 3: Measurements

Scale	Itens	Authors
Attitude towards entrepreneurship	5	Liñán, Rodríguez-Cohard and Guzmán (2011), Matlay et al (2014), Solesvik (2013)
Subjective norms for entrepreneurship	8	Carr and Sequeira (2007), Solesvik (2013)
Perceived behaviour control	5	Solesvik (2013), Souitaris, Zerbinati and Al-Laham (2007), Zhang, Duysters and Cloodt (2014)

4.3 Attitude towards entrepreneurship

The items of attitude towards entrepreneurship were measured on a five-point Likert scale and included the following statements: 1. "Being an entrepreneur implies more advantages than disadvantages for me", 2. "A career as an entrepreneur is attractive to me", 3. "If I had the opportunity and the necessary resources, I would like to open my own company", 4. "Being an entrepreneur generates great satisfaction for me", 5.

"Among the various options in the job market, I prefer to be an entrepreneur". The reliability analysis of scales was assessed by calculating Cronbach's alpha and principal component analysis (PCA). The Cronbach's alpha of the attitude scale was 0.871 and the PCA found that all five statements loaded on a single component.

The score of the variable was obtained by calculating the mean of the answers obtained in the scale items.

Figure 1 shows the attitude towards the entrepreneurship of the students of the management school and the engineering school. Both distributions present outliers answers, that is, respondents who register lower values in the attitude towards entrepreneurship (as their answers were considered valid, they were chosen for their maintenance). Regarding the distribution of the answers, engineering students tend to be lower than their management colleagues.

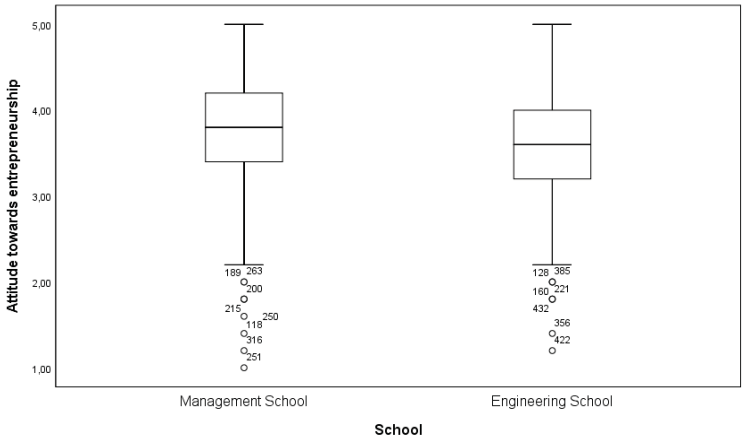

Figure 1: Students' attitude towards entrepreneurship by school

The Kolmogorov-Smirnov test concluded that the data from the two samples did not follow a normal distribution (p=0.042). Thereafter a nonparametric Mann-Whitney test was used to test significant differences between students' schools in attitude towards entrepreneurship confirmed that there was a significant difference in attitude between management and engineering students (Mann-Whitney U=20477.5, p=0.012).

4.4 Subjective norm for entrepreneurship

The items of subjective norms were measured on a 5-level semantic differential scale (1- "Extremely negative" to 5- "Extremely positive") and included the following statements: 1. "My parents consider _____ that I create my own business", 2. "My boyfriend/girlfriend considers _____ that I create my own business", 3. "My brother(s)/sister(s) consider _____ that I create my own business", 4. "In general, my relatives consider _____ that I create my own business", 5. "My neighbours consider _____ that I create my own business", 6.

"My colleagues consider _____ that I create my own business", 7. "In general, my acquaintances consider _____ that I create my own business", 8. "My closest friends consider _____ that I create my own business".

The Cronbach's alpha of the subjective norms scale was 0.876 and the PCA found that all eight statements loaded on a single component.

The score of the variable was obtained by calculating the mean of the answers obtained in the scale items. Figure 2 shows the subjective norm for entrepreneurship by students' school. Both distributions present outliers answers. In the case of the school of management, the outlier is a student with lower perceived subjective norm for entrepreneurship compared to those of his schoolmates. In the case of the engineering school, there are three respondents who register higher values in the subjective norm for entrepreneurship. In both situations the answers were considered valid and they were chosen for their maintenance. Regarding the distribution of responses, management students present a distribution of responses with left asymmetry. The distribution of responses from engineering students is more symmetrical, but has a lower median than that of management students.

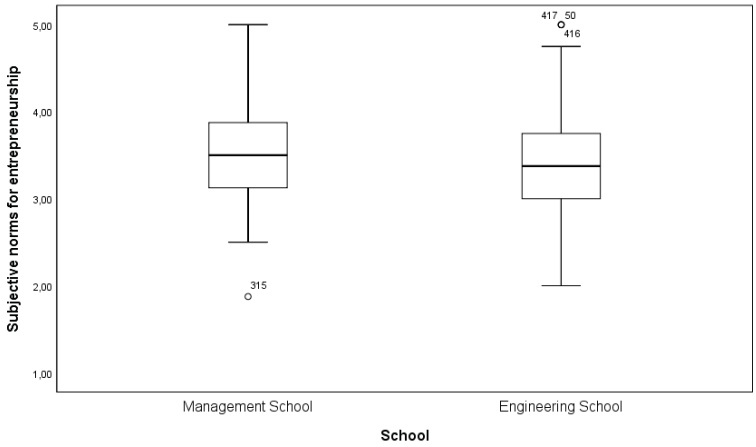

Figure 2: Students' subjective norms for entrepreneurship by school

To explore the existence of differences of the subjective norm for entrepreneurship between the two schools, as the data did not follow a normal distribution (Kolmogorov-Smirnov test with p=0.017) the non-parametric Mann-Whitney test was performed. The test confirmed that there was a significant difference in attitude between management and engineering students (Mann-Whitney U=20861.5, p=0.026).

4.5 Perceived behaviour control in entrepreneurship

The items of perceived behaviour control were measured on a 7-level semantic differential scale and included the following statements: 1 "For me, being a self-employed would be... (from 1- "Very difficult" to 7- "Very Easy")", 2 "If I wanted to, I could easily pursue a career as a self-employed (from 1- "I totally disagree" to 7- "I totally agree")", 3 "As a self-employed person, the control I would have over the situation would be (from 1- "No control" to 7- "Full control")", 4 "The number of events outside my control that could prevent me from being self-employed are (from 1- "Many" to 7- "Few")", 5 "If I were a self-employed person, my chances of success would be (from 1- "Unlikely" to 7- "Very likely")". The Cronbach's alpha of the perceived behaviour control scale was 0.721 and the PCA found that all five statements loaded on a single component.

The score of the variable was obtained by calculating the mean of the answers obtained in the scale items.

Figure 3 shows the perceived behaviour control in entrepreneurship by students' school. Both distributions present outliers answers, with lower perceived behaviour control in entrepreneurship compared to those of his schoolmates. Regarding the distribution of responses, management students present a more symmetric distribution of responses. The distribution of responses from engineering students has a left asymmetry with a lower median than that of management students.

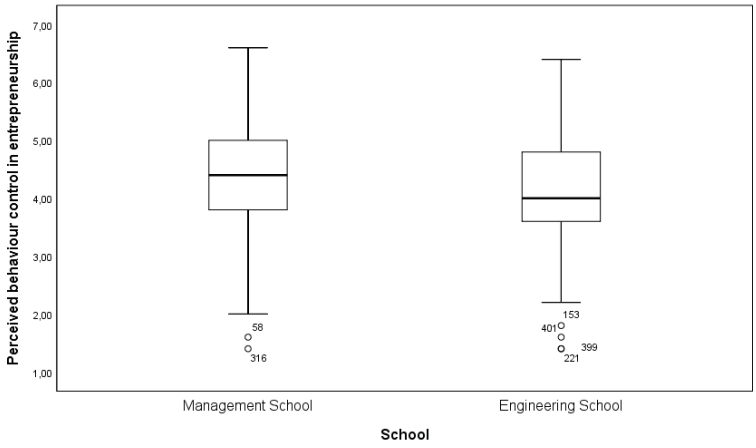

Figure 3: Students' perceived behaviour control in entrepreneurship by school.

As the data did not follow a normal distribution (Kolmogorov-Smirnov test with p=0.003), a non-parametric Mann-Whitney test was performed to explore the existence of differences of the perceived behaviour control

in entrepreneurship. The test confirmed that there was a significant difference in perceived behaviour control in entrepreneurship between management and engineering students (Mann-Whitney U=19937.5, p=0.005).

Thus, at the level of attitude towards entrepreneurship, subjective norms for entrepreneurship and perceived behaviour control in entrepreneurship were found statistically significant differences between the two schools.

Table 4 summarizes the results.

Table 4: Attitude, subjective norms and perceived behaviour control vs. schools

Scale	Management School	Engineering School	Mann-Whitney
Attitude towards entrepreneurship	3.69	3.53	**
Subjective norms for entrepreneurship	3.55	3.45	**
Perceived behaviour control	4.41	4.17	*

(* p-value<1%; **p-value<5% e ***)

4.6 Entrepreneurship intention

In order to understand the entrepreneurship intention, as a career option, the students were asked to indicate their response to three questions (using a semantic scale of 3 items with 7 levels of response adapted from Souitaris, Zerbinati and Al-Laham (2007)):

1. "If you had to choose between your own business and being hired by someone, what would you prefer?" (From -3- "I would rather be hired by someone" to +3- "I would rather have my own business");
2. "How likely are you to be self-employed?" (From -3- "Unlikely" to +3- "Very likely");
3. "How likely are you to work in an organization?" (From -3- "Unlikely" to +3- "Very likely").

In the first question ("If you had to choose between your own business and being hired by someone, what would you prefer?") students indicate prefer have rather their own business with 62.16% of positive responses (the sum of the answers + 1, + 2 and +3). The management students present a bigger preference for their own business (65.77% positive responses against 58.41% for the engineering students).

In the second question ("How likely are you to be self-employed?") only 51.15% of the respondents assume they are likely to have their own business (positive responses). When analysing the students' school, it is interesting to compare the 57.66% of positive responses from the management students and the 44.39% of positive responses from the engineering students. It suggests a lower entrepreneur intention by the engineering students.

In the last question ("How likely are you to work in an organization?") respondent students assume as moderate to high the probability to work in an organization (81.80% of positive responses). When comparing schools, there are no major differences (81.69% of positive responses in engineering students and 81.90% in management students). Given the answers obtained in question 2, we expected lower values, at least on the part of management students. One could try to find a justification such as the age of the students (they are very young, with a mean age of 19.96 years) associated with high expectations of easily finding a job after graduation.

The results obtained are presented in Table 5.

A chi square test was conducted to determine whether there was an association between school and students' entrepreneurial intention. A significant relationship was present between school and the first intention question ("If you had to choose between your own business and being hired by someone, what would you prefer?") (χ^2= 13.505 (6), p=0.036) and the second intention question ("How likely are you to be self-employed?") (χ^2= 14.254 (6), p=0.027).

Table 5: Students' entrepreneurship Intention

	Total		Engineering School		Management School	
	n	%	N	%	n	%
"If you had to choose between your own business and being hired by someone, what would you prefer?"						
I would rather be hired by someone (-3)	31	7.11%	12	5.61%	19	8.56%
-2	38	8.72%	21	9.81%	17	7.66%
-1	31	7.11%	22	10.28%	9	4.05%
0	65	14.91%	34	15.89%	31	13.96%
+1	74	16.97%	39	18.22%	35	15.77%
+2	113	25.92%	55	25.70%	58	26.13%
I would rather have my own business(+3)	84	19.27%	31	14.49%	53	23.87%
Positive responses (sum 1+2+3)	271	62.16%	125	58.41%	146	65.77%
"How likely are you to be self-employed?"						
Unlikely (-3)	27	6.19%	13	6.07%	14	6.31%
-2	31	7.11%	14	6.54%	17	7.66%
-1	51	11.70%	33	15.42%	18	8.11%
0	104	23.85%	59	27.57%	45	20.27%
+1	117	26.83%	55	25.70%	62	27.93%
+2	80	18.35%	28	13.08%	52	23.42%
Very Likely (+3)	26	5.96%	12	5.61%	14	6.31%
Positive responses (sum 1+2+3)	223	51.15%	95	44.39%	128	57.66%
"How likely are you to work in an organization?"						
Unlikely (-3)	1	0.23%	0	0.00%	1	0.45%
-2	6	1.38%	2	0.94%	4	1.81%
-1	12	2.76%	5	2.35%	7	3.17%
0	60	13.82%	32	15.02%	28	12.67%

+2	144	33.18%	74	34.74%	70	31.67%
Very Likely (+3)	76	17.51%	36	16.90%	40	18.10%
Positive responses (sum 1+2+3)	355	81.80%	174	81.69%	181	81.90%

5. Conclusions

In order to raise awareness and arouse individuals' interest in entrepreneurship, several authors call for the role that educational institutions should play in creating initiatives for young students to develop tools and new business ideas. Since technical and academic knowledge are important for the creation of an entrepreneur, students of engineering and socio-economic sciences have been mentioned by several studies as the individuals, who due to their technical skills will have a greater aptitude to build businesses with great success.

The EMPREENDE 2017 Project had as main objectives to understand and compare the entrepreneurial potential of the students of engineering and management. Taking into account the proposed objectives, a survey among graduation students from University of Minho allowed a total of 436 responses. The student's entrepreneurial intention and the factors that could influence it (attitude, subjective norms and perceived behaviour control) were compared between the two groups of students: 1) students of the Engineering School, 2) students of the Management School.

The study identified statistically significant differences between schools concerning attitudes towards entrepreneurship; subjective norms for entrepreneurship; perceived behaviour control in entrepreneurship and entrepreneurship intention. Results suggest a higher awareness from management students when compared with their engineering colleagues:

- have an higher attitude towards entrepreneurship,
- perceive a higher support from family and friends for entrepreneurship,
- have a higher perceived behaviour control in entrepreneurship
- show a higher entrepreneurship intention

What can explain the differences identified? First, the higher attitude of management students can be explained by being more aware of the theme of entrepreneurship, especially in the school context. Second, the increased family and friends support perceived by student management may result from positive reinforcement from peers and friends (an analysis at response levels revealed strong pro-entrepreneurship support from siblings, boyfriends, and friends). Third, management students possess a specific knowledge that is considered important in the creation of a business of their own, that is, the financial, strategic and economic

viability of a business, something that engineering students may not be so keen on. Finally, the highest intention is the result of the combination of the stated factors.

Despite the growing number of studies on entrepreneurial intention, studies on entrepreneurship in engineering are scarce in Portugal. The present study intends to contribute to the discussion of the theme of entrepreneurial intention in students of higher education, in particular comparing the students of engineering with the students of management. Although not generalizable, the conclusions result in important insights of the entrepreneurial intention, revealing differences based on the context of the students' academic formation.

Compared with their management colleagues, the results of engineering students suggest the need for greater awareness-raising and preparation for entrepreneurship as a future work option.

The Relationship between Business Environment and Innovativeness of SMEs in the Czech Republic and Slovakia

Zuzana Virglerova
Tomas Bata University in Zlín, Czech Republic
virglerova@utb.cz

Abstract: Innovation plays an important role in the business environment and can be a key competitive advantage for an enterprise. Several factors influence innovation activities of SMEs, including the economic environment, the legislative environment, technological factors and social factors. The aim of the article is to evaluate and compare the influence of individual factors on the innovation and further development of micro and SME enterprises in the Czech Republic and Slovakia. The article deals with the partial results of the empirical questionnaire survey which was conducted in 2018 at the Tomas Bata University in Zlín in the Czech Republic. The survey addressed the owners of micro and SME enterprises and asked about the perception of the quality of the business environment. This article deals with the part of survey focused on innovativeness of SMEs. The research works with 329 valid answers from respondents from the Czech Republic and 312 respondents from Slovakia. Research focused on small and medium-sized enterprises, as they are a major catalyst for the economic growth of individual economies. Within the European Union, 98% of the business sector represents and covers two thirds of the employment contracts in the private sector. Three research questions were set to analyze the difference in the perception of business environment and its impact on SMEs in the Czech Republic and in Slovakia. In the process of solving the formulated research questions, the following statistical tools such as tables, descriptive characteristics (mean, variance, standard, and deviation), and Person coefficient of contingency were used. Research results can be used by the government to address key issues related to SME support. Finally, the results indicate that the perception of macroeconomic environment and its impact on innovativeness of SMEs is different in the Czech Republic and in Slovakia. Entrepreneurs in the Czech Republic are more skeptical about a support of macroeconomic environment in the innovation area. Slovak entrepreneurs are also more confident that current banks' interest rates help innovativeness in SMEs (only 34% of Czech entrepreneurs agree with this statement). The article concludes with a discussion of the possible causes of these differences.

Keywords: innovativeness, SME, business environment, support, financial institution, interest rate

1. Introduction

Globalization has a huge impact on entrepreneurs, especially on SMEs. Economic turbulence in the business world increases uncertainty and risk, which increases the pressure on businesses and SME (Hussain et al., 2015). The SMEs are a very important part of world economy. In line with that, Henderson and Weiler (2010) state that SMEs could be identified as the most important catalyst for economic growth. Bhaiard (2010) states that 99% of all European and American enterprises are from the SME segment.

The economic importance of SMEs wasn't only detected in the Czech Republic or the EU. The predominance of small businesses in the Japanese economy is well documented. About 75% of manufacturing employment in Japan is in small and medium-sized companies, in contrast to about 35% in the United States. (Haward 1990). The vitality of SMEs has been a major factor in the creation of new jobs and the economic renewal of certain regions in Europe, such as the region Emilia-Romagna, Tuscany, Venezia in Italy (Emilia-Romagna, Tuscany, Venezia) or Jutland in Denmark.

Innovativeness of entrepreneurs should drive the market and create competitive advantage (Zortea-Johnston et al. 2012). Veliu et al. (2018) stated that high competition in SMEs has its effect on employees not providing the opportunity to develop their creativity due to minimization of costs. It is important to motivate companies to invest in innovations to maintain the economic growth.

In this article, the influence of individual factors on the innovation and further development of micro and SME enterprises in Czech Republic and Slovakia has been evaluated.

2. Literature Review

The SME segment is a major driving force of growth, innovation and competitiveness, and SMEs are also a major employer in the Czech Republic. The proportion of the added value of SMEs to the total of the Czech Republic was 56,2% in 2016 (MPO, 2017). The SME segment is also important for national economies and their

stability. SMEs only rarely leave the home country and also only rarely transfer the capital out of the country. (Breckova and Havlicek 2013).

A fundamental element of entrepreneurship is innovation which is captured in the form of creating new products or processes (Covin and Miles 1999). Innovation will make new ventures successful (Ireland & Webb, 2007) and will enhance SMEs' performance, especially in the furniture industry (Otero-Neira et al. 2009).

However, for SMEs to achieve a competitive edge and enhance the rate of success of their business, they need to make risky decisions and engage in risky activities so that they can protect the innovativeness of delivering projects (Vargas-Hernandez, 2011).

It is not easy to gain innovations without favourable business environment. The entrepreneurs have to listen to the customers' needs and they have to manage all their activities to be profitable. The base for innovativeness is favourable business environment and good access to the financial sources. In this paper, the following key conditions: macroeconomic environment, access to the financial sources and also costs of bank loans (interest rates) were analysed. In accessing bank finance, compared to large and established companies, small firms are disadvantaged by their information opacity, the relative scarcity of collateralizable assets, and disproportionately high monitoring costs (Beck and Demirguc-Kunt 2006). Microenterprises have lower profitability and higher debt than other enterprises. Empirical results indicate that microenterprises must provide much higher collateral and more guarantees while asking for bank loans than other enterprises, and they must also pay higher interest rates. (De Mitri et al. 2013).

The quality of business environment is determined by of SMEs' possibility to access financial resources. In this context, several authors discussed the financial gap for SMEs and its risks. (Belás et al. 2014, Májková 2012). The restricted access to the financial resources is caused by high risk level of these firms, and they can be limited to pay their commitments. The similar view is also presented by other authors, for instance Ozturk and Mrkaic (2014), Kundid and Erecgovac (2011).

With limited financial resources is also connected their price. In case of many SMEs, it was found out that banks are charging a higher risk premium (Ayadi 2005). Especially after the crisis, increasing bank funding costs were detected. Higher interest rates were detected for the SMEs, not for the large firms. The results of research made by Altman et al. (2010) confirmed that firms aged within 3-9 years are more vulnerable to failure.

A number of papers found that SMEs are more financially constrained than large firms and, importantly, lack of access to external finance is a key obstacle to firm growth, especially for SMEs. (Schiffer and Weder 2001, Cressy 2002). Hernández-Cánovas and Martínez-Solano (2010) state that there is a limit for the degree of concentration of bank relationships in the SMEs area. SMEs that maintain two bank relationships have the lowest interest charges, followed by firms borrowing from only one bank, while firms working with more than two banks have the most expensive debt. Where the relationship between firms and banks is based on trust (in a housebanking relationship), there SMEs improve their access to bank financing and also reduce the cost of debt, but firms have to pledge more guarantees.

3. Aim and Methodology

The aim of the article is to evaluate and compare the influence of individual factors on the innovation and further development of micro and SME enterprises in the Czech Republic and Slovakia. The results are the partial results of extensive research, which was conducted at Tomas Bata University in Zlín in 2018.

The survey was carried out on a sample of 9400 enterprises from Slovakia (S) and 7800 enterprises from the Czech Republic (CR). Entrepreneurs were selected from the database "Albertina" (CR) and "Cribis" (S) by randomized numbers using mathematical functions "RANDBETWEEN". The statistical unit of the research was one enterprise. Individual companies were directly addressed by email or by phone or by a personal meeting.

641 responses from enterprises (312 enterprises CR and 329 enterprises S) were collected. Percentage of the completed questionnaire in form of positive feedback reactions was accounted for 4%. Two socio-demographic factors were selected for evaluation of impact on the perception of business environment:

education and length of action on the market. Following research questions were evaluated to fulfil the main objective of the article:

RQ1: Entrepreneurs in SMEs from the Czech Republic perceive the influence of the macroeconomic environment on their innovative approach differently than entrepreneurs from Slovakia.

RQ2: Entrepreneurs in SMEs from the Czech Republic perceive differently the influence of interest rates of banks on innovation activities of companies than entrepreneurs from Slovakia.

RQ3: Companies in the Czech Republic have better access to the bank loans than companies in Slovakia (according to the entrepreneurs' opinion).

The statements to each research question were formulated to meet the objective and statistical evaluation of them. Entrepreneurs could answer with one of the following choices: (1) I totally agree, (2) I agree, (3) I do not take a stand, (4) I disagree, (5) I totally disagree. The following answers were consolidated for evaluation: (1) and (2) = agree, (4) and (5) = disagree. For every research question, two determinants (entrepreneur's education and length of business) was analyzed. The partial aim was to find out if there are any statistical significant differences in the perception among enterprises in the Czech Republic and Slovakia according to these determinants.

The structure of the sample according to the size of entrepreneur was as follows: (Czech Republic/Slovakia): micro (258/234), small (43/71) and medium (11/24). One of the factors was also the length of the company's business. Most respondents have had their business for more than 10 years (CR/S: 208/147), 48/78 of the entrepreneurs for 5-10 years, and the rest (56/104) of the entrepreneurs have operated their business for 1-5 years. The survey involved all regions of the Czech Republic and Slovak Republic. Education (CR/S): university education (127/224), other education (185/105).

Questionnaires were addressed to entrepreneurs from different areas of the economy: most of them were from service companies, commercial companies, manufacturing companies, the construction area, from transportation and some of them from agriculture.

The following statistical tools of descriptive statistics were used: contingency and association tables, descriptive characteristics - cumulative frequency. These methods were used to apply Z-test method for evaluation of the formulated research questions. Subsequently, we applied statistical methods as absolute abundance and simple sorting of the statistical character. In the simple sorting method, attention was drawn to the expression of the relative number of entrepreneurs according to the selected statistical features (the length of operating the business in the business environment and the highest completed education of the entrepreneur).

The next methods were the classification according to two statistical features, the dependence between qualitative plural statistics (contingency table, contingency intensity). The contingency intensity was measured by the Pearson coefficient of contingency based on the square contingency. By comparing the selected groups of enterprises according to the selected statistical features, the significance of the statistical feature was determined, i.e. the research questions were verified using the above-mentioned tests. The individual questions were verified at a 5% level of statistical significance, with a p-value of less than 0.05 leading to the rejection of the statement on the independence of the variables. The Z-score was used to identify significant statistical differences between individual statistical character changes in selected groups of entrepreneurs. To evaluate the Z-score of parameters we used the p-value of the normal (standardized) distribution. The conditions for performing the Z-test (normal distribution of the statistical character and large sample size) have been fulfilled. The calculations through sophisticated SPSS Statistics software were used.

4. Data Analysis and Research Results

RQ1: Entrepreneurs from the Czech Republic and Slovakia evaluated the following statement: "The current macroeconomic environment supports innovative business activities".

Structure of respondents' answers:

- in the Czech Republic: 81 (26%) agree, 153 (49%) don't take a stand, 78 (25%) disagree;
- in Slovakia: 125 (38%) agree, 86 (26.1%) don't take a stand, 118 (35.9%) disagree.

Among enterprises in the Czech Republic and Slovakia, there are statistically significant differences in the perception of macroeconomic environment and its support of innovative business activities (Z-score = -3.2605, p-value = 0.001).

Table 1: The current macroeconomic environment supports innovative business activities (according to the length of business)

RQ1	Length of business						Z-score (p- value)		
	Czech Republic (CR)			Slovakia (S)			CR/S	CR/S	CR/S
	1-5 years	5-10 years	More than 10 years	1-5 years	5-10 years	More than 10 years	1-5 years	5-10 years	More than 10 years
Agree (%)	18 32.1%	13 27.1%	50 26%	38 36.5%	35 44.9%	52 35.4%	-0.556 0.576	**-1.997** **0.045**	**-2.325** **0.020**
I do not take a stand (%)	28 50%	22 45.8%	103 49%	28 26.9%	21 26.9%	37 25.2%	**2.919** **0.001**	**2.174** **0.030**	**4.624** **0.001**
Disagree (%)	10 17.9%	13 27.1%	55 25%	38 36.5%	22 28.2%	58 39.5%	**-2.459** **0.014**	-0.136 0.889	**-2.593** **0.009**
Chi-square	2.664			3.208					
P-value	0.616			0.524					

Source: author

In the opinion that the current macroeconomic environment supports innovative business activities, the length of operating the business is not a statistically significant factor among selected groups of entrepreneurs in the Czech Republic (Chi-squared = 2.664; p-value = 0.616). It was found out that:

- 44.9% of enterprises in Slovakia with 5 - 10 years of activity in the business environment agreed with the RQ1, compared to 27.1% of enterprises in the CR;
- there are no significant differences in the agreed RQ1 position (p-value = 0.576) between enterprises from the Czech Republic and Slovakia with 1 to 5 years of activity in the business environment;
- there are significant differences in positive attitude to the first statement among enterprises from the Czech Republic and Slovakia with more than 5 years of business activity (5-10 years: p-value = 0.045, more than 10 years: p-value = 0.020).

Table 2: The current macroeconomic environment supports innovative business activities (according to Entrepreneur's education)

RQ1	Entrepreneur's education				Z-score (p-value)	
	Czech Republic (CR)		Slovakia (S)		CR/S	CR/S
	University Education	Other Education	University Education	Other Education	University Education	Other Education
Agree (%)	44 34.6%	37 20%	88 39.3%	37 35.2%	-0.864 0.389	**-2.861** **0.004**
I do not take a stand (%)	56 44.1%	97 52.4%	58 25.9%	28 26.7%	**3.499** **0.001**	**4.258** **0.000**
Disagree (%)	27 21.3%	51 27.6%	78 34.8%	40 38.1%	**-2.667** **0.008**	-1.857 0.006
Chi-square	**8.488**		0.538			
P-value	**0.014**		0.764			

Source: author.

In the opinion that the current macroeconomic environment supports innovative activities of companies, education of entrepreneurs is not a statistically significant factor among selected groups of entrepreneurs in Slovakia (Chi-squared = 0.538; p-value = 0.764). On the contrary, in the Czech Republic, entrepreneurship education is significant in assessing the claim (Chi-squared = 8.488; p-value = 0.014). A comparison of opinions between entrepreneurs in the Czech Republic and Slovakia in selected business groups according to the business period was found out:

- 35.2% of entrepreneurs in Slovakia with non-university education agreed with the statement, compared to 20% of entrepreneurs in the Czech Republic;
- there are significant differences between answers of the entrepreneurs from the Czech Republic and Slovakia with non-university education (p-value = 0.004);
- there are no significant differences between the answers of the entrepreneurs from the Czech Republic and Slovakia with university education (p-value = 0.389).

On the basis of the above-mentioned results of the current macroeconomic environment in enterprises in the Czech Republic and Slovakia, RQ1 was confirmed. There are statistically significant differences between selected groups of enterprises regarding the length of business activity in the business environment as well as the education of entrepreneurs.

RQ2: Entrepreneurs from the Czech Republic and Slovakia evaluated the following statement: "Interest rates in banks have a positive impact on the innovative activities of companies".

Structure of respondent's answers:

- in the Czech Republic: 107 (34.3%) agree, 111 (35.6%) do not take a stand, 94 (30.1%) disagree;
- in Slovakia: 134 (40.7%) agree, 81 (24.6%) do not take a stand, 114 (34.7%) disagree.

There are no statistically significant differences among the enterprises in the Czech Republic and Slovakia in the evaluation of this statement (Z-score = -1.681, p-value = 0.093).

Table 3: Interest rates in banks have a positive impact on the innovative activities of companies (according to the length of business)

RQ2	Length of business						Z-score (p- value)		
	Czech Republic (CR)			Slovakia (S)			CR/S	CR/S	CR/S
	1-5 years	5-10 years	More than 10 years	1-5 years	5-10 years	More than 10 years	1-5 years	5-10 years	More than 10 years
Agree (%)	17 30.4%	19 39.6%	71 34.1%	33 31.7%	31 39.7%	70 47.6%	-0.179 0.858	-0.017 0.984	**-2.557** **0.010**
I do not take a stand (%)	21 37.5%	16 33.3%	74 35.6%	30 28.8%	14 17.9%	37 25.2%	1.121 0.263	**1.969** **0.049**	**2.084** **0.037**
Disagree (%)	18 32.1%	13 27.1%	63 30.3%	41 39.4%	33 42.3%	40 27.2%	-0.910 0.363	-1.724 0.085	0.629 0.528
Chi-square	0.997			**10.335**					
P-value	0.910			**0.035**					

Source: author.

The length of the business is not a statistically significant factor in entrepreneurs' opinion in the Czech Republic (Chi-squared = 0.997; p-value = 0.910). On the contrary, the length of business is significant in the attitude of Slovak entrepreneurs (Chi-squared = 10.335; p-value = 0.035). By comparing the opinions among entrepreneurs in the Czech Republic and Slovakia in selected groups of enterprises according to the business period, it was found:

- 34.1% of enterprises in the Czech Republic with more than 10 years of activity in the business environment agreed with the statement, compared with 47.6% of enterprises in Slovakia.
- within the group of entrepreneurs with more than 10 years of activity in the business environment there are significant differences in the agreed position of statement (p-value = 0.010) between the Czech Republic and Slovakia;
- there are no significant differences between the Czech Republic and Slovakia within the group of entrepreneurs with less than 10 years of activity in the business environment (less than 5 years: p-value = 0.858, p-value = 0.984).

In the opinion that banks' interest rates positively affect the innovative activities of companies, the entrepreneurial education is not a statistically significant factor among selected groups of entrepreneurs either

in the Czech Republic (Chi-squared = 0.040; p-value = 0.980), nor in Slovakia (Chi- squared = 1.319; p-value = 0.517).

By comparing the opinions among entrepreneurs in the Czech Republic and Slovakia in selected groups of enterprises according to the entrepreneur's education, it was found out:

- 33.9% of entrepreneurs in the Czech Republic with university education agreed with the statement, compared to 42.9% of entrepreneurs in Slovakia;
- there are no significant differences in the agreed answer between entrepreneurs in the Czech Republic and the Slovakia with other education (p-value = 0.787) or with university education (p-value = 0.097).

Based on the above-mentioned results of the impact of interest rates on innovative activities in companies in the Czech Republic and Slovakia, RQ2 was declined. Statistically insignificant differences exist between selected groups of enterprises regarding the length of the business, as well as the education of entrepreneurs.

RQ3: Entrepreneurs from the Czech Republic and Slovakia evaluated the following statement: "Companies have good access to bank loans".

Structure of respondents' answers:

- in the Czech Republic: 141 (45.2%) agree, 89 (28.5%) do not take a stand, 82 (26.3%) disagree;
- in Slovakia: 163 (49.5%) agree, 68 (20.7%) do not take a stand, 98 (29.8%) disagree.

There are no statistically significant differences among the enterprises in the Czech Republic and Slovakia in the evaluation of this statement (Z-score = -1.103, p- value = 0.274).

Table 4: Companies have good access to bank loans (according to the length of business)

RQ3	Length of business						Z-score (p- value)		
	Czech Republic (CR)			Slovakia (S)			CR/S	CR/S	CR/S
	1-5 years	5-10 years	More than 10 years	1-5 years	5-10 years	More than 10 years	1-5 years	5-10 years	More than 10 years
Agree (%)	25 44.6%	22 45.8%	94 45.2%	50 48.1%	34 43.6%	79 53.7%	-0.415 0.674	0.246 0.803	-1.587 0.112
I do not take a stand (%)	13 23.2%	11 22.9%	65 31.3%	26 25%	13 16.7%	29 19.7%	-0.251 0.803	0.868 0.384	**2.424** **0.015**
Disagree (%)	18 32.1%	15 31.3%	49 23.6%	28 26.9%	31 39.7%	39 26.5%	0.696 0.484	-0.961 0.337	-0.639 0.522
Chi-square	3.403			6.143					
P-value	0.493			0.189					

Source: author.

The length of the business is not a statistically significant factor in entrepreneurs' opinion neither in the Czech Republic (Chi-squared = 3.403; p- value = 0.493), nor in Slovakia (Chi-squared = 6.143; p-value = 0.189).

By comparing the opinions among entrepreneurs in the Czech Republic and Slovakia in selected groups of enterprises according to the length of business and entrepreneurs' education, it was found out:

- 45.2% of enterprises in the Czech Republic with more than 10 years of activity in the business environment agreed with the statement, in comparison with 53.7% of enterprises in Slovakia;
- there are no significant differences between the Czech Republic and Slovakia (1-5 years: p-value = 0.674; 5-10 years: p-value = 0.803; more than 10 years: p-value = 0.112).
- 54.3% of entrepreneurs in Slovakia with other education agreed with the statement, in comparison with 47.6% of entrepreneurs in the Czech Republic;
- there are no significant differences in the agreed answer between entrepreneurs in the Czech Republic and Slovakia with other education (p = value = 0.271) or with university education (p-value = 0.312).

Based on the above-mentioned results of the impact of companies' access to the bank loans in the Czech Republic and Slovakia, RQ2 was declined. Statistically insignificant differences exist between selected groups of enterprises regarding the length of the business, as well as the education of entrepreneurs.

5. Discussion and Conclusion

The performed research showed that there are differences between perception of business environment and its impact on innovative activities between Czech and Slovak companies. The Slovak entrepreneurs (38%) evaluate current macroeconomic environment as more supportive for innovation in business activities than the Czech entrepreneurs (26%). Furthermore, there are statistically significant differences in perception of macroeconomic environment and its help to innovative business activities, in terms of the business activity length. The answers of entrepreneurs which are active in business for more than five years differed more than those of the entrepreneurs who are active for less than 5 years. It can indicate that Czech entrepreneurs hoped for better business conditions, but they are disappointed by the business development. The real GDP during years 2007-2016 indicates that the development in both countries is similar. There were bigger differences before 2008 in favour of Slovakia, but other years are almost stable. (Fig. 1)

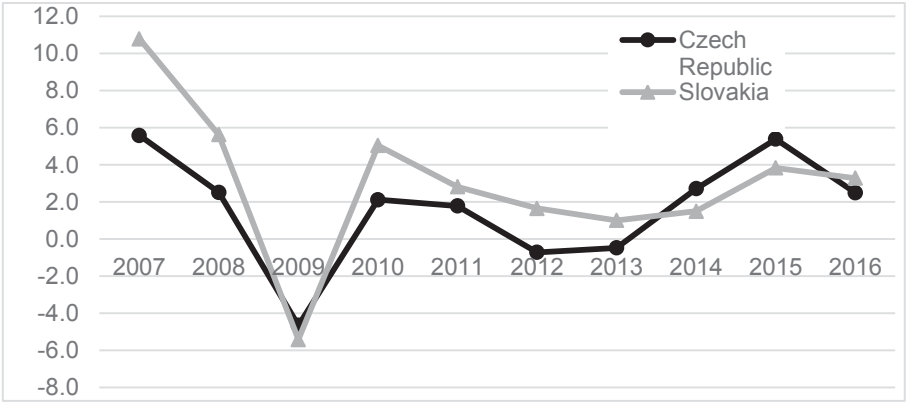

Figure 1: Real GDP in the Czech Republic and Slovakia in years 2007-2016. Source: (OECD, 2018)

The next reason for this difference can be a pessimism of Czech entrepreneurs which can lead from Czech people's character. Despite the fact that the development of business environment is favourable, Czech entrepreneurs can only see a negative impact on their business. The result confirms the statement of European Comission (2013) which declares that innovativeness of the EU as a whole is increasing every year, despite the ongoing economic crisis, although differences in the innovativeness of individual countries' are deepening.

This result corresponds with the research of Dobes et al. (2017) which states that entrepreneurs from the Czech Republic have very critical view of the state's role within the business environment. The same finding was reached by Hamplova and Provaznikova (2015). They came to the conclusion that Czech entrepreneurs classify Czech business environment as administratively demanding and overregulated and they judge the business environment in the Czech Republic critically.

The entrepreneurs' education was identified as a significant factor for perception of macroeconomic environment impact on innovative business activities. 35.2% of entrepreneurs in Slovakia with non-university education agreed with the statement, compared to the 20% of entrepreneurs in the Czech Republic.

Slovak entrepreneurs are also more confident that current banks' interest rates help the innovativeness in SMEs (only 34% of Czech entrepreneurs agree with this statement). There are significant differences in the positive opinion on the statement (p-value = 0.010) between the Czech Republic and Slovakia within group of entrepreneurs with more than 10 years of activity in the business environment. It can signify that entrepreneurs with longer activity in business have more experiences with bank loans applications, so bank loans are more accessible to them.

Entrepreneurs from the Czech Republic and Slovakia have the same opinion on companies' access to the bank loans. Almost 50 % of them state that the bank loans are accessible for entrepreneurs. There is no significant

difference between the countries, regarding neither the entrepreneurs' education, nor the length of the business.

This paper has several limitations. The survey is geographically limited to SMEs from the Czech Republic and Slovakia. Another possible limitation can lead from misunderstanding the questions by the respondents or them providing untruthful answers. Because of these limitations, the results of the survey cannot be generalized.

Japanese Expatriate Entrepreneurs in Asia: Cases from Myanmar

Kazuko Yokoyama and Sarah Louisa Birchley
Toyo Gakuen University, Japan
kazuko.yokoyama@tyg.jp
sarah.birchley@tyg.jp

Abstract: This research is the continuation of a project conducted on Japanese self-initiated expatriate entrepreneurs (SIEEs) working in Southeast Asia. Myanmar is strategically located between India, China and other countries in Southeast Asia and its growth is providing many new opportunities for outside investment. For Japanese companies, Myanmar is an exciting new investment opportunity. There are currently 149 Japanese companies registered with the Japan Myanmar Association. According to Matsui (2017) in the Nikkei News, Honda Motor opened its 115th dealership in Myanmar in 2017, an increase in 40% from 2016. The current GDP per capita is around $1,300, yet the strategic location of Myanmar in terms of its proximity to India means that purchasing power is higher among the border consumers; it is also likely to be Southeast Asia's fastest-growing economy in 2018 (The World Bank, 2017). Taking a social-constructivist approach, five in-depth interviews were conducted with Japanese self-initiated expatriate entrepreneurs in Myanmar. This research shows how these individuals develop their careers overseas and take advantage of the business opportunities presented in emerging economies. By examining these cases we can see the types of mindset that entrepreneurs inhabit, how they navigate their social and cultural identities both inside and outside Japan, and the importance of community and brokerage when building new businesses overseas. Compared to Japanese entrepreneurs in Cambodia, those in Myanmar seem less concerned with social entrepreneurship and more concerned with spotting a key niche in the new market, using their skills and experience to exploit opportunities provided by the presence of larger global companies in the host country and favorable economic conditions. By presenting the entrepreneurs successes and failures empirically, research can be used to inform entrepreneurship education, particularly through developing teaching materials that can provide Japanese young people and entrepreneurs with role models as they seek their own employment opportunities in South East Asia.

Keywords: Self-initiated expatriate entrepreneurs, Japan, Myanmar, entrepreneurship education.

1. Background

Since 2015 the authors have been exploring Japanese self-initiated expatriate entrepreneurs (SIEEs) in Thailand, Cambodia, Hong Kong and Myanmar. Initial research found that for both Japanese males and females, who were educated and trained in Japan, exposure to overseas in the exploration stage (Super, 1980) of their career was a significant influencing factor, when deciding to become an expatriate entrepreneur (Yokoyama 2017). This research paper shares the context, characteristics, and outcomes of five Japanese self-initiated expatriate entrepreneurs in Myanmar. We begin by defining SIEEs and presenting literature on and definitions of expatriate entrepreneurship and international employment trends in South East Asia, before presenting explicit cases from Myanmar. We conclude by suggesting how knowledge of these SIEEs can be used in higher education contexts in Japan to improve entrepreneurship education.

2. Self-Initiated Expatriate Entrepreneurs

SIEEs differ from traditional organizational expatriates (OE) as they have not been sponsored or assigned by a parent organization. Instead, they seek out self-initiated work opportunities in a global context. As Andresen and Biemann (2012, p. 105) define, an SIE 'as an employee who migrates voluntarily to a foreign country on his or her own initiative' and in our context, an SIEE, chooses to set up his/her own enterprise in the host country.

The term indicated a great degree of choice and independence to move abroad, putting the entrepreneur in charge of his/her own international mobility and success. Cerdin & Selma (2013) propose four conceptual criteria that can be used as a common denominator for SIEs, namely (a) self-initiated international relocation, (b) regular employment (intentions), (c) intentions of a temporary stay, and (d) skilled/professional qualifications. The entrepreneurs in this study have chosen to internationally relocate, their businesses provide them with regular employment and they are often highly skilled. Although they may have intentions of a temporary stay, many decide to stay long-term.

3. Immigration and Entrepreneurship

Research shows that immigration can be a driver of economic growth in host countries especially through the promotion of immigrant entrepreneurship (Wennekers et al., 1997, Hunt and Gauthier-Loiselle, 2008, Peroni et al., 2016, Yokoyama & Birchley, 2018). In Asia, immigrant entrepreneurs provide often necessary skilled

human capital resources that may be lacking in the home country (Neville et al., 2014). Surprisingly, OECD reports, have shown that immigrants are more likely than non-immigrants to engage in entrepreneurship activity (Desiderio and Mestres-Domènech, 2011, Mestres, 2010).

Research by Shami et.al. (2017) explores the influence of institutional environments on immigrants and entrepreneurship. Their research on the the relationship between features of the institutional environment of the host country and individual characteristics of immigrant entrepreneurs, we suggest, can be applicable to SIEEs. They refer to the *interactive model,* which suggests that immigrant entrepreneurial activity takes place because of opportunities perceived by immigrants originating from their exposure to host country market structures and institutional environments (Aldrich and Waldinger, 1990, Peroni et al., 2016), further developed to include the idea of "mixed embeddedness", where immigrants (or in our case expatriates) belong to specific ethnic networks but they are also entrenched and predisposed to the unique political and socioeconomic institutional environments of their hosting country (Peroni et al., 2016).

4. Myanmar as a Destination for Entrepreneurship

Myanmar is strategically located between India, China and other countries in Southeast Asia. It has a large agricultural sector which makes up approximately 1/3 of the Gross Value Added (GVA), although the share has decreased from 27.9% in 2014 from 47% in 2005 (UNCTAD, 2016). The country has experienced a tumultuous economic situation over the last 5 years which saw the GDP hitting 58 billion US dollars in 2013, rising to 64 billion US dollars in 2015 (UNESCO, 2016, World Bank, 2016). The government developed a new National Economic Development Plan in 2014 which highlighted agriculture, biotechnology, water preservation, renewable energy and building construction and transport as priority areas (Scimago 2016); all industries that could benefit from inward investment. Yet, in terms of global competitiveness, Myanmar is considered to be underperforming when compared to other ASEAN countries. There is currently no entry for Myanmar on the Global Entrepreneurship Monitor and it ranked 131st out of 140 in terms of the World Economic Forum's 2015-2016 Competitiveness rankings. Similarly, it ranks 138th out of 141 on the Global Innovation Index.

Infrastructure developments are seen as key to opening and developing trade between Myanmar and its ASEAN neighbours. According to research by Chakravarty (2017), there has been a 312.64% increase in trade through the India-Myanmar border towns in 2015-2016 with the Indian government identifying Myanmar as a key partner in developing an ASEAN gateway.

5. The Study

5.1 Research Questions

This research explores what kind of people seek out an international career as an expatriate entrepreneur, more specifically, what kind of mindset do they have, what networks facilitate their advancement, and what can we learn from such cases to improve entrepreneurship education?

5.2 Case Study and Narrative as a Research Tool

This research employs a social constructivist approach. Using in-depth case study and narrative analysis the researchers can form a thick description (Geertz, 1973) of the social and cultural context of the entrepreneurs lived experiences, based on the premise that individuals organize their experiences and their interactions with each other, their groups, and culture into narratives. Narratives tell us how people assign meaning to their experiences. Through dialogue between the researcher and the entrepreneur we can ascertain patterns or themes in the individual's life, explore the way in which the individual looks at him/herself and how they make meaning of their context. By collecting individual cases we can use them to better understand the specific community of self-initiated expatriate and the importance of the cultural and social context, how that context changes over time and how these changes affect the individual.

In this study, in-depth interviews were conducted in Yangon, Myanmar in 2018. Interviews were transcribed and coded accordingly. The research went through open coding, axial coding and selective coding and Box 1 shows the both codes derived from our previous study in Cambodia (Yokoyama & Birchley, 2018).

Box 1: Codes for Analysis

High need for achievement	Autonomy Dominance
Low need for conformity	Tolerance for ambiguity and uncertainty
High propensity for risk-taking	Adaptability

Flexibility	Sense of self-esteem	
Self-confidence	Self-assurance	
Alertness	Ability to create a vision	
Ability to build social networks	Evidence of social networks	
Communication capabilities	Cross-cultural sensitivities	
International orientation	Cosmopolitan outlook	Ability to be global
business savvy Passion for diversity		
A sense and quest for adventure	Intercultural empathy	
Interpersonal impact	Diplomacy	
Knowledge of sustainability	Cultural intelligence	
International experience	Self-correction	
Shares credit	Breaks free of structures	
Crosses disciplinary boundaries	Works quietly	
Strong ethics	Involved in community	
Shows concern for social equity		

6. The Cases

The following section describes the five primary cases for analysis.

Table 1: Case A (Male) Career Path (57 at time of interview)

Late teens	Worked part-time at a jeans store, municipal junior college of science and technology, dropped out.
21	Opened his own jeans store.
31	Bored looked for new opportunities, left the store in the hands of his subordinates, moved to the U.S.A., opened a licensing company in Los Angeles, working with major surfing companies.
37	Company folded
38	Returned to Japan, hospitalized with an illness.
39	Transferred the rights of the jeans company to his colleagues, set-up a PR company.
43-54	Continued to grow the PR company, developed a client base of 1,700. Went on to establish an internet mail order company with 40 employees, sold out in 2014.
51-53	Moved to Shanghai and enrolled at university to study Chinese.
52	Decided to start a women's fashion magazine but political unrest halted production. Travelled to Myanmar with his wife for sightseeing. Took second visit with a friend in the Japanese Myanmar Friendship Association, conducted market research. Saw a gap in the market for a magazine aimed at expatriates in Myanmar.
53	Decided to move to Myanmar and start a magazine publishing company. Published first free paper in Myanmar.
57	Celebrated the 50th issue of his magazine. Acts as Vice Chairman of the Myanmar Friendship Association, is on the Special Committee of Japanese New Business Association and is a representative of the Yangon Chamber of Commerce.

Case A's current Free Paper business has four sections; advertising, leasing and introductions to business, HR support and company advancement support consultations. Throughout his career Case A has had a few mentors in Myanmar but primarily works with Japanese companies and people involved in politics. His career anchor is to meditate, to make the mind clear and free. He is extremely satisfied with his work and life yet cited a shortage of quality human resources in Myanmar as an issue for his business.

Table 2: Case B (Female) Career Path (49 at time of interview)

High School	Took part in an international exchange project in the Philippines, stayed with a host family. Is still in contact with the host family and they meet up every two years.
University	Studied English and in the 2nd year took a year out studying abroad in Perth, Australia. Took six months of language classes and one year at vocational school studying business. Returned to university and changed courses to psychology. Had a part time job at a cultural village in Japan.
23	Graduated and took a job at a major Japanese company, working in their real estate and hotel division but left company.
24-27	Got a job at Bali Intercontinental Hotel and was in charge of guest relations and sales.
27	Transferred to Singapore Intercontinental Hotel and was in charge of VIP correspondence and Japanese companies. Moved to the Shangri-la Hotel and was in charge of sales to Japanese companies. Was dissatisfied with the management style in Singapore and visited Myanmar with a friend. Decided to move to Myanmar.
28	Moved to Myanmar and set up a travel agency with some friends. However, she experienced some problems in working with others and sold her share to go into business alone.
29	Married a Myanmar national
30-47	Had children and with her husband, set up a Japanese division of a European-bound travel company. Also started to manage a cram school franchise. Husband died suddenly in a maritime accident so she sold the travel company but kept the cram school franchise. She currently has between 40-50 employees and 1,500-1,600 students at any given time.
47	Started a temp staff agency working with Japanese-based vocational schools.

Case B had a number of mentors throughout her career, of note was her relationship with a former British Airways Cabin Attendant she met at her first workplace who inspired and encouraged her to work in a hotel in Bali. She also has a number of close friends and female company managers in Myanmar. She doesn't have a wide social circle as she doesn't tend to go out but values the close connections she has with friends, family and her employees, many of whom are international. Her work is her priority but she is working hard for her children's education. She had difficulty fitting into a male dominated office culture in Japan and said that working in Japan, she felt that the workplace society lacked a human element but she feels free working overseas and able to express her emotions. She is extremely satisfied with her work and life and has two phrases that anchor her: "it will be ok" and a Japanese expression "calm, charming face, with quiet and warm words."

Table 3: Case C (Male) Career Path (38 at time of interview)

18	Took a year out of education.
19	Entered a university and majored in information technology.
22	Took a leave of absence from university and backpacked around Europe, Morocco, Turkey and China. Did various part time jobs during university in order to save money for travel. Didn't concentrate on classes but spent time working and saving for two overseas trips per year.
24	Graduated and worked at a temp staff agency dispatching engineers. Spent three years working in sales operations and three years working in career counselling.
30	Became a sales manager
33	Decided to make a change in his career. Had two choices a). work for his family's sports store or b). work abroad. Decided to work overseas. First considered becoming a sushi chef but thought it would be bored and was offered a job in Cambodia but after finding out more about Myanmar he decided to go there.
34	Moved to Myanmar, worked for a web venture company.
35	Recognized a niche in the market and decided to found his own company. Launched *Growth.Myanmar*, a car rental and driver company.
38	He employs 95 people, owns a fleet of 80 cars and has two partner companies that he works with. He is also an editor of the Myanmar Business Partner magazine, free paper and is working on a new education project.

Case C had three senior mentors throughout his career. One mentor inspired him through his bright and positive attitude to life, a second mentor taught him how to think logically, and the third taught him how to be empathetic and increase his EQ. He also takes advice from Japanese executives from Singapore and from people in his networks, such as local Japanese expatriates and managers. In his private life he spends time coaching baseball with his kids. He likes the freedom he has as an entrepreneur as he can decide things 100% for himself. He learned Japanese skills and etiquette in his positions in Japan and takes those practices into his business now. His motto is to enjoy working and to enhance his customer's satisfaction and that of his employees. He wants to make the best of the best. He has support from his wife, who is a housewife yet they worry that the business is at risk due to increased competition in the marketplace, the development of A.I. and driverless cars, his own health and the professional development of his staff.

Table 4: Case D (Female) Career Path (41 at time of interview)

Childhood	Travelled with parents to Australia and travelled throughout her working years.
18	Graduated from high school and found employment selling cosmetics in department stores.
24	Moved companies and specialized in skincare and make-up, became a store manager.
29	Got married.
30	Had a child.
29-31	Housewife but took various aesthetic qualifications over three years with a view to open her own beauty business in the future.
31	Made bracelets at home as a hobby. Met a lady from Myanmar related to precious stones.
36	Continued making bracelets, went to Myanmar to source stones for her creations. Decided to separate from her husband and got divorced.
37	Took her child and moved to Myanmar, took her savings of USD20,000. Lived in Yangon living off her savings and supporting herself by providing beauty services to Japanese clients in Myanmar. Started to sell bracelets online, was successful, opened a gem store in Myanmar.
39	Realized her dream of opening a jewellery store in Tokyo.

Case D's company name is *Culumito* which is derived from the Latin meaning healing ties. She wants her brand of jewellery to help women to strengthen and heal the ties of their hearts. She is self-taught as a jewellery designer but over the years she has taken various classes at vocational school to acquire new skills. In her personal life, she went through some trying episodes, namely when her son decided he didn't want to live with her in Myanmar but instead wanted to live with his father in Tokyo. As such this incident and the ailing health

of her grandmother, who was her primary caregiver as a child, encouraged her to open a salon in Tokyo which she did in 2017. Since then she was working three weeks in Tokyo and one week in Yangon per month. She has since closed the store in Yangon in order to focus her energy on her family and new venture in Tokyo. Case D had no mentors as she was developing her career but does have various networks with local craftspeople, Japanese colleagues and jewellery teachers. Her work is good and she was relatively satisfied with her work and life in Myanmar but less satisfied when her son decided to go back to Japan so moving back to Japan and starting her Tokyo salon has increased her work life balance and satisfaction. Her motto is that "in case of hardship, the customer will save us." She does not know what the future will hold but for the moment she is back in Japan caring for her grandmother and has more regular access to her son.

Table 5: Case E (Male) Career Path (47 at time of interview)

18	Took a year out after high-school.
19	Went to university, studied in a faculty of commerce.
19	Took part in a short term study abroad in the USA for 45 days in his first year of university.
21	Took a leave of absence from the university, took a working holiday in New Zealand. Wanted to pursue his dream of becoming a professional skier so trained during this time.
23	Graduated from university, spent one month in Australia, one month in New Zealand, visited Fiji and decided to spend a year at language school in Australia.
24	Took the domestic travel business manager qualification.
26	Became a domestic tour rep and decided to move overseas. Moved to Palau and managed the sales at the Nikko Hotel in Palau.
33	Moved to Myanmar after being recommended to by a friend. Worked at the Nikko Hotel as Restaurant Manager.
34-36	Transferred to the Shangri-la Hotel, became their sales manager.
35	Met his wife while working at the Nikko Hotel, got married.
36	Moved industries to become sales manager at a company, which sell cosmetics and stationary goods in Myanmar, due to financial difficulties the head office in Myanmar was absorbed into the main company, made redundant. Returned to Japan and his parent's home but was unable to find fulfilling work in Japan, decided to go back overseas.
40	Took a job working for an expatriate fruit and vegetable import company in Egypt however with his family still in Myanmar he was looking for a way to move back.
43	Decided to return to Myanmar and open a Japanese restaurant.

Throughout his career, Case E had a mentor who worked at the Nikko Hotel in Palau. He also has strong expatriate and business networks with his customers. In his private life he relies on Facebook and social media to keep in contact with old friends around the world. He greatly values the time he has with his family and makes sure that Saturdays are family days to spend time with his children. His motto for life is the Japanese phrase '*ichi-go-ichi-e'* which means "once in a lifetime." He works hard to support and protect his family but worries that it is difficult to hire good quality staff in Myanmar and thus worries that his business will not survive without him.

7. Discussion

7.1 Mindset

Similar to the research conducted on Japanese SIEEs in Cambodia and Thailand, the expatriates in Myanmar show all the personality traits of entrepreneurs, such as a high need for achievement, autonomy and dominance; low need for conformity; tolerance for ambiguity and uncertainty; high propensity for risk-taking, adaptability and flexibility; sense of self-esteem, self-confidence, self-assurance and alertness. In addition, they have strong communication capabilities and are able to develop interpersonal relationships with both fellow Japanese expatriates and host country individuals. In terms of entrepreneurial behaviours, they have all shown a commitment to Myanmar; their businesses are proactively seeking out growth opportunities in the emerging economy and they have created a strong vision for their future activities in the country. They possess all the traits of a global mindset, particularly in their cosmopolitan outlook and strong self-efficacy and confidence when operating in a global cross-cultural context and in particular Case A shows the ability to deal with failure in a cross-border context and has shown how one can be resilient and tenacious throughout one's life. Yet, in contrast to the Japanese SIEEs in Cambodia, the cases in Myanmar showed less of a propensity towards social or sustainable entrepreneurship, and there were no cases that exemplified a high-impact self-initiated social entrepreneur (Yokoyama & Birchley, 2018).

7.2 Social and Cultural Identity

In terms of traditional family and societal roles, the males in this study, Cases A, C, and E all exemplify a traditional Japanese family model where the male is the breadwinner and the wife is a supportive housewife;

maintaining the home and raising the family, allowing the male to engage in entrepreneurship, take risks and travel internationally. Female cases B and D both expressed an inability to '*fit in*' in Japan. They are both very strong female characters; one who has dealt with divorce, and one who has coped with life as a widow and as such, they are dominant female role models; far from the stereotyped Japanese housewife that is prominent in current cultural and societal discourse. They are prime examples of successful women who can balance work and life and who can be as successful as their male counterparts as entrepreneurs. Cases F and E also expressed the struggles they experienced when returning to Japan from overseas. This transition was problematic and highlights the difficulties that Japanese face when trying to integrate back into their own society having spent time overseas.

7.3 Community and Brokerage

The importance of networks and brokerage is particularly interesting in the Myanmar cases. Although Japanese SIEEs in Cambodia showed evidence of being engaged in a strong expatriate network, the ties and brokerage activities between Japanese SIEEs and OEs in Myanmar appear more entrenched and essential for doing business. This may be due to the kind of work that the SIEEs engage in; most Japanese SIEEs start businesses that are connected to pre-existing companies in Myanmar, while in Cambodia, the social-sustainable businesses that SIEEs build, primarily rely on communication and connections between the SIEES and host country individuals. As such, Free Papers are seen as the primary vehicle for the development of networks. These papers provide cultural and social brokerage to the new SIEEs. In addition, social media is becoming increasingly important in terms of brokerage and networks. New technology enables individuals to expand their networks with greater speed than in the past.

7.4 Business Idea Development

In terms of the triggers and venture idea generation of these individuals, we can see the role that effectuation and bricolage plays as the Japanese entrepreneurs examine their passions, their resources and their abilities and how they can utilize them to make a business. Each case not only saw a niche in the market and took advantage of that gap but they also drew on their prior knowledge and experience. They each pursued something they were personally interested in. Their enterprises were self-funded some family support, thus taking great risks with their own capital and investment, making them fully responsible for the success of their ventures. The expatriate brokers mentioned above were instrumental in each entrepreneur developing and sustaining their business in Myanmar as they were crucial to network development. Yet the problem of a lack of quality local human resources was cited by many as an area for concern, highlighting the need to develop stronger networks, training programs and brokerage between expatriates and locals the host community.

7.5 Career Development

All the respondents had a key moment – a 'turning point' or 'epiphanies' (Denzin, 1989; Strauss, 1962) in their early thirties when they needed to make a crucial decision about their future. They took stock, revised and re-evaluated their future path. This point at the beginning of the exploration stage of their career highlights the need for career development support for early and mid-career individuals. In each of the cases we can see how they have blended their social and cultural factors with their personal choices and how as entrepreneurs, they merge their individual preferences with opportunity that in some ways incorporates serendipity (Hodkinson & Sparke, 1997). The individual's identity is constantly evolving through the journey of becoming an entrepreneur and the early 30's is a key time for growth and development.

8. Conclusion

As this research has shown, Japanese SIEEs in Myanmar exhibit strong entrepreneurial and global mindsets and experience key career turning points at the early exploration stage of their career, yet they also show a propensity towards profit-seeking business over social-sustainable, altruistic endeavours, choosing to settle in Myanmar as a destination due to its fast-growing economy, abundant human resources, community and brokerage.

zhaisanova15@gmail.com

Abstract: Innovative development of the economy is considered now as a necessary condition for increasing its competitiveness. The most important mechanism for implementing this strategy is the development of the National Innovation System. In developing the directions and mechanisms for the development of the Kazakhstani innovation system, the experience of foreign countries in the field of stimulating innovative activity and the formation of effectively functioning national innovation systems becomes particularly topical. The developed countries (the United States, Great Britain, Germany, Finland, Sweden, Switzerland, Japan, etc.), as well as the states that are intensively developing innovative systems (South Korea, China, Hong Kong, Singapore, the countries of Latin Of America). These countries are characterized by high dynamics of the development of research and development (R & D), significant expenditures for maintaining and stimulating innovations, active support of the education and research complex, and careful attention of governments to the development of national innovation systems. Experience South Korea is particularly interesting due to the fact that this country is one of the most dynamically developing in the innovation plan. The article examines the methodological aspects of the study of the innovative eco-environment by the example of a cross-national study of Kazakhstan and South Korea. The author, relying on the results of the study of actors of the innovative eco-environment in Kazakhstan and South Korea, demonstrates the possibilities of combining qualitative and quantitative research methods, placing emphasis on interviewing and case studies for the derivation of the theory. This article describes the most problematic issues in the collection and analysis of actors in the innovative environment in different countries, taking into account country differences. Recommendations are formulated to conduct research on various representatives of the innovative environment. Along with this, the opportunities for applying the resource-oriented approach for analyzing the internal environment of the innovation company are also described. As a result, an author's qualitative model is proposed for analyzing the innovative environment in a cross-national perspective, which allows describing the environment statically and dynamically, and can also be modified depending on research tasks, national innovation environment.

Keywords: national innovation system, case study, innovative eco-environment, innovation research methodology, cross-national research, qualitative research models, innovative environment of Kazakhstan, innovative environment of South Korea, resource-oriented approach.

1. Introduction

The necessity of forming the National Innovation System (NIS) in Kazakhstan is an opportunity to overcome the raw material orientation of the economy, transforming it into a knowledge economy. Today, knowledge becomes not only the most important production factor, but also a factor in the rapid development of high-tech industries, the basis for ensuring the competitiveness of the national economy and its security. Thus, the investigated problem is multifaceted, when evaluating its development, it is also necessary to take into account research related to the development of theoretical, methodological and practical aspects of NIS construction. At the same time, up to the present time such aspects of the problem as the relationship of NIS with the economic development of the country remain insufficiently developed; factors that influence the formation of NIS in modern conditions; concept of the innovation system of developed countries. In this article we attempted to determine the basic principles and guidelines for innovative development of the economy of Kazakhstan, to identify the features and factors of NIS development, to conduct a conceptual analysis of the NIS of developed country – South Korea.

In this regard, there is an important issue of implementing a set of measures for the transition of the Kazakh economy to an innovative type. One of such instruments is the legislative initiatives of the Government of the Republic of Kazakhstan.

2. Research Methodology

The study was conducted in three stages. At the first stage, a toolkit for the quantitative analysis of innovation networks was created, which is necessary for the study of the innovative eco environment. The second stage of the research emphasizes the role of the context for the analysis of innovations rooted in the local economy

and culture in particular, which is proved by the network theory. The third stage is represented by a qualitative research method - the case study method. At this stage, a cross-national study of innovative systems in Kazakhstan and South Korea was carried out.

3. Literature review

3.1 Innovative economic environment

Currently, there is a significant amount of research in the field of innovation. However, despite the fact that a wide range of economic, social and technological incentives are offered as driving forces for innovation, there is hardly a consensus on how and to what extent innovation activity is deterministic of changes in the social or economic environment. In fact, modern studies confirm that there are many theories that determine the factors that influence the development of innovation and that the universal theory in this case seems unrealistic. Nevertheless, it should be noted that the perspective that takes the driving forces of innovation is often associated with technological shifts and a long-term evolution of the economy, not least evidence of lengthy and still ongoing discussions about the driving forces of the industrial revolution and the origins of industrial capitalism (Crafts, 1985, 1995; Mokyr, 1990, 2009; Allen, 2009; Bottomley, 2014).

A study of many sources allows us to emphasize the set of "positive" driving forces for innovation, for example, the growth of market demand for innovation and "negative" factors, the closure of the innovation process. In many economic models, innovations are motivated by the expected private return on innovation, which is more or less secured by intellectual property rights, for example, patent laws (see Nordhaus, 1969, Scotchmer, 1991, Moser, 2005, 2013) or due to increased market demand and the needs of consumers (Schmookler, 1962; Lundvall, 1985, 1988, von Hippel, 1994). Other structures view innovation as a result of progress in the field of knowledge (Arrow, 1962, Romer, 1990, Aghion and Howitt, 1992), useful knowledge (Mokyr, 2002), new technological possibilities (Klevorick et al., 1995) and diffusion of general-purpose technologies (Bresnahan and Trajtenberg, 1995; Lipsey et al., 2005).

3.2 Network theory of innovation

In his original article titled "In Search of a Useful Innovation Theory," Nelson and Winter (1977) sought "to outline some areas that would seem to be fruitful" in innovative research and policy based on "selected aspects of the prevailing theoretical understanding of innovation" (page 36). Nelson and Winter (1982) followed this book, The Evolutionary Theory of Economic Change, which was based on the field of technology and innovative research (Fagerberg, 2005). Although the innovation process is socially contextualized in the evolutionary economy - in terms of subprograms, trajectories and regimes - the sociological perspective has so far remained largely a complement to the further development of this field of research (Ahrweiler, 2010; Fagerberg, Fosaas, & Sapprasert, 2012; Leydesdorff & Van den Besselaar, 1994).

The constructivist turn and increased attention to reflexivity in research in the field of science and technology led to the fact that sociologists of science and technology theorized innovation as an evolutionary factor in the transition to a knowledge-based economy (Martin, Nightingale and Yegros-Yegros, 2012; see Schumpeter , 1943, 1964, pp. 62ff.). However, various metaphors, such as the "transdisciplinary mode-2 knowledge production" (Gibbons et al., 1994), "trajectories in landscapes" (Geels, 2002), "Risk Society" (Beck, 1992, see Beck, Bonn and Lau, 2003) and the triple spiral of university-industry relations and government (Etzkowitz & Leydesdorff, 2000) provide averages that have informed economic and geographic analysis in a wide range of applications (Geels, 2007).

Theories of diffusion studies and technology assessment focus on the consequences of the enhanced role of organized knowledge in society (eg, Rip, Misa, & Schot, 1995; Teece, 1986). In addition, a social network analysis (eg Powell, White, Koput, Owen Smith, 2005) makes it possible to study the relationship between media in neoinstitutional organizations (Powell & DiMaggio, 1991).

In our opinion, the evolutionary model and the dynamics of technological changes, nevertheless, were refined in the main works of sociological literature, but, unfortunately, in disintegrated, and sometimes mutually antagonistic ways. In a special issue of Mind and Society, one of us called for the sociology of innovation from the point of view of cultural theory (see Adolf et al., 2013; Ahrweiler, 2013; Ahrweiler & Keane, 2013; Mast, 2013). In this study, we collect elements from three or four sociological traditions and determine the prospects for empirical research on this basis.

Thus, the two levels - historical organization and evolutionary self-organization in the environment of choice - can be viewed as independent incentives for innovation that lead to action. Unlike historical changes with a time arrow, innovations absorb reflexivity in interpersonal communication as one of the sources of "creative destruction" (Schumpeter, 1943, pp. 81-86). Thus, historical ties can be dissolved and replaced in anticipation of performative improvements.

3.3 From system expertise to system level comparisons

One of the first comparative studies of NIS was carried out by Porter (Porter 1990). This and other early comparative studies did not correspond to the formalized structure and covered only two or three countries. None of the authors of the early comparisons took into account the social, economic and political situation of the respective countries. This had the same effect on their ability to develop and use technological knowledge as systemic, that is, material characteristics. Therefore, one can state whether it is possible to use the national NIS, unlike other national influences, as a tool for managing the competitive environment of another nation.

Nevertheless, the way to benefit from these comparative studies is to keep political consequences. Institutions such as the OECD or the EU encourage policy-oriented studies that often combine the NIS approach with the idea of benchmarking. The OECD Working Group on Technology and Innovation Policies (TIP), for example, conducted a four-year study on policies related to a systems approach to innovation (OECD, 1999). Some of the conclusions in this report stem from previous OECD studies, such as the 1998 publication "Technology, Productivity and Job Creation: Best Political Practices" (OECD, 1998). In 2000, the EU decided to "develop indicators and a methodology for comparing national research policies" (European Commission, 2000, p.3).

Research of this kind is aimed at identifying "best practice strategies" and "better behavior" among the countries studied by examining different indicators of innovative results or efforts. Based on the results of the search for best practices, recommendations were developed.

Nelson (Nelson, 1993) responded to the lack of a clearly defined analytical framework. He conducted a study in fifteen countries, which was intended to highlight the institutional arrangements that supported technical innovation in these countries. He stressed the similarities and differences and initiated, at least, a preliminary discussion of how these differences arose and seem to matter (Nelson, 1993b).

In the future, we will consider in more detail the NIS of South Korea and Kazakhstan. We will study the composition and strength of these systems by looking at them at the system level in a formalized manner, and not just by comparing system characteristics.

4. Comparison of South Korea and Kazakhstan

4.1 Institutional functions

4.1.1 Development of a policy on technology and innovation

In Korea, various independent ministries and departments carry out activities in the field of science and technology (R & D), which may include research and development (R & D). Duplication and conflict between individual politicians create inefficiency within the system. In order to minimize this inefficiency, a policy coordination and budget coordination process is underway (Chung 2001).

To coordinate policy, the Ministry of Science and Technology (MOST) is the legally central point of policy in the field of science and technology. Ultimately, long-term technological forecasting was added to the role of MOST. Every five years, MOST uses the Delphi method and returns results to policies and research and development (Chung 2001).

In many respects inefficient due to the lack of political power and financial resources, MOST actually acts as the secretariat of the National Council for Science and Technology (NSTC). The NSTC was established in accordance with a special law on scientific and technical innovations in 1997 under the chairmanship of the President of Korea. The NSTC solves the political agenda, policies, priorities for the distribution of R & D and the evaluation of national R & D programs. The Ministry of Planning and Budget (BCH) carries out budgetary coordination, which includes the preparation of the annual budget guidelines and the allocation of budgets.

Previously, MPB had the greatest power in S & T policy; However, it is likely that the balance of power in the future will shift towards the NSTC (Chung 2001).

Innovative policies play an important role in Kazakhstan's economic strategy. To improve the sustainable development of Kazakhstan, on the basis of diversification and modernization of the economy, clear goals and tasks are set for moving from a raw material economy to a knowledge-based economy through the use of revenues from the oil, gas and mining industries. An increasingly important focus in Kazakhstan is on innovation, the country strives to develop scientific and technological capabilities and to close integration of science and business.

Kazakhstan has concentrated considerable efforts on activating innovative activity as a means to accelerate economic development and diversify the economy. Initiatives are aimed at improving the components of the national innovation system, in particular, on the creation of state institutions to support innovation. Attention was also accentuated on increasing the productivity of companies, regional features of the innovation system and the demand for innovation. However, despite the political decisions confirmed by some program documents, practical activities were focused mainly on improving institutional support.

However, the legal environment for innovative regulation is not sufficiently developed in Kazakhstan. Not developed a number of laws that would help in innovative regulation, as well as in the innovation process.

The authorized state body, the leading stages in the creation and implementation of policies in the field of industrial and innovative progress, is the Ministry of Investment and Development of the Republic of Kazakhstan, whose tasks include:

- the generation of ideas and the direction of development in the Government of the Republic of Kazakhstan on the main lines of innovation;
- implementation of innovative grants;
- conducting an accompanying monitoring of implementation and evaluating the effectiveness of the introduction of innovative projects produced through innovative grants;
- state control over the implementation of the legislation of the Republic of Kazakhstan on state support of innovation activities, including the progress of the complex of measures for innovative development.

The organizational structure of the innovation policy in the Republic of Kazakhstan is as follows (Figure 1).

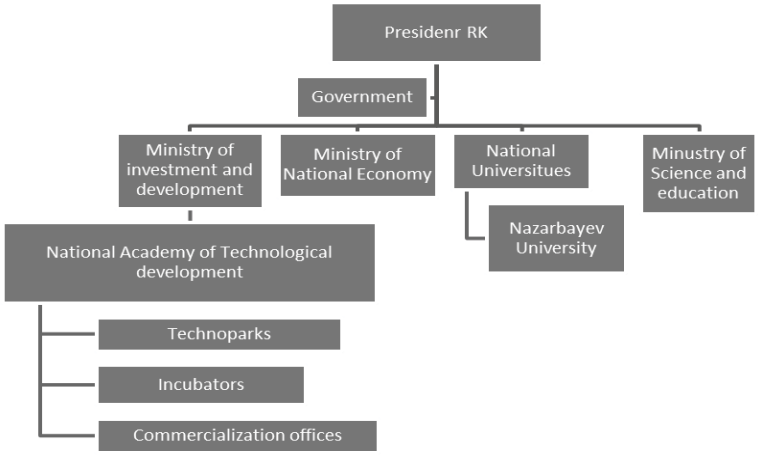

Figure 1: Organizational structure of innovation policy in the Republic of Kazakhstan

The Ministry of Education and Science of the Republic of Kazakhstan is the authorized body responsible for the formation, implementation and coordination of all fundamental and applied research conducted in the country, the state and development of the research infrastructure, the training and professional development of scientific personnel, and the conduct of the State Scientific and Research Expertise scientific projects and programs implemented at the expense of the state budget.

4.1.2 Performing research and development

Over the past two decades, the Korean government has shifted its position from the fact that since the 2000s it has been actively engaged in research and development and encouraged private firms to do research and development. South Korea is spending heavily to achieve its goal. In 1999, the country's investment in research and development (R&D) totaled 2.07% of its gross domestic product (GDP), just below the average for nations in the Organisation for Economic Co-operation and Development (OECD). In the latest figures, the country has stretched out a clear lead at the top. The 4.29% (63.7 trillion won, or US$60.5 billion) that South Korea invested in R&D in 2014 outstrips runner-up Israel (at 4.11%), as well as regional competitor Japan and the United States.

The low level of innovation activity of R & D in Kazakhstan results from the structure of industrial production with its raw materials orientation and foreign direct investment. Contrary to the fact that in recent years the development of the oil and gas complex has served the country's economic development, the demand for R & D has not increased and production growth has not been observed. Large enterprises in the extractive industries use often imported technologies, which national R & D institutes do not produce.

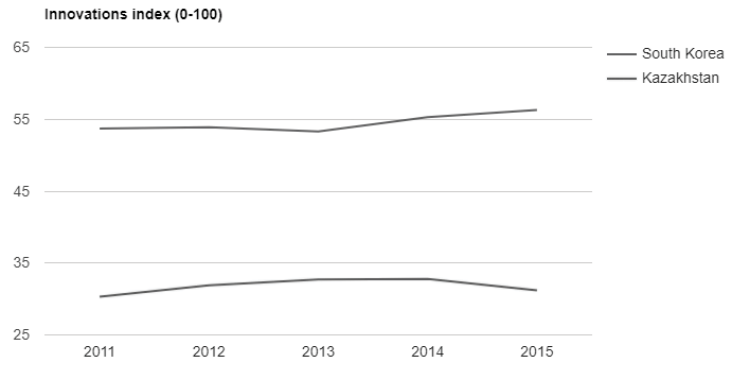

Figure 2: Innovation Index of Kazakhstan and South Korea

For the period 2004-2015 in the Republic of Kazakhstan there was a continuous increase in the costs of enterprises for technological innovation. A characteristic feature is the prevalence of the acquisition of ready equipment and machines. Comparatively not significant funds were allocated specifically for research and projects. An even smaller share of costs was received by the industrial design, that is, the preparation of buildings and structures for the installation of equipment. And very little money was allocated for training and training of production personnel, purchase of software, patents and licenses. On the one hand, this is due to the extreme deterioration of the basic technological equipment and the inevitability of its urgent replacement. And on the other hand, low interest of foreign investors in the full intellectual content of their actually pro-production technologies in our country. The wide development and dissemination of electronic means of communication makes it possible to remotely control almost completely automated production processes in real time.

The type of research and development carried out in Korea has shifted to the development of technology in comparison with the basic ones. In addition, Korean state-owned companies, cheybols, have reached the technological frontier from reverse engineering, and efforts have been directed to research and development to enhance international competitiveness. On the contrary, the most common type of innovation in Kazakhstan is gradual. Alcorta and Peres (1998) set out three reasons for this behavior:

- Great management capabilities. Managers tend to "react, emphasizing commercial and financial decisions, rather than technological ones." Therefore, when problems arise, they are looking for solutions in terms of reducing overhead, rather than improving the product.
- Lack of knowledge in the field of innovation. Firms still view human capital as a value, not as a resource.
- Lack of medium-term / long-term vision. Firms do not have a vision of long-term competitiveness.

4.1.3 Financing R & D

Research and development expenditure (% of GDP) in Kazakhstan was reported at 0.16944 % in 2015, according to the World Bank collection of development indicators, compiled from officially recognized sources.

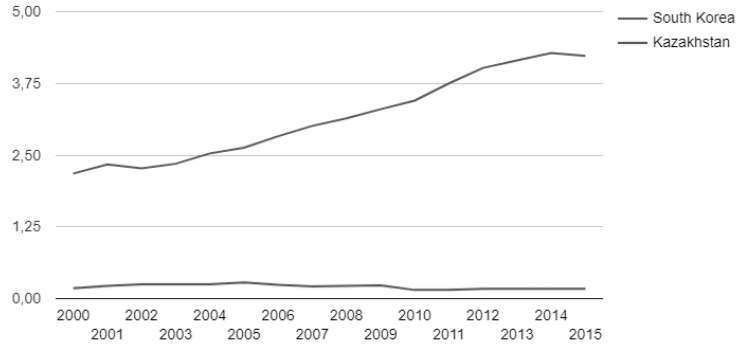

Figure 3: R7D expenditure, percent of GDP

South Korea spends hugely on R&D. Led by technology companies such as Samsung and LG, it invests more than most advanced economies. It was narrowly beaten by Israel to the title of top R&D spender, devoting 4.23 per cent of gross domestic product in 2015, compared with Israel's 4.25 per cent, according to OECD data.

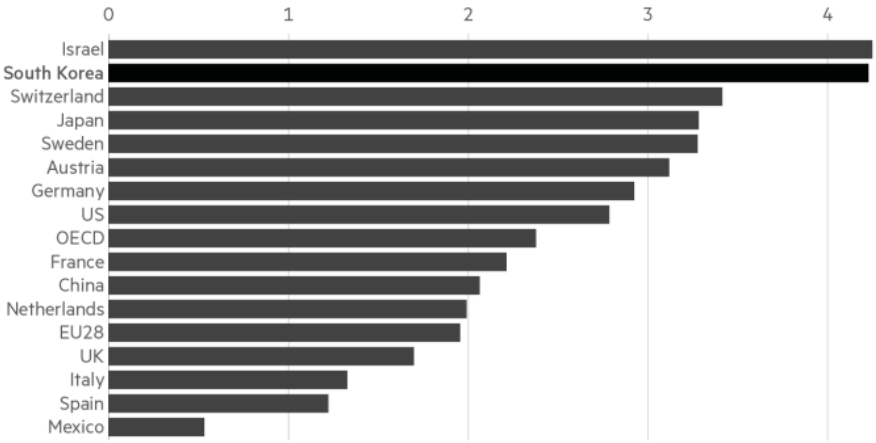

Figure 4: Spending on R&D, as a share of GDP (%)

Investment has been driven mainly by the private sector, although public R&D spending is high. Almost three-quarters of South Korea's R&D is business-led; nearly 90 per cent of that is invested in manufacturing, with the focus tilted towards applied research for industrial competitiveness. Industrial R&D also favours technology industries such as electronics.

An R&D scene dominated by conglomerates has come at a price, however. Industry watchers bemoan that the country lacks "blue sky innovation", especially in software and services, as R&D activities are concentrated on big companies and state-run research institutes. There are too few upstarts with innovative ideas as the chaebol's dominance hinders new entrants.

4.1.4 Promotion of human resources development

The illiterate labor force in the 1950s (22.0% in 1953) to almost 90% of the literacy rate for two decades demonstrated the high priority that Korea has for education. Expenditure on education in comparison with general government expenditures increased from 2.5% (1951) to 5.07% (2015). Despite the high costs, this still represents only one-third of the total cost of education; the rest - through private firms and parental contributions. This rapid growth created a highly skilled workforce. Foreign education has also become the main factor - a hangover since the US assistance in Korea after colonization (Kim 1993). In Kazakhstan in 2000 expenditures were 3.26% of GDP, in 2015 - 2.79%.

Although the number of students has increased dramatically, the quality has declined in both countries. In Korea, according to the Ministry of Education in higher education institutions, there were 19.9 students per teacher in 2000, and in 2015, 13.2 students per teacher. The number of universities increased from 107 to 175 over the period from 1990 to 2007. Kim (Kim, 1993) argues that because of this

Tracing the change in the number of personnel engaged in research and development by sector of activity, one can note a slight increase in their number in the public sector - by 2.7 thousand people, or 35%; in the IT sector - by 0.4 thousand people, or 0.3%; in the NCO sector there is a negative trend, that is a slight decrease of 0.2%. At the same time, the decrease in the number of personnel engaged in research and development in the business sector, by 0.5 thousand people, or 11%, is of particular concern. After all, in the modern market economy, the entrepreneurial sector accumulates a large part of its scientific potential. This is the case in South Korea, where about 2/3 of the total number of researchers are employed in the business sector. These data reflect the low investment interest of domestic entrepreneurs in innovation and development, thereby further exacerbating the prevailing common negative situation.

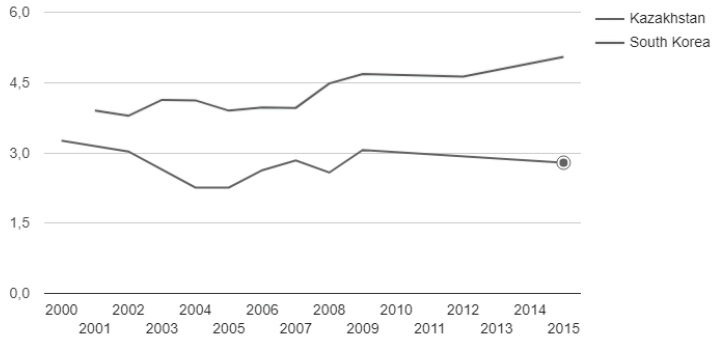

Figure 5: Public spending on education, percent of GDP

4.1.5 Encouraging technological entrepreneurship

Despite their importance, in the 1980s, the chabols began to abuse their economic power and stifled entrepreneurship in small and medium-sized firms (SMEs) (Kim 1993). To respond, the Korean government has taken two actions - they have created sanctuaries and a venture industry. In the sanctuaries 205 business-terrorist acts operate, in which shabols and related subsidies cannot enter - this allowed SMEs to flourish in the high-tech sectors (Kim 1993). Secondly, the first venture company was created within the framework of a special partnership between public and private companies. The subsequent Law on the Formation of Small and Medium-sized Enterprises in 1986 led to the creation of 12 more venture capital firms financed by a combination of public and private sectors (Kim 1993). In addition, the Law on the Promotion of the Financing of New Technologies in the Field of Commercialization, created in 1986, helped to form financial institutions that financed only the high-tech sector (Kim and Dalman 1991).

While entrepreneurs in Korea have a constant capital stock, Kazakhstan does not have the same luxury. There is little venture capital in Kazakhstan, and it is debatable whether there are business opportunities. There is no literature on this, but it seems that the lack of innovations in industry, applied research in the university and capital will lead to stagnation of the entrepreneurs' proposal.

4.2 Interaction of institutions

4.2.1 Cooperation in the field of R & D

Cooperation in both countries is very weak. In Korea, MOST estimates that only 35% of its national research and development is carried out by a combination of universities, research institutes and industries (Chung 2001). Cooperation between universities and the private sector is the weakest link in the Korean NIS. Due to insufficient funding from universities, as mentioned above, industry views universities as not having sufficient capacity for their own purposes, and therefore they attract very little from the private sector. Instead, informal cooperation is more common through the use of consultations from individual members (Kim 1993).

Between branch and state research institutes, cooperation is more frequent, since the government provides subsidies and financial incentives for such cooperation. Recently, large private firms have preferred to keep their R & D secrecy in order to maintain a competitive advantage, despite short-term financial incentives. These interactions are mainly used to support SMEs.

In official forms of R & D among institutions in Kazakhstan, no literature was found. Indeed, it is doubtful whether there is any industry in the industry, since such a small number of firms perform R & D. At the same time, the experts of the JSC "Center for Trade Policy Development" note that the degree of innovation in SMEs in Kazakhstan is limited, which is also indicated by the relatively low percentage of income from new products - 28% in 2015. Despite the fact that the Government highlights the development of entrepreneurship and innovation as priority directions, emphasizing their decisive importance for economic diversification and improving the country's competitiveness, the GPIIR for 2015-2019 does not provide for specific target indicators related to the increase of innovative activity in the business sector. Secondly, a large number of innovative enterprises face barriers such as lack of knowledge and experience among staff, a lack of investment in innovation, a lack of risk capital for innovative projects, and a lack of demand for new products among the local population. Thirdly, in the sphere of innovative activity development, there are gaps in the provision of venture capital to new innovative enterprises that are in the early stages of development.

4.2.2 Diffusion of technology

The role of foreign direct investment (FDI) in both countries varies widely. Kazakhstan's gross direct inflow of foreign investment was $ 7.9 billion in 2005, and rose to $ 20.6 billion in 2015, and Korea received only $ 3.6 before 1986, and it's no wonder, that their role in the Kazakhstan NIS is of paramount importance. Since the 1960s, there has been a clear government policy in attracting FDI. "This was not only to protect the local market, but also to provide significant subsidies and a special regime for foreign investors." (Dahlman and Frischtak, 1993). However, with weak intellectual property rights, foreign companies tend not to invest their most advanced technologies (Dahlman and Frishtak, 1993). However, in Korea, the lack of foreign direct investment is deliberate. The government's policy in Korea requires that all foreign investment be approved by the state - an attempt to neutralize the independence of Korean companies from multinational enterprises (Viotti 2002). This turned out to be decisive in the 1980s: while Korean companies could specialize and switch to innovation, Kazakhstan formed its scientific innovation system from the "fragments" of the Soviet innovation system and there was no interest on the part of enterprises in innovations, the introduction of new technology was necessitated fulfillment of relevant tasks from above.

There is a "strong dependence" on foreign licensing and technology expertise (Arocena and Sutz 2001). This compensates for the lack of internal R & D. While the situation in Korea is the opposite, Chaebols have aggressive own R & D laboratories for "absorbing, assimilating and adapting imported technologies" (Kim 1993). In the 1980s, the Korean government created state research institutes for the sole purpose of spreading technology. The lack of resources meant that they could not create prototypes or perform any effective research and development. Although this may seem like a failure of goals, it actually gave the same effect as researchers from these institutions, and also from state-funded companies joined the industry to lead the research and engineering departments, carrying with them the knowledge gained from government institutions.

In addition, the Korean NIS does not have any "explicit policy instruments" (Kim and Dalman 1991) about the spread of technology. Indirect instruments, such as consulting engineering firms and manufacturers of commodities, allowed the government to focus on these agencies to promote the diffusion of technology. In addition, in connection with the supply and demand for technology, two main tools were used. For SMEs, six government agencies provide various technical services that range from training and automation to assisting firms with product quality. Secondly, scientific and technical information is disseminated through scientific articles in technical information centers (Kim 1993).

4.2.3 Staff mobility

No literature was found on the mobility of personnel in both countries, which indicates its insignificance in both NIS. Kim (1993) notes that the Korean war, in spite of the destruction of large parts of the industrial infrastructure, actually helped "... further economic development by completely transforming the traditional rigid society into a highly mobile one, forcing geographic mobility" (Kim 1993). It is clear that mobility played

an important role in the initial process, and the Koreans probably retained this mobility, because Korea is a relatively small country compared to other industrialized countries such as Indonesia or China.

However, in Kazakhstan there are no hints at the role of mobility, since public R & D is largely dominant, the role of mobility - if it exists - will be insignificant, since they will be carried forward only within the same type of institutions, not from -institution.

5. Conclusion

Drawing conclusions from the comparison between South Korea and Kazakhstan, it must be repeated that there is no such thing as a full-scale institutional structure that would include all possible interdependencies between different institutions.

The above approach mainly revealed differences in the characteristics of the two countries. A systematic approach to innovation is established as a useful basis for studying technical changes and their determinants, but one can state whether generalizations can be made and whether Kazakhstan, if it copied the Korean NIS, would have the same success.

We fill in the weaknesses with the map of Chang and Shi. The four fundamental groups proposed by Chang and Shi to capture this abstract functioning of the system either were not documented in the literature (mobility of staff and informal interactions) or did not show great differences (R & D cooperation). Only technological diffusion of foreign knowledge has shown significant differences in the practice of countries, but the spread of innovations created in the respective countries does not have any significant references in the literature. Authors such as Viotti (Viotti 2002) who innovate the templates disprove the usefulness of the NIS concept in the case of technological backwardness when it indicates: "The NIS approach is not suitable for processing the processes of technical changes typical for industrialization of the economy that are very different from the economically industrially developed countries".

However, the fact that only fragmented innovation systems were only empirically discovered in low- and middle-income countries does not mean that the structure of NIS is useless in these conditions. Sagieva and others (Sagieva & Zhuparova, 2013) do not refrain from using the NIS approach, and have weaknesses, it has nevertheless proved to be a useful and astute tool for analyzing South Korean and Kazakhstan NIS. Within our framework, we have analytically discussed ten aspects of the NIS, and we hope that with the help of such studies it will be possible to make wider implications for public policy. Consequently, governments of industrialized countries can learn and improve their economic progress.

Design Thinking as a Methodology for Teaching Entrepreneurial Mindset in Primary Education

Blaž Zupan[1], Anja Svetina Nabergoj[1] and Franc Cankar[2]
[1]University of Ljubljana, Slovenia

Aco.cankar@gmail.com

Abstract: This article provides insights into a way to develop creativity, innovation and an entrepreneurial mindset in young people as a universally applicable skill. The research questions were: How did teachers use Design Thinking as a methodology for teaching the entrepreneurial mindset to adolescent students? and What was the context in which the teaching took place, and what factors influenced the completion and outcomes of the projects? A total of 146 seventh and eighth-grade students age 12-14 and 20 teachers, 2 per class, from 10 Slovene schools took part in the study. Teachers used the Design Thinking method to facilitate hands-on student projects. During the course of the project, the participating teachers attended two meetings to present their progress. In addition, one of the study facilitators visited each school several times to discuss the project with the teachers, observe the class and take notes. Both teachers submitted a combined final report of their experience and observations. Reports collected have been coded using NVivo software. Three factors are recognised, the characteristics of the project, the environment in which it was carried out, and the characteristic of the learning and teaching. The study demonstrates that adolescents respond very favourably to an entrepreneurship assignment and that the entrepreneurship exercise builds skills in multiple developmental areas, rendering such a project very useful within existing curricula.

Keywords: adolescent education, innovation, entrepreneurship education, entrepreneurial mindset, elementary school, Design Thinking

1. Introduction

This paper focuses on efforts in education to encourage and develop young people's 'entrepreneurial mindset,' which McGrath and MacMillan (2000 p. 32) defined as 'the ability to sense, act, and mobilize under uncertain conditions.' In 2012, the European Commission released the report Entrepreneurship Education at School in Europe: National Strategies, Curricula, and Learning Outcomes, which outlines strategies to enhance creativity, innovation and entrepreneurship at all levels of education and training among 31 European countries (Bourgeois 2012). The report notes that the Republic of Slovenia's Development Strategy (SDS), adopted by the government in 2005, states, 'entrepreneurial skills at all education levels should be developed, the entrepreneurial spirit of young people should be encouraged and positive notion of entrepreneurship established, training programmes for running small enterprises and entrepreneurial knowledge for young people should be provided' (Bourgeois 2012: 71). In Slovenia the subject of entrepreneurship remains optional for upper secondary school students (schools for university-bound students aged 15-18). However, in primary education (aged 6-14), Slovenia has established learning outcomes associated with 'economic and financial literacy', and entrepreneurship is loosely included in the compulsory subjects of maths, sciences, and technology. However, entrepreneurship education has much room to grow.

1.1 Teaching the entrepreneurial mindset

It is crucial to understand which concepts related to the development of creativity, innovation and an entrepreneurial mindset can be implemented in schools and how. Despite limited research on effectiveness and implementation of entrepreneurship education at the pre-university level, some scholars have argued that childhood and adolescence is the ideal time to teach entrepreneurial skills and foster a positive attitude towards entrepreneurship (Peterman and Kennedy 2003). In his book In the Beginning was Entrepreneurship, Johannisson (2010) suggests that children are born enterprising; however, this characteristic is not encouraged much while growing up. Johannisson (2010) argues that the entrepreneurial mindset must be perceived as a phenomenon constructed by individuals, rather than an external development process. In addition, the pedagogical concept of developing an entrepreneurial mindset and skills is a process in which mentality, sources and people are organised in new patterns. These patterns, however, are a result of the possibilities that were identified during activities and social interactions. Therefore, the following questions become

relevant: could the development of an entrepreneurial mindset and skills in the current school system be realised? Or is it merely a current trend that has accidentally become the focus of education-related research? Over the past decade, at the core of developing an entrepreneurial mindset is an idea of promotion of creative and innovative problem-solving as a universally applicable skill. Several pieces of research have dealt with this position, which emphasises an anthropological and educational focus (Katz 2003; Frese 2009; Neck and Greene 2011; Fayolle 2013). Several authors have proposed a modern paradigm of enterprise education (Rasmussen and Sorheim 2006; Neck and Greene 2011; Sarasvathy and Venkataraman 2011). They argue that classic administration of entrepreneurship education, which focused on the teaching of developing business plans, often fails to foster creativity and innovation in young people, especially elementary school students (Garavan and O'Cinneide 1994; Honig and Karlsson 2004). These scholars suggest that the promotion of creative and innovative problem-solving curricula can provide students a generally applicable skill for personal and professional life that is useful to society (Martin 2007; Kelley and Littman 2005; Meinel and Leifer 2011).

1.2 The Design Thinking method

The change in perception of the entrepreneur solving social problems required different approaches to creative problem-solving in real-life situations. The method of Design Thinking (Figure 1) evolved as a result; it promotes the development of creativity, innovation and an entrepreneurial mindset with a strong focus on understanding the needs and desires of the end user (Rauth et al, 2010). Design Thinking has been taught in several universities for many years, particularly Stanford University, which not only teaches Design Thinking but also conducts research on the use of Design Thinking in compulsory and higher education settings.

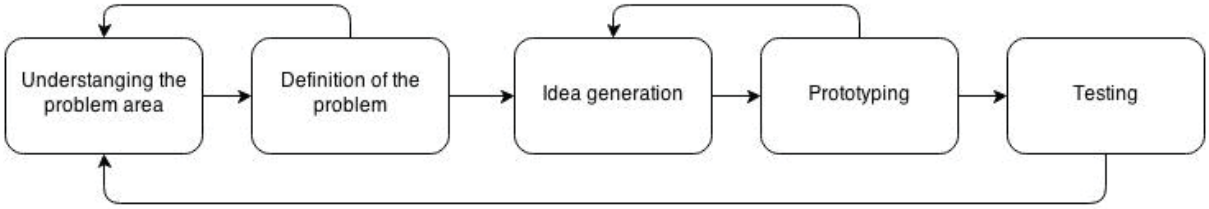

Figure 1: The Design Thinking method; source Brown 2008; Rauth, Köppen et al, 2010

The Design Thinking method involves conducting research with existing and potential users of a product or service to understand their needs and identify product challenges (Brown 2008; Rauth et al, 2010; Meinel and Leifer 2011). This requires the use of various techniques of collecting data about users and their surrounding environment. It is a combination of different methods, which may involve field observation, interviews, focus groups, surveys, experiments, videography and photo diaries, among others. These methods mainly include ethnographic techniques of data collection. In addition, less traditional sources of data may be used, such as talks by experts, Internet discussions and newspaper articles (Carroll et al, 2010). After collecting sufficient information about the users and their problem, the problem is then defined and ideas are generated according to different criteria. Next, the prototyping process involves different methods to visualise, physically create and test the solution to the problem. The process is intended to be cyclical and iterative, as some steps in the process, or the entire process itself, are repeated to continuously improve the product.

2. Methodology

To identify the potential of Design Thinking as a method for teaching the entrepreneurial mindset to young students in Slovenia, we monitored the progress of a Design Thinking project in selected Slovene elementary school classrooms, each with 10 to 20 students and 2 teachers. We also investigated the implementation of the projects in the involved schools, how they were connected to the respective local communities, and whether they enabled the students to learn in real-life situations.

This study used ethnography to examine the experience of teachers in facilitating a Design Thinking project in their classroom. The research questions were:

1. How did teachers use Design Thinking as a methodology for teaching the entrepreneurial mindset to adolescent students?
2. What was the context in which the teaching took place, and what factors influenced the completion and outcomes of the projects?

The project took two hours of classroom time per week for 17.5 weeks (35 hours total). A total of 146 seventh and eighth-grade students age 12-14 and 20 teachers, 2 per class, from 10 Slovene schools (labelled A-J in subsequent text) took part in the study.

To gain training in the Design Thinking method and ethnographic research in preparation for the classroom project, the participating teachers attended a two-day seminar facilitated by the researchers. Teachers were instructed on creativity, the entrepreneurial mindset, current and best practices, and the Design Thinking method. Additionally, they were trained in field observation and note-taking. The teachers were instructed to take regular notes of progress over the course of the project, focusing on the phases of the project. They also had to describe their role and circumstances in managing the project and highlight the issues they encountered. We were interested in the teachers' experience and understanding of the project. During the course of the project, the participating teachers attended two meetings to present their progress. In addition, one of the study facilitators visited each school several times to discuss the project with the teachers, observe the class and take notes. Both teachers submitted a combined final report of their experience and observations. A total of 10 teacher reports and 10 researcher notes from class visits were analysed. The collected information and presentations were compared with the submitted written reports, and no discrepancies were found thus confirming the credibility of the reports.

Using a grounded theory approach (Charmaz 2006), three raters coded the reports using NVivo software. The codes were first categorised according to the Design Thinking phases of the project and additional themes were identified throughout the coding process that were based on repeated or interesting ideas, concepts and keywords. Thirteen additional themes were identified (see Table 1).

3. Results and Discussion

The results presented here are organised according to the Design Thinking phases and other insights, and supported with illustrative excerpts from the teachers' reports.

3.1 Phase 1 & 2: Understanding and defining the problem, and Observation

Each of the classrooms came up with an innovative project idea to address a problem in their school, social circle or community. The classrooms undertook field observations to identify problems, some of which were done in their own school and some in the local community. Some students were also provided the opportunity to return to their field location more than once or make observations in their own free time. School H reported, 'The students had one week to observe their school and its surroundings.' This particular phase of the project supported the intended learning outcome of understanding different ways to observe, compare and analyze people's needs. School D reported, that the students were able to learn about the problems of the locals by interviewing them and were able with the help of teachers to assess the possibilities of solving thereof.

Students appeared to be very enthusiastic, active and creative during the observation phase. School G reported, 'We came up with 240 different answers or problems to draw ideas from.' The observation phase supported the intended learning outcome of developing personal qualities necessary for the successful realization of ideas, such as creativity, self-confidence, enthusiasm, courage, and cooperativeness. Interesting to note is that the students did not have to be coerced into working, since, as school J reports, they volunteered for the jobs connected with observation and data collecting. Following the field observations, the students identified problems to work on.

3.2 Phase 3: Ideation

It appeared that the brainstorming phase was one of the most active ones for students. School C reported, 'The students had so many suggestions, but we had to postpone them until further notice.' During this phase, the classrooms were successful in identifying one feasible project each to work on. For example, in School B, which addressed the problem of an underutilised forest trail, the students decided to organise a science day and install three additional educational displays on the trail. School J, which identified the need for a 'school gift,' chose to create a soap using local ingredients. School I developed an audiobook because a relative of one of the students has dyslexia and the students sought ways to help that relative.

Some of the ideas that children proposed were too complex to be completed without outside assistance or resources, or within the timeframe of the project. However, in some cases, the teachers were able to access

outside assistance, which enhanced the project. In School E, which addressed the problem of their school's poor quality school lockers, the students were able to work with a carpenter to design and build a prototype of a new locker.

An interesting finding was how the teachers helped facilitate the student's negotiation process of choosing a few ideas from many suggestions. School C, which worked on a clothing line, reported, 'We agreed that every group had to incorporate as many ideas as possible into the clothes, even the most unusual and 'crazy' ones.' This particular phase of the process appeared to support the learning outcomes of developing interpersonal communication and learning to take risks, negotiate and compromise.

3.3 Phase 4: Prototyping and testing

Students collaborated with teachers from other subject areas or external partners such as entrepreneurs, designers and university professors, to create their prototypes. School C, which worked on a clothing line, collaborated with a local fashion designer who came to the school and provided mannequins. Because of this collaboration, School C reported, 'Our ideas were slowly becoming applicable; we managed to create prototypes from affordable materials.' The students decided to make women's dresses and handbags using a creative 'collage' technique incorporating metal and materials from seatbelts.

A range of different prototyping approaches was reported, from the use of simple materials that were manipulated by hand (e.g., cloth and wood), to the use of more complex technologies such as 3D modelling. School F, which worked on designing sports equipment, reported, 'The students first sketched their ideas on paper; then they produced 3D models of the cupboards using Google Sketch Up.' The prototyping phase was one of discovery. School J reported, 'The students were surprised by the change in smell and colour of the soap when adding fragrances and spices.' It was also a project highlight for some of the classrooms. School H reported that compared to the other phases of the project, the students were most enthusiastic about their interaction with practical, hands-on work.

Once the prototypes were finished, the students tested them with different users, such as their peers or guests they visited during the field observations or tourists. School D reported, 'We designed a prototype of the [postcard] and asked parents, teachers, our headmaster and visitors to evaluate it.' Certain schools organised multimedia presentations of their products for their users. School E, which developed prototypes of new lockers, reported, 'Each group presented their prototype with a short video and tested its applicability with users.' Some students also changed their prototype during the testing phase to meet users' wishes, thus opening up new possibilities and ideas. School G, which worked on marketing materials for Lipica, reported, 'Test results gave rise to new ideas for upgrading and improving the prototypes.' Some schools also sought feedback from external collaborators on how to present their products to users. School J reported, 'The head of the company Dima Center explained the significance of marketing and added value of a product.'

3.4 Phase 5: Implementation

During the implementation, the schools finalised their projects, presenting them for assessment or in some cases, putting them into actual use. School H, which developed new school lockers, reported that the students presented their entire idea from conception to realisation to the school leadership.

Some schools even presented their results to community leaders. School E reported, 'The students published their results in various media and presented them to municipal representatives.'

Some schools also sold their products at a school bazaar (School D) or other venues. School C, which developed a clothing line, reported, 'We organised a fashion show in the centre of Celje and offered our clothes to be sold at a charity auction.' Some schools found that this activity was one of the best ways to understand users and their needs. School I, which created an audiobook for challenged readers, reported, 'It was nice to assume the role of sellers and see how they [customers] think.'

A positive finding from the study was the numerous examples of schools' on-going relationships with external collaborators after the project. School B, which worked on upgrading a forest trail, reported, 'We will organise guided tours along the educational path for seventh-grade students of neighbouring schools. We will also join forces with the local Tourist Association and the Pensioners' Association.' School F, which developed sports equipment, presented their prototype to a local company and agreed on future cooperation.

3.5 Other findings

Based on the analysis of the reports, which highlight situational and contextual learning, we identified several project factors that contributed to students' entrepreneurial competency over the course of the project.

Table 1: Three factors that contributed to the development of entrepreneurial mindset

Project factors	Environmental factors	Learning and teaching factors
• Field work and the duration of the project • Trained and enthusiastic teachers • Relevant and meaningful problems to work on • Interactive, hands-on projects	• External approval from school, leadership, parents and community members • Opportunities to work with external collaborators in an authentic environment • Adequate infrastructure, including time, resources, and external assistance • Applied use of new tools, resources and technologies in the classroom, particularly prototyping tools • Testing prototypes in the environment	• Student-centered education and including all students in the work • Team work and an interdisciplinary approach • Studying different options and assessing ideas critically • A culture of trust and safety

Results show (Table 1) that the projects on all ten participating schools involved field work. The problems the respective schools highlighted and worked on were closely connected with the lives of their local communities.

Frequently the students sought solutions to their own problems or those of their peers. Some schools transferred the education process into their respective partners' offices or manufacturing halls; some partner firms also invited their own partners to the education process. The students often obtained information needed to complete their projects at home.

The role of the teachers in facilitating the project was critical. First, some schools noted that the teams of two teachers were helpful. School H reported, 'Two mentors working together was an excellent idea.' Second, some indicated that the teacher training for the project was important. Some teachers alluded to the unpredictability of the project. Teachers from School C reported, 'Although we carefully planned the work for the project, the events sometimes took a different turn.'

Also, teachers' enthusiasm for the project and their ability to allow students to lead their own work was critical. A teacher from School J reported, 'We encouraged crazy ideas, playfulness, humour and the feeling of freedom in the group.' Another teacher from School H reported, 'My role as teacher was different [than how I normally teach], because we wanted the students to find the best ideas by themselves.' The second factor, no less important, are the effects of the environment, especially the support of the school leadership, parents, and also the local community. School H reports that they have presented their idea from conception to finalization to their school's management. The schools joined forces and cooperated with a number of external institutions and collaborators. The students and their teachers visited companies and entrepreneurs and worked with local schools and experts. The students of school A presented their prototype to the local community and managed to arrange further collaboration. Collaboration with outside partners and the local community provided the students with many opportunities for discovering new challenges and creating fresh ideas.

Adequate infrastructure is necessary to carry out the project, especially in the prototyping phase. The reports suggested that the schools possessed adequate spatial and material means for the project. In many cases, the students brought some of the necessary equipment and materials from home, while external collaborators

provided the rest. In some of the schools, the educational process took place on the premises of external collaborators

The third decisive factor that meaningfully rounds out the educational environment, suitable for developing an entrepreneurial mindset in primary education, is the teaching and learning methodology. School H reports that the students were most enthusiastic about the practical work. The teams collaborated with outside partners. 'Our ideas that we complemented with those of a fashion designer felt really great,' they wrote in school C. Students explored different options. Students from school D decided to encourage 'each team to implement as many ideas as possible into the clothes-designing process'. The report of school J, which decided to create a new soap, is also very telling. The school reports that 'the students were surprised to witness the fragrance and the colour of the change as they added incenses and spices. They worked in teams and were not afraid of making mistakes'. At the same time all the participating teachers mentioned using teaching methods that are uncommon for regular lessons. However, they agreed that the nature of the project increased their engagement and workload and that training was necessary before taking up the project.

4. Conclusion

Our findings indicate first that an entrepreneurial project such as the one incorporated here meets multiple academic outcomes within the elementary school curriculum and thus can be incorporated seamlessly into existing curricula and lesson plans. Second, the development of creativity and innovation as the basic components of the entrepreneurial mindset and skills in young people requires a systematic and comprehensive approach. Third, implementing high-quality entrepreneurship education calls for a comprehensive framework and the identification of effective practices and support from local and regional bodies. However, as this study suggests, elementary schools can relatively easily incorporate contextualized problem-based teaching practices aimed at developing entrepreneurial competencies on their own, without any major changes at the national or global levels where the chances of significant progress in the near future are unlikely. Initial changes do not need to be made at the upper-most levels, but can be incorporated from the bottom up through teacher education and teacher self-initiative.

Teachers report that the participating students were more focused on the process than they were on the product itself, so their work and learning were to a large extent self-regulated. This means that they were active in a metacognitive, motivational, and behavioural way. Studies show (Elstad and Turmo 2010; Kolovelonis, Goudas and Dermitzaki 2011), that self-regulated students, in contrast to peers who are not self-regulated learners, are highly internally motivated. They are more confident and more involved during classes, and use different learning strategies. They can organise their learning environment well and achieve mere academically. Apart from that, the opportunity for creative work, readiness for risk-taking and putting a lot of effort into work grow through self-regulation, which an entrepreneurial mindset helps offer.

This study has many strengths but also a few limitations. First, we relied upon disparate teacher reports of student behaviour and learning. Different teachers may assess the success of this assignment differently, clouding the results. However, since individual teachers do all of the assessing for their students in all areas of instruction, it is appropriate to rely on teachers as accurate assessors of their students' progress. Second, this assignment was tested on only one age group: 12-14 year-olds. Thus, these results are limited to generalizing within this age group. This limitation provides a logical segue into suggestions for future research however, as future studies can assess the effectiveness of such a program at lower and higher ages. Future research can also assess whether repeating this type of assignment at multiple ages can further entrench this way of thinking, or whether there is an ideal age at which to teach the entrepreneurial mindset to achieve maximum effects.

This study demonstrates that the Design Thinking method is an effective pedagogical approach to teaching entrepreneurship education in elementary schools and developing young students' entrepreneurial mindset. To achieve the desired results in the classroom, it is very important to train teachers and school management teams so that they would, with a 'high degree of certainty' (De Corte, 2013), support and create learning environments and thus gradually alter the positions on and convictions about teaching and learning. As we have shown, entrepreneurialism can very effectively be taught to adolescents, engendering an entrepreneurial mindset in people's formative years and preparing the track for greater entrepreneurialism within society as these students eventually enter the working world.

Abstract: The aim of this study is to explore the role of government and private institutions in supporting early stage entrepreneurs in Saudi Arabia. Entrepreneurship has attracted a fair amount of academic attention; however, to date, only little empirical work has explored the relationships between regulatory, cognitive and normative dimensions of the institutional profile, support for entrepreneurship and business performance, and specifically, in the context of early stage entrepreneurs in Saudi Arabia. This study takes a two-stage mixed methods approach to data collection. Quantitative data acquired by an online survey of early stage entrepreneurs (117) will inform a subsequent qualitative stage involving interviewing support institution officials and early stage entrepreneurs in order to gain deeper understanding of support agencies' role towards entrepreneurs and to explore how participants view the process of application for support. The online survey results reveal that finance and consultation are the most used forms of support, while entrepreneurial education is the least used. Respondents were predominantly opportunity entrepreneurs; fewer than 10 per cent established businesses out of necessity. Participants perceived cognitive and normative aspects of support favourably, but expressed considerable uncertainty about aspects of legal and financial support. All types of support, but especially regulatory, have positive influence on business performance of start-ups. Implications from the findings are drawn for the forthcoming qualitative investigation.

Keywords: Early Stage Entrepreneurs, Entrepreneurship, Formal Institutional Support, Saudi Arabia

1. Introduction

In many countries in the world, governments have consciously supported entrepreneurship to promote employment and achieve economic diversification, development and welfare (Schumpeter 1934; Acs and Audretsch 1988; Wennekers and Thurik 1999; Baumol 2002; Acs et al. 2008). Accordingly, many institutional frameworks for entrepreneurship have been developed by various countries (Smallbone et al., 2010).

The Kingdom of Saudi Arabia is among those countries that have sought to encourage entrepreneurship, in order to boost economic diversification and create employment for her youths. The country has therefore created a number of institutions to provide various forms of support for start-up of entrepreneurship and small business.

While there has been substantial research on the roles of institutions, their impact on entrepreneurship and small business has rarely been investigated, especially within the context of developing economies in the Middle East (Ahmad, 2012). More specifically, there is limited research in this direction in the Kingdom of Saudi Arabia, a traditional but rapidly-developing society and one of the richest countries in the Middle East and the world (World Bank Report, 2016). It is therefore of interest to evaluate to what extent the institutional policies and practices introduced by the Saudi Arabian government are succeeding in their aim of promoting entrepreneurship among Saudis and supporting small business start-ups and early-stage performance.

This paper presents an ongoing investigation of Saudi of entrepreneurship, with a focus on formal institutional support. It presents initial results from the first (quantitative) phase of the study and draws implications for the forthcoming qualitative phase.

2. Research questions

This section states the research questions. When thinking about research questions, the researcher certainly has begun to think about the purpose of the research (Saunders et al., 2012:138). The purpose of this research is to gain an understanding of the kinds of entrepreneurship support offered to and taken up by early stage entrepreneurs and their impact on the business with a view ultimately to forming recommendations for enhancing this sector.

Accordingly, the main research question is:

What is the role of formal (government and private) institutional support (finance, training and education, consultation, coaching, mentoring, and networking) for early stage entrepreneurs in Saudi Arabia?

The main question is approached via three sub-questions, as follows:

1. What types of institutional support are used by early stage entrepreneurs in Saudi Arabia?
2. What are the most important reasons for starting a business in the context of Saudi Arabia?
3. To what extent do the **regulatory**, **cognitive** and **normative** support dimensions affect early stage entrepreneurship (business) performance?

3. Entrepreneurship

Entrepreneurship has applications in many fields such as economics, history, sociology, anthropology, finance, marketing and management (Kaufmann and Dant, 1999; Acs and Szerb, 2007; Ahmad and Seymour, 2008; Gutterman, 2012). This has posed difficulty in selecting a suitable definition of entrepreneurship (Cunningham and Lischeron, 1991), and research reflects "the absence of a consistent definition" (Gutterman, 2012:1). Hence, scholars have defined entrepreneurship in different ways.

Schumpeter (1934) viewed the entrepreneur as an innovator who makes positive changes in the economy by bringing new products or services to the market. This makes him one of the first to associate entrepreneurship with innovation (Gutterman, 2012). Cunningham and Lischeron (1991: 46) state that entrepreneurship encompasses "a wide range of activities such as creation, founding, adapting, and managing ventures." Then they continue to say, "No single discipline provides the tools for managing an entrepreneurial venture", and they suggest that it is "not surprising that a consensus has not been reached about what entrepreneurship is" (Cunningham and Lischeron, 1991: 46). Johnson (2001) and Nijkamp (2003: 396) viewed entrepreneurship in similar terms, although this simple view does not fully capture the variety and complexity of entrepreneurship.

One approach to entrepreneurship is to focus on the traits supposedly possessed by entrepreneurs (Venkataraman, 1997). For example, Ahmad and Seymour (2008: 5) state that "the concept of entrepreneurship generally refers to enterprising individuals who display the readiness to take risks with new or innovative ideas to generate new products or services". Other approaches view entrepreneurship as a set of behaviours (Vanderwerf and Brush, 1989; Carree and Thurik, 2003) or functions (Carlsson et al., 2013). Recent definitions feature three main themes: wealth creation (Drucker, 2015) innovation (Gutterman, 2012) and exploitation of opportunity (Shane and Venkataraman, 2000). However, it is also recognized that some entrepreneurs are motivated solely by necessity, especially in developing countries (Thurik et al., 2008; Benzing et al., 2009). A recent trend, moreover, is recognition that entrepreneurship depends on the nature of the national institutional framework and culture (Shane and Venkataraman, 2000; Rauch and Frese, 2000).

4. Institutions and entrepreneurship

Institutions are defined as the "rules of the game in a society", comprising "the humanly devised constraints that shape human interaction" (North, 1990: 3). They may be formal (e.g. constitutional, legal, and organizational frameworks) or informal (e.g. codes of conduct, values, and norms) (Welter and Smallbone, 2011; Hopp and Stephan, 2012). However, this paper is more concerned with the formal institutions, since, as Welter and Smallbone (2011) note, "In all countries, the development of entrepreneurship and the behaviour of entrepreneurs are influenced by the appropriateness and operation of formal institutions" (p. 109). As Hopp and Stephan (2012) point out, government support impacts the likelihood of entrepreneurial success; A supportive institutional environment and availability of resources positively affect entrepreneurs' motivation and self-efficacy and promote positive business outcomes. Acs et al. (2008: 219) noted that the environment, defined as the nexus of economic development and institutions, affects the "quality of governance, access to capital and other resources, and the perceptions of entrepreneurs." Hence, differences in the institutional environment explain why entrepreneurial activities' contributions vary so greatly worldwide. Following Scott (1995), institutions are commonly classified into three dimensions, **regulatory**, **cognitive** and **normative**, which constitute the national institutional profile (Kostova, 1997; Busenitz et al., 2000). The **regulatory** dimensions comprises government-instituted laws and systems, such as taxation (Estrin and Mickiewicz, 2010), property rights (Boettke and Coyne, 2003) and capital market development (Hoskisson et al., 2005) that shape opportunities (Welter and Smallbone, 2011). The **cognitive** dimension refers to shared knowledge, such as

information about how to establish a business (Busenitz et al., 2000). The **normative** dimension refers to societal beliefs and values (Veciana and Urbano, 2008) that determine the legitimacy and desirability of courses of action.

5. Methodology

This paper concerns the first stage of a two-stage mixed methods study. Quantitative data was acquired from an online survey based on Busenitz et al. (2000), sent to 447 early stage entrepreneurs who have used support programmes in Saudi Arabia, with a valid response rate of 27 per cent (*n = 117*). 25 per cent of respondents were female. The survey elicited information on types of support accessed by participants, and their motivations for starting a business. It also captured perceptions (measured on 5-point Likert scales from 1: strongly disagree to 5: strongly agree) on features of the three dimensions of the Saudi institutional profile.

Participants were also asked to rate the performance of their business (net profit, sales volume, cash flow and company value) since commencement, relative to expectation. Questions 1 and 2 were answered via descriptive statistics, Question 3 by Pearson product- moment correlation test and correlation coefficients.

6. Results

RQ1 – Types of support
Participants were asked to identify all types of support that they used. Table 1 shows the outcomes; as percentages of all responses.

Table 1: Types of support used by entrepreneurs

Support type	**%**
Finance	45.3
Training	20.5
Education	10.3
Consultation	47.9
Coaching	27.4
Mentoring	22.2
Networking	35.9

The data reveal that finance and consultation were the most use types of support, each being used by almost half the respondents. Networking was also relativity widespread, reported by over a third of respondents. The least used form of support was entrepreneurial education, raising questions as to the availability of such support, or why, if it is available, it is not taken up by entrepreneurs.

RQ 2 - Reasons for starting a business
Participants were asked to identify their main reason for setting up their current business. The responses are reported in Table 2.

Table 2: Most important reason to start-up

Most important reason to start-up	**Percent**
-To take advantage of support provided to entrepreneurs	13.7
-To take advantage of an opportunity	26.5
-No better choice (i.e. Out of necessity. E.g. Unemployment)	9.4
-Combination of the first two options above	20.5
-Employed, but seek additional sources of income	24.8
Others (please state)	5.1
Total	100.0

The responses show that very few respondents were necessity entrepreneurs, setting up a business because they had no alternative or better means of livelihood. The largest concentrations were those who founded a business to take advantage of an opportunity, or to supplement their income, each declared by about a quarter of respondents. Only 13.5 per cent set up a business specifically to take advantage of government support, although this was a contributing factor for a further 20 per cent, who reported a combined motivation. This means that overall, government support was a factor in the business foundation for a third of the entrepreneurs surveyed.

RQ 3 – Relationship between regulatory, cognitive and normative dimensions and early stage business performance

Table 3 shows perceptions of the three dimensions of support. Participants perceived the normative dimension of support favourably, but mean scores below 3.0 for items (4 to 7) and (11 and 12) indicate considerable disagreement with these items; there were high levels of uncertain responses for several of these items.

Table 3: Provision (country profile) of institutional support - Regulatory, cognitive and normative dimensions

Item number	Item	Mean
	The regulatory dimension	
1	Saudi Arabian government sponsors individuals starting their own business	**3.50**
2	In Saudi Arabia, there is sufficient financial support available for new start-ups	**3.32**
3	New and innovative businesses can get easy loans from financial institutions	**3.04**
4	There are sufficient subsidies available from entrepreneurship sponsors for new firms	**2.56**
5	State laws (rules and regulations) are favourable to starting and running a new business	**2.72**
6	The government provides legal protection to most newly-created businesses	**2.72**
7	All property rights are clear and protected by law	**2.82**
	The cognitive dimension	
9	Individuals know how to legally register and protect a new business	**3.43**
10	Those who intend to start a new business know how to manage risk	**3.36**
11	Most people know where to find information about markets for their products	**3.45**
12	University and college education provides adequate entrepreneurship education	**2.34**
13	Universities and other learning institutions provide advisory and development support for a new business	**2.54**
	The normative dimension	
15	Saudi society at large welcomes new venture creation	**3.72**
16	Innovative and creative thinking is viewed as the route to success	**4.21**
17	Entrepreneurs in Saudi Arabia are seen as successful role models	**3.92**

Table 4 shows the mean scores for participants' ratings of their business performance, as worse than, the same as, or better than expected.

Table 4: Business performance

Item number	**Business performance**						
	Item	**Strongly Disagree**	**Disagree**	**Neutral**	**Agree**	**Strongly Agree**	**Mean**
1	With regard to net profit (Sales minus operational cost) situation is	8	15	47	35	12	**3.24**
2	In regard to development of sales (change or growth in the volume of sales) situation is	2	21	50	36	8	**3.23**
3	In regard to Cash flow (inflows minus outflow of money) situation is	2	27	50	32	6	**3.11**
4	In regard to growth of the company's value (Net Asset) situation is	8	18	40	41	10	**3.23**

The correlations between the regulatory, cognitive and normative dimensions of the institutional profile of Saudi Arabia and the early-stage entrepreneurs' business performance show that both formal and informal institutional support are related positively to the business performance of start-ups. However, the regulatory (formal) dimension is somewhat more influential than the cognitive and normative (informal) dimensions (accounting for 11 per cent and 8 per cent respectively, of the variance in business performance ratings, see table 5).

Table 5: Correlations

Correlations test		Bus_Performance
Regulatory_Dim	Pearson Correlation	.329**
	Sig. (2-tailed)	.000
	N	117
Informal_Dim	Pearson Correlation	.280**
	Sig. (2-tailed)	.002
	N	117

**. Correlation is significant at the 0.01 level (2-tailed).

7. Discussion and Conclusion

Initial data has been reported from a survey conducted as part of an ongoing investigation of formal institutional support for entrepreneurship in Saudi Arabia. The percentage of female participation is promising in the context of Saudi Arabia, and may reflect the role of technology in facilitating the process of starting up and conducting business easier by affording women means of engaging in business despite the cultural constraints preventing direct interaction with men other than relatives.

The results indicate that participants tended to be opportunity rather than necessity driven. Availability of institutional support was a factor in around a third of start-ups. However, the low proportion of respondents using educational support, the high levels of uncertainty regarding many regulatory and education-related items, and the weak relationships between institutional dimensions and business performance raise potential issues for further investigation. Questions arise as to the adequacy of the kinds of support and protection available, and participants' awareness of and confidence in them. Such issues will be explored qualitatively in forthcoming interviews with support organisation officials and early-stage entrepreneurs.

This research contributes to fill a number of gaps in extant literature, particularly with regard to entrepreneurship in a non-Western, developing country context. The insights derived from the under-researched context of Saudi Arabia will help to enrich the entrepreneurship literature and add to understanding of how context-specific institutional factors may influence entrepreneurial success.

Financial Literacy Importance for Entrepreneurship: A Literature Survey

Atanásio Jaime Cossa, Mara Madaleno and Jorge Mota
Universidade de Aveiro, GOVCOPP, Portugal
atanasiojaime@ua.pt
maramadaleno@ua.pt
jorgemota@ua.pt

Abstract: In this paper we performed a systematically review of literature on the relationship between financial literacy and entrepreneurship as a way to identify research gaps, suggestions for research proposals, and to prepare empirical works to be implemented in the Mozambican context. For its elaboration we resorted to the bibliographical research of several scientific papers, surveys and empirical literature available. Our findings indicate that entrepreneurship plays a leading role in alleviating poverty, creating new employment opportunities, enabling individuals to make goods and services available, improving their well-being, and improving economic growth and development. Additionally, it was also documented that financial literacy enhances the decision-making process of individuals, allowing for appropriate choices on financial issues. Finally, it was found that financial literacy improves entrepreneurs' skills, making them confident in the decision-making process of savings and financial management of their enterprises. For future research, an empirical work in Mozambique is suggested to verify the relationship between financial literacy and entrepreneurship, considering gender, experience, academic level and training area, by entrepreneurs' activity sector in the three regions (North, Center and South) and a comparison of the results with the studies performed in the neighbouring countries. We finish presenting policy directions regarding how financial literacy may be promoted as a way to ensure entrepreneurship survival and maintenance in the market, to ensure economic growth, employment creation and regional development.

Keywords: Financial Literacy; Entrepreneurship; Decision Making; Savings.

1. Introduction

Entrepreneurship is often viewed as the process that allows individuals or groups to integrate resources and competencies to explore opportunities the environment offers, creating and adding value, with results that include new ventures, products, processes, markets, and technologies. Entrepreneurship responds to some current challenges, such as unemployment, and has been recognized as an important key to sustainable economic development (He, Lu & Qian, 2018). According to Li (2008), although there are several studies on entrepreneurship, it is important to map the course of the studies and develop a tool to guide more studies.

Financial Literacy is assumed to be the skills and knowledge that allow the analysis and understanding of the financial principles needed to make informed judgments and make better financial decisions (Atkinson & Messy, 2012; Taylor & Wagland, 2011). It enables people to weigh all the variables and information as possible, so as to profit from these decisions. In a dynamic and uncertain environment, financial literacy is of great importance, as it will enable individuals to better manage financial resources in order to improve their well-being and of their neighbours (Agnew et al., 2013; Arrondel, Debbich & Savignac, 2013).

Entrepreneurs, who often act intuitively, take a number of risks. Sometimes, due to overconfidence and optimism, they do not weigh all the information that comes to them concerning the business they embrace, and can therefore incur in several losses. Financial literacy performs an important role for entrepreneurs as it gives them the skills to make the judgments they need on the information available and make the most appropriate financial decisions. Entrepreneurship and financial literacy are two issues on the international agenda, since it was assumed that they allowed the efficient use of financial resources. Adequate financial education favours the intelligent selection of financial products, based on informed decisions (Betancourt, 2017; Atandi, Bwisa, & Sakwa, 2017).

Several studies on financial literacy and entrepreneurship have already been conducted in several countries [South Africa (Oseifuah, 2010); Nigeria (Wodi, 2012); Swaziland (Brixiová, Ncube, & Bicaba, 2015); Kenya (Atandi et al., 2017); Portugal (Couto, 2013); Romania (Ignat, 2012); Mexico (Betancourt, 2017); Chile (Maldonado et al., 2017); India (Gawali & Gadekar, 2017); China (He et al., 2018); Malaysia (Ayadurai, 2011)].

In this context, the present study seeks to systematically review the literature on financial literacy and entrepreneurship as a way of preparing an empirical work in the Mozambican context.

2. Methodology

According to Vilelas (2009), a bibliographic research is elaborated from already published material, namely, books, papers and other materials. The research in this paper consisted in the review of several papers that address issues related to entrepreneurship, financial literacy and development.

For the accomplishment of this research it was sought (Vilelas, 2009): to know and explore a set of useful bibliographical sources in the area of entrepreneurship, financial literacy and development, with the use of research in scientific journals; to read the papers considered important for the topic in research, with privileged focus in recent papers; collection of the ideas and findings of previous authors, extracting concrete aspects that embody the present research; comparison and intersection of existing information, establishing divergences and similarities, as well as the position of the author; and preparation of conclusions and proposals for future research ideas.

3. Entrepreneurship and development: opportunities

In the 1970s, the European and North American markets experienced moments of saturation, due to the increasing spread of Japanese models. This, combined with the oil crisis and stagflation, contributed to the reduction of jobs, which gave rise to entrepreneurship (Rosas & Sauaia, 2009). Therefore, entrepreneurship emerged as a way of responding to a problem, creating new forms and procedures different from the usual ones (thus crisis and unemployment drive entrepreneurship).

Entrepreneurship was accepted as the fourth factor of production (after land, labour, and capital). Entrepreneurship must be dynamic, resorting to new sales markets, new processes, new production resources, new products and new types of organization (Dogan, 2015). Entrepreneurship concepts vary depending on the approach and area. Some authors emphasize the economic, sociological, and psychological and management view. However, it must be accepted that entrepreneurship is a multidimensional concept (Bula, 2012).

Schumpeter (1934) states that an entrepreneur is an innovator who makes combinations that give rise to new products, markets, production methods, sources of supply or reorganization of the industry. The combinations made include the introduction of new goods or new production methods; opening up new markets or new sources of supply and new organizations. Therefore, the entrepreneur contributes to generate imbalances in the economy, by breaking with the practices assumed as common and normal, introducing new and original practices.

Gries e Naudé (2011) define entrepreneurship as a process in which individuals use the market opportunities for the creation and development of new businesses. In fact, the entrepreneur must seek to take advantage of the opportunities created by a given situation, resulting from the markets dynamics, to implement new practices with a differential in the value chain.

The Schumpeter concept (1934) differs from the others, by highlighting the issue of innovation. The activities to be considered as entrepreneurs need to modify the common way of producing goods and services and to do business by introducing new knowledge that can innovate and improve well-being. This is the perspective taken as the basis for the realization of this work, considering that the modification of traditional forms of production constitute the basis of entrepreneurship. In the Mozambican context, there is a generalized perception, which leads to the consideration of any commercial activity as an entrepreneur. But, based on the evidence element of innovation, it can be assumed that not all commercial activities qualify as entrepreneurs.

Economic growth results in more opportunities for entrepreneurship, which consequently result in great incentives for entrepreneurs to work on them. Entrepreneurship leads to growth, which ultimately results in greater entrepreneurship. For this reason, entrepreneurship is an important determinant of economic growth.

The start-ups of new firms - entrepreneurial activities - facilitate the externalities of knowledge, which enables greater economic growth (Prieger, Bampoky, Blanco & Liu, 2016). Thus, entrepreneurship has a negative correlation with poverty and a positive correlation with development and employment (Coulibaly, Erbao &

Mekongcho, 2018). The increase of entrepreneurship allows the reduction of poverty. This time, entrepreneurship allows (i) the creation of new jobs, which leads to the reduction of unemployment rates in the economy; (ii) increases Gross Domestic Product (GDP) and Gross National Product (GNP); (iii) it improves the social well-being and the standard of living of the people living in the communities; (iv) allows the availability of goods and services at an acceptable rate; and (v) can improve the level of economic growth and development of a country (Wodi, 2012). In the same perspective, Karadag (2016) affirms that entrepreneurship constitutes a vector of socio-economic development, due to its role in GDP growth (increase in employment rates).

In recent decades, entrepreneurship has become an increasingly important generator of economic development. The contribution of entrepreneurship to economic development is greater in developed countries than in developing countries (Lepojević, Đukić & Mladenović, 2016). Entrepreneurship is considered the engine for economic development (Bubou & Okrigwe, 2011). Thus, emerging and developed economies adopt business incubators to boost new business and technology creation and are responsible for the success of more than 80% of new ventures. Consequently, countries' benefit from various effects: knowledge transfer, job creation and wealth creation (Bubou & Okrigwe, 2011).

Based on the Schumpeterian perspective, Ferreira, Fayolle, Fernandes & Raposo (2017) state that development necessarily involves the introduction of new combinations in the economic life cycle: entrepreneurs launch innovative initiatives that can trigger cyclical discontinuities in the economy. The economic function of entrepreneurship has effects on innovation and the holding of the opportunity that can give rise to entrepreneurship and generate jobs. In the same perspective, Aparicio, Urbano & Audretsch (2016) affirm that it is possible to obtain economic growth by encouraging the increase of entrepreneurship. They affirm that institutions play an important role in explaining entrepreneurial activities. Opportunity-based entrepreneurship fosters economic development, so it is important for policymakers to pay close attention to these issues.

Thus, entrepreneurship can be assumed as a factor leading to economic development in Mozambique. The recognition of this role of entrepreneurship for development is the basis for the approval of Decree No. 09/2009, of December 15, establishing the District Development Fund (FDD). According to number 2 of the aforementioned decree, the FDD aims to boost entrepreneurship in meeting the basic needs of local communities by providing loans. Therefore, these are some evidences of the strategies carried out by the Government in order to boost entrepreneurship and, therefore, development. However, the results of the application of these funds are below the desired level.

4. Financial literacy and development: opportunities

Individuals are confronted with complex financial instruments, seeking to increase their financial security, but many are not properly prepared to make financial decisions. This aroused interest in the knowledge of financial literacy levels. Effectively, financial literacy significantly influences financial decision making. To this end, some countries (Portugal, the United Kingdom, New Zealand, the United States of America, Australia, among many others ...) have begun to stimulate knowledge of financial literacy, and in some of these countries this already constitutes a public policy norm (Huston, 2010; Rahmandoust et al., 2011). In this context, governments and non-governmental organizations promote financial education programs in schools as a means to instill financial behaviours that may persist into adulthood. Those who attend these programs, after nine months, exhibit different financial behaviors, for example improving levels of savings (Berry, Karlan & Pradhan, 2017).

Financial literacy is an input to model the need for financial education and explain the variations in financial gain. Therefore, properly defining and measuring financial literacy is essential to understanding the educational impacts and barriers to making a financial decision (Huston, 2010). Financial education is the process by which financial consumers improve their understanding of financial products and concepts through information, instruction and counselling in order to develop the skills to become more aware of financial risks and make choices to find out where to get help and to make other effective choices to improve their well-being (OECD, 2005). Financial literacy is the ability to make informed judgments and make effective decisions about the use and management of money (Taylor & Wagland, 2011). Financial literacy is the combination of financial awareness, knowledge, skills, attitudes and behaviour required to make a sound financial decision

and achieve financial well-being (Atkinson & Messy, 2012). Financial literacy generally refers to a set of skills that allow people to manage their money wisely, with some understanding of essential financial concepts, not simply the trade-off between risk and return. Financial Literacy is not just about markets and investments, but also about economics, budgeting, financial planning, banking basics, and most importantly about being "Financially Smart" (Bendre & Singh, 2017). Therefore, financial literacy must be seen as more than minimizing risk and maximizing returns. It should be seen as the understanding and practice of financial aspects, which make it easier for holders to make better financial decisions.

Training methods and resources for people with low financial literacy should be adequate and understandable (Rahmandoust et al., 2011). To be financially literate, individuals must demonstrate literacy and skills necessary to make financial choices (Huston, 2010). Financial literacy involves the ability to read and understand financial information, including gains, financial statements, and cash flows (Brown et al., 2006; Samkin et al., 2014). It is from this perception that entrepreneurs may be able to separate profit from revenues, for example, to prevent them from diverting all revenues from their investments and jeopardizing their continuity.

Financial literacy is considered an important complement to promoting financial inclusion, consumer protection and ultimately financial stability. The relationship between financial literacy and financial inclusion is critical to enable any individual to understand the needs and benefits of products and services offered by formal financial institutions. Financial literacy is low in adolescents and adults in general (Agnew et al., 2013).

Specifically, financial illiteracy is more noticeable in women, minorities, and people with low income and with low level of schooling. However, high levels of schooling do not guarantee financial literacy. People who demonstrate high financial literacy or high confidence in their math or personal finance skills have higher financial returns: they resort to low interest rates and plan their savings and reforms (Agnew et al., 2013).

Arrondel et al. (2013) conducted a study in which they found that some population subgroups have lower financial literacy: women, young and old, people with low levels of schooling and are likely to present more difficulties when facing fundamental financial concepts such as diversification, inflation and interest compounds. The level of financial literacy differs between rural and urban areas; old people with low educational level also perform poorly on issues related to financial literacy (Beckmann, 2013). Therefore, financial literacy is positively and significantly related to savings and investments. This leads to the realization that entrepreneurs with high levels of literacy can achieve higher returns on their investments.

Oseifuah (2010) states that the financial literacy literature demonstrates the following skills and knowledge: (i) mathematical knowledge and basic knowledge of numbers; (ii) financial understanding of the nature and forms of money, how it is used and the consequences of consumption decisions; (iii) financial skills such as understanding the main characteristics of banking services, attitudes to spend money and savings, understanding financial records, knowledge of the risks associated with financial products and the risk-return relationship; (iv) financial responsibility, which refers to the ability to make appropriate choices on financial matters.

According to Kabakova and Plaksenkov (2018), there are three configurations of factors that affect financial inclusion: high socio-demographic and political factors in the absence of economic development; high social, technological and economic factors in the absence of political development; and political and economic factors in the absence of social and technological development. This design seeks to relate financial inclusion to ecosystem factors. Focusing on the reality that one intends to study - Mozambique - it will be interesting to understand how these diverse factors affect the financial inclusion.

5. Entrepreneurship and financial literacy: cross causalities

Each entrepreneur or manager needs to have a good level of financial literacy (Eniola & Entebang, 2017). Financial awareness of individuals can be measured from financial planning, financial analysis and control, accounting, understanding of sources of finance, business terminology, finance and information skills, and the use of technology. However, entrepreneurs have a low level of financial awareness (Kumar & Naidu, 2017).

Reality dictates that each entrepreneur owns either a micro, small, or medium enterprise. However, not all have an acceptable level of financial literacy (Eniola & Entebang, 2017). Entrepreneurs' success is strongly associated with their financial literacy. Njoroge (2013) shows that business managed by entrepreneurs with high financial literacy tend to have more successes than others. Entrepreneurs should have basic financial knowledge so that they can manage their projects, resources and by using their skills they should take advantage of the environment opportunities. Understanding financial issues allows the individual greater control over the environment and events that may affect him either directly or indirectly, allowing them to make informed decisions about life's problems (Maldonado et al., 2017).

According to Eniola & Entebang (2017), it is proven that financial literacy can increase the company's performance. However, entrepreneurs' financial knowledge and awareness are not the only requirements for the good performance of their ventures. Bosma & Harding (2006) affirm that the lack of financial literacy, the insufficient acuity in the business, compromises the development of the entrepreneurial activities. Dahmen e Rodriguez (2014) conducted a study focused on entrepreneurs facing financial difficulties and rarely looking for financial information. All admitted that they had financial difficulties and avoided financial advice. This association attests to the strong relationship between financial literacy and business success. Moreover, Kimunduu & Erick (2016) conducted a study that revealed a strong and significant positive relationship between financial literacy and financial performance of entrepreneurs. They concluded that high levels of entrepreneurial financial literacy lead to greater financial performance. Therefore, they recommended the creation of a conscience in the entrepreneurs to value financial education.

Many Small and Medium Enterprises (SMEs) tend to go bankrupt or close their doors shortly after their creation. About 1/3 of SMEs close in their first two years and about half will in less than 4 years. Bankruptcy rates are higher when businesses have fewer workers. Financial issues have been at the root of these company closures (Rahmandoust et al., 2011). Nunoo & Andoh (2012), for Ghana, use a direct measure of financial knowledge to conduct an empirical investigation of the relationship between financial literacy and the use of financial services by SMEs. The results revealed a modest level of financial literacy in small and medium entrepreneurs, and that entrepreneurs with the highest levels of financial literacy used financial services.

Some of the entrepreneurs with low levels of financial literacy hire third parties to take care of the financial aspects of their companies, which increase their costs. But, people with high literacy levels understand fairly the financial aspects of their business. Thus, financial literacy enables them to have confidence that their business will continue to have financial successes and generate profits in the future (Samkin et al., 2014).

It is critical that individuals acquire financial literacy to make more informed decisions. A high level of financial literacy favours the development of entrepreneurs' activities. Financial literacy makes them efficient because it enables them to assess the information they need to make decisions that have ramifications or financial consequences (Brown et al., 2006).

For Nunoo & Andoh (2012) financial literacy is the basis for stimulating entrepreneurship. Entrepreneurs with high levels of financial literacy can save more and manage risks better. Since basic education provides the entrepreneur with basic numeracy skills, this has a positive influence on entrepreneurship where managers have high financial education. In the same vein, Gawali & Gadekar (2017) concluded that accounting and financial knowledge, financial information interpretation skills, entrepreneurs' attitudes and their involvement in financial aspects of the business are largely responsible for the success or failure of enterprises.

Cruz (2012) states that entrepreneurship encompasses the most diverse domains, of which the economic and financial environment can be highlighted, which will allow verifying the feasibility of the business opportunity. The preparation of the business plan involves the preparation of budgets, which undoubtedly require financial knowledge. Oseifuah (2010) points out that financial literacy contributes significantly to improve the skills of entrepreneurs. Atandi, Bwisa & Sakwa (2017) found that financial literacy makes entrepreneurs confident in the process of making savings decisions, which allows them to better financial management. Therefore, they propose that training around financial issues should be provided to entrepreneurs before engaging in financial contacts. Betancourt (2017) states that adequate financial education allows for an intelligent selection of financial products, based on informed decisions (see also OECD, 2017).

6. Conclusion

The present research sought to make a systematic review of the literature on financial literacy and entrepreneurship, as a way of preparing an empirical work in the Mozambican context. It was found that entrepreneurs are those who modify the common form of production of goods and services and do business introducing new knowledge that can innovate and improve well-being. However, in Mozambique there is an extension of this concept, being applied to any commercial activity as an entrepreneur. It is seen that entrepreneurship is an important vector for the development of countries, as it contributes to the creation of new jobs, an increase in the availability of goods and services, GDP and GNP, improves social welfare and standard of living of people, alleviates poverty, and improves the level of economic growth and development of a country. These foundations have boosted the Mozambican government to finance entrepreneurship through FDD since 2009.

It was found that financial literacy presupposes the ability to read, analyze, manage and discuss financial issues that allow economic well-being to the individual. It ensures the understanding and practice of financial aspects, which make it easier for individuals to make better financial decisions. Therefore, financial education should be considered as a long-term and repetitive process. Financial education is a means of empowering individuals with financial literacy.

Entrepreneurs should have basic financial knowledge so that they can manage their projects, resources and by using their skills they should take advantage of the opportunities of the environment. Financial literacy makes entrepreneurs confident in the process of making savings decisions, which allows them to perform better financial management.

Given these findings, it would be interesting to create public policies conducive to the massification of financial literacy in formal education and to entrepreneurs. These policies would ensure the development of skills that enable understanding of key financial concepts, namely, markets, investments, economics, budgeting, financial planning, banking basics, which will allow wise money management. By way of this it would be possible to contribute to the improvement of the well-being of individuals and the reduction of poverty.

It is suggested to carry out research that tries to attest to the tripartite relationship: entrepreneurship, financial literacy and innovation. From the literature review it was not possible to find research that relates, simultaneously and directly, these three variables. Equally, it would be interesting to measure the level of financial literacy of entrepreneurs in Mozambique and compare it with those of neighbouring countries and to map the main financial problems in order to allow a concrete plan of action (policies) to be developed that would minimize these problems. For this study it would be important to analyse the influence of gender, experience, academic level and training area, activity sector and regional differences (North, Center and South). It would also be interesting to understand how ecosystem factors affect financial inclusion.

Entrepreneurial Capability Versus Entrepreneurial Propensity: Why Take the Non-Actors Even More Seriously?

Francis Dams[1] and Jesse Segers[1, 2]

Abstract: Scholars have moved beyond the view that entrepreneurs are born as entrepreneurs (Gartner, 1988) and the antecedents of entrepreneurial propensity and capability have been broadly researched. Still policymakers are seeking measures (European-Commission, 2013) to develop more entrepreneurs with ambitious, high-growth potential, aiming beyond the mere creation of more entrepreneurs. If not enough suitable candidates respond to this call, then one can wonder why this is the case. It's interesting to note that a group of potential entrepreneurs is possibly being overlooked. As Ramoglou (2011) argued, individuals who possess entrepreneurial abilities might decide not to engage in entrepreneurial behavior even if opportunities and a favorable environment are present. The literature, however, does not provide quantitative data to assess whether passivity of the capable non-actor can be considered to be an exception or not. As a first step to address this issue, this article reviews previous research on the antecedents of entrepreneurial propensity and capability and outlines the number of factors that have similar effects on these both constructs in comparison to the number of factors that have opposite effects on entrepreneurial propensity and capability. We have found a disproportional number of factors that have opposite effects on both constructs. We conclude that an individual who has entrepreneurial capabilities should not be expected to automatically aspire to a career as a founder of a new organization. This is a paradoxical conclusion for some, as they see initiative-taking capacity as an important antecedent of entrepreneurial capability. Our conclusion suggests that this unexploited source of entrepreneurial capability is more sizeable than expected and therefore continued research on the factors that govern the entrepreneurial propensity of entrepreneurially capable individuals is recommended. We close by calling for research to expand existing models on entrepreneurial career transitions in order to explain this paradox.

Keywords: Entrepreneurial capability, Entrepreneurial propensity, Entrepreneurial career transitions.

1. Introduction

"Reigniting the entrepreneurial spirit in Europe" and "Our challenge – More entrepreneurs for Europe" are the title and subtitle of the European Commission's Entrepreneurship 2020 Action Plan (European-Commission, 2013). Striving for more entrepreneurs aligns with entrepreneurial propensity, a first dimension we define in this study as how close an individual is to becoming an active entrepreneur. Qualitatively this dimension ranges from being non-interested, to having different levels of favorable orientations, dispositions, attitudes and desires, and to intending and displaying the actual entrepreneurial behavior. Quantitatively this can be operationalized by the probability that one will become active as an entrepreneur in the coming 5 or 10 years (Kennedy, Drennan, Renfrow, & Watson, 2003).

Together with the call for more entrepreneurs consensus is growing that actions promoting entrepreneurial activity should aim beyond the mere creation of more entrepreneurs (Blanchflower, 2004; Burke, FitzRoy, & Nolan, 2000; Shane, 2009; van Praag & van Stel, 2013). Shane (2009) stresses the need for focusing on start-ups with high growth potential. He recommends that policy makers focus support at fewer but better start-ups, aiming for high entrepreneurial venture performance. However, venture performance is undefined before the venture is founded and certainly, before the entrepreneurial opportunity is identified. As the call for more entrepreneurs addresses individuals before they have started as an entrepreneur, we define entrepreneurial capability as the subset of entrepreneurial performance that is fully attributable to the individual even in the absence of any entrepreneurial opportunity, propensity or activity. Therefore, if one pursues more high performance entrepreneurship, it seems reasonable to call for the activation of non-entrepreneurs who are positioned high on the entrepreneurial capability dimension. Baum, Locke, and Smith (2001) report on the capabilities of ventures' CEOs as direct and indirect predictors of venture growth.

If not enough suitable candidates respond to this call to found a new business, then one can wonder why this is the case. The literature, however, does not provide quantitative data to assess whether passivity of the capable non-actor can be considered to be an exception or not. As a first step to address this issue, this article

reviews previous research on the antecedents of entrepreneurial propensity and capability and investigates which antecedents have similar effects on both constructs and which antecedents have opposite effects on both constructs.

2. Methodology

In order to determine the most researched antecedents related to entrepreneurial capability and propensity, we searched for literature review papers on entrepreneurship research in the Web of Science and the Business Source Premier databases (July 2015). We identified the 4 meta-analytic reviews that provide the longest lists with researched items related to entrepreneurial capability and propensity (Jain & Ali, 2013; Jain, 2011; Rauch & Frese, 2007; Unger, Rauch, Frese, & Rosenbusch, 2011). These four papers report on 41, 18, 51 and 42 items respectively. We used the longest list by Rauch and Frese (2007) with 51 personality antecedents as a starting point and then we added experience and education from the review of Unger et al. (2011). This meta-analytic review of human capital and entrepreneurial success shows that education and experience subjects are the most frequently researched items (20 out of 42 items). Finally, we cross-checked with the lists published by Jain and Ali (2013) and Jain (2011) and we added social networking, social intelligence, family background, venture teaming, ability to raise financial capital and utility. Utility covers the needs for money/wealth, social security, recognition and respect. We also combined 6 factors in other items as they are similar or antonyms (Table 1: items 3, 7, 8). We disregarded factors that are not attributable to the individual, like legislation, infrastructure and environmental dynamism. All this resulted in the 53 items in Table 1. In March 2018 we carried out a topic search in the Web of Science database with these 53 items as keywords, each in combination with the search term “entrepren*”. In the third column of Table 1 we recorded how many documents were returned by the Web of Science database. Figure 1 shows a scree plot of the number of documents obtained per item.

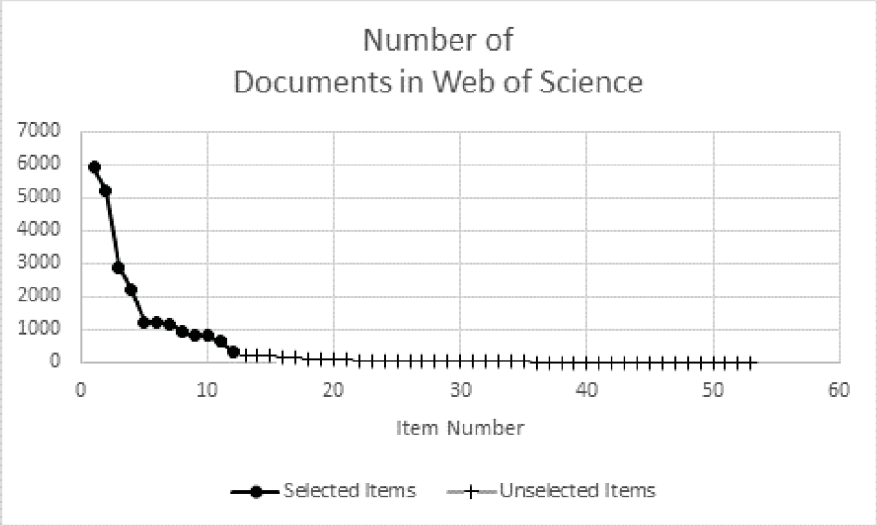

Figure 1: Scree plot of number of documents in Web of Science per antecedent.

As of item 13 the number of documents returned was less than 5% of the number of documents which were returned by the first item. Therefore we selected the first 12 items for further investigation in this study as they cover more than 92% of the returned documents.

26	Family background (3) (4)	44	53	Norm orientation (1)	0
27	Conscientiousness (1)	44			

Using these 12 antecedents, we reviewed previous research with specific attention for work that attributes opposite effects with respect to entrepreneurial propensity and entrepreneurial capability. When earlier research was identified as showing an opposite effect, we considered this factor as an antecedent with the potential to explain a paradoxical effect without making quantitative claims on the frequency or size of this effect.

3. Results

In the result section, we summarize the conclusions from our literature review and we infer for every antecedent whether we did or did not find potential for opposite effects.

3.1 Education

Plural literature review papers are available on the effects of education on entrepreneurial propensity and capability. Bae, Qian, Miao, and Fiet (2014) conclude that the research on entrepreneurship education in view of entrepreneurial intentions has yielded mixed results and after controlling for pre-education entrepreneurial intentions, the relationship between entrepreneurship education and post-education entrepreneurial intentions was not significant. Unger et al. (2011) present a meta-analytical review of human capital research in entrepreneurship. They found a small but significant relationship between human capital and success. They report that the relationship is stronger for the outcomes of human capital investments (knowledge / skill) than for the investments themselves (education / experience). Van Praag, Witteloostuijn, and Van der Sluis (2009, p. 2) express the results of their research on a US longitudinal sample with 66,000 person-year observations as follows:

> *"We show that education affects people's decisions to become an entrepreneur negatively. We show furthermore that entrepreneurs have higher returns to education than employees (in terms of the comparable performance measure 'income')".*

We deduce that education shows an opposite effect. Education can be a factor that works against entrepreneurial propensity, but it provides positive effects on entrepreneurial capability

3.2 Experience

According to the meta-analytic review of Unger et al. (2011), experience is an investment in human capital and shows a moderate but favorable effect (r = 0.07) on firm performance. Additionally, task related investments, like start/up, owner, industry specific and management experience, show a higher effect on firm performance (r= 0.11). This is in line with Chandler and Jansen (1992, p. 234), who conclude carefully: "Marginal evidence suggests that a business education and experience in general managerial positions may help to lay the groundwork for a successful entrepreneurial career". However, with respect to entrepreneurial propensity, Zouhar and Lukeš (2013, p. 12) report and explain an opposite effect of industry experience on the chances of starting an operational business: "People with higher industry experience may eventually start only businesses with a higher chance of success and disengage from efforts with low success probability". We conclude that experience can have an opposite effect on entrepreneurial propensity and capability.

3.3 Innovation, need for innovativeness

Frese and Gielnik (2014) show correlations between innovativeness and business creation effects and between innovativeness and business performance effects of respectively r = 0.24 and r = 0.27. Innovativeness is consistently described as an important entrepreneurial ability but also as a reason for starting a business (Jain, 2011). We conclude that innovativeness is an important antecedent for entrepreneurial capability as well as for entrepreneurial propensity. We have not found any research showing an opposite effect.

3.4 Dominance, need for power

Since McClelland (1975), the need for power (nPower), defined as the need to have control over others to influence their behavior, has consistently been seen as a motivator and as an antecedent for entrepreneurial intent (Oosterbeek, van Praag, & Ijsselstein, 2010; Ramsay, Pang, Ho, & Chan, 2017; Van Gelderen & Jansen, 2006). De Vries (1977) analyzes the entrepreneurial personality and covers the link between nPower and entrepreneurial performance. He concludes that optimal performance is to be expected when nPower is moderate (McClelland, 1975) as cited in (De Vries, 1977, p. 39): "High nPower … with ... lack of inhibition or self-control limits their effectiveness as large institution builders in spite of their success in inspiring people in the initial stage of growth of the organization". Van Gelderen and Jansen (2006) add that nPower as driver for autonomy is favorable for setting high growth objectives and performance, but also that nPower acts against delegation and empowerment of personnel. We conclude that high nPower has a favorable effect on entrepreneurial propensity but can have an opposite effect on entrepreneurial performance.

3.5 Entrepreneurial Teams

Ensley, Hmieleski, and Pearce (2006, p. 228) show empirical evidence that shared leadership outperforms vertical leadership of the lone founder CEO. This conclusion is based on the study of more than 200 startups in the USA:

> *"Within this context, the explanatory value of shared leadership goes above and beyond that of vertical leadership. This suggests that high profile cases of prodigal entrepreneurs, whose individual creativity and charisma have led them to fame and fortune, are more myth than reality. If nothing else, the leadership of the principal founder is only part of the story behind most successful startups. It takes the leadership of an array of talented individuals to develop and grow new ventures. This highlights the great importance in selecting and developing top management teams, rather than simply attracting a superstar CEO: It is time to move beyond the moribund myth of the heroic entrepreneur as the sole leader of the firm."*

Cooney (2005) in his editorial on entrepreneurial teams and Klotz, Hmieleski, Bradley, and Busenitz (2014) in their literature review, they agree that on average entrepreneurial teams outperform the lone entrepreneur. However, they also stress the complexity of forming the right team adequate for an entrepreneurial endeavor.

With respect to entrepreneurial propensity and the formation of a founding team Fadul Ramirez (2016, p. 2) concludes: "… that the Founding Team formation process is a highly complex, lengthy, dynamic, random and sequential one". This leaves us with the paradoxical conclusion that entrepreneurial teams perform better but start slower.

3.6 Creativity

In their book "Creativity and Entrepreneurial Performance" Mcmullan and Kenworthy (2016) conclude that creativity correlates positively with entrepreneurial intention, behavior and performance. They underline the robustness of their conclusions with more than 80 references to earlier research, which shows practical and statistical significance across different methods and measurements. Their creativity measures include innovativeness and openness to experience. We conclude that creativity is an important antecedent for entrepreneurial capability as well as for entrepreneurial propensity. We have not found any research showing an opposite effect.

3.7 Self-efficacy, self-confidence, over-confidence and optimism

In their meta-analytic findings Frese and Gielnik (2014) report the highest correlation r = 0.38 between self-efficacy and business creation. This aligns with a high level of convergence in the literature that self-efficacy and perceived behavioral control (Ajzen, 1991) are important antecedents explaining entrepreneurial intent (Boyd & Vozikis, 1994; Chen, Greene, & Crick, 1998; Rauch & Frese, 2007). Although self-efficacy is undoubtedly a strong predictor for entrepreneurial propensity, scholars address the issue that self-efficacy is not necessarily a guarantee of actual entrepreneurial capability. Bayon, Vaillant, and Lafuente (2015) measure perceived and actual entrepreneurial ability in a group of 26,388 respondents in Spain and they report a significant but low correlation of 0.12 between perceived and actual entrepreneurial ability. This illustrates the proposition made earlier by Chen et al. (1998, p. 298): "There may be many individuals who shun entrepreneurial activities not because they actually lack necessary skills but because they believe they do."

More specifically Koellinger, Minniti, and Schade (2007) researched self-confidence and over-confidence. They determine positive correlations $r > 0.50$ ($p<0.01$) between self-confidence and the percentage of established entrepreneurs. This confirms that self-efficacy is a strong predictor for entrepreneurial behavior across countries. However, Koellinger et al. (2007) find negative correlations $r < -0.25$ ($p<0.01$) between self-confidence and the ratio between established and nascent or new entrepreneurs. This ratio is used as a proxy for entrepreneurial performance and underlines that self-confidence can have opposite effects on entrepreneurial propensity and capability. In this respect we also highlight the research of Hmieleski and Baron (2009) on optimism and performance of the entrepreneur. Their study analyzes about 1,000 young firms in the USA and reports negative correlations between optimism of the entrepreneur and firm performance. We conclude that self-efficacy, optimism and self-confidence correlate positively with entrepreneurial propensity, but paradoxically, they are not a guarantee of entrepreneurial capability.

3.8 Flexibility, rigidity and discipline

Even if these key words return 554, 38 and 354 documents respectively from the Web of Science database (March 2018), the number of publications that relate to entrepreneurial propensity and capability is very limited. Various authors agree that the ability of the entrepreneur to adapt to changing conditions, has a positive effect on venture performance (Bingham, Furr, & Eisenhardt, 2014; Bird, 1988). However, we find arguments that this flexibility should go together with an optimal amount of structure, perseverance, rigidity and discipline and that the correlation between structure and performance has an inverse U-shape (Bradley & Cowdery, 2004; Crilly, 2018; Davis, Eisenhardt, & Bingham, 2009). In relation to opportunity selection, too much flexibility can lead to opportunistic entrepreneurial activity. This can be seen as a positive correlation with entrepreneurial propensity as high flexibility increases the chance that an individual will pursue an opportunity. Furthermore, Bingham et al. (2014) explain that more focus and rigidity at opportunity selection in combination with higher flexibility in the execution phase are expected to give the best results. They call this "The opportunity paradox".

3.9 Autonomy, independence

In their meta-analytic study Frese and Gielnik (2014) report a correlation of 0.31 between autonomy and business creation effects and according to Hessels, Van Gelderen, and Thurik (2008, p. 325) "Autonomy or independence is one of the most cited pull factors for starting a business." In their editorial Caliendo and Kritikos (2011) express that "A main driver of entrepreneurship is the need for autonomy". Over the years this

has consistently been supported by multiple authors (Blanchflower, 2004; Sexton & Bowman, 1986). However, there are less favorable conclusions about the link between the need for autonomy and entrepreneurial capability. Mcmullan and Kenworthy (2016, p. 120) explain how the need for independence can hinder the collaborative ability of an entrepreneur:

> *"Collaborative ability. Shane (2003 , p. 99) indirectly suggests that entrepreneurs tend to be disagreeable, difficult people: 'The evidence supports the proposition that people who are friendly, socially conforming, compliant, flexible, trusting, cooperative, forgiving, tolerant, softhearted and courteous are likely to be less entrepreneurial.' He (2003 , pp. 106–107) also indicates that a, '…desire for independence tends to be associated with the likelihood of self-employment.' Interestingly, '…people who have a greater desire for independence actually perform worse at entrepreneurial activities' (Shane 2003, p. 108). It would appear then, that successful entrepreneurs are rather prickly people who happen to know how to act interdependently. It appears that a strong spirit of independence is needed to launch a promising venture, but it may be potentially toxic once the venture is launched. These countervailing tendencies of the independent entrepreneurial personality might be labeled the independence paradox."*

Van Gelderen and Jansen (2006) also address paradoxical effects related to the autonomy motive depending on the underlying sources for the need for autonomy: resistance to bosses and rules; the need to set self-congruent goals; or the need for power and control. These underlying motives can be incongruent with firm growth. We conclude that the need for independence and autonomy is an antecedent that can have opposite effects on entrepreneurial propensity and capability.

3.10 Risk propensity

Risk tolerance is broadly reported as an antecedent for entrepreneurial propensity (Beugelsdijk & Noorderhaven, 2004; Hao, Seibert, & Lumpkin, 2009). The link between risk-taking propensity and entrepreneurial capability and performance is much less clear. Hao et al. (2009) measure an insignificant effect of risk-taking on entrepreneurial performance. They even expect based their study of the literature (p.389) a negative effect on firm performance:

> *"In our view, an 'appetite' for risk propels one to undertake an entrepreneurial venture, but this same proclivity to take risks may be detrimental after the launch of the new venture. This is because, after the initial stage of new venture founding, entrepreneurs are typically required to manage risk very carefully to maximize profitability and preserve the new venture's limited resources. A strong propensity for risk may lead the entrepreneur to gamble firm resources on new and untested products, technologies, markets, or strategies when persistent exploitation of a known competitive advantage would be more effective. Thus, although we expect risk propensity to be positively related to entrepreneurial intentions, we expect it to be negatively related to firm performance."*

Begley and Boyd (1988) also find an insignificant correlation between risk propensity and entrepreneurial performance, however, their data prove a curvilinear effect, showing that maximum return on assets is associated with moderate risk-taking. Delmar (1996, p. 105 110) reports that successful entrepreneurs are capable of managing risk and seem to exercise a certain degree of caution and he concludes that success of a business is attributable to a combination of risk adversity and high motivation to expand the business, which is never without risk. We conclude that risk-propensity is a proven antecedent of entrepreneurial propensity.

However, the effect on entrepreneurial capability can be negative or has at least an inverse U-shape.

3.11 Need for achievement

Since McClelland (1961) discovered that entrepreneurs score high on need for achievement (nAch), scholars have confirmed that nAch is an antecedent of entrepreneurial propensity (Begley & Boyd, 1988; Beugelsdijk & Noorderhaven, 2004; De Vries, 1977). With respect to entrepreneurial capability and entrepreneurial performance scholars also report a positive correlation with nAch (Collins, Hanges, & Locke, 2004; Johnson, 1990; Lee & Tsang, 2001) as cited in (Jain, 2011). We conclude that nAch correlates positively with both entrepreneurial propensity and capability, although the cited literature claims there is a stronger effect on entrepreneurial capability and performance (Collins et al., 2004).

3.12 Utility, need for money/wealth, social security, recognition and respect

Scholars have argued that entrepreneurial choice includes a utility maximizing decision process (Campbell, 1992; Kautonen, van Gelderen, & Tornikoski, 2013; Monsen, Patzelt, & Saxton, 2010; Poschke, 2013). However Van Praag and Versloot (2007, p. 985) find that non-tangible utilities must play a role in order to explain the preference for self-employment as the mean income is not higher than the mean income of employees.

Hartog, Van Praag, and Van Der Sluis (2010) elaborate on this point further and conclude that:

> *"The same individual has a 30% higher return to general ability when active as an entrepreneur than when working as an employee. Nevertheless, the results suggest that the expected earnings levels in entrepreneurship relative to wage employment are higher only for the upper echelon of the general ability distribution. This is due to the fact that, for the average individual, the expected earnings levels in spells of entrepreneurship are lower than in wage employment."*

This shows that the instances of higher entrepreneurial income go together with higher entrepreneurial capability and that the less capable individuals opt for an entrepreneurial career for reasons other than financial reasons. In conclusion this provides another indication that entrepreneurial propensity does not necessarily go together with high entrepreneurial capability and performance.

4. Conclusion

We reviewed the 12 most studied factors related to entrepreneurial propensity and entrepreneurial capability. For three of these factors: need for achievement; innovativeness; and creativity, we did not find references to opposite effects on entrepreneurial propensity and entrepreneurial capability. For the other nine factors, we found research indicating opposite effects on entrepreneurial propensity and capability. This study of the literature does not provide a quantitative proof of significantly negative correlation coefficients. However, if factors like the need for independence, 'self-efficacy, optimism and overconfidence', risk propensity, the need for power, education, experience, teamwork, financial utility, and flexibility all can have opposite influences on entrepreneurial propensity and capability, then it seems reasonable to conclude that entrepreneurial propensity and entrepreneurial capability do not go together automatically. On the contrary, we should expect the opposite: individuals who engage into entrepreneurial activity might possess antecedents that work against optimal entrepreneurial capabilities, whereas individuals who score high on the entrepreneurial capability dimension probably possess antecedents that counteract their intention to choose for active entrepreneurship. Therefore we presume that the passivity of the capable non-actor is not an exception, and that this passivity, which Ramoglou (2011) says should be respected, is not just a choice, it is upheld by the mechanisms that govern entrepreneurial propensity and capability.

5. Discussion and further research

This opposite relationship between entrepreneurial propensity and capability justifies the existence of a considerable group of individuals who miss either capabilities or propensity factors. The less capable active entrepreneurs have been sufficiently caricatured in literature.

> *"Sometimes the same creative energy that drives an entrepreneur has its source in destructive internal needs that can ruin a career or a company. … Many entrepreneurs are misfits who need to create their own environment." (Kets de Vries, 1985).*

However, the group of capable non-actors, should get more attention in further research. Our conclusions support the view that this group are more sizeable than expected and their entrepreneurial capabilities are by definition antecedents of ventures with ambitious high growth potential, which are the kind of entrepreneurial ventures policy makers seek to promote.

Therefore, we call for research into what governs entrepreneurial propensity among individuals who possess strong entrepreneurial capabilities and we call for research on how theory can be extended in order to explain and understand why the same antecedents often have an opposite effect on propensity and capability.

Digital B2B-Platforms and How to Find the Right One

Marvin Drewel and Jürgen Gausemeier
Heinz Nixdorf Institute, Paderborn, Germany
marvin.drewel@hni.upb.de
juergen.gausemeier@hni.upb.de

Abstract: Digital platforms have been reshaping the structure of whole industries. While previous developments mainly have taken place within the B2C- or C2C-market, the B2B-market is at the edge of the so-called platform economy. Leading companies are stepping out of their core business and develop their own platforms. Additionally, agile start-ups begin to build platform solutions and services for digital platforms. For most of the SMEs in the machine building industry the development of digital platforms is not a suitable option as it exceeds their know-how and resources by far. These companies tend to participate in existing platforms instead of developing their own platform. The paper at hand presents a methodology that enables companies 1) to analyse which of their products and services are suitable for digital platforms 2) to find fitting digital platforms 3) to evaluate these platforms and 4) to develop an actual platform business model. The findings presented in the paper are the result of various projects with companies of the machine building industry and of over 40 interviews with management personalities within this segment. The results show that the intensity of the transaction and the individualization of products and services determine their suitability for digital platforms. We recognised distinct characteristics that can be used to evaluate platforms and we developed a role model which is the key to design a platform business model. The characteristics can be used within an identified softwaretool to search for suitable platforms. The findings will be of use for leading personalities within the machine building industry. Companies within this industry are put in a position to develop strategies for an advantageous positioning in the future platform economy. Furthermore the findings add a new approach to the well-established methodology toolbox of strategic planning.

Keywords: Digital Platforms; Platform Business Models; Machine Building Industry; B2B-Markets; Platform Economy; B2B-Platforms

1. Digital Platforms and B2B-Markets

The concept of digital platforms or IT-platforms has been the subject of a veritable hype in recent years (Engels et al., 2017). Nowadays, the majority of the biggest companies in the world are platform enterprises or so-called matchmakers (Evans and Schmalensee, 2016). Former well-established enterprises are now dominated by platform enterprises. This change took place in various industries, e.g. the hotel industry. While the previous developments mainly have taken place within the Business-to-Consumer (B2C) or Consumer-to Consumer-market (C2C), the Business-to-Business-market (B2B) is at the edge of the so-called platform economy. Leading companies are stepping out of their core business and develop their own platforms.

Additionally, agile start-ups begin to build platform solutions and services for digital platforms (Libert et al., 2016). Well-known examples are 365FarmNet and ADAMOS. Figure one shows some examples for the historical development of digital platforms in B2C/C2C and B2B-markets.

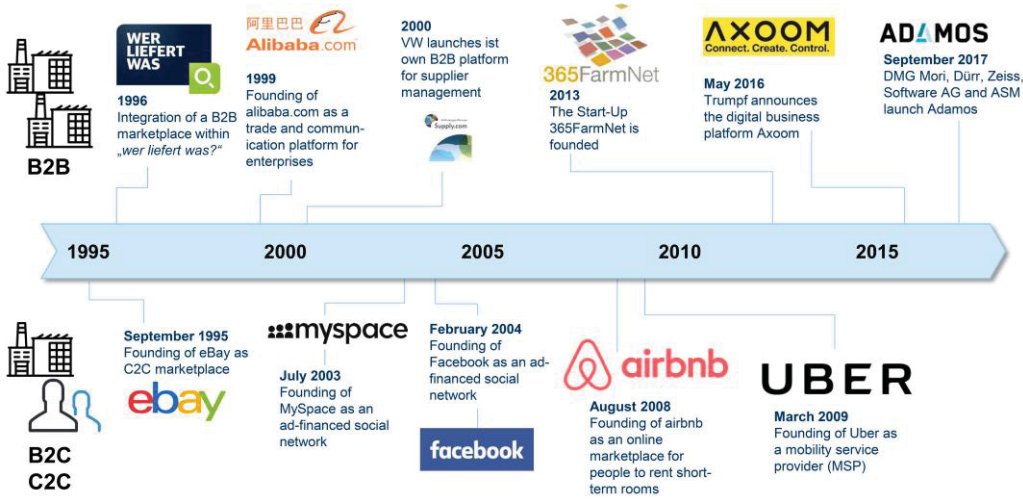

Figure 1: Historical development of digital platforms in B2C/C2C and B2B-markets

The key for the success of digital platforms is the so-called network effect (Alstyne et al., 2016). The network effect describes how the customer value of a product changes when the number of customers of the same product or complementary products changes. A distinction is made between a direct and an indirect network effect. The direct network effect was described in 1986 by Katz and Shapiro and states that a products value changes with the total number of consumers of that product (Katz and Shapiro, 1986). Often referred examples for this effect are telephones and fax machines. Within the context of digital platforms the direct network effect occurs, e.g. on social media platforms such as Facebook. The indirect network effect occurs when the value of a product changes as soon as the number of consumers of another product changes without a direct relationship between these products (Shapiro and Varian, 1998). The indirect network effect is characteristic for two- or multisided markets. Thereby, an increased number of participants on the one side of the market tends to increase the number of participants on the other side of the market. This effect is the driving force behind digital platforms. Positive network effects are the foundation for digital platforms. Thus, the more users a platform has the more attractive it becomes for other users. This is the reason why for each market only a very limited number of platforms can economically exist (Eisenmann et al., 2006).

But what exactly is a digital platform? We define digital platforms as a two- or multi-sided market in which the various players are brought together by an intermediary. Figure two represents the assembly of roles within a digital platform. If the number of producers increases, the platform becomes more attractive for consumers and vice versa. This is referred to as self-reinforcing “chain reactions” which – once initiated – lead to the rapid growth of a digital platform (Eisenmann et al., 2006).

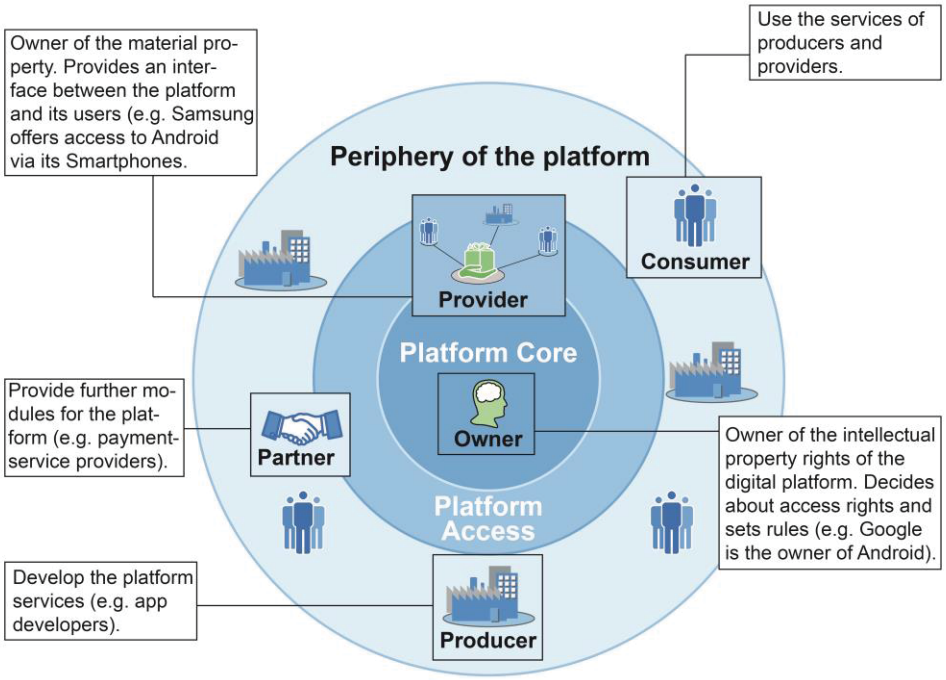

Figure 2: Arrangement of roles within a digital platform (according to Drewel et al., 2017)

The challenges to design such a network effects-based platform are often underestimated by the management (Choudary, 2015). For most of the small and medium enterprises (SMEs) within the machine building industry the development of digital platforms is therefore not a suitable option as it exceeds their know-how and resources by far. These companies tend to participate in existing platforms instead of developing their own platform (Engels et al., 2017). Moreover the majority of new platforms will fail (Morvan et al., 2016) which is not a suitable option for most SMEs. This raises various questions that are discussed within this paper:

1. Which products or services are suitable for digital platforms?
2. Which platforms exist and how can companies find them?
3. How can platforms be evaluated in terms of suitability for access?
4. How can companies develop a business model for digital platforms? In the following chapter a methodology for a strategic entry into digital platforms is presented which helps to answer the four questions above.

2. Methodology for a strategic entry into digital platforms

The paper at hand presents a methodology that consists of four phases, as presented in figure three. In the following, the methodology is going to be presented in detail. The methodology has been validated in projects with a medium-sized German machine-building company (called M.B.C. in the following). However, a project with the German National Academy of Science and Engineering is the foundation for the methodology. Within this project we conducted over 40 interviews with management personalities within the machine building industry. We identified distinct characteristics that can be used to evaluate platforms and we developed a role model which is the key to design a platform business model (Engels et al., 2017). The findings presented in the following chapters will be of use for leading personalities within the machine building industry and enables them to participate in digital platforms. Furthermore the findings add a new approach to the well-established methodology toolbox of strategic planning.

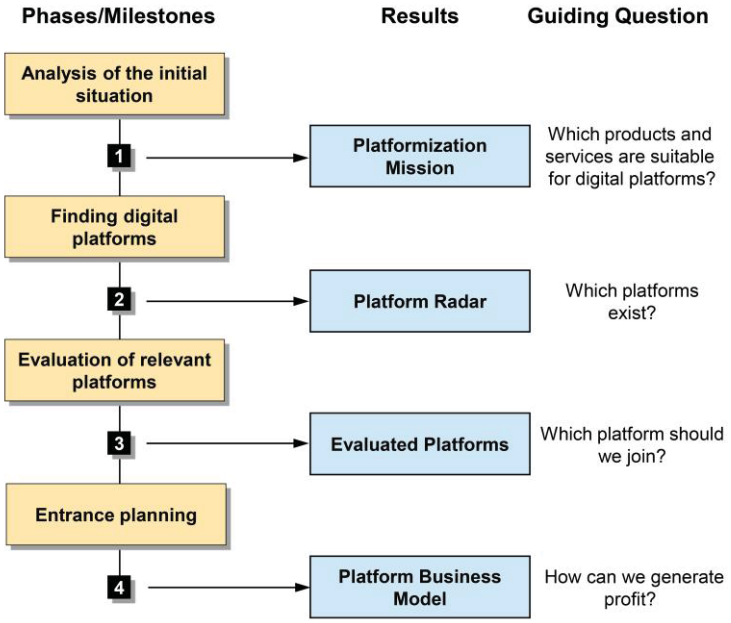

Figure 3: Methodology for a strategic entry into digital platforms

2.1 Analysis of the initial situation

The first step for a strategic entry into digital platforms is an analysis of the initial situation of an enterprise.

Therefore the company's product portfolio needs to be analysed in terms of applicability for a digital platform business model. Our survey revealed that one of the main barriers to enter digital platforms is that companies don't know how to transform their current existing business model into a platform business model. Moreover thinking barriers prevent companies from transforming their business model (Engels et al. 2017). We found that the *Business Model Transformation Board* by Linz et al. can be applied to analyse a company's current dominating business model type. Following Linz et al. the inclusiveness of the transaction and the customization of the offering can be used to differentiate business models. Four business model types can be differentiated: 1) Products, 2) Projects, 3) Solutions and 4) Platforms. If a company wants to transform the business model of one of its offerings it can chose between four different transformation paths (Linz et al., 2017):

1. **Enhancement:** Instead of offering not just a single product, but a comprehensive and integrated offering, companies can enhance their inclusiveness, e.g. by creating a stream of continuous revenue.
2. **Focusing:** To transform a business model from platforms and solutions to products and projects, companies can focus on single products or projects, e.g. by creating unique selling points within single products and solely focus on these products.
3. **Personalization:** Companies can use the personalization-path to tap into new market segments which they cannot serve with their existing mass-produced goods, e.g. by developing the ability to flexibly handle and implement customer requirements.

4. **Standardization:** The transformation towards a standardized business model can make sense once a standard has formed in the market and price competition prevails. This requires some new abilities, e.g. a scalable production.

Figure four shows the results of a project with the above mentioned SME in the machine building industry. We used the *Business Model Transformation Board* to rate the suitability of the current business models within the SME.

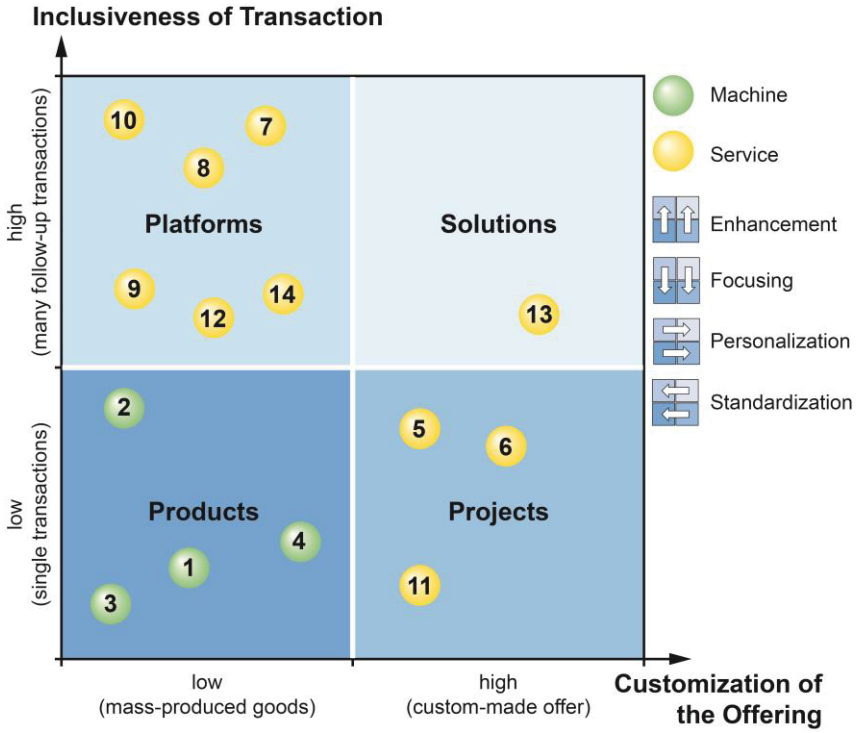

Figure 4: Business Model Transformation Board (according to Linz et al., 2017)

We elaborated that six of the services of M.B.C. are already suitable for a platform business model. Moreover, one machine of the company can be transformed from a product- to a platform business model by slightly enhancing the inclusiveness of transaction. Therefore the company needs to offer not just a single product, but a comprehensive and integrated one. The platformization misson in figure 5 shows the resulting demand for action.

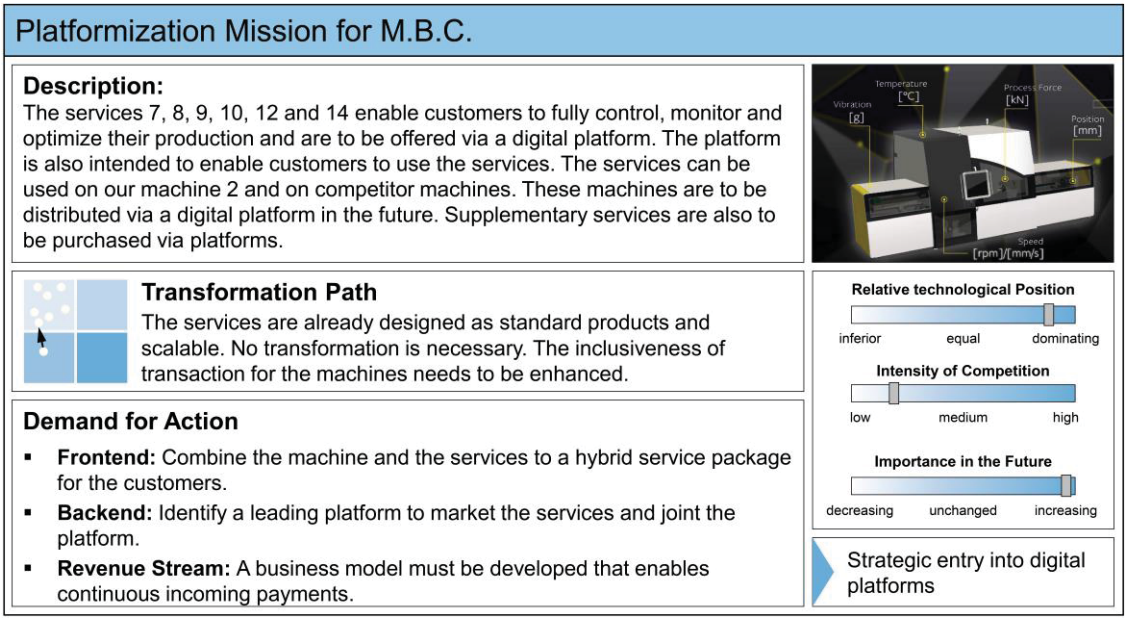

Figure 5: Example for a platformization mission for M.B.C.

The analysis of the initial situation shows that a strategic entry into digital platforms is the most favoured option for M.B.C. Therefore the company needs to adjust the frontend and backend as well as the revenue stream of its machine and services. The following chapter answers the question which suitable platforms exist.

2.2 Finding digital Platforms

A search request needs to be defined to find suitable platforms. Referring to Markides the search request should answer the following three questions which are the structuring elements for this chapter (Markides, 1999):

1. Who is looking for a digital platform?
2. What is the ideal solution?
3. Where can the ideal solution be found?

The **first question** can easily be answered for the presented example. The project team of M.B.C. is looking for a digital platform. In general the competencies of these teams need to fit the task at hand. A detailed description of how a project team is put together is not given here; this can be read at Echterhoff 2014, for example. In our case employees from hardware- and software-development, sales, marketing and in particular the management were involved.

Second question: To focus the search on a digital platform that fits the needs of a searching company it is necessary to know what a company is looking for (Ries, 2011). Therefore digital platforms need to be differentiated by distinct characteristics. While conducting over 40 interviews with management personalities within the machine building industry we found nine features that can be used to differentiate digital platforms, e.g. *Openness*, *Coverage* or *Competition*. Each feature has between two and four characteristics. The *Openness* of a digital platform is determined by the existing balance of power within the platform. *Coverage* addresses the markets that are covered by the platform, e.g. *National*, *European* or *International*. The interviewees revealed, that the presence of a company's *competitors* is a crucial feature for the suitability of a digital platform. While some interviewees stated that they would only enter a platform where their competitors are not involved, others declared that they especially would enter platforms where competitors are participating (Engels et al., 2017). Table one shows an excerpt of the features and characteristics we found. The highlighted characteristics are favoured by M.B.C.

Table 1: Favoured characteristics of digital platforms for M.B.C. (excerpt)

Feature	Characteristic			
Openness	Open	Half-Open	Closed	
Coverage	National	European	International	
Hosting	German-Hosting	European-Hosting	International-Hosting	Own-Hosting
Expandability	None	Low	Medium	High
Type of Platform	Transaction	Innovation	Integrated	Meta
Competition	Should be available	Can be available	Must not exist	

Third Question: The features and characteristics can be applied to search for suitable platforms. The search can be conducted in various ways (desk research, personal contacts, IT-tools). We decided to use the IT-tool KNIME (**K**o**N**stand **I**nformation **M**in**E**r). KNIME is used for data and text mining and is developed by KNIME.com and the Chair for Bioinformatics and Information Mining at the University of Konstanz (KNIME, 2018). Certain terms and their synonyms need to be considered to find suitable solutions, e.g. "digital platform", "IoT-Platform", "Connected Devices", "Smart Services" and so on. The search revealed more than 100 platforms which we than characterized by the features and characteristics presented in table 1. We used some of the features as KO criterions to eliminate inadequate solutions. M.B.C. would for example only choose a platform that is hosted in Germy. This lead to 33 remaining digital platforms which are considerd for an strategic entry.

These remaining platforms are classified in a multidimensional scaling (MDS) by using the features and characteristics mentioned above. The MDS makes it possible to classify platforms into a two-dimensional overview. The favoured characteristics of M.B.C. represent the ideal solution – the so called target platform which doesn't exist in most cases.The distances between the remaining 33 platforms are determined so that similar platforms are close to each other. The goal is to see which remaining platforms are close to the ideal solution. These are the so called relevant platforms (see figure six).

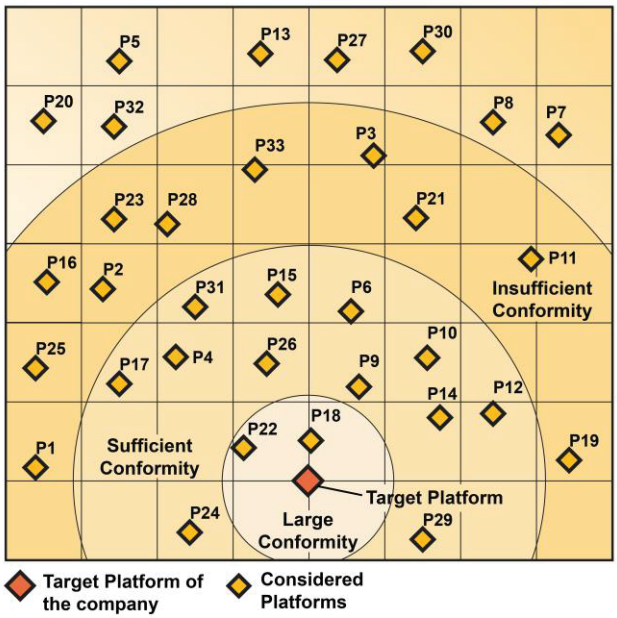

Figure 6: Multidimensional scaling of the remaining digital platforms for M.B.C.

The multidimensional scaling shows that 14 platforms have a large or at least a sufficient conformity to the ideal solution. These relevant platforms are evaluated in the following phase.

2.3 Evaluation of relevant platforms

Once, the relevant platforms are found they need to be evaluated. Therefore the **reachability**, **attractiveness** and the **strategic fit** of the remaining platforms are calculated. This answers the question: *"Which platform should we join?"* Figure 7 shows the result of the evaluation of relevant platforms for the exemplary project.

Reachability: The reachability determines how easily a company can enter a certain digital platform. We found various barriers that prevent companies from entering digital platforms. We use these barriers to evaluate the reachability of platforms. The most significant barrier is the *lack of know-how for platform business models*.

Furthermore, *general uncertainties* and the resulting *fears* are regarded as strong barriers. This was often associated with *thinking barriers* in the workforce and a *restrained approach to acceptable risks*. However, a lack of *willingness to invest* is seen by few experts as an obstacle. *Technological hurdles* are also considered to be of secondary importance. A comprehensive collection of barriers is presented by Engels et al., 2017. First the general importance of the barriers is evaluated, then the expected impact of each barrier for each platform is rated. For example, the lack of know-how for platform business models has a lower impact for a platform that provides a distinct business model for its participants than for a platform that leaves it to its participants to develop their own platform business model. Within our projects we provide a distinct set of barriers to evaluate the reachability. However, for certain cases it can be necessary to evaluate further criterions, e.g. direct costs of using a platform or the organisational expenditures to implement the platform.

Attractiveness: The attractiveness describes the potential market growth for the entering company triggered by the platform. It is crucial to rate the attractiveness by using distinct criterions because for most companies the estimation of how attractive a platform is, is simply not possible (Engels et al., 2017). We use the *market penetration*, *revenue* and *number of participants* of the potential platform as well as the resulting *competitive differentiation* caused by the platform to evaluate the attractiveness.

Strategic fit: We define the strategic fit of a platform as the conformity of entering a certain platform to the corporate strategy. Following Gausemeier and Plass the elements of a corporate strategy are: *corporate mission statement, core competencies, strategic business segments, strategic programs and the corporate culture* (Gausemeier and Plass, 2014). The conformity of entering a certain platform to each element of the corporate strategy is rated to evaluate the strategic fit of the platform.

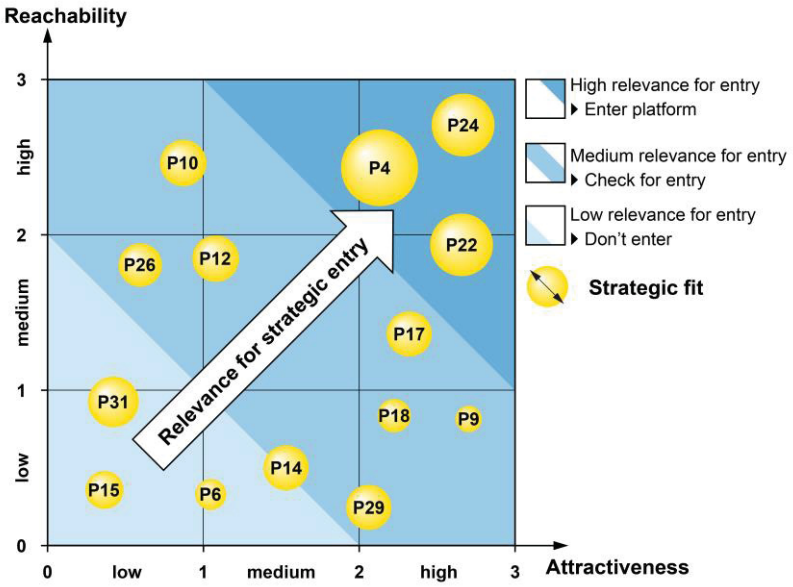

Figure 7: Evaluation of relevant platforms

The evaluation reveals that three platforms have a high relevance for entry. At this point the question whether a company wants to join one platform or more than one platform needs to be answered. M.B.C. decided to join platform 4 and wants to keep platform 22 and 24 in mind for future decisions.

2.4 Entrance planning

Following the evaluation of relevant platforms the actual entrance needs to be planned. Within platforms cooperation is more important than competition (Parker et al., 2016). Therefore, the relations between the various players in the target platform need to be pointed out. Figure 8 represents the arrangement of exemplary players within platform 4.

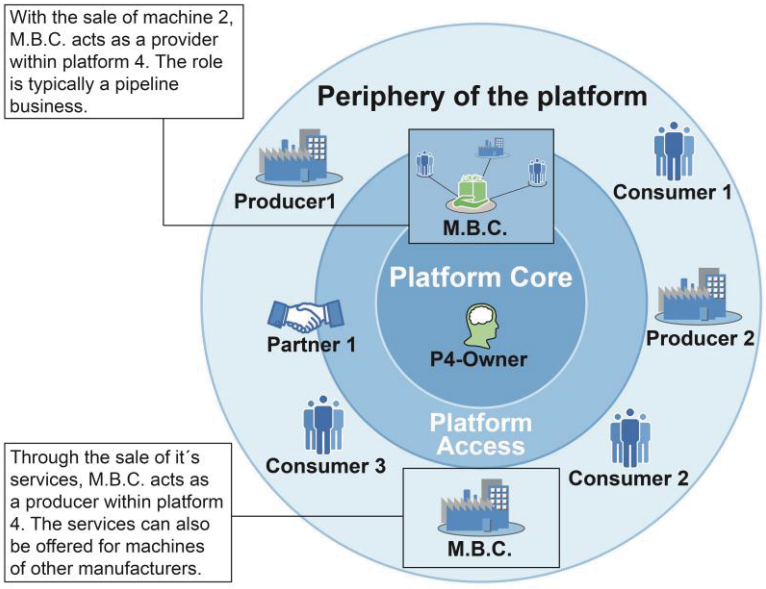

Figure 8: Arrangement of exemplary players within platform 4 for M.B.C.

M.B.C. has the opportunity to continue its historical pipeline business by selling machine 2 as a provider for the platform. Moreover, M.B.C. acts as a provider for the platform by selling services 7, 8, 9, 10, 12 and 14. The services can also be offered for machines of other providers. This enables M.B.C. to implement a complementary platform business model besides it´s currently existing pipeline business model.

As Choudary states a robust business architecture is necessary for a scalable and sustainable platform business model (Choudary, 2015). We therefore propose that once the business architecture is designed (see figure 8) the platform business model needs to be defined. The well established and widely used business model canvas, as provided by Osterwalder and Pigneur (Osterwalder and Pigneur, 2010), is the right tool for representing a pipeline business model, but quickly reaches its limits when visualizing platform business models (Libert et al., 2016). In a pipeline business model, goods are processed along the value chain and sold to one or more customers. However, a digital platform acts as an intermediary between several producers and consumers, as is the case in the example. If these relationships are to be represented in a business model canvas, it often becomes confusing or very superficial. To avoid this, the visualization of M.B.C.s business model is based on Drewel et al. (Drewel et al., 2017). The platform business model, as shown in Figure 9, contains four shells. These are divided into four areas according to the four roles on a digital platform without it´s partners. The outermost level contains the respective players within the roles. The platform's promise of benefit to the players is shown on the third shell. It shows that all players benefit from the platform and is essential for the willingness to join the platform. The recurring exchange of values between the platform and the players can be found on the second shell. This distinguishes between values that flow from the platform to the players and values that flow from the players to the platform. The inner shell contains the core components of the platform.

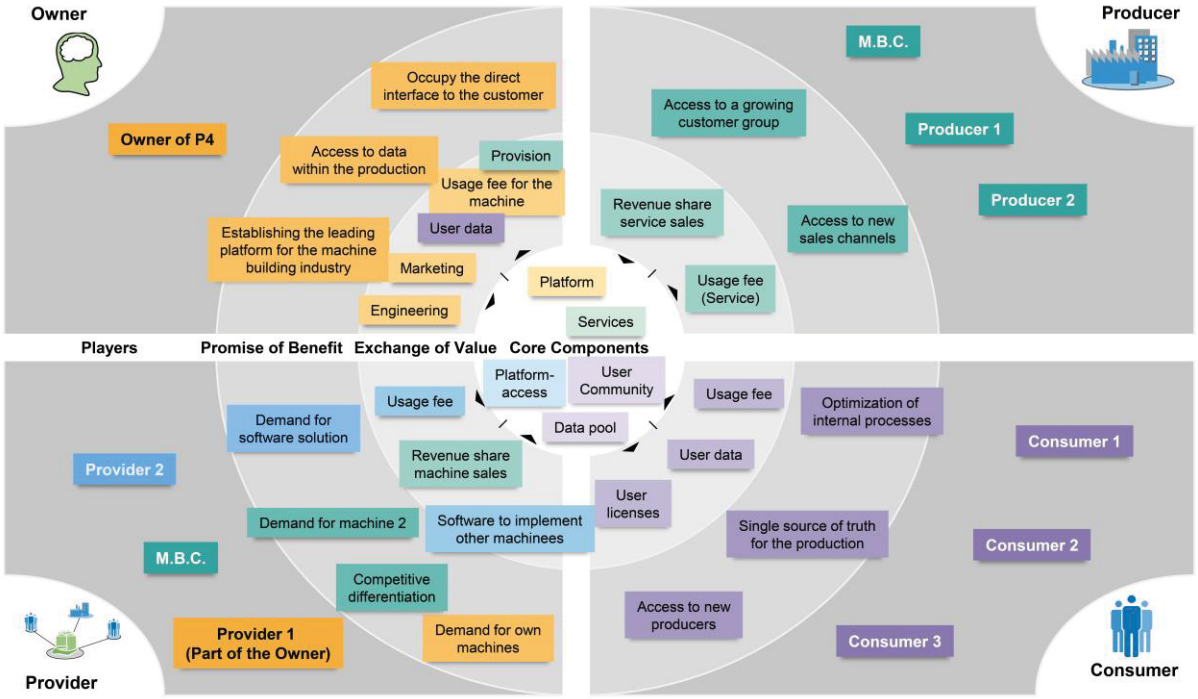

Figure 9: Business model of M.B.C. for platform 4

3. Discussion and Conclusion

The findings represent the results of various projects with companies of the machine building industry and of over 40 interviews with management personalities within this segment. The results show that the intensity of the transaction and the individualization of products and services determine their suitability for digital platforms. We identified distinct characteristics that can be used to evaluate platforms and we developed a role model which is the key to design a platform business model.

The findings will be of use for leading personalities within the machine building industry and enable them to participate in digital platforms. Furthermore the findings add a new approach to the well-established toolbox of strategic planning. However, additional research is necessary to identify approaches to actually build platforms instead of joining existing platforms.

Mindfulness Embedded in Entrepreneurial Wisdom

Zohreh Hassannezhad and Dave Valliere
Ryerson University, Toronto, Canada
zhassannezhad@ryerson.ca
valliere@ryerson.ca

Abstract: They say "your inner world is what creates your outer world". In this regard we tried to investigate the relation between mindfulness and entrepreneurial alertness. Alertness is a foundational concept in current understandings of the spotting and exploitation of entrepreneurial opportunities. Its two broad aspects from psychology have been explored and a model has been generated; reflecting the hierarchical relation between alertness aspects and mindfulness factors. Results show that mindfulness mediates the relationship between alertness and novelty creation. We used Interpretive Structure Modelling (ISM) to create the model of entrepreneurial alertness and mindfulness. The model is generated on the basis of the experts' votes. Ten experts who have the experience and knowledge about one or both of these topics were interviewed. They voted the mutual relation of the elements. The results showed that alertness fosters mindfulness, which then leads to the creation of novel things. This also shows that mindfulness deserves more investigation for its potential role in other parts of entrepreneurial process.

Keywords: Mindfulness, Entrepreneurial Alertness, Intrinsic Alertness, Phasic Alertness, ISM

1. Introduction

Finding ways to foster different aspects of entrepreneurial process have always been of interest among entrepreneurship scholars. Entrepreneurial alertness (EA) is a foundational concept in current understandings of the spotting and exploitation of entrepreneurial opportunities. Yet, despite the increasing use of cognitive psychology approaches in the field of entrepreneurship, the broader psychological basis of the entrepreneurial alertness construct has somehow been neglected. In the general cognitive psychology literature, "alertness" is considered as an aspect of attention that includes both intrinsic and phasic aspects (Sturm and Willmes 2001).

Intrinsic alertness can be considered as a person's endogenous cognitive control over their wakefulness. It is defined as the internal control of arousal without needing any external cue (Sturm et al. 1999; Sturm and Willmes 2001; Sturm et al. 2004). In contrast, phasic alertness can be considered as increasing readiness in response to exogenous cues (Sturm and Willmes 2001). It is the ability to increase readiness for response in a shortest time after an external cue or warning (Posner 1978), or the ability to heighten attention for a given warning stimulus (Sohhlberg and Mateer 1987). Despite having its roots in psychology and cognitive science, the development of the entrepreneurial alertness construct by entrepreneurship scholars has not fully reflected this original conception. Researchers of EA have mostly limited their efforts towards exploring the cognitive roots of the concept. By borrowing a variety of theoretical lenses from cognitive science, such as pattern theory (Baron 2006), schema theory (Gaglio and Katz 2001; Valliere 2013), regulatory focus theory (Tang 2009), signal detection theory (Baron 2004), and attention theories (Valliere 2013), scholars have started to map out the entrepreneurial implications of phasic alertness. Following the alertness theory of Israel Kirzner (Kirzner 1973), which was a phasic perspective on alertness, scholars started to explore phasic alertness and its components (Yu 2001; Tang et al. 2012). But the potential implications of intrinsic alertness remain unexplored.

2. Literature Review

2.1 Entrepreneurial Alertness and Mindfulness

Our understanding of the phasic aspects of EA has its roots in the objective view of opportunities. When Kirzner defines entrepreneurial alertness as "the ability to notice without search opportunities that have hitherto been overlooked" (Kirzner 1979), he implies that opportunities objectively exist in the outer world and that the reason they have been overlooked lies in a lack of alertness on the part of the entrepreneurs; entrepreneurs must prime themselves to stay alert in order to detect any opportunities that surround them.

Following on this, the majority of EA scholars have since worked from this same assumption as the foundation for their theorizing, and have investigated the factors that might boost the phasic alertness of entrepreneurs for detecting external opportunities.

But relying solely on this view runs counter to more recent thinking associated with the creativity view of the nature of entrepreneurial opportunities, a view in which opportunities are endogenously created through purely abductive processes (Sarasvathy et al. 2003; Alvarez and Barney 2007). Opportunities do not exist independent of entrepreneurs. Rather, "they are created, endogenously, by the actions, reactions, and enactment of entrepreneurs exploring ways to produce new products or services" (Alvarez and Barney 2007).

The essence of EA in this subjective perspective is comparable to the intrinsic alertness concept in cognitive psychology. From this perspective, there is no external cue to be apprehended and reacted to. Rather, entrepreneurs have executive control over their internal cognitive mechanisms and, by exercising them deliberately, can enhance their intrinsic EA and become able to create novel opportunities from pre-existing objective conditions. However, it may not be easy for individuals to have good control over their internal cognitive mechanisms and their emotional or sensational systems. In fact, it is considered to be one of the important issues in current psychological studies. There exist several theories in psychological sciences related to the intrinsic and metacognitive mechanisms of individuals, including mindfulness theory, metacognitive awareness theory, self-regulation theory and others.

Among all these theories, mindfulness theory has been chosen in this article to address the lack of an intrinsic aspect of alertness in the entrepreneurial context. There are two approaches toward mindfulness theory: the Eastern approach and the Western approach.

2.2 Eastern view

The Eastern view of mindfulness is embedded in Buddhist philosophy. In Theravada Buddhism mindfulness is associated with two different meanings: a) to remember and b) to develop a lucid awareness. According to the first view, mindfulness is related to memory and so mindfulness enhances one's ability to remember past experiences. In the second view, mindfulness is related to what is happening in the present moment (Khoury 2017). Within Buddhist thought a key reason for practicing mindfulness is long-term spiritual development and reduction of suffering that comes from attachment and grasping, rather than just symptomatic relief of stress.

2.3 Western view

Ellen Langer is a leading theorist for the Western view of mindfulness. According to her mindfulness is considered as containing components of (a) openness to novelty, (b) alertness to distinctions, (c) sensitivity to different contexts, (d) implicit, if not explicit, awareness of multiple perspectives, and (e) orientation in the present (Langer 1992).

In this research, Langer's theory of mindfulness (1992) has been applied. The overall components of mindfulness in her theory are well-compatible with alertness theories.

3. Method

Interpretive Structure Modelling (ISM) is a comprehensive methodology which is used for exploring and theorizing relationships within complex issues. In this research, in order to create a graphical representation of complex interaction between the specific elements of alertness and mindfulness (Khan et al. 2017), the ISM methodology has been used. In the following section, the ISM process used in this research is explained.

4. Analysis

4.1 Identify issues

Based on the literature review that we did on mindfulness and alertness, we generated constructs for a model that is aimed to reflect the relationship between alertness and mindfulness. This is the first step in the ISM process. According to the roots of alertness in cognitive psychology, both intrinsic alertness and phasic alertness are included. In addition, four constructs of mindfulness were selected based on the Langer (1992) theory of mindfulness. These constructs are: sensitivity to context, awareness of multiple perspectives, novelty seeking, and novelty producing.

4.2 ISM type

Warfield (1994) has classified several types of ISM modelling types or approaches, which are shown in table 1. As the aim of this research is to explore the interrelation between mindfulness and entrepreneurial alertness

factors, the intent structure is the best approach to be used because we want to understand the mutual influence between the elements of any model.

Table 1: Types of ISM

Type of structure	Element class	Relation type	Examples
Intent	Interrelation between objectives, goals and intentions	Influence	"would help to achieve", "supports"
Priority	Rank a number of items in order of priority	Comparative	"is of equal or higher priority", "is equal or higher value than", "is more important than"
Attribute enhancement	interrelations between a set of factors, problems or opportunities	influence	"strongly contributes to"
Solution sequence or process	Unknown variables	Influence, temporal	"is a function of", "should be computed before"
Complementary	Any	Any	"is a complement of"

4.3 Participants

ISM requires participants with specific knowledge of the domain of interest and the expression of influence among elements. In this research the participants were categorized as follows:

- *Experts in the field*: These participants were the experts who have the necessary content knowledge related to the issue of entrepreneurship, mindfulness, or both. We invited eight experts to participate in our study.
- *Stakeholders:* These participants are the people who are affected in some way by the outcome of the investigation. Three of our participants were technology entrepreneurs who were also mindfulness practitioners.
- *Modellers and Facilitators:* The research team for the study did the facilitating and modelling activities.

4.4 Elements Set

The elements of the model have already been mentioned. Four elements were representative of mindfulness, being sensitivity to different context, awareness of multiple perspectives, novelty seeking, and novelty producing. We also included intrinsic alertness and phasic alertness as two aspects of general alertness. In this stage a worksheet to capture the mutual relationships among the elements was prepared. We then asked the experts and entrepreneurs to opine on these relationships in the ISM session (i.e., which elements have influence on which others). After individual voting, the experts and the entrepreneurs were informed of the other votes and worked together to produce a consensus on the relationships among the constructs.

4.5 Interactions

Based on the votes that we obtained from the ISM session, we generated the structural self-interaction matrix (SSIM). In order to demonstrate the relationship between the constructs we examined each pair of constructs and used the following coding symbols for the relationships:

V: factor *i* will help achieve factor *j*
A: factor *j* will help achieve factor *i*
X: factors *i* and *j* will help achieve each other
O: factors *i* and *j* are unrelated.

Based on the relationships the SSIM is developed as shown in table 2:

Table 2: Structural self-interaction matrix (SSIM)

	STC	AMP	NS	NP	IA	PHA
STC		X	A	X	A	X
AMP			A	X	X	X
NS				V	A	X
NP					A	A
IA						V
PHA						

4.5.1 Reachability matrix

After the SSIM was made, it was transformed into a reachability matrix by changing the information in each entry of SSIM into 1s and 0s. The substitution of 1s and 0s were made per the following rules:

1. If (*i*, *j*) entry in the SSIM is V, then (*i*, *j*) entry in the reachability matrix becomes 1 and the (*j*, *i*) entry becomes 0.
2. If (*i*, *j*) entry in the SSIM is A, then (*i*, *j*) entry in the reachability matrix becomes 0 and the (*j*, *i*) entry becomes 1.
3. If (*i*, *j*) entry in the SSIM is X, then (*i*, *j*) entry in the reachability matrix becomes 1 and the (*j*, *i*) entry also becomes 1.
4. If (*i*, *j*) entry in the SSIM is O, then (*i*, *j*) entry in the reachability matrix becomes 0 and the (*j*, *i*) entry also becomes 0.

The resulting reachability matrix is shown in table 3. The values shown in in the Driving column of each factor illustrates its overall influence or "power" over the other factors. The value in the Dependence row of each factor signifies the degree to which it is influenced by other factors.

Table 3: Reachability matrix

	STC	AMP	NS	NP	IA	PHA	CR	Driving
STC	1	1	0	1	0	1	0	4
AMP	1	1	0	1	1	1	1	6
NS	1	1	1	1	0	1	0	5
NP	1	1	0	1	0	0	0	3
IA	1	1	1	1	1	1	0	6
PHA	1	1	1	1	0	1	0	5
CR	0	0	1	1	0	0	1	3
Dependence	6	6	4	7	2	5	2	32

4.6 Level Partitions

From the reachability matrix, reachability and antecedent sets are developed for each factor. The reachability set includes the factor itself and the other factors that it impacts. The antecedent set consists of the factor itself and the others that have an impact on it. The intersection of the reachability and antecedent sets will signify factors where both impact each other. The constructs with fewer factors in the reachability and intersection sets are assigned to the higher level of an ISM hierarchy. In fact, the top level factors are the ones which do not lead to any other factors. At each level of this hierarchy, the top-level factors are successively identified and removed from the table in an iterative fashion, as shown in table 4. The ISM model is then constructed on the basis of these emergent levels.

Table 4: Iterations

Level	Variable	Reachability	Antecedents	Intersection
I	1	1,4	1,2,3,5,6	1
	2	1,2,3,4,5,6	1,2,3,5,6	1,2,3,5,6
	3	1,3,4,6	3,5	3
	4	**4**	**1,2,3,4,5,6**	**4**
	5	1,2,3,4,5,6	5	5
	6	1,3,4,6	3,5,6	3,6
II	**1**	**1**	**1,2,3,5,6**	**1**
	2	**1,2,3,5,6**	**1,2,3,5,6**	**1,2,3,5,6**
	3	1,3,6	3,5	3
	5	1,2,3,5,6	5	5
	6	1,3,6	3,5,6	3,6
III	3	3,6	3,5	3
	5	3,5,6	5	5
	6	**3,6**	**3,5,6**	**3,6**
IV	**3**	**3**	**3,5**	**3**
	5	3,5	5	5
V	**5**	**5**	**5**	**5**

Boldface highlights the variables that were removed in each iteration. 1 = Sensitivity to Context, 2 = Awareness of Multiple Perspectives, 3 = Novelty Seeking, 4 Novelty Producing, 5 = Intrinsic Alertness, 6 = Phasic Alertness

4.6.1 Driving and Dependence

In order to analyze and the factors based on its driving power and dependence, we conducted a MICMAC analysis. MICMAC is a graphical approach in which driving power is plotted along the X-axis and dependence along the Y-axis, as in figure 1. In MICMAC analysis, factors are classified as follows:

1. Autonomous enablers: The factors with weak driving power and weak. They are almost not related to any other factors.
2. Dependent enablers: The factors with weak driving power but strong dependence. They are strongly affected by many other factors.
3. Linkage enablers: The factors with both strong driving power and strong dependence. These factors affect other factors and are also affected by other factors.
4. Driving variables: The factors with strong driving power but weak dependence. They have strong influence over many factors. (Vinodh et al. 2016).

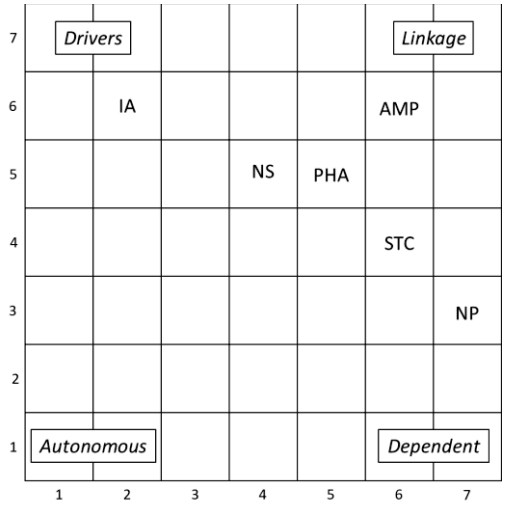

Figure 1: Driving power and dependence (MICMAC analysis)

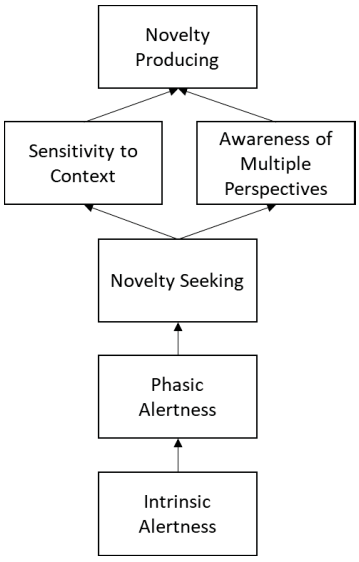
4.7 Proposed Model

The iterations presented in table 4 have identified the corresponding hierarchy level for each variable or construct within the model. For example, in the level I iteration the Novelty Production construct (variable 4) was removed, indicating that it represents the ultimate dependent factor among all the constructs.

Conversely, the Intrinsic Alertness construct (variable 5) survived until the final level V iteration, indicating that it represents the ultimate antecedent factor among all the constructs. On this basis, the model shown in figure 2 can be said to capture the full range of influences that were implicit in the opinions of the participating experts and entrepreneurs.

Figure 2: Model of factor influences among EA and mindfulness constructs



5. Discussion

The model of alertness and mindfulness developed here and provided in figure 2 suggests that intrinsic alertness is a major driver of innovation and novelty production, which in an entrepreneurial setting may manifest as opportunity spotting. This driving force is mediated by dimensions of mindfulness, as represented in Langer's Western theory. But this major driver of entrepreneurial alertness is completely neglected in the entrepreneurial literature. As currently conceived, entrepreneurial alertness rests in phasic alertness alone.

This view appears to be incomplete, both from the perspective of our experts and from the perspective of current cognitive science. Intrinsic alertness appears to have a role to play too.

Expert opinions captured in this study revealed that it is important for people to have intrinsic alertness and be alert to their inner thoughts, emotions and sensations if they want to enhance their alertness toward external cues and entrepreneurial opportunities. This initial model is addressing a crucial factor which is considered as a major antecedent of entrepreneurial ability to be alert to opportunities, and the tendencies of entrepreneurs toward seeking and producing novel things or ideas. A review of the psychology literature on the issue of entrepreneurial alertness suggested that the intrinsic aspect of alertness has been neglected in entrepreneurial research, and that scholars need to pay more attention to it.

This study has also revealed the important mediating role of mindfulness. Especially so when viewing entrepreneurial opportunity spotting from the "creation" perspective. Being mindful can now be considered as an essential linkage from the alertness of entrepreneurs to their tendency to create opportunities (rather than discovering or recognizing them). Intrinsic and phasic alertness create the conditions for increased mindfulness; mindfulness provides the sensitivity and internal awareness necessary for the creation of entrepreneurial opportunities that do not simply exist in the objective environment.

This research has its own limitations and weaknesses. Most significantly, this is just an initial model which needs to be empirically tested with data from a representative population of entrepreneurs. In addition, this study used only a Western mindfulness theory in order to address the gap of intrinsic alertness. There are several theories in psychological sciences that deal with the intrinsic aspects of human cognitions and emotions. This is a new stream of research in entrepreneurial cognition which we believe can lead to major results in entrepreneurship studies.

Reframing Social Innovation and other Neighbouring Phenomena from a Qualitative Cases Analysis

Blanca Herrero de Egaña Muñoz-Cobo
Universidad Pontificia de Comillas, Instituto Universitario de Migraciones y Desarrollo, Madrid, Spain
Blanca.hmc@benefactor.es

Abstract: We can affirm that social innovation is a frequently used (and abused) term but also that not all those who use it refer to the same things. It might seem that social innovation is the sum of the meaning of two words: innovation and social; but, as I will show with some examples, not everything that is innovative is social, nor all that is social is innovative. Until recently the term social innovation has been a catch-all in which there was room for almost everything that was innovative and social, however those of us who believe that social innovation has a specific weight in the future of humanity, we are convinced that it is time to homogenize this term. During the years 2013-2018, and for the research of my doctoral thesis, I have identified, compiled, codified, compared and analyzed thousands of data related to social innovation and social innovation in Spain. From this qualitative analysis, conducted following the Grounded Theory, hundreds of social innovation case studies emerged that allowed me, among other things, to determine a new framework for social innovation, a new definition of the term social innovation, as well as its distinction from other phenomena adjoining, such as CSR, ICT, social entrepreneurship and the world of patents and inventions. This paper aims to fill the existing void in the absence of a unique and updated definition of what is meant by social innovation.

Keywords: Social innovation concept, Spanish social innovation, Social innovation and neighbours, Qualitative research, Grounded Theory

1. Background

During the years 2013-2018 I developed the research of my doctoral dissertation trying to unravel and understand social innovation in Spain: its management, triggers, good practices and frequent mistakes. I carried out my research following the principles of the Grounded Theory and so, I identified, compiled, codified, compared and analyzed thousands of data related to social innovation and social innovation in Spain. The first surprise was to realize that there was no single definition of social innovation but that it was, and is nowadays, a concept under construction.

For the analysis to be as rigorous as possible and the conclusions of scientific evidence rooted in the data, the corpus of the research has been considerable. Thus, I compared more than 3,000 entries on social innovation, of which more than 500 were cases or examples, which allowed me, among other things, to determine a new framework for social innovation, a new definition of the term social innovation, as well as its distinction from other neighbouring phenomena, such as Corporate Social Responsibility (from now on, CSR), Information and Communication Technologies (from now on, ICT), social entrepreneurship and the field of patents and inventions

Therefore, it is important, first, to make a brief reference to the Grounded Theory, to explain how, through the collection, coding, comparison, saturation and analysis of thousands of data, a substantive theory, related to social innovation in Spain, has been generated and validated by them.

Secondly, I will describe the work of constant comparison between the different definitions of social innovation in space and time, and I will propose a concept that surpasses the previous ones, which represents its multidimensional nature.

Thirdly, and based on the empirical study of more than 500 cases of social innovation and 50 cases of Spanish social innovation, —in accordance with the proposed definition— I will make a distinction between this concept and what I have called other *neighbouring phenomena*.

This document aims to fill the existing gap in the absence of a single and updated definition of what is meant by social innovation, a definition rooted in the data that distinguishes the phenomenon from the others. This distinction may seem banal, but, on the contrary, ambiguity subtracts the power of a true weapon of social transformation.

2. The Grounded Theory at a glance and how I applied it in this research

The sociologists Barney Glaser and Anselm Strauss (1967), in their work *The discovery of Grounded Theory: Strategies for qualitative research,* propose the basic principles of Grounded Theory as a method of approaching and analysing social reality, whose main objective is to generate theory from the data, resulting in a theory grounded in the data.

Hereafter I will make a brief reference to the principles of the Grounded Theory as it was enunciated and define the key concepts that it proposes, and how I applied them specifically in this investigation.

- **Construction of theory versus verification:** Unlike other methodologies used in social sciences, it does not place emphasis on verifying pre-existing theories or demonstrating preconceived hypotheses, but on constructing and systematizing the theory that emerges from the analysis and the constant comparison of the data. "Our basic position is that generating grounded theory is a way of arriving at the theory suited to its supposed uses. We shall contrast this position with theory generated by logical deduction from a priori assumptions, that generating grounded theory is a way of arriving at the theory suited to its supposed uses" (Glaser and Strauss, 1967, p 2).
- **Generation of theory as a process**: The generation of a theory implies a research process. Likewise, the generation of a theory from the data means that most hypotheses and concepts come from the data, systematically worked in the course of the investigation. "Our strategy of comparative analysis for generating theory puts a high emphasis on theory as process, that is, theory as an ever-developing entity, not as a perfected product" (Glaser and Strauss, 1967, p 32).
- **Importance of the data:** the theory must be anchored in the data, comes from the data and originates from them.
- **All data are susceptible to generate theory**: "Although the emphasis on qualitative data is strong in our book, most chapters also can be used by those who wish to generate theory with quantitative data, since the process of generating theory is independent of the kind of data used" (Glaser and Strauss, 1967, p 18).
- **The accumulation and analysis of the data must be done simultaneously***:* "In the beginning, one's hypotheses may seem unrelated, but as categories and properties emerge, develop in abstraction, and become related, their accumulating interrelations form an integrated central theoretical framework, the core of the emerging theory. The core becomes a theoretical guide to the further collection and analysis of data. […] When generation of theory is the aim, however, one is constantly alert to emergent perspectives that will change and help develop his theory. These can easily occur even on the final day of study or when the manuscript is reviewed in page proof: so the published word is not the final one, but only a pause in the never-ending process of generating theory. When verification is the main aim, publication of the study tends to give readers the impression that this is the last word" (Glaser and Strauss, 1967, p 40).
- **The importance of comparative analysis**: "In discovering theory, one generates conceptual categories or their properties from evidence; then the evidence from which the category emerged is used to illustrate the concept. The evidence may not necessarily be accurate beyond a doubt (nor is it even in studies concerned only with accuracy), but the concept is undoubtedly a relevant theoretical abstraction about what is going on in the area studied. Furthermore, the concept itself will not change, while even the most accurate facts change. Concepts only have their meanings re-specified at times because other theoretical and research purposes have evolved" (Glaser and Strauss, 1967, p 21 f.).
- **Theoretical sampling**: "Theoretical sampling is the process of data collection for generating theory whereby the analyst jointly collects, codes, and analyses his data and decides what data to collect next and where to find them, in order to develop his theory as it emerges. This process of data collection is controlled by the emerging theory, whether substantive or formal" (Glaser and Strauss, 1967, p 45).

So, I did not start this research based on an a priori definition of social innovation or trying to demonstrate what its relationships with other phenomena are that are close to it, on the contrary, I started collecting what the self-described social innovators understood as social innovation.

This is when I realized that social innovators referred to different things when they talked about social innovation: sometimes they were social entrepreneurs (but not necessarily innovative), sometimes they were inventors, but not necessarily social, etc. The same thing happened when I looked for more or less academic

definitions of social innovation, although very similar, there was no single or generally accepted definition, but we could definitively infer is that social innovation is a dynamic phenomenon and a dynamic concept too.

As data compilation, codification, and comparison is essential, we must talk about the corpus of research in figures, namely: more than 3,000 entries, which have been codified, compared, analysed and saturated, during more than 5 years (2013-2017) and more than 500 social innovation examples and 50 Spanish social innovation case studies.

3. Towards a New Concept of Social Innovation

3.1 Social Innovation: first approach

It might seem that social innovation is the sum of the meaning of two words: innovation and social; but, as I will show with some examples, not everything innovative is social, nor all that is social is also innovative.

To better explain the topic of the thesis, what is covered and what is not, I propose a series of three examples having something in common: the food.

- On October 10, 2014, the famous chef FerranAdrià was awarded the prize for disruptive innovation at the South Summit 2014 ("FerranAdriàpremio a la InnovaciónDisruptiva" 2014), an event that "connects the most innovative entrepreneurs with the most important investors in the world and corporations that seek to improve their global competitiveness through innovation" ("Who is behind the South Summit?", n.d.), for their creativity in cooking and gastronomy.
- It is undeniable that Adrià is a great innovator in his field, gastronomy, and that has been, even, disruptive, in the sense that he opened a gap in the pre-existing market and created something totally new. However, despite being one of the precursors of deconstruction, decontextualizing this concept of the art world (consisting of isolating the various ingredients of a dish, generally typical, and reconstructing it in an unusual way, so that the appearance and texture are completely different while the flavour remains unchanged), of the foams (created using siphons), of the spherification (use of alginates to form small balls of liquid content), as well as the use of liquid nitrogen, etc., we can not to say that we are dealing with a social innovator or that these contributions, although very innovative, are about social innovations.
- In the same way, social canteens for people without resources, despite having considerably increased their presence and number of people assisted in Spain during these past years of crisis, are imminently social, but they are not innovative, given that they represent assistance measures dating from the 18th century.

We could find numerous examples in both fields, the innovative and the social, and we would not be talking about social innovation.

Therefore, in reality, social innovation is not the sum of innovation and social, but it is about researching the examples where these two concepts merge and operate as one.

- The Solidary Fridge initiative from Bilbao (NeveraSolidaria,n.d.) refers to a refrigerator placed on the street (surpassing all legal requirements, such as the use of public land, safety, health and food consumption requirements), so that those people who have prepared food can deposit it into the fridge, and people who need or want homemade food can take it: here, we can clearly face a case of social innovation. And a social innovation with capital letters: it is a new idea that fights against a social problem. Never before it had been proposed an action as simple as bold and innovative, to put a fridge in the street, to fight locally against the waste of food and against the hunger of the excluded people. Needless to say, The Solidary Fridge is part of the case studies of this research.

This research, then, collects, analyzes and compares this type of examples, where the innovative and the social are intrinsically linked.

Social innovation is not only the sum of two elements, the new and the social, but it is about finding, "the space in which both concepts meet and merge".

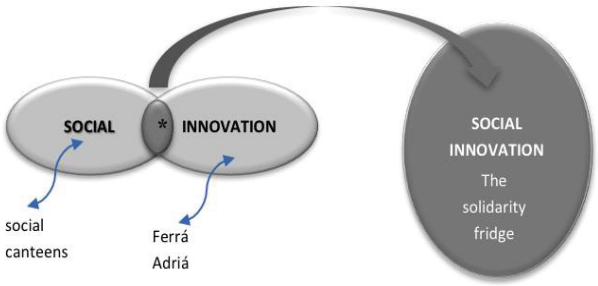

Figure 1: What we mean by social innovation

(Source: Herrero de Egaña, forthcoming)

3.2 Social Innovation: key elements

Although the expression social innovation is frequently used, it is convenient to define the basic elements of it, innovation and social.

By making a basic exegesis of the two parts of the expression, I refer in the first place to innovation, which I define in its most open and generous sense: it is not necessary that it be an invention or a patent; to be innovative, it is not necessary that we have never seen or heard anything like it, it is enough to include some novel element.

Thus, for example, Mohamed Yunus, founder of the Grameen Bank, awarded the Nobel Peace Prize of 2006 "for his efforts to encourage social and economic development from below," (Yunus,n.d.) is understood by many as the quintessential social innovator.

Yunus was the promoter of microcredits and although credit as we know it today exists since the 12th century, he is a great innovator who has generated a great social change by including in a pre-existing institution —the credit— a novel element —the guarantee solidarity— that has revolutionized society in Bangladesh and other parts of the world, allowing the poor, without theoretical repayment capacity, access to credit and with it their development and social, labour, productive and human inclusion.

Therefore, a pre-existing idea, project or activity that includes a variation, however small it may be —the geographical space, the social group to which it is directed, etc.— may be an innovation. Paradoxical as it may seem, a source of innovation can be found in the past and in what is not new.

Obviously, it is inherent in the idea of "new" or "novel" that is more effective, efficient or that produces a greater impact. Recall here the aforementioned definition of Mulgan, Tucker, Ali and Sanders (2007, p 8) as "new ideas that work".

Analyzing the second term of the expression, "social", I will show that it comprises three necessary dimensions to understand in all its depth what social innovation is.

Indeed, with the expression "the social" I mean three vectors that must be given at the same time to qualify and qualify social innovation.

These developments must, first, respond to a relevant social challenge (RSR) or a problem that matters to society as a whole and whose solution is a priority challenge for it. I have already mentioned (and in this chapter I will explain in depth) how the research itself and the methodology used to carry it out determine the relevant social challenges (RSR) for Spanish social innovation.

Phills Jr., Deiglmeier, and Miller (2008) define social innovation as "a novel solution to a social problem that is more effective, efficient, sustainable, or just than existing solutions and for which the value created accrues primarily to society as a whole rather than private individuals". In this definition, the second dimension of the social aspect begins to emerge: not only has to be good for society, but also from society.

It is interesting to dwell a moment on this nuance "from and for society", because it leads us to reflect on the agents of social change or social innovation, which is also one of the contributions of this thesis, and which I will develop next.

Mulgan, Tucker, Ali and Sanders (2007, p 8) define social innovation as “innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly developed and diffused through organisations whose primary purposes are social.”

Phills Jr., Deiglmeier& Miller (2008) make an important contribution by pointing out that social innovation dissolves borders and promotes a dialogue between the public, private and non-profit sectors.

As pointed out by Murray, Caulier-Grice and Mulgan (2010, p 3), social innovation is defined as “new ideas (products, services and models) that simultaneously meet social needs and create new social relationships or collaborations. In other words, they are innovations that are both good for society and enhance society’s capacity to act.”

Therefore, the social is as much in the process, the how and the why of the social objectives and of the society that is desired to reach and also strengthens or generates the relations between the different social agents: the individual, the crowd, the private and the public, the organizations and movements of civil society and large multinational companies.

The characteristics inherent to social innovation are:

- New, novel (and better than previous ones)
- Social,from society
- Social, for society (faces social challenges relevant to society)
- Social because it generates new social relations or strengthens existing ones.

Going back to the content of that “space in which its founding the innovative and the social” in figure 2 reflects how social innovation has to be made up of a proportion of these four elements.

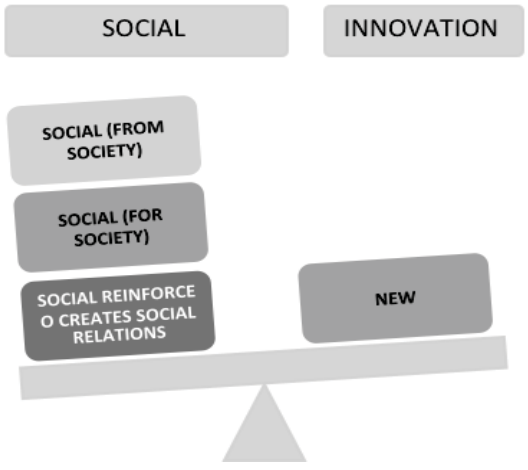

Figure 2: Social Innovation: Key elements

(Source: Herrero de Egaña, forthcoming)

3.3 Social innovation: definitions comparison and new definition

Naturally, there are definitions of social innovation, but the debate about the concept is not banal, since there is no clear and univocal definition.

In their publication *Social Innovation. What it is, Why it Matters and How It Can Be Accelerated,* Mulgan, Tucker, Ali and Sanders (2007, p 8) say “innovation is new ideas that work”; thus, social innovation would be new ideas that work to solve or manage a social problem.

In 2010, the European Commission, in the communication entitled Emblematic Initiative of Europe 2020. Union for innovation, defines social innovation as something desirable, in order

> *to find new ways of meeting social needs which are not adequately met by the market or the public sector (… or) to bring about the behavioural changes which are needed to tackle the major societal challenges (… and therefore to) empower people and create new social relationships and models of collaboration. They are thus innovative in themselves and good for society's capacity to innovate* (European Commission, 2011, p 23).

According to the report Social innovation and cooperatives: the social impact of cooperatives and socially innovative experiences,

> *Facing the task of establishing a concept on Social Innovation is a job not lacking in difficulties. In fact, if we consult the latest research conducted by the European Commission, it can be seen how sometimes researchers have rejected the idea of making a 'static' definition of the concept, preferring to use different "notions" and interpretations, clarifying that the concept of social innovation is not used to describe or explain social reality but "social innovation must be recognized as a particular mode of action and social change", thus defining "Social Innovation as a changing and adaptive process to social change"* (FAECTA, 2014, p 16; my translation).

Indeed, in the report *Social innovation research in the European Union Approaches, findings and future directions Policy Review* (2013b), three definitions are gathered from among many, chosen to cover more aspects and nuances of it:

- Social innovations are new solutions that simultaneously meet a social need and lead to new or improved capabilities and relationships and better use of assets and resources. In other words, *social innovations are good for society and enhance society's capacity to act.* (Tepsie [= The Theoretical, Empirical and Policy Foundations for Building Social Innovation in Europe])
- *Social innovation must be structurally aimed at meeting social need* (social challenge); must involve a new or significantly improved product, process, marketing method, and/or organizational model. (Selusi [= Social entrepreneurs as lead users for service innovation])
- *Social innovation is a process* where civil society actors develop new technologies, strategies, ideas and/or organizations to meet social needs or solve social problems. (SPREAD [= Social platform on sustainable lifestyles 2050])

Many authors consider it necessary to talk about innovation in general before talking about social innovation. In the paper "Social innovation as a solution to the crisis: towards a new paradigm of development", it is pointed out that

> *It is mandatory to talk about innovation in general as a previous step to refer to social innovation. The concept of innovation has been gaining weight over the years, becoming a fetish concept in vogue since the 60s (E. Rogers 1962, R. Nelson / E. Phelps 1966). However, it was Schumpeter who introduced the relevance of the concept and its analysis, emphasizing that "innovation is a process through which new products and techniques are introduced into the economic system" (Schumpeter, 1947). Schumpeter's perception of innovation as a process of "creative destruction" was confined to the business world, the market and technology. In any case, we must recognize that parallel in time, when Schumpeter described innovation as an eminently economic process, Kallen (1949), did so in terms of "cultural changes or social processes", extending its reach beyond the economic prism and technological (Hochgerner, 2009). And the economic future itself was confirming this fact.*
>
> *The Meadows report in 1972 already set the limits to exponential growth by saying that the use of technology, which it did not oppose, did not solve the most pressing problems in the world, but could in some cases intensify them and generate collateral effects and social problems. This highlighted the need for "another economy". The United Nations Conference in Rio de Janeiro in 1992 took that witness when talking about sustainable development from an ecological, social and economic point of view. More recently, it has been observed that neither technology nor the paradigm of industrial society are*

> *sufficient to achieve the Millennium Development Goals, but rather through the stimulation of social innovation* (ZSI 2008, p.28) (Fernández Fernández, Montes Pineda and AsiánChaves, 2012, pp 1086 f.).

In any text or document of those mentioned up to now and practically in any other material on social innovation, reference is made to a definition of the term social innovation, precisely because there is no unambiguous concept accepted by all.

At the beginning of this section I mentioned that of Mulgan, Tucker, Ali and Sanders, because one could say that they are authors, in a way precursors of the practical discourse on social innovation. Some years later, Murray, Caulier-Grice &Mulgan in the publication *The open book of social innovation* (2010) specify and extend the previous definition:

> *Our interest is in innovations that are social both in their ends and in their means. Specially, we define social innovations as new ideas (products, services and models) that simultaneously meet social needs and create new social relationships or collaborations. In other words, they are innovations that are both good for society and enhance society's capacity to act* (Murray, Caulier-Grice &Mulgan, 2010, p 3).

In the *Guide for Social Innovation*, social innovation is defined as

> *the development and implementation of new ideas (products, services and models) to meet social needs and create new social relationships or collaborations. It represents new responses to pressing social demands, which affect the process of social interactions. It is aimed at improving human well-being* (European Commission, 2013a, p 6).

In addition, it contains the somewhat more specific definition of the BEPA(Bureau of European Policy Advisors, n.d.) report which outlines the following three key approaches to social innovation:

- Social demand innovations which respond to social demands that are traditionally not addressed by the market or existing institutions and are directed towards vulnerable groups in society (European Commission, 2013a, p 6).
- The societal challenge perspective focuses on innovations for society as a whole through the integration of the social, the economic and the environmental (European Commission, 2013a, p 7).
- The systemic change focus, the most ambitious of the three and to an extent encompassing the other two, is achieved through a process of organizational development and changes in relations between institutions and stakeholders(European Commission, 2013a, p 7).

Most recently we have found another definition which defines four key dimensions: «Social Innovation must share the following key dimensions: (1) be oriented towards the common good, aiming to satisfy or solve social problems; (2) be a participatory / collaborative process involving different stakeholders or stakeholders; (3) imply an improvement over previous solutions (greater efficiency, science and / or sustainability); and (4) suppose an effective transformation in social behaviours and practices at the micro, meso and macro levels» (Álvarez-González et al, 2017).

The combination of these elements, the new and the social, both in the media and in the ends, leads us to a new definition of social innovation as "*new or innovative ways that society has to face the relevant social challenges (RSR), which are more effective, more efficient and more sustainable or that generate greater impact than the preceding ones and that contribute to making it stronger and more articulated*" (Herrero de Egaña, forthcoming) that synthesizes all the fundamental elements of social innovation and overcomes the previous definitions, representing a timeless definition of what social innovation is.

3.4 Social innovation and other neighbouring phenomena

Under the term *neighbouring phenomena* I refer to fields that have a lot to do with social innovation but that many times are not social innovation. As I mentioned before, there are four characteristics that constitute the notes inherent in social innovation: they must be present, to a greater or lesser extent, in all cases. In this process, in which I compared cases and examples that were labelled a priori as social innovation, I identified some of them which did not always comply with the four essential characteristics of social innovation determined by the research itself and that are part of the proposed definition mentioned above.

These concepts or phenomena, which I have called *neighbouring*, may have a "new" or "novel" high component, or a high "social" component (in one or more of its three dimensions) but may miss one or more of them. I´m talking about:

1. Information and Communication Technologies (or ICT), before new technologies (or NNTT)
2. Patents or inventions
3. Corporate Social Responsibility (or CSR)&
4. Social entrepreneurship.

This distinction may seem vain but nevertheless weakens the true social innovation, as we have previously defined it and its differentiation is fundamental to denoting social innovation and generating strategies for its diffusion.

As we can already see from the name of the phenomena themselves, the weight of the preponderant element is appreciated; thus, in the first two the innovative element is almost inherent and in the second one a social component is inferred (in its meaning for society). Figure 3 shows how far or close are theseneighbouring phenomena from social innovation but the best way to explain it is through the examples, which I analyzed and which are precisely those that gave me the clue that there was a field, or some fields, that were "neighbors" or adjoining and that it was worth defining and delimiting in order to know more precisely what we are talking about when we talk about social innovation, which, being a flexible concept, is not a "tailor's drawer" in which everything fits.

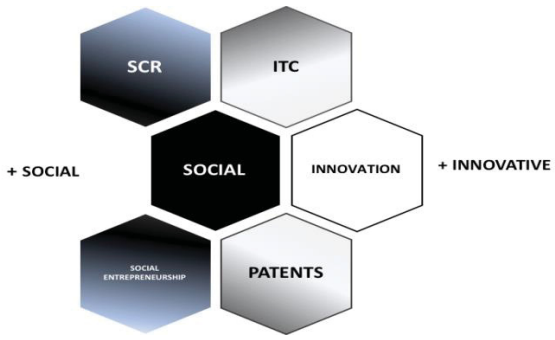

Figure 3: Social Innovation and other Neighbouring Phenomena

(Source: Herrero de Egaña, forthcoming)

So we could mention many APP platforms and applications (such as Meetic, "one of the most recommended network for singles" (Meetic, n.d.) or Gaydar "one of the main dating sites for gay and bisexual men. Millions of guys like you, looking for friendships, dating and relationships" (Gaydar, n.d.) both are innovative but they are not social as they do not respond to problems that are considered priority for society as a whole) or patents (like the mop, the lollipop or the botijo. They are Spanish patents, that had, at the time, a high innovative component, and although it is evident that they have also reverted for the benefit of society, we cannot affirm that they fit with the definition of social innovation that we propose in this work.) that are technically innovative but not social and, some CSR or social entrepreneurship projects which are eminently social but not innovative.

3.5 Social entrepreneurship is one of the most confusing areas

In fact, In the Guide for Social Innovation, the differences between Social Innovation, Social Entrepreneurship and Social Economy are established (European Commission, 2013a, p.12), that is to say, that one begins to try to distinguish between social innovation and other phenomena or concepts.

According to the aforementioned project Social Innovation and Cooperatives: the social impact of cooperatives and socially innovative experiences:

> *This differentiation of the concepts can be interpreted following the popular phrase "neither are all who count, nor count all who are." In other words, there is a clear intention from the European Commission*

> *that the concept is not monopolized by any sector or social tendency, but rather to establish a broad framework of action for the development of Social Innovation (FAECTA, 2014, p 16 my translation).*

However Ashoka organization that defines itself as the largest organization in the world in social entrepreneurship, confuses or uses both concepts indistinctly. Mohamed Yunus, Ashoka social innovator by antonomasia points out:

> *"A social business is a company with a social mission at its core. Set up to solve a specific problem to the benefit of poor or disadvantaged members of society, social businesses operate exactly like normal companies except for a few small differences. Unlike a charity, a social businesses generates profit and aims to be financially self sustaining. Removing the need for fundraising allows social businesses to re-invest profits back into generating sustainable social impact. A social business is a company that either creates income for the poor or provides them with essential products and services like healthcare, clean water or clean energy. 100 % of the company profits are reinvested in continuing the company's social mission» ("What is social business?",n.d.).*

Of all the data analyzed, a high percentage is connected with one or several of these 4 phenomena, whether or not they are social innovation.

As we can see in Figure 4, 45% of the 50 Spanish social innovation cases are connected to ICT, 29% to CSR, 22% to social entrepreneurship and 4% to patents or inventions.

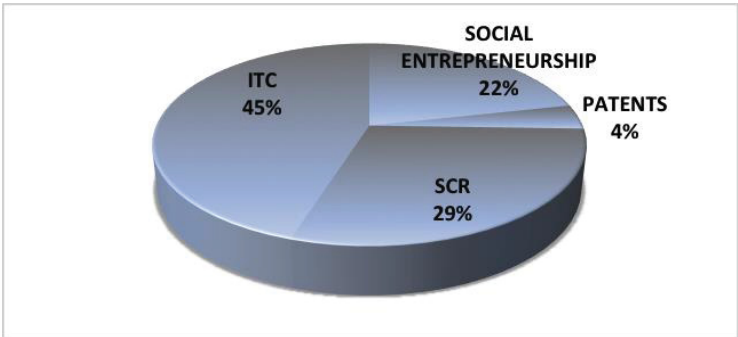

Figure 4: Percentage in which the analyzed cases are connected with neighbouring phenomena.

(Source: Herrero de Egaña, forthcoming)

4. In conclusion

In conclusion, in my research I was able not only to discover that there was not a single concept of social innovation, but also to propose a definition that surpassed the previous ones, which allowed at the same time, to distinguish what is social innovation from other phenomena with which it can share elements, but they are not exactly the same.

Knowing and spreading the common elements and the differences between these neighboring phenomena, helps to identify the true cases of social innovation and therefore to disseminate, promote and scale them.

This definition and proposal of differentiation, based on the data, allows progress towards the consolidation of the phenomenon and ultimately towards the construction of a better, more just and more human world.

On Ethereal Grounds: Cultural Resources and Innovation Success

Ahmad Hijazi and Shameek Sinha
IE, Madird, Spain
ahmad.hijazi@outlook.com
shameek.sinha@ie.edu

Abstract: This paper examines impacts that cultural resources have on the success of innovation-promotion efforts. We explore how cultural structures can imbue messages with different cognitive, affective, and behavioural qualities, bridging gaps resulting from uncertainty and ambiguity, and improving the chances of innovation success. We examine how increasingly innovative (more complex, more ambiguous) products benefit more from being associated with certain cultural resources. A process of flow from the 'culturally-loved' resource to the innovation alters responses, and is mediated by a number of variables we explore. We validate this by employing a web-administered experiment that considers varying innovativeness and examines the mediating variables.

Keywords: Innovation, Cultural Resources, Brands, Associations, Excess Meaning.

1. Cultural Resources and Innovations

Many consumer decisions regarding innovations are made under circumstances of incomplete information, where ambiguity and uncertainty pervade the decision process. How decisions are made in such situations, and the behavioural outcomes of these encounters with innovation, are the subjects of increasing importance in an age of relentless innovation.

With incomplete information, individuals might move further from the purely cognitive and analytical route, and resort to other sources of legitimation and validation. Those might include affect, heuristics, and mental shortcuts (Kahneman and Tversky, 1982; Darke et al, 2006).

Here, relatively stable cognitive structures that reflect hidden values and assumptions, cultural resources, come into the picture (Schein, 1984). This paper presents a specific modeling of cultural differences, the Cultural Resource Set, to understand processes by which such resources can cause cognitive, affective, and behavioural impacts on consumer responses to innovation (Kebir and Crevoisier, 2008; Swidler, 1986).

1.1 Cultural resource sets: relevance and theory

Among the popular approaches for modeling culture relevant to management today are those by Hofstede (1983) and House et al (2002), representing cultures by behavioural/value variables. These have been criticized by opponents as light on the context and content inclusion dimensions and their possibly economic, not cultural, underlying denominators (Jackson, 2011; Baskerville, 2003; Tang and Koveos, 2008). Other scholars have called for more dynamic (time and context dependent) and robust frameworks (Patel and Rayner, 2012) arguing for the importance of representing contexts, content, and variability more richly (e.g. Gannon, 2005).

Based on the above conversation, we have selected 'Cultural Resource Sets' to model cultural differences. This model is flexible and robust, and it fits closely with our focus on the 'markets' perspective. It is accommodating of a number of characteristics that can be inferred as 'necessary' based on the going conversation on the modeling of cultural differences. These characteristics include the fact that individuals' have multiple and complex identities, cultural differences are dynamic and varying with time and contexts, they are content-rich and can have diversely different origins (as opposed to being mostly national), and are more accurately represented by a 'set' of elements rather than a 'value' or a 'dimension'.

1.2 Cultural resources and excess meaning

Cultural resource sets are sets of elements (cultural resources) that include artefacts possessing 'excess meaning'. This 'excess meaning' links the different elements within the resource set together and with the culture's value themes. Although it can mean very little to individuals with no link to a specific culture, it can – by connecting to other elements (to whichever level in the hierarchy proposed by Schein (1984) they belong: artefacts, values, or assumptions) within the 'Cultural Set' – lead to various cognitive, affective, and behavioural impacts in individuals identifying with that specific culture.

People identifying with the American national culture for example will recognize and react in specific ways when encountering artefacts and symbols representing this culture as they respond to the excess meaning contained in them. They will likely think differently and experience a different set of feelings. Seeing the statue of liberty, or the flag, might for example, in addition to being recognized more extensively, bring to memory other elements and symbols belonging to the cultural set, or even values that are thematic of this culture like liberty or individualism.

1.3 Innovations and the continuum of radicalness

Innovations, defined as ideas, practices, or artefacts, perceived as new by the relevant unit of adoption, can be considered to constitute a continuum whose distribution is captured by the degree of radicalness. Radical innovations represent fundamental and revolutionary departures from the existing practice, while incremental ones only represent minor departures. An increased new knowledge component and higher risk are associated with the radical side of this continuum (Dewar and Dutton, 1986). There are specific needs in innovation communication and persuasion contexts (product, service, or even social) for extra cognitive clarity, affective influences, and behavioural impacts. These needs, intended to offset the inherent increases in complexity and ambiguity, are expected to increase as we move to the 'radical' side of the continuum.

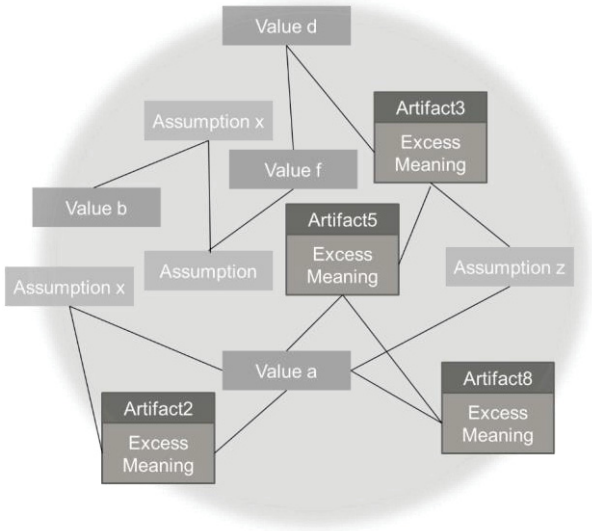

Figure 1: A Model of a Cultural Resource Set

2. Mechanics: Innovation Dilemmas and Affect, Cognition, Behaviour

"Cultural Resource Sets" are templates on which actors can build to construct meanings and novel actions, and this is where our modeling particularly contributes to the innovation discourse. It is our argument that this cultural set will be able to imbue messages on which it is invoked with affective and cognitive traces, leading to behavioural impacts. The 'meaning transfer' process (from the cultural resource, to the message, to the message subject), mediated by excess meaning, happens through the use of certain literary devices, like metaphors, analogies, allegories, and stories, and through general mechanisms by which meanings and affect move from one context to another (Nanaka, 1991; Boje, 1999; Hirschman, 2000; Holt, 2002; Morris & Waldman, 2011). The cultural resource sets model focuses on 'visible' (or 'audible') elements that can be communicated and expressed explicitly, while carrying 'excess meaning' that isn't explicitly represented. This enables the model to give an insight into the role of communication devices in loading messages with this extra meaning.

2.1 Cultural resources and affective gains

In the absence of enough information and structured detailed analysis, individuals can be expected to respond quickly to novel situations by invoking emotionally grounded responses (Kahneman and Tversky, 1982). Increases in uncertainties within the innovation adoption process thus can lead to increasing reliance on affective and emotional dimensions.

Values, which are higher-level cultural components (Schein, 1984), invoked by excess meaning contained in cultural resources, frequently serve as criteria to justify personal actions and decisions, and to evaluate people and events (Byrne and Bradley, 2007). Moreover, culturally-driven improvements in socio-political (Suchman, 1995) or cultural legitimacy (Archibald, 2004) of certain actions can affect these evaluations.

Cultural integration changes the expressive potential of an innovative item, and assists in the formation of personal narratives including it, improving the overall affective evaluation of a novelty, and increasing the consumer's level of involvement (Petty & Caccioppo, 1979). A 'more positive' affective attitude towards innovations framed in relation to cultural resource sets, especially when these innovations are more radical (and thus more uncertain) and uncovers some mediators of this effect (namely legitimacy, expressiveness, and involvement).

All this is supported by Polegato and Bjerke's (2009) description of the relation between overall liking of an ad, and liking a specific element-component within it.

2.2 Cultural resources and cognitive gains

Cultural resources can form cognitive structures that can inform decision making and action (Emirbrayer & Goodwin, 2008). According to the Elaboration Likelihood Model (Petty & Caccioppo, 1979) a higher level of involvement and more content-based processing can be expected for messages related to more 'personally significant' products and messages. We can expect the integration of cultural resources to increase the perceived personal relevance of a message/product since it invokes personally meaningful ideas. Cultural Resources have been demonstrated to contribute to adding a layer of meaning (familiarity) to otherwise-commoditized products (Kebir and Crevoisier, 2008). The 'familiar' aspect within the included cultural resource can provide a starting unambiguous island within an otherwise complex message.

Cognitive fluency, defined as the ease of ongoing conceptual and perceptual cognitive responses, leads to judgments of frequency, correctness, fame, among other factors, when experienced (Unkelbach, 2006). Because of the familiar links within a positively valued set of cultural resources (by definition), we expect higher fluency for processing these messages to result.

Integration of cultural resources in innovation-promoting is expected to have a positive cognitive effect by better integrating the product within an existing cognitive system.

2.3 Cultural resources and behavioral gains

The functions of understanding, reaction, legitimation, and potential action demarcate how culture constitutes the world by supplying it with meaning (McCracken,1986). Culture can, according to Noordegraaf and Vermeulen (2011), be 'actualized strategically to achieve results'. Cultural resources can be utilized as such in different situations to construct action strategies (Swidler, 1986). The role of cultural resources as a tool for mobilization and motivated action becomes more evident as it creates resonance by combining the cognitive and affective, while providing the legitimate and contextually-valid action route. The previously discussed gains, on the cognitive and affective dimensions will be expected to contribute to making the behavioural response (willingness to act) more pronounced.

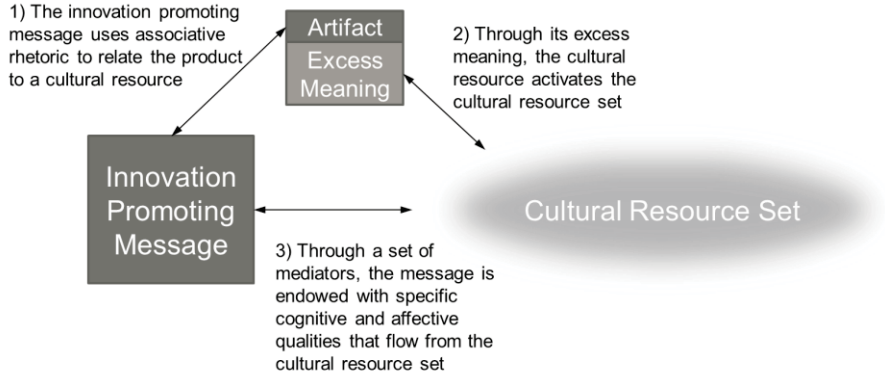

Figure 2: Cultural Resources and the flow of meaning

3. Hypothesis Statements

Based on the above discussion, we present the three sets of Hypotheses that describe the expected responses of consumers to different types of innovation-promoting messages:

H1C (H2C, H3C): Innovation-promoting messages, integrated with favourable cultural resource sets, correspond to affective (cognitive, behavioural) gains when compared to:

1. A : similar ads not integrated with those resources, and,
2. B: enhanced ads focusing on cognitive and behavioural (affective and behavioural, affective and cognitive) responses.

H1G (H2G, H3G): Innovation-promoting messages, integrated with cultural resource sets, correspond to a more favourable affective (cognitive, behavioural) ad outcomes when the cultural resource is more positively-valued.

H1I (H2I, H3I): Messages with higher uncertainty, ambiguity, and complexity [corresponding to more radically innovative products] will be associated with higher affective (Cognitive, Behavioural) gains when integrated with favourable cultural resources.

H1M: Affective gain on the evaluation of innovations (due to cultural resources) is partially mediated by increased legitimacy, expressiveness, and involvement.

H2M: The cognitive gain on the evaluation of innovations (due to cultural resources) is partially caused by increased cognitive fluency and elaboration likelihood.

H3M: The behavioural gain on the evaluation of innovations (due to cultural resources) is partially caused by increased legitimacy, and improved cognitive and affective outcomes.

4. Experiment and Results

4.1 Experiment description

A randomized 3x2 between groups web experiment was used to validate the hypotheses. One of fourteen ads is randomly shown to test subjects, and their assessment and responses are recorded afterwards. The ads belong either to a radically innovative product, or to an incrementally innovative one (less complexity, more certainty). For each product, there are three types of ads. Plain Ads contain a basic explanation of the products. Enhanced Ads are three ads containing improvements beyond the plain ads, including celebrity endorsement, promotion, and extra explanation. Cultural Ads are three ads that contain and utilize elements belonging to one of three cultural resource sets: A national culture (US), an occupation-related culture (IT), and one originating from cultural industries (Superhero).

The dependent variables (affective outcome, cognitive outcome, and behavioural outcome), and the mediators (legitimacy, elaboration likelihood, involvement, expressiveness, narrative…), were self-reported and measured using instruments previously used in the marketing and consumer behaviour literature. The independent variables were the existence and degree of cultural affiliation, which was measured determining cultural salience, cultural love, and cultural identification.

4.2 Summary of findings

Almost all the hypotheses are supported and significant (5%), with the exception of H1CB, H2CB, H3CB, which were only partially supported (10% significance). This is mainly attributed to Enhanced/Explanation ads performing better than expected, where their cognitive improvements extended to the affective and behavioral dimensions as well. We can say based on our experiments that:

1. General: Inclusion of a Cultural Resource Set can significantly modify the affective, cognitive, and behavioral outcome of the innovation-promoting message containing it.
2. Quantitative generalization: a more favorably viewed cultural resource set has a greater its ability to improve affective, cognitive, and behavioral outcomes of an including ad.

3. Innovativeness: The impact of Cultural Resources is moderated by the degree of innovativeness. The 'familiarity' of cultural resources fills in the gap and compensates for increases in ambiguity and complexity, causing more obvious gains in cases where a product is seen as more radical.
4. Mediation: The mediation analysis describes the routes by which different dimensions of impact happen. It was done following the methodology proposed by Hayes (2013). Legitimacy, expressiveness, involvement, and elaboration likelihood are found to mediate the impact of cultural resource sets on outcomes.

5. General Discussion

The paper presents a practical and applied modeling of cultural variables, particularly suited for understanding their effect in cases of increased complexity and uncertainty (innovation). The model of the Cultural Resource Set, integrates different levels of understanding, starting from visible artefacts, to the underlying network of meanings and values that is accessed by the 'excess meaning' component. The effects of inclusion in innovation promoting messages are projected into three dimensions: affective, cognitive, and behavioural. The latter is achieved partly due to the effects of the prior two, and the overall effect happens through a set of mediators that are explored and validated.

The fact that gains on evaluation outcomes attributed to favourable Cultural Resource Sets was much more pronounced in cases of increased innovativeness, helps shed the light on a phenomenon in which the familiarity contained within cultural resources was bridging the affective and cognitive gaps caused by the decreased familiarity of the innovation. Cognitively, whether a higher level of understanding was truly achieved due to the inclusion, or whether the understanding was perceived (wrongly) as being higher, the fact remains that the perceived cognitive deficit was compensated for. The affective deficit caused by increased uncertainty was similarly reduced, helping illuminate the processes of flow and transfer of meaning and affect from the Cultural Set to the innovation with which it was being associated.

Also, the inclusion of a wide set of possible mediators from the literature, helps position this research and link it to existing work in the field. The mediators of Elaboration Likelihood (Ability and Motivation), Legitimacy (Socio-political and Cultural), Narrative (Drama and Personal Story), Expressiveness (Personal and Social), and Perceived Credibility, all help understand the mechanisms by which Culture can frame our responses to novel situations and offerings.

6. Contributions and Managerial Implications

The modeling for culture presented in this paper focuses on a 'markets' perspective and transcends a number of dimensionalist approaches that are static, usually nationalistically oriented, and unitary. Instead the 'Cultural Resource Sets' view is dynamic, pluralistic, and flexible. The research expands the marketing innovation literature, by examining cognitive, affective, and behavioral consumer responses to innovations with varying levels of complexity and uncertainty. It also integrates the findings to the existing literature by exploring and validating variables that mediate these responses.

Managerially, the work presented can serve as a utility for understanding actionable consumer collective (cultural) characteristics, that can be harnessed as a latent resource. It also presents a different approach to bridging complexity gaps caused by innovations under specific circumstances. Overall, the work can contribute to efforts for managing complexity in a global and increasingly pluralistic marketplace.

Features of the Formation of a Complex of Marketing Communications of Social Innovative Projects

Elena Litvinova and Gulnara Chernobaeva
Omsk State University, Russia
ya.litvinova-es@yandex.ru
ch_g@bk.ru

Abstract: The active use of the innovative approach to the development of individual organizations and national economies has already proved its effectiveness. In a long list of technological, food related, organizational and other innovations that have already become customary, a special place today is occupied by social innovations. Innovations in the social sphere are designed to provoke social changes and promote the solution of socially important tasks by introducing new ideas, technologies, and strategies. The innovative approach to the organization of activities has traditionally been enhanced by the use of project management technologies. This leaves an imprint on the methods of using marketing tools to accompany social innovation. After all, marketing technologies can ensure the effectiveness of each stage of the life cycle of the project, from the initiation of social innovation to ensuring its acceptance by potential receivers of social benefits. The importance of the competent use of the complex of marketing communications in raising the effectiveness of social innovation projects is justified within the framework of this research. The study also defines additional requirements for the technology of forming a complex of marketing communications of social innovations imposed by the use of the project approach. These requirements relate to an additional target-oriented, timing and resource integration of social innovation project marketing communications. The paper also presents the results of the first stage of research aimed at identifying the features of the formation of a complex of marketing communications of social innovation projects initiated by two groups of entities: representatives of government bodies and representatives of commercial organizations.

Keywords: marketing communications, social innovative projects

1. Introduction

Social innovations today are not just one of the ways of solving such problems as poverty, ecology and aging. Social innovation is being seen as the source of systemic solutions and a proactive rather than reactive mechanism for managing to social problems.

The World Economic Forum (2017-2018) announced studying and replicating successful models and practices of social innovation to be one of the main tasks. At the same time, empathizing on the possibility of creating both a commercial and social value with the help of social innovations.

Social innovations - new ideas that meet social needs, create social relationships and form new collaborations. These innovations can be products, services or models addressing unmet needs more effectively (European Commission, 2018). It is possible categorize projects directed on creation of new social systems, education systems, public health services, systems of public communications as social innovations projects. These projects create new socially significant results using innovative approaches and / or technologies. The results of social innovation projects must cause social changes in society.

One of the main tools that provoke both the emergence and implementation of social innovation projects is marketing. The specificity of social innovation projects requires a more attentive attitude to marketing communications.

The purpose of this study is to identify features of the formation of a marketing communications complex of social innovation projects.

To achieve this goal, the following tasks are being accomplished within this stage of the study:

1. Identify the features of the formation of a marketing communications complex of social innovations projects, which are caused by using the project approach;
2. Identify features of the formation of a marketing communications complex for social innovation projects, depending on the type of initiating entity of the social innovation project;

3. Identify the features of the formation of a marketing communications complex of social innovations projects, depending on the willingness of the external environment to provoke the creation and accept the results of social innovation projects.

2. Theoretical foundations

Unfortunately, some fundamental works are not devoted to the problems of developing a marketing communications complex for social innovation projects. But today great results have been achieved in researching the theory of different types of innovations, their nature, t features of the innovation process, evaluating innovation potential by scientists such as Schumpeter (1934), Peterson (1972), Brown (1995), Trifilova (2003, 2005), Bessant and Tidd (2007, 2009), Glazyev (2003,2010,2011), Gokhberg (2007,2019,2013). Today such scientists as Phills, Deiglmeier and Miller (2008), Mulgan, Tucker, Rushanara and Sanders (2007), Bates (2012) are engaged in studying issues of social innovation.

A lot of fundamental and applied research is devoted to the marketing of innovations. And today is a special marketing innovation engaged Christensen and Bower (1996), Christensen (1997), Gupta and Lehmann (2004), Gupta and Mina (2008), Day (2011), Kotler (2012).Some works are devoted to the development of social marketing: Domegan, (2008), Kotler et al., (2002); Andreasen, (2002), Hastings (2003).

Various aspects of project management are at the center of attention of Archibald (1976, 2003), Razu (1994), Baguley (1999), Fischer (2000), Tovb and Tsips (2003), Voropaev (2006) and other famous scientists.

3. Methodology

The main methodological approach was the integration approach, which assumes simultaneous research both vertically (between individual elements of the management system) and horizontally (at different stages of the life cycle). This approach allows us to consider the possibility of managing marketing communications of the social innovations project within the framework of a diverse portfolio of projects of various types of organizations. The integration approach allows us to consider the issues of increasing the effectiveness of marketing communications of social innovation projects in the context of minimal marketing budgets. In addition, the used approach allows us to consider the simultaneity of the formation, with the help of marketing communications, of a positive attitude toward a concrete project of social innovations and form an environment conducive to their emergence and development.

We also used a project approach that determines the possibility of using various methods and tools of project management in the marketing support of social innovation projects.

For the collection of primary information, we used methods of included and unincorporated observation, questioning and expert survey. The paper presents the results of the first phase of the study, implemented from 06/2017 to 04/2018. Fifty-four projects were analyzed during the study. The sample structure is presented in Table 1.

Table 1: The structure of the sampling of social projects in Omsk

Social project typology	Type	Type		Term, months			Social change presence	Territory of impact	
		Project	Program	Up to 6	6-12	Over 12		City	AD*
Innovative	69%	82%	18%	42%	47%	11%	100%	76%	24%
Not innovative	31%	100%	0%	100%	0	0	79%	0	100%

* AD - Administrative District

Questionnaires were created at various stages of the project life cycle to determine the features of marketing support for social innovation projects. Seventy-eight respondents were questioned: managers of social projects and subjects responsible for marketing support of 54 analyzed projects.

An expert survey was used to assess the level of development of the environment conducive to the emergence and spread of social innovations. The group of experts included 7 people: project managers, implementing projects of social innovation for at least the last five years, representatives of authorities responsible for the social sphere development.

4. Research and results

4.1 Features of the formation of marketing communications complex of social innovations projects, depending on the state of the marketing environment

A survey of experts aimed at assessing the readiness of the regional environment to provoke the creation and accept the results of social innovation projects showed an average level of readiness of 3.86 out of 10 (for details see Table 2).

Table 2: The results of the assessment of experts on the readiness of the environment for social innovation (0-10)

№	Criterion for assessing the readiness of the environment	Assessment
1	Formation of different audiences interest to social innovations	2
2	The availability of social initiatives	4,1
3	The provocative nature of innovation by the regional environment	6,3
4	Information provision of real and potential consumers of social innovation	2,7
5	Integration of the processes of creating and implementing social innovations	4,2
Simple average for all criteria		3,86

Let us consider the impact of each criterion for assessing the readiness of the environment from the table by 2 to form a complex of marketing communications.

1. 1. Edelman research in 2015 showed that the barometer of public confidence in business is at its lowest level since 2008. In these conditions, the complex of marketing communications of any social innovations project should constantly create impulses that enhance the understanding of representatives of various business spheres to demonstrate their own, for example, corporate social responsibility through participation in the development and implementation of similar projects.

   However, involving representatives of the initially "non-social" business in social innovation projects requires the formation of marketing tools for identifying and assessing the impact on the image of companies of their participation in a particular project. Then companies will be able to assess the changing marketing environment, and more successfully build mechanisms for impact on it. The project marketing communications complex should include universal tools, tools and integrated communication technologies that simultaneously attract new "non-core" participants to the social innovation project and the willingness of the environment to accept the results of similar projects. Unequivocally, the low value of the indicator of the formation of interests in projects of social innovations is not only the result of an unbalanced complex of marketing communication support for projects. But experts have assessed this impact as determining.

2. Formed complexes of marketing communications of already implemented social innovations projects should influence the development of the market of social innovations. The already implemented projects, access to successful practices, transparency of the infrastructure mechanisms of this market directly indicate the formation of the market, the availability of social initiatives to any interested entities. Experts noted that they only found out about the possibility of taking a part in the creation of social innovation projects or about the possibility of joining existing projects through formal and informal marketing communications projects. Similarly, experts noted the significant impact on the perception of the availability of the implementation of social innovation marketing communication support for projects at the early stages of the life cycle of the project. This ensures the achievement of the "transparency of technology" effect of the project.

3. The marketing environment of the region should not only facilitate, but also provoke innovation.
   This is a large-scale task. It can not be solved even with the integrated tools of the marketing complex of individual social projects. This task can be solved more effectively within the framework of marketing support for projects united in programs. The initiators of such projects are the state-owned and municipal institutions or directly the authorities. Due to the specifics of the organization of

activities of these structures in Russia, the technology of forming a complex of marketing communications projects is less flexible and complex in budgeting and approval procedures.

4. According to experts, one of the serious problems of the development of social innovations is the unreadiness of consumers to choose (consume) products of social innovation. Intermediate results of a survey of potential consumers, launched in March 2018, allows us to conclude that information on social innovations is unavailable through traditional information channels for these entities. Accounting for the principles of stimulating marketing and the continuity of the impact of a complex of marketing commutations, as well as inter-project integration of communications should solve this problem.

5. Experts noted that the problem of the integration of processes of creating and implementing social innovation projects is not yet sufficiently well resolved. In Russia, there is an active growth of projects to create social innovations, but they do not always end up being introduced. Marketing communications, formed within the project creation project should provoke the interest of the parties interested in its implementation.

4.2 Features of marketing communications related to the project nature of social innovations management

In earlier studies (Chernobaeva, 2013), we identified features related to the project nature of innovation management, but not dependent on the type of innovation:

1. Marketing support of an innovative project should simultaneously provide a marketing impact on a multi-level target audience.
2. When organizing marketing support for innovative projects, internal marketing tools are of particular importance.
3. Marketing support of innovative projects should be carried out continuously at all stages.

Let us briefly consider the manifestation of these features within the process of forming a set of marketing communications for social innovation projects.

In the course of analyzing the readiness of the regional environment for social innovations, we have already noted the need to influence social innovation projects on a multi-level target audience. The projects analyzed during the research allow us to say that the marketing impact on the representatives of the authorities is of great importance. This is due to the fact that 100% of the analyzed projects of social innovations were implemented on the terms of full or partial funding from the grant support provided by federal, regional or local authorities. Representatives of target audiences, which promote the replication of the technologies of social innovations or products of their use, were also noted.

The most significant impact audiences were identified for the main groups of analyzed social innovation projects with the use of the questionnaire. The survey revealed the priorities in the technology of forming marketing communications used by the project managers used today. The results are shown in Table 3. When developing the technology for forming an IMC complex, it is necessary to clarify the actual significance of each group of entities.

Table 3: Distribution of marketing communications influence priorities for target audiences of social innovation projects * (1-10, where 1 is the maximum significance of the audience)

Subjects / Project Groups	Project product consumers	The project team	Representatives of public authorities	Investors	Sponsors	Contractors, subcontractors	Public interest groups	Independent experts	Non-governmental organizations	Mass media
Creative development	1	2	6	4	3	9	5	7	8	5
Civil-patriotic education	3	4	1	7	5	6	2	3	7	2
Education	1	2	1	5	3	6	1	2	4	1

Ecological education	2	3	1	5	2	6	3	4	4	2
Physical Culture and sport	1	2	1	2	3	5	2	3	4	2
Prevention of deviant behavior	3	2	1	3	2	7	4	6	5	5

*1-10, where 10 - the maximum significance of the audience. The definition of audiences as equivalent was allowed.

The abundance of internal marketing communications used to increase the effectiveness of the project assumes increased importance in projects of social innovations. After all, the main function of internal marketing is to improve the level of satisfaction of the company's employees in order to improve customer satisfaction. Social innovation projects require a high level of involvement in solving other people's problems. However, initially non-responsive subjects may be involved in the project team. The complexity of the subject area of the project, the focus on social changes at different levels, requires maximum social involvement not only of the team members, but of the entire organization. Solve this problem, create a constant sense of its participants a sense of satisfaction and pride in the results of their work, a feeling of optimism will help soft instruments of internal marketing communications.

Continuity of marketing support for projects at all stages of the life cycle of social innovation projects is complicated by the principle of a credible change in the number of stakeholders. Possessing low profitability, but high heterogeneous risks, determined at times by long periods of innovation development, most projects at any stage of the life cycle try to attract additional investors. Marketing communications aimed at this group of breakers should be changed depending on the increment of positive results of the implemented stages of the project. The transmitted information must clearly communicate the real commercial, marketing and social benefits of the investor.

Already considered requirements for marketing communications of social innovation projects, determined by the level of readiness of the environment, also determine the need for uniformity and continuity of impact on all subjects of the market of social innovations.

Listed features of marketing support for social innovations managed using the project methodology, in our opinion, are complicated by the need to include the complex of marketing communications of the project in the already existing marketing policy of the enterprise. This can be done only through careful integration of all marketing communications that accompany the emergence of a new social value as a result of the project activity, with the already formed or still forming image of the company. At the same time, the results of the survey showed that special importance should be given to Target (by purpose), Time (in time), and Resource (by resources) integration.

From the point of view of the project management process organization, it better to raise the about the initial development of the marketing complex of any type of project aimed not only at bringing the results of the project activity to the consumer, but also the complex that reinforces or corrects the existing image enterprise, rather than the issue of "inclusion".

4.3 Features of the marketing communications complex, depending on the type of initiating entity of the social innovation project

Social entrepreneurship projects are realized by subjects of different types and forms. In the course of our study, we have projected projects with partial or full coverage of expenses at the expense of various grants. As we have already noted, the peculiarity of social innovation projects is the involvement in the project implementation of a large number of subjects of various types and organizational and legal forms.

The hypothesis of this stage of the research was that the marketing communications management can be implemented both by the initiator and other participants. At the same time, the integrated marketing communications management system (IMCMS) will be modified, which will require the development of several types of management models.

This hypothesis has not been confirmed. Table 4 presents the structure of the analyzed projects according to the origin of the initiators to different groups.

Table 4: The structure of the analyzed projects according to the origin of the initiators to different groups

	State organizations and authorities	Commercial organizations,	Parity participation of state and commercial organizations	Individuals	Non-Profit Organizations
Initiator of the project	68%	13%	16%	0%	3%
Participation of representatives of other organizations in the project team	100%	83%	100%	0%	100%
Do not transfer responsibility for MCMS	100%	100%	100%	0%	100%

The initiator of the majority of the analyzed projects are state organizations and representatives of authorities of different levels that do not transfer marketing communications projects of social innovation projects to the entities that implement it. This phase of the study will be completed in December 2018.

The technologies used today in the Omsk region to form a complex of marketing communications by commercial organizations and state organizations are significantly different in terms of the low level of strategic integration for the purposes of the latter. For commercial organizations where social innovation projects are implemented in parallel with typical commercial projects, the issue of forming strategic programs or project portfolios is acute, with the corresponding synergistic effect of joint management, on the combination of social and commercial benefits, and the multiplicity of communication effect.

5. Conclusion

The paper presents the results of the first stage of the study of the features of the formation of a marketing communications complex for social innovation projects in a particular region. The obtained results allow us to draw a conclusion about the expediency of using project management tools to ensure the continuity of the communication impact of similar type's projects on representatives of a multi-level target audience. Studies have shown the dependence of the priority of the impact on different target audiences depending on the scope of the social innovation project.

The project approach also allows us to provide integration processes in management of marketing communications of projects. The conducted survey showed insufficient experience and, as a result, low indicators of integration of marketing communications by goals, time, and resources. Detailed study of technologies for integration of marketing communications in these areas will be devoted to the following stages of the study.

The non-confirmation of the hypothesis about the transfer by the initiators of the project of marketing communications management to representatives of other companies in the project team led to the exclusion from the research plan of the development phase of the adaptive mechanism for the transfer of control functions of the IMC.

The study also made it possible to determine that organizations do not fully use the tools of project management in the practice of marketing support for social innovations. Although in the context of "low" budgets and the need to accumulate and subsequently replicate successful practices, it is advisable to use the formation of "project archives" and individual "problem projects". Inclusion of these tools in the process of forming an integral complex of marketing communication support for social innovation projects will be one of the tasks in achieving the main objective of the study.

Abstract: The field of social innovation has received scholarly and policy interest during the last two decades (Adams and Hess, 2010), this has been driven by increased attention to such trends as the social engagement of citizens, and different organizations, in innovative processes. This has been sharpened by criticism aimed at dominant classical business models and narrow economic outlooks on development that sometimes put aside the social development and the needs of societies where innovation is about solving social problems (Van der Have and Rubalcaba, 2016). However, despite the growing interest in research on social innovation, so far there is no universal definition of the phenomenon. This leads to the fact that social innovation studies lack a clear perspective on how to measure the successful implementation of social innovation. As a result, studies that are dedicated to the impact of social innovation in general and its impact in regional development specifically are still represented in a small scale. Answering the research question on how social innovation might influence the regional development, this paper aims to give an overview of the concept of social innovation. Based on this overview, the paper further explores the relationship between social innovation and regional development and the impact that social innovation might have on regional development. Following this, some ideas on how several existing approaches might be used in order to access the impact of social innovation in the regional development will be given. To illustrate the need for such metrics, the example of a social innovation implementation in Portuguese sub-region Baixo Alentejo will be presented.

Keywords: social innovation, regional development, impact of social innovation, regions

1. Introduction

In recent years interest in the applications and impacts of social innovation (SI) within the field of regional development has grown. The issues of social innovation and regional development have long been dealt with separately by the European Union in its policies, and by different groups of scholars and researchers. Only recently, awareness has grown that the regions are important areas for social innovation and that there is a need to merge the studies on social innovation together with regional development studies in order to better understand how social innovation emerges, develops and influences the reality in regions. Having perceived this research gap, this paper tries to investigate the theoretical approaches related to social innovation and focus on the impact that social innovation has regarding the development of innovative solutions to existing problems in a regional context.

This paper is interested in examining four key issues within the contemporary field of SI. These are: the ways in which SI is conceptualized; the links between SI and regional development; the ways in which its impact is measurable; and the effects of SI impact within a given region (here the paper looks at one example in the Baixo Alentejo sub-region of Portugal).

The paper breaks down into several key sections related to the abovementioned themes. Section 2 examines some of theoretical understandings that underpin notions of defines SI. This guides the paper's understanding vis-a-vis the object of study, and gives background on the main literature and trains of thought influencing research into this matter. In the next section the paper discusses the connection between SI and regional development (Section 3), examining both the theoretical and applied impacts. This implies that some changes may be attributable to the activities of SI organizations/actors, though, conversely, the same changes may be caused by distinct variables. As such, there is some discord in the literature about the manner in which one can reliably measure said impacts. In Section 4, this paper attempts to present two existing ideas on how to measure SI impact and how it might be further developed and applied for further research. Following previous sections, Section 5 provides an overview from the field of SI, its implementation and its impact based on the experience of the Association for the Development of the Municipality of Moura (A Associação para o Desenvolvimento do Concelho de Moura, ADCMoura) whose purpose is to support and promote the sustainable development of the municipality of Moura in the Baixo Alentejo sub- region. The paper concludes with a summary and suggestions for further investigation.

2. Social Innovation: definition and concept

According to the report prepared by the European Commission in 2013, social innovation represents the development and implementation of new ideas (products, services and models) that opt to meet social needs and create new social relationships or collaborations that also aim to provide new responses to existing pressing social demands, which affect the process of social interactions (European Commission, 2013).At the same time, a very similar definition was proposed by the CrESSI project where social innovation was defined as "the development and delivery of new ideas and solutions (products, services, models, markets, processes) at different socio-structural levels that intentionally seek to change power relations and improve human capabilities, as well as the processes via which these solutions are carried out" (Ziegler et al, 2017).

In the discourse about social innovation, Mumford and Moertl (2003) define social innovation as the "generation and implementation of new ideas about people and their interactions within a social system" (Mumford and Moertl, 2003). Further linking to the previous works of scholars, the author argues that social innovations are a specific form of representation for significant forms of creativity, that respectively lead to the formation of new institutions, new industries, new policies, and new forms of social interaction (Drazin, Glynn and Kazanjian, 1999). In this respect, social innovation changes reality not only by representing new solutions for existing problems but also by being a stimulus for institutional or organizational change.

Moreover, social innovation differs from other forms of creativity in that the development, and eventual implementation, of new ideas involves large numbers of people and alters their interactions. As a result, most forms of social innovation can be expected to require a substantial investment of resources, as well as elite support (Dougherty and Hardy, 1996).

Following previous ideas, Neumeier (Neumeier, 2012) in his article argues that, according to the common understanding of innovation, it is still mainly associated with the concepts of technical and economic innovation. This perspective leads to the argument that, whereas innovations associated with economics and technology are well researched and defined, "understandings of so-called social innovations are not as well elaborated" (Adams and Hess, 2008). In this matter there is a substantial difference between social innovations and, what scholars describe as, business innovations that are aimed at profit maximization and are distributed through or adopted by organizations that are primarily motivated by profit maximization (Mulgan et al, 2010). However, this comparison is very important in understanding the specific form that social innovation takes, or the way in which it is being developed and implemented. When it comes to social innovation, scientists often argue that the definition of such may become stymied by the nature of the phenomenon. Concentrating on technological innovations, scholars in the field of innovation argue that the complexity of societies and the different ways of introducing social innovation in those societies impose restrictions and challenges vis-a-vis social innovation.

Pol and Ville (2009), after discussing different ways of addressing social innovation, came to the conclusion that the term social innovation had several overlapping meanings, including concepts such as institutional change, social purposes and the public good (Pol and Ville, 2009). Based on these ideas, they suggest defining social innovation as "any new ideas with the potential to improve either the macro-quality of life (quality of life in relation to a group of individuals) or the quantity of life" (Pol and Ville, 2009). As a result, the authors suggest conceptualizing social innovations as driving forces for the improvement of the overall living conditions of people (Pol and Ville, 2009).

Moulaert et al. (2005), following on from other scholars, argue that social innovation is the structuring concept, and, according to these scholars, "for local development to be successful, various domains of intervention (economy, housing, education and training, local democracy, culture, etc.) had to be integrated" (Moulaert et al., 2005). For these authors social innovation is a comprehensive concept, pointing to a multidimensional process of social change. So it can be concluded that social innovations in the sense of Moulaert et al. are new forms of civic involvement that contribute to an empowerment of disadvantaged groups and lead to better citizen involvement which may, in turn, lead to a satisfaction of the unsatisfied needs of a given society, resulting in an improvement in the quality of life in a given environment.

On the basis of the above mentioned definitions, social innovation is understood in this paper to represent new ideas that attempt to meet social needs and improve the living conditions of people in a given

community at a given level (whether that be the local, regional or national) by providing new responses to existing pressing social demands, improving institutional structures, creating new opportunities for network building and interaction between actors, and involving people in decision-making.

Taking into consideration the above evidence, the literature suggests that SI is comprised of new ideas being deployed with an aim to provide solutions that meet social needs. SI tends to inspire changes in institutions, organizations and interpersonal interactions creating new realities that may produce greater civic involvement leading to empowerment for the socially disadvantaged. As a driving force for social purposes aimed at the public good, social innovation is distinct from innovation in the generalized private sector, which is driven by profit maximization rather than the social good. Furthermore, there is a possibility that technological and social innovations overlap and intersect.

Having defined what is understood by the term social innovation in this paper, focus now moves to the interplay between SI and regional development.

3. Social Innovation and the role it plays in regional development

Local and regional development, as well as the implementation of social innovation, has become an important activity for national, regional and local governments across the world since the 1960s and 1970s. Regional development is usually associated with the geography of welfare and its evolution, and it has played a central role in such disciplines as economic geography, regional economics, regional science and economic growth theory. Some authors point out that the concept is not static in nature, but refers to complex space-time dynamics of regions (Capello, Nijkamp, 2010). In the meantime, the context for local and regional development has experienced dramatic alterations caused by economic changes and the new challenges presented by globalization, which have made the performance of regions more challenging. According to Pike et al (2011), the economic system has become more internationalized, even 'globalized', knowledge intensive and competitive. This contemporary emergence has raised the specter of the "deepening of the unevenness in development for particular territories and sharpened geographical inequalities in prosperity and well-being of certain regions" (Pike et al, 2011). Thus, some regions have faced difficulties in both adjusting to their new environment and finding ways to improve their economic situation. In overcoming these difficulties and tackling the challenges, social innovation might be of a great help.

Social innovations are considered to be an important tool when it comes to regional development and also an important way to achieve competitiveness in remote or structurally weak regions (Dinis, 2006). According to Dinis (2006), regions face many challenges when it comes to their socio-economic situation, and in such circumstances the implementation of social innovations becomes crucial. Nevertheless, Dinis argues that innovative solutions can be found in these areas specifically because they face said challenges in the social and economic spheres of regional development. The argument presented by the author is that innovation and also marketing perspectives are useful tools for the implementation and adaptation of a sustainable strategy for these regions to progress both at societal and organizational levels.

As a result, debates about local and regional development have shifted from a focus on the quantity of development to a concern with its quality. Initially, this involved a focus on the impact of economic development on the natural environment and the constraints this placed on development, but has evolved into a more general concern with questions related to quality of life. To help in solving existing problems in such regions, social innovation and entrepreneurship are both seen as the driving factors for growth.

Moreover, scholars point out the importance of entrepreneurship in enhancing the innovative capacity and growth potential of regions. Simultaneously, the debate on entrepreneurship and innovation has prompted the emergence of new concepts such as innovative regions, innovative milieus, learning regions, or knowledge-based regions where innovation has become the critical survival factor in a competitive space-economy and, in turn, determines the direction and pace of regional development.

According to the literature, SI represents an opportunity to close some of the existing cleavages (economic, social, developmental etc.) between regions in the modern globalized world. It is thought to achieve this by stimulating competitiveness and being a driver for regional growth, as profits are fed back into the region and innovativeness is fostered among the people. As social entrepreneurship begins to take over some of the

functions previously the purview of state actors, there has been a shift in the debate from one of quantity to one of quality of innovation. In this sense SI represents a tool by which regions can gain competitiveness, regenerate their economies, produce new exploitable resources (such as knowledge), and improve their organizational capacities. That being said, SI may, in some cases, be a response to a negative developmental situation rather than a tool being deployed to actively push a growth agenda. In the next section this paper attempts to approach a metric by which the impact of such innovation could potentially be measured.

4. Assessment of the SI impact: existing and emerging measurements

The issue of measuring social innovation has been discussed by both practitioners and academics due to the very high demand for a unified, more common approach to how to measure SI and its impact (Mulgan, 2006; Pol and Ville, 2009). According to the TEPSIE report published in 2013, in a time of emerging as well as pressing existing social challenges, and the imperative to meet the current social needs of different groups in a more effective way, the issue of social innovation measurement has become a "significant priority for individual national states and Europe as a whole" (TEPSIE, 2013). In the existing literature on the topic of social innovation, there is a view that the measurement of its impact is made more problematic by the little studied and complex nature of the phenomenon. However, the report of the TEPSIE project (TEPSIE, 2013) notes that, despite attempts to create a unified system of indicators for measuring social innovation and its impact had been undertaken by many scientists, until present no single system had been developed. This is due to factors such as the set of extant definitions for social innovation, the specific context in which social innovations are implemented (for example, the different political contexts of different countries and, therefore, regions), as well as the complex nature of social innovation that is not conducive to measurement with existing tools.

According to Gibbon and Dey (2011), the objective of impact measurement in the third sector is to understand (in social, environmental and economic terms) what difference an organization's activities make to the world and to communicate that value to the organization itself and to its stakeholders (Gibbon and Dey, 2011). At the same time, social impact measurement can help social enterprises set realistic objectives, monitor and improve performance, prioritize decisions and access capital markets more competitively (Nichols, 2007).

Therefore, based on several ideas found in the field, a short summary of how it might be possible to measure the impact of social innovation can be given.

4.1 Social impact measurement: potential tools

The first tool that might be implemented in measuring the impact of social innovation in a given region is the European System of Social Indicators (GESIS), which is an instrument that might be used to analyze the individual and societal well-being of European citizens in terms of quality of life, social cohesion and sustainability and, therefore, changes in the social structures of European societies. The European System of Social Indicators suggests the two dimensional approach that covers both objective and subjective dimensions of the quality of life. Despite the fact that the indicators developed within the framework of the program for measuring the quality of life cannot be applied to measure the impact of SI without adaptation, some of them measuring, for example, the level of civic participation promoted with the help of SI, can still be adapted for the purpose of measuring SI impact. Covering different life domains such as health, environment, social security, social and political participation and integration of citizens, this system provides a useful basis for further development of indicators that potentially could be very helpful in measuring the SI impact in regional development. This is due to the fact that social innovation can generate changes in the integration policy of the region (for example, social enterprises that promote integration of Roma people in Baixo Alentejo sub-region) and can influence the economic development of the region and entrepreneurship activities (ADCMoura, EPAM Project), thereby influencing the situation in region as a whole.

The TEPSIE project mentioned previously offers another perspective on measuring the impact of SI. According to Schmitz et al (Bund et al, 2013), social innovation is much more service-based and even more importantly explicitly includes new "models, markets and processes", so that the output measures used for the impact of technological innovation are much harder to apply for SI impact measurement. Thus, there is a challenge of measuring specific aspects for SI and, therefore, it is necessary to both adopt existing metrics and complement them with new aspects. The proposed idea for SI measurement is based on the idea proposed by NESTA (2009) foundation which focuses on framework conditions for innovation that might provide resources for firms to innovate knowledge creation, entrepreneurship, selection of innovation and mobilizing resources. However, it was taken further by TEPSIE and adopted into a system that seems more suitable for measuring the impact of

social innovation in regional development focusing on the impact, not the social innovation itself. Bund et al proposed to frame social innovation measurement based on three interrelated levels that form part of the innovation cycle: entrepreneurial activities, field specific outputs and outcomes and framework conditions (Bund et al, 2013). In this regard, each of the level should be briefly explained. Entrepreneurial activities refer to a set of actions, characteristics, attitudes and behaviours that can be traced back to the innovator and represent active forces working towards innovation ('push factors') (Bund et al, 2013). The second level of measurement is the level of field specific outputs and outcomes that allows looking at the results of the innovation activities. Outputs, in this case, refer to measurable results that can be linked to an individual or an organization. At the same time, outcomes are much harder to measure and it is hard to connect them directly to separate organizational or individual activity (Bund et al, 2013). The last level of measurement is the level of framework conditions which represents so called "pull-factors" for SI and includes four sub-levels which are political, institutional, societal climate and resources framework. Each one of them enables the fostering of social innovation directly or indirectly, covers the existence of shared needs in a society and gives the legitimacy within society for these which are crucial for SI since it is assumed to be a new solution for social problems that are considered important and legitimate by the members of a given society. Moreover, the resources framework considers the existence and availability of resources which might be potentially relevant for the innovation process, such as financial resources, available networks of people dealing with SI. Giving an example which will be further discussed (see Section 5), the promotion of the EPAM project in Baixo Alentejo sub-region helped to create a network of producers both on the local and regional level (resources framework) which, in turn, promoted the involvement of more individuals and organizations (societal climate network) and, therefore, might potentially increase openness to the development and innovation from the local and national government (institutional framework).

In the following section, the example of how SI might be implemented in a regional and local level focusing on ADC Moura and the EPAM project will be given.

5. An example of SI implementation in Baixo Alentejo

To illustrate how social innovation is implemented and applied in practice, this article will consider the example of The Association for the Development of the Municipality of Moura (ADCMoura) in the Baixo Alentejo sub-region of Portugal and one of its current projects EPAM (Empreender na Fileira das PAM em Portugal). ADCMoura is a non-governmental, non-profit organization, whose purpose is to support and promote the sustainable development of the municipality of Moura and other parts of the Alentejo region, dealing with environmental education, entrepreneurship, business creation and promotion, providing equal opportunities, promoting gender equality, and fostering institutional and strategic cooperation among the actors involved. Despite the fact that the organization has implemented and been involved in many projects, in this article, the EPAM project will be given as a primary example of their activities.

The EPAM project, started by ADCMoura in 2011, with support from the National Rural Network Program (RRN), incorporates a set of tools to support the development of aromatic and medicinal plant production in Portugal. It acts at the levels of network building, research and provision of information, training, internal and external promotion and representation. One of the foundations of the EPAM process is the promotion of collaborative solutions, attempting to promote business development and cooperation between producers of the plants, researchers and companies, doing so in two ways: first, by organizing local meetings and workshops, and second, by providing access to the project´s online platform wherein the above mentioned actors can share and exchange their experience. In theory this would provide a platform where the growth of this industry is supported by the sharing of best practice, creating a sense of community around the enterprise and solidarity among those engaged in it.

One of the main objectives of the EPAM project is to promote social innovation for sustainable economic and rural development of the Baixo Alentejo region. According to Stöhr, there has been a paradigm shift in regional development strategies (Stöhr, 1984) that resulted in changes of understanding of regional development which was seen as not merely quantitative anymore but rather quantitative (e.g. the broad development of human capabilities based on their respective societal conditions) (Stöhr, 1984). Therefore, the innovation orientation was the main goal of such a development where innovations were not restricted to technological innovations but also included organizational and institutional innovations. This point might be proven by the activities of EPAM network. The work of ADCMoura has provided, through the EPAM project, a gateway to

important information vis-a-vis best practice through the organization's access to other bodies such as Center d'Etude et de Développement Durable Euroméditerranéen (CEDDEM) and European Herbs Growers Association (EUROPAM). Furthermore, the website of the organization under the auspices of their EPAM project, allows the agents involved to increase the collaborative potential and efficiency of the agents, and third parties, through helping them to coordinate their actions more effectively. Moreover, by organizing different workshops and events and therefore fostering the networking, the EPAM project contributes to the development of new skills and capabilities of both local population and regional actors. From the evidence above it can be said that EPAM represents a social innovation in line with the definitions encountered earlier in this paper: it employs an existing idea (that of internet connectivity) in order to address various social needs (by attempting to foster sustainable employment) by promoting participation of various stakeholders and creating networks (through its website). Therefore, EPAM project contributes to the regional development of Baixo Alentejo by creating new employment opportunities for local population, fostering and developing networks between actors involved as well as by providing new ways of knowledge and skills exchange among actors. However, social enterprises face a challenge when it comes to measuring the effectiveness of their actions. Despite the demand for a common approach on how to measure the impact of innovative solution by both policy makers and practitioners, this kind of approach still does not exist. Therefore, despite the above, there is little evidence at present of the impact of these initiatives.

6. Conclusion

In this article SI represents the deploying of novel ideas so as to improve the living conditions of people in structurally weak regions by addressing social issues, building up institutional and intrapersonal capacities and democratizing socio-economic decision-making. SI has the capacity to change the dynamics of regional society in a way that may potentially empower those at risk of social marginalization or depravation, and this is a key to addressing issues of interregional inequities. This is achieved by the social dynamic of SI, which emphasizes the reinvestment of profits into the local economy in the shape of sustainable employment, the fostering of a knowledge economy and the driving of regional economic growth.

Considering that this phenomenon represents a potential boon in the field of regional development, and the betterment of the situation of those suffering from social deprivation, there is still no robust metric by which to measure the outcomes of this phenomenon. The social impact measurement has been addressed by both academics and practitioners who point out the importance of such a tool in order to evaluate the activities and their results in different fields. Moreover, the effective impact measurement will provide an opportunity to social enterprises to prove the effectiveness of their achievements. Therefore, existing approaches in different fields, such as European System of Social Indicators (GESIS), might be adopted and implemented in order to measure the impact of SI in the area of local and regional development. As such this represents a valuable area of future investigation, which could have positive outcomes in various fields of SI in the future, including resource allocation, promoting investments and targeting specific issues with best methods.

Attitudes, Abilities and Aspirations in the Worldwide Entrepreneurship Ecosystem

Abstract: Since 2011, The Global Entrepreneurship Index (GEI) has measured the health of the entrepreneurship ecosystem in several countries. The index combines multiple dimensions of the entrepreneurial environment and classifies the data into three main areas: attitudes, abilities and aspirations. The attitudes component measures the local population's attitudes toward entrepreneurship, and weights it using institutional variables. The abilities component measures a set of important characteristics regarding the entrepreneur's abilities and the business technological profile. The aspirations component measures innovation, technological transfer and diffusion. Our investigation, however, has identified a lack of studies that test the possible linkage between the GEI components. Given the importance of this research field, we aim to assess the relationship between attitudes, abilities and aspirations in the entrepreneurship ecosystem. Based on annual data for the GEI from 2011 to 2017, we propose a structural model to identify the effects of attitudes and abilities on entrepreneurial aspirations. Assuming that the structural relationship between attitudes, abilities and aspirations might differ across countries, the model is estimated using quantile regression in a panel data setting. Control variables were included, in addition to dummy variables that identify the particular effect of attitudes and abilities over different regions, such as Europe and Latin America. Our findings show a positive effect of attitudes and abilities on aspirations; however, the magnitude is significantly different across quantiles. Furthermore, the effect of the European region is positive and significant only for lower quantiles. This effect declines and becomes negative in the right tail, reflecting the reduction of entrepreneurial aspirations in countries with high GEI results. Specific policies are needed to reverse the declining trend of aspirations in European countries. These findings may be useful for formulating public policies involving entrepreneurship and also contribute to the debate about the effects of attitudes and abilities on different levels of entrepreneurial aspirations.

Keywords: Global Entrepreneurship Index, Attitudes, Abilities, Aspirations, Quantile Regression, Entrepreneurship ecosystem

1. Introduction

Schumpeter (1982) was the first to emphasize the importance of entrepreneurs in the innovation process. Entrepreneurs are responsible for the creative process, using their accumulated knowledge and skills. Innovative entrepreneurs create new products and processes that drive the economy (Schumpeter, 1982). It is recognised that entrepreneurship boosts productivity, innovation, job creation and economic growth (Hoffman 2007).

Since the start of the 21st century, entrepreneurship has been increasingly investigated in theoretical and empirical studies (Cătălin, Sorin-George and Răzvan, 2017), resulting in a considerable evolution and better understanding of the concept. The OECD (2008) defines entrepreneurship as a human action in search of generating value through the creation or expansion of economic activity, identifying and exploring new products, processes or markets. As the debate has matured, metrics and indicators for measuring entrepreneurship have been developed to capture its essence and allow comparison between localities, regions and countries.

Szerb, Komlósi and Páger (2016) argue that there are several concepts of entrepreneurship that attempt to measure the phenomenon. The authors state that entrepreneurship at the country level is a systemic phenomenon and should be addressed as such. Entrepreneurship is also multifaceted, and therefore impossible to measure in its totality. Moreover, the literature has proposed a number of methodologies such as the Global Entrepreneurship Index (GEI), which seeks to measure entrepreneurship ecosystems using composite indicators.

Created in 2011, the GEI comprises a combination of multiple dimensions of the business environment and classifies the data into three primary areas: attitudes, abilities and aspirations. Positive attitudes are understood as being necessary for competent individuals to choose entrepreneurship rather than alternative

occupations. Ability reflects the quality of new undertakings and Aspirations seek to reflect the potential of enterprises to achieve rapid growth and high productivity.

Our investigation identified a lack of studies that empirically assess the possible connections between the GEI components. As such, we aim to evaluate the relationship between attitudes, abilities and aspirations in the entrepreneurship ecosystem, based on GEI data between 2011 and 2017. We test the hypothesis that attitudes and abilities affect aspiration results in the GEI, using a quantile regression model in a panel data setting. Dummy variables were also included to capture the particular effect of different regions on aspirations. This study analyses the GEI with a different focus, and the results are potentially important for policy makers that seek to improve the entrepreneurship ecosystem.

2. Entrepreneurship ecosystem

Ács, Szerb and Autio (2013) report that, in addition to the factor endowment of a particular locality, the role of entrepreneurship must also be considered when analyzing economic performance. According to Ács and Szerb (2009), Ács and Szerb (2012), Ács et al (2009) and Ács, Szerb and Autio (2013), the entrepreneurship ecosystem consists on complex collaborative networks of dynamically interacting systems and sub-systems within a set of dependencies and inter-dependencies that is continuously changing.

Szerb, Komlósi and Páger (2016) recognise the systemic nature of entrepreneurship at the national level, and that entrepreneurship is drived by individuals. Ács, Szerb and Autio (2014) argue that, in the entrepreneurship ecosystem, individuals incorporate business attitudes, abilities and aspirations in a dynamic interaction process. Figure 1 illustrates the theoretical concept of the entrepreneurship ecosystem.

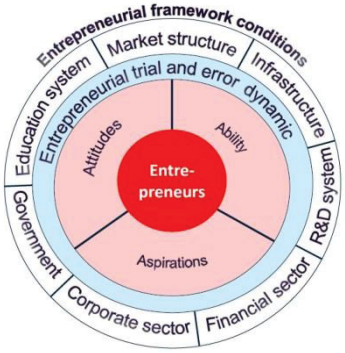

Figure 1: Theoretical Concept of Entrepreneurship Ecosystem

Source: GEI (2017)

Innovative entrepreneurs are the core of the system and they are characterised as having varied levels of business abilities and aspirations. They start a business in search of perceived opportunities, which are validated in a process of trial and error (GEI, 2017). Entrepreneurship is regulated by a series of structural conditions (market, infrastructure, R&D system, financial sector, corporate sector, government, educational system). The GEI report (2017) explains that a healthy entrepreneurship ecosystem will lead to an efficient allocation of resources and will increase the Total Factor Productivity through innovation.

Following Schumpeter (1982), the GEI (2017) understands that the entrepreneur has the responsibility of coordinating the allocation of scarce resources and the activities needed to achieve growth. This innovative entrepreneur will guarantee that the invention will have some usefulness and will contribute to raising productivity and economic growth. Aidis and Estrin (2013) recognise the role of institutions in the entrepreneurship ecosystem. Institutions determine the rules of the game, including intellectual property rights and market regulations. The importance of institutions lies on its influence o on economic incentives and resource allocation.

The entrepreneurship ecosystem is concerned with the quality of incentive mechanisms created by institutions, and its impact on economic growth. According to Aidis and Estrin (2013), institutions create incentives to allocate entrepreneurial talent to activities with higher private returns. The GEI (2017) observes that entrepreneurship ecosystems can allocate resources to a more productive use and generate innovative activities that drive this process. In addition, the literature on entrepreneurship recognises the importance of

financing opportunities and the need to garner resources, which is not trivial, especially when discussing resource allocation from existing activities into new ones. There is always associated risk in this process, and the lack of resources prevents a good ecosystem performance. Venture Capital may be a solution to this problem but is relatively scarce in underdeveloped countries.

2.1 Global Entrepreneurship Index

The Global Entrepreneurship Index was introduced in 2014 by the Global Entrepreneurship Network (GEN), following an earlier version between 2011 and 2013. It is an annual index that measures the entrepreneurship ecosystems of several countries. In 2017, the index was calculated for 137 countries. The GEI assumes that the entrepreneurship ecosystem at a socioeconomic level exhibits self-organisation, stability and sustainability.

Szerb (2017) observes that the GEI is based on a holistic view of different aspects of the entrepreneurship ecosystem. The Index methodology consists of constructing sub-indices at several levels. For each country, the data contains 28 variables related to 14 sub-areas, which generate three sub-indices (Attitudes, Abilities and Aspirations) that result in the Global Entrepreneurship Index (Table 1).

Table 1: Composition of the Global Entrepreneurship Index (GEI)

	Sub-index	Pillars	Variables
Global Entrepreneurship Index	**Attitudes Sub-index**	**Opportunity Perception**	*Opportunity Recognition*
			*Freedom (Economic Freedom*Property Rights)*
		Start-up Skills	*Skill Perception*
			*Education (Tertiary Education*Quality of Education)*
		Risk Acceptance	*Risk Perception*
			Country Risk
		Networking	*Know Entrepreneurs*
			*Agglomeration (Urbanisation*Infrastructure)*
		Cultural Support	*Career Status*
			Corruption
	Abilities Sub-index	**Opportunity Start-up**	*Opportunity Motivation*
			*Governance (taxation*Good Governance)*
		Technology Absorption	*Technology Level*
			Technology Absorption
		Human Capital	*Educational Level*
			*Labour Market (Staff Training*Labour Freedom)*
		Competition	*Competitors*
			*Competitiveness (Market Dominance*Regulation)*
	Aspiration Sub-index	**Product Innovation**	*New Product*
			Tech Transfer
		Process Innovation	*New Technology*
			Science (Gerd(Average Quality of Scientific Institutions + Availability of Scientists and Engineers))*
		High Growth	*Gazelle*
			*Finance and Strategy (Venture Capital*Business Sophistication)*
		Internationalisation	*Export*
			Economic Complexity
		Risk Capital	*Informal Investment*
			Depth of Capital Market

Source: GEI (2017)

According to the GEI (2017), the business attitudes sub-index captures entrepreneurial attitudes given some important institutional variables. It involves the entrepreneurial opportunities the population perceives, weighted by economic freedom and property rights; the start-up abilities the population perceives, weighted by the quality of education; risk acceptance, that is, the fear of failure in entrepreneurship, combined with a measure of a country's risk; entrepreneurial support networks (ease of access); how the population view entrepreneurs in terms of status and career choice and how the corruption level affects this view.

The entrepreneurial abilities sub-index measures important entrepreneur characteristics that determine to what extent new start-ups will have the potential to grow, such as: motivation based on opportunity rather than based on necessity (weighted by the combined effect of taxation and the quality of government services); the potential of start-up activity (combined with the ability to absorb new technology); the educational level of entrepreneurs (weighted by the percentage of start-ups founded by individuals with academic degree or

secondary education, by a measure of the entrepreneur's propensity to training their employees, and by labour freedom); the level of product exclusivity or start-up market exclusivity, combined with the market power as well as the effectiveness of competitive regulations (GEI, 2017).

Finally, the entrepreneurial aspirations sub-index captures the distinctive and qualitative aspects of the entrepreneurial activity: the tendency of companies to create new products, weighted by a country's ability to transfer technology; the use of new technologies for start-ups, combined with Gross Domestic Expenditure on Research and Development (GERD) and the potential of a country to perform applied research; percentage of high-growth companies that intend to hire at least ten employees and plan to grow by more than 50% in five years; the availability of venture capital and the sophistication of business strategies; the degree of internationalisation, measured by the company's export potential and weighted by the country's economic complexity; the informal investment at earlier stages and a measure of the depth of capital markets.

2.2 Empirical Literature

In order to identify the empirical literature on the GEI we used two important platforms: Web of Science and SCOPUS, and a Brazilian search engine (PERIÓDICOS/CAPES). Only one keyword was used (Global Entrepreneurship Index) in searching for titles, abstracts, keywords and texts. In total, 101 related articles were identified in the Web of Science database and 122 in SCOPUS. After excluding duplicities and investigating the remaining texts, 11 relevant papers were selected: 9 of them are in SCOPUS and 2 are in Web of Science.

The empirical studies have heterogeneous results, but they have one point in common: the use of the Global Entrepreneurship Index (GEI) in their scientific research. Ács and Szerb (2009) were the precursors of the Global Entrepreneurship Index (GEINDEX). The authors hypothesised that the relationship between entrepreneurship and economic development is slightly S-shaped, not U or L-shaped, and provided evidence that entrepreneurship across countries is positively related to economic development.

Bulut, Mutlu and Nazli (2013) examined six methodologies that measured entrepreneurship and innovation, as follows: IUS (Innovation Union Scoreboard), GEM (Global Entrepreneurship Monitor), GII (Global Innovation Index), ICI (Innovation Capacity Index), GEINDEX (Global Entrepreneurship Index) and WCY (World Competitiveness Yearbook). The study also mapped and compared sample size, the quality of the indices, method of measurement and frequency, among other specifications. Ghazinoory, Bitaab and Lohrasbi (2014) used the GEI data to investigate the influence of different social capital dimensions on the National Innovation System (NIS) in 34 countries. Using exploratory factor analysis and structural equation modelling, these authors detected a strong positive effect of institutional confidence and networking on entrepreneurship.

Nataraajan and Angur (2014) analysed the impact of the knowledge economy, using the Knowledge Entrepreneurship Index (KEI), and the business activity, using the Global Entrepreneurship Index (GEI), on the quality of life (QoL) in a country. The data were analysed using correlation and regression analysis, and it was found that the KEI and GEI have a significant effect on quality of life. Inácio Júnior et al. (2016) studied the Brazilian entrepreneurship ecosystem using the GEI and the National System of Entrepreneurship (NSE) theory. The study indicates that the institutional interaction in Brazil have a low-to-middle quality, being the social context the primary bottleneck in the national entrepreneurship ecosystem. The authors also demonstrated that the Brazilian entrepreneurship ecosystem shows low internationalisation of its companies and reduced innovation in products and processes, among other problems.

Szerb, Komlósi and Páger (2016) explain how the GEI methodology is projected to trace the profile of National Entrepreneurship Systems. The authors used the Penalty for Bottleneck (PFB) methodology to compare the business performance of the European Union (EU) and the USA, and the evidence shows that the former lags behind the latter. Szerb, Komlósi and Páger (2016) report that a uniform policy does not work in the EU member states, which requires the application of different combinations of policies to improve the GEI scores.

Atiase et al (2017) investigated the role of four critical resources (credit, electrical energy, contract enforcement and political governance) on explaining the entrepreneurship quality and the business support in Africa (response variables). The authors used the the GEI data for 35 African countries, some important covariates obtained from the World Bank (credit access, electricity access and contract enforcement in Africa) as well as the Ibrahim Index of African Governance and other control variables (GDP, Foreign Direct

Investment, population and education). The authors used OLS regressions and discovered that electricity access and governance policy were statistically significant and positively correlated with the GEI. Credit access was not significant to explain the response variables.

Jovanovic et al (2017) studied and compared the metrics of composite indices used in Technology Management (TM): The Global Competitiveness Index (GCI), The Global Innovation Index (GII) and the GEI. The authors also analysed the correlations between the GCI and GII pillars and found that the indices perform Technology Management (TM) treatment. However, they observed a lack of composite indicators used exclusively for TM performance measured globally by official institutions. Cătălin, Sorin-George and Răzvan (2017) investigated the evolution of the GEI in the top ten countries between 2015 and 2017. The authors found an absolute dominance of the USA and the growing presence of European countries. Szerb (2017) examined the possibilities for developing Hungarian entrepreneurship with the help of the GEI. The author identified the following weaknesses in the Hungarian entrepreneurship ecosystem: opportunity recognition, product innovation, financing and competition.

The empirical literature revealed a number of important insights, such as the scarcity of studies on the results of the GEI. However, not a single study investigated the relationship between attitudes, abilities and aspirations in the entrepreneurship ecosystem.

3. Methodology

This is a quantitative study based on documentary research. Information on the sample design and empirical strategy is provided in the following sections.

3.1 Sample Design

Our sample was constructed based on the availability of the GEI sub-indices (attitudes, abilities and aspirations). The sub-indices are available in the Global Entrepreneurship Network (GEN) annual reports, between 2011 and 2017. However, the current year GEI is always based on country data of the previous year. Thus, for estimation purpose, we decided to lag the GEI sub-indices by one year (2010 to 2016). Table 2 shows that the first year of the GEI covered only 71 countries, increasing significantly to 137 in 2016.

Table 2: Number of countries mapped by the GEI that presented the results of sub-indices

Countries covered by the GEI	2010[1]	2011[1]	2012[1]	2013	2014	2015	2016
Total	71	79	118	120	130	132	137

Source: The authors. 1- Note: The GEI data for 2011 to 2013 correspond to the previous version (Global Entrepreneurship and Development Index), which varied between 0 and 1. To reconcile the earlier version with the current one, the data for 2011 to 2013 were multiplied by 100.

Given the changes and discontinuity in the GEI structure, we decided to conduct the investigation using all available data (both time series and cross-sectional data). This resulted in an unbalanced panel. In addition to the GEI sub-indices, we control for some variables related to intellectual property, as follows: i) Gross Domestic Product Per Capita based on Purchasing Power Parity - GDP PPP international dollars based on the 2011 ICP round; ii) Number of scientific and technical journal articles Per Capita iii) Number of patent applications (non-residents and residents) Per Capita; iv) Number of trademark applications (non-residents and residents) Per Capita. These variables were obtained from the World Bank.

3.2 Empirical Model

Assuming high heterogeneity in the structural relationship across countries and the presence of unobserved individual characteristics, we estimate a quantile regression model with fixed effects in a panel data setting, as suggested by Dahl and Kristensen (2013). In addition to controlling for time-invariant unobserved heterogeneity, panel data quantile regression can assess the effect of a particular covariate across different quantiles of the response variable, which makes the inference more informative and robust.

Koenker and Bassett (1978) were pioneers on quantile regression. Koenker (2004) further refined the method, allowing its application for longitudinal data. According to the literature, there are still a number of limitations, such as including a large number of fixed effects and their influence on the conditional response of different quantiles. Powell (2014) also developed an estimator that addresses this problem and is unconditional of the fixed effects.

Bache, Dahl and Kristensen (2013) address the problem of assuming fixed effects in short panels (which generally occur if we attempt to forcibly balance a panel). The authors propose a solution using the correlated-random-effects (CRE) estimator, which controls for the possible (time invariant) dependence between the fixed effects and a set (or possibly all) of covariates. Since the fixed effects are not directly estimated, the distribution of the response variable, although conditional on the covariables, is unconditional of the fixed effects.

We estimate a CRE model following that of Bache, Dahl and Kristensen (2013):

$$y_{mt} = x_{mt}^{T}\beta + s_{m}^{T}\pi + \varepsilon_{mt}, \quad (1)$$

where m is the index for countries and t is the index for years. The time-invariant unobserved effects are controlled by the covariate vector s_m, constructible from repeated measurements of the time-varying covariates in x_{mt} (time-invariant covariates, such as geographic region, are not used to construct s_m). In general, s_m is constructed using the t-means (averages over time) of the time-varying covariates in x_{mt}. This allows for unobserved characteristics to correlate with x_{mt}. In addition, the unobserved effects can affect both the scale and location of the response distribution. The s_m vector enters linearly in the criterion function and the unobserved effects are allowed to vary with each quantile.

The model was estimated using log variables (coefficients are elasticities) and dummies to capture the particular effect of different regions on aspirations. The regions follow the United Nations criteria: EUR = Europe; NAC = North America; LCN = Latin America and the Caribbean; CSA = Central and Southern Asia; SEAO = Southeast Asia, East Asia, and Oceania; NAWA = Northern Africa and Western Asia; SSF = Sub-Saharan Africa. Table 2 shows that the number of countries in the GEI vary annually. Nevertheless, the estimator proposed by Bache, Dahl and Kristensen (2013) allows the use of unbalanced panels (s_m is constructed using the years available for each country).

4. Results

Table 3 shows the estimated results for all variables. In general, the effects of attitudes and abilities are positive and significant across quantiles (attitudes are not significant for lower quantiles and abilities are not significant for the 90% quantile). This result demonstrates the importance of attitudes and abilities in determining the aspirations of countries. Furthermore, the magnitude of the abilities effect tends to decline as we move from the left to the right tail, and it disappears on the 90% quantile. Thus, it is reasonable to assume the hypothesis that countries with different levels of entrepreneurial aspirations respond differently to their abilities. However, this cannot be clearly inferred with respect to attitudes, since there is an unexpected break in quantile 50.

The (observed) control variables captured some important effects on aspirations. It is important to highlight the significant and positive effect of GDP per capita between the 20% and 90% quantiles. GDP per capita appears to have a high elasticity in the right tail of the aspirations distribution. If we assume that GDP per capita is a proxy for economic development and that the aspirations sub-index is a proxy for entrepreneurship, the results confirm the hypothesis of Ács and Szerb (2009) regarding the relationship between entrepreneurship and economic development.

Although the positive result for patent applications filed by residents is expected (since resident applications may materialise into innovative products and processes that will be exploited by domestic individuals), we have a significant and negative effect for domestic applications on the 90% quantile. One possible hypothesis to be tested is that in countries with higher aspirations, competition for patents is so intense that it may reduce aspirations by discouraging incumbent inventors. As such, the competitive environment for patents is good, but perhaps not in excess. A similar reasoning may be used for the number of scientific and technical journal articles, which also exhibits an interesting negative effect in the right tail. Increasing scientific competition (proxied by scientific production) may reduce aspirations in countries that already have higher aspirations results (and thus, that have been experiencing a more intense scientific competition).

Patent applications filed by non-residents may also be reducing domestic aspirations because they are potential innovations that will be monopolised by foreign agents. This expectation may be causing a significant

negative effect for the lower quantiles. However, this effect tends to decrease as aspirations rise. Countries with higher aspirations may have a higher probability to protect themselves more efficiently against the impact of non-resident patents, and they may even absorb these prospective patents in favour of domestic entrepreneurship, which would alter the negative effect into a positive or insignificant one. Nevertheless, this argument implies that patent applications filed by residents and non-residents have a sort of opposite effect on aspirations when we move to the right tail. Furthermore, countries with low aspirations may be correlated with "inefficient" domestic patent offices that haver a large Pending Patent Backlog in comparison to the patent offices of countries with higher aspirations (USA, Canada, Europe, etc).

Source: the authors

With respect to the regional dummies (relative to CSA - Central and Southern Asia), we find a significant and positive effect of the European continent on aspirations only at lower quantiles. The effect eventually declines and becomes negative between the 70% and 90% quantiles, reflecting the decrease in entrepreneurship aspirations in countries that already have better results for this sub-index. This requires the adoption of new and specific policies to reverse the declining trend in the entrepreneurship aspiration results in Europe, as reported by Szerb, Komlósi and Páger (2016). The Latin American and Caribbean region also produced an overall reduction in aspirations.

5. Concluding remarks

Our study aimed to assess the linkage between abilities, attitudes and aspirations on the entrepreneurship ecosystem, as measured by the Global Entrepreneurship Index. It was found that the sub-indices of attitudes and abilities have a positive but heterogeneous effect across the quantiles of the response (aspirations) distribution. We found, for example, that the entrepreneurship abilities contribute more to aspirations at lower quantiles, in comparison to the smaller effect found at higher quantiles.

In general, the effect of the control variables is asymmetrical across the conditional distribution of the response variable. We understand that more specific investigations are needed in order to analyse some controversial results. It would be particular interesting to investigate the negative relationship between aspirations and the variables that proxy intellectual property rights. Additional methodological approaches, such as using a dynamic model and controlling for other institucional variables, may provide a significant contribution to future studies.

This study contributes to the discussion by presenting evidence that entrepreneurial activities and the quality of new enterprises indirectly impact on economic growth captured by aspirations. The results require the attention of public and private authorities and Economic development agencies since aspirations can be maximised by improving attitudes and abilities in the entrepreneurship ecosystem.

Acknowledgements

We are grateful for the support given by the State Agency to support Research and Technological Innovation of Sergipe (FAPITEC/SE) and the Coordination for the Improvement of Higher Education Personnel (CAPES/BRAZIL). The authors also thank László Szerb (one of the creators of the GEI), University Professor at the Institute of Business Administration, Faculty of Business and Economics, University of Pécs, Hungary.

Abstract: Musicians are entrepreneurs, despite a lack of specific literature treating them thus. Musicians take the risk of launching themselves as performers, often with very little to fall back on if it does not work out. Musicians are not accustomed to creating a business plan for their careers and, more generally, lack an understanding of business models and financial investments, as often the return for hours of individual practice is simply not cost-effective. Many musicians also have careers in teaching, juggling a mix of music-related activities to make ends meet. Music is a life of passion and not one where riches are expected to flow. Additionally, at a time when the pressure to perform well is increasing daily, due also to added competition, and with performing musicians starting their music studies and careers earlier and earlier, at ever more tender ages, the probability of suffering a severe injury during one's career is exceedingly high. This research intends to discuss a process of prolonging careers and minimizing injury, while also maximizing performance, by way of leveraging technology. Research is in fact lacking linking classical music to technology, and this study shows that a biomechanical approach can produce significant changes in the hand position over the violin. All violinists and violists face the difficulties of playing on a non-symmetrical instrument, which makes it quite easy to create wrong postures and techniques. Retroreflective markers were placed on the joints of the left hand, and their movement during violin play captured by a MoCap system (Qualisys AB, Sweden) operating at a sampling frequency of 200 Hz. A violinist was asked to play a score (A1) using his usual playing technique and next to perform the same score using the enhanced technique (A2). The resulting data was analysed in the Visual 3D software (C-Motion, USA) in order to extract relevant parameters and metrics. Very positive and encouraging results were captured. The enhanced technique seems to allow the violinist to play the same score with less tension in the hand, with greater amplitude of the fingers, and a more natural position with angulations closer to the natural ones, allowing to play faster and with smaller pattern deviation, and so with more precision.

Keywords: performance, injuries, violin, excellence, technique, music, scientific innovation

1. Introduction

Should musicians become experts at marketing their own work and product (Teixeira et al., 2018)? How many musicians actually become products with exponential valuations (Au-Yong-Oliveira et al., 2018)? What training on internationalization should musicians receive (Oliveira et al., 2012, 2013)? Should musicians solely focus on improving their product and their performances – practicing hours on end? This article is about the latter, rather than about teaching musicians basic business and marketing expertise.

This is not the first time that top performers in their chosen area have turned towards anatomical aspects of their professions and techniques in order to improve their performance and to explain positions of excellence.

For example, in golf, the late Ben Hogan, one of the all-time golfing greats, was a pioneer in linking certain anatomical movements to excellent golf swings. Movements such as pronation and supination, of the forearms, were words introduced into golfing language by Ben Hogan as Ben Hogan did a full analysis of the body, linked to golf. Hogan published the ground-breaking book entitled: *Ben Hogan's five lessons: The modern fundamentals of golf* (Hogan, 1957). In this book, there is one whole chapter dedicated to how a golfer should grip the golf club. In proportion to the whole length of the book (which only had five chapters, the last being a

summary and review), this was very significant. Much as with this study, the concern is with the basics and the fundamentals. This study is also concerned with the placing of the left hand on the violin, much as Hogan (1957) dedicated much of his work to how to grip the golf club.

Only those who put tremendous effort into practice may reach a point whereby they are able to question certain modes of functioning which have been taken for granted for centuries.

Pianists, for example, are known to have injuries linked to excessive practice. Certain musical compositions have even been written for one hand only, so that pianists do not have to stop playing entirely. With the violin it is not possible to play with only one hand. Thus the importance of this research – to aid in increasing levels of performance, while diminishing the number of injuries incurred.

A single violinist participated in this study (the lead author) since the new technique under development was of his authorship, and therefore he was, at the time, the only expert available. The lead author of this study, an expert violinist, first played a score (A1) using his usual playing technique and then performed the same score using the enhanced technique (A2). The resulting data was analysed in the Visual 3D software (C-Motion, USA) in order to extract relevant parameters and metrics such as the flexions/extensions and abduction/adduction angles of the fifth finger (little finger), as well as the frequency of movement during the fast phase. The enhanced technique allows the violinist to play the same score with less extension and flexion of the fourth finger and at the same time promoting its adduction. This allows the finger to be kept at a more natural position, and by decreasing the abduction it releases some tension in the surrounding muscles.

This study is a small part of the doctoral research being undertaken by the lead author. It includes some of the major points raised by the research as well as some of the images used to portray and explain the anatomical issues involved. In the lead author's own words, during over twenty years of an intense and passionate career linked to the violin, a number of curiosities and queries have arisen, which have subsequently motivated analysis. As a student, then a performer, and later on as a teacher, several frailties linked to generalized problems of violinists and violists have been discovered. Time has been spent with students / violinists of all ages and in what may be considered an intense way. As a performer, and so from a more personal perspective, and having worked in several orchestras, done symphonic and opera programmes, performed recitals and solo performances with orchestras all over the world, the realisation is that there are several limitations on diverse levels, which have provided the motivation to seek more in-depth solutions, from a more scientific and provable perspective. Below, a set of problems and circumstances which originated this research project will be discussed.

One may well adopt the perspective that musicians are entrepreneurs, who depend on their talents, initiative and efforts to make a living in their chosen profession, as their own bosses – which will often benefit greatly from a passion for music, in its many forms. Being able to practice longer and while also avoiding injury is considered to be a major breakthrough in music and for the musician-entrepreneur. To analyse performance in a laboratory, as described herein, is also a form of innovation, so essential to the entrepreneurship process.

2. Literature review

2.1 Innovation

"Innovation enhances employment and society through its improvement of competitiveness" (Oliveira et al., 2008, p.353). Musicians as entrepreneurs also depend on innovation to achieve desired success rates. Innovation for performing artists is linked to how they convey their message and to novel ways of interpreting musical scores (their degree of passion, how they dress, how they move their bodies to capture the attention of audiences, among others).

Educational innovation is innovation (Au-Yong-Oliveira et al., 2015) pertaining to educational contexts (Moreira et al., 2017) and may be seen as innovative activities undertaken to improve the learning experience, including across national borders (Spyrtou et al., 2018). This research paper pertains to this category whereby the objective is to improve advanced performance learning of the violin following an innovative form of analysis using technology.

The current research may also be named research pertaining to high performance work systems (HPWS), as discussed by Zhu et al. (2018), where an entrepreneurial orientation has a positive effect on the outcomes achieved, indeed as should occur in a teacher–student relationship.

We consider that the teacher and the quality of the learning experience may greatly contribute to the attainment of competitive advantage, by students. When students are competing at the international level as well as in other performances, as musicians, and aimed at the general public with an interest in high-performing artists and, in this case, classical music, their mentors, past and present will have had a tremendous effect on how well they are able to perform.

A sustainable competitive advantage will exist when a student may practice and study his or her instrument for a longer period of time without incurring an injury due to excessive practice and while maintaining exceptionally high levels of performance while doing so. This article shows how this may be possible.

2.2 Muscle Diseases in Musicians

Regardless of the instruments used, the left wrist is till the body zone most affected by musculoskeletal problems (Frank & Muhlen, 2007). Between the various groups of musicians studied, most studies point to string players as those with a higher prevalence of musculoskeletal problems. In addition, when comparing the two arms of violinists and violists, they also demonstrate that those groups have twice the prevalence of muscle disorders in the upper left limb compared to the upper right limb. This can be justified by the fact that the right-hand flexors do not have great mobility, only having the task of holding and controlling the movements of the bow.

Moraes & Papini (2012) argue that the great majority of musculoskeletal problems in violinists and violists stem from technical inaccuracies or muscular tensions that violinists develop in the performance of their instrument in a specific passage or in a more generalized approach. Both advocate that the amount of force, coordination, speed and fine motor control required in the daily performance of the instrument done for hours, added to a poorly conscious or even incorrect technique, can effectively lead to quite serious musculoskeletal problems that can result, in the last instance, in the termination of all such professional activity.

Work-related musculoskeletal disorders (WMSD) are common in the upper limbs and in the spine vertebrae associated to the various professions in which physical movements are very repetitive, such as the study and performance of string instruments (Sousa, 2010). One is able to enumerate a list of inflammatory and degenerative diseases, associated to repetitive movements, muscular overload and incorrect body posture that result in professional risk factors (Zaza, 1998).

2.3 Violin Methods

The entire literature regarding the violin, which includes methods, and other documents such as theses and literature on the performance of the instrument and its technique, is quite diverse and is based essentially on three different approaches. The first deals with purely technical aspects through a simple theoretical explanation of the various competences and how to develop them: placement of the violin, placing of the hand on the bow, operation of some types of bow strokes, vibrato and its development, improvement of the tuning and coordination, and issues such as left-hand functioning, vibrato, double stops, finger placement, thumb and others (Fischer, 1997).

The second type of approach deals with more meta-theoretical and generalist issues concerning the life of a violinist, his career as a recitalist, orchestra musician or soloist, psychological questions about performance and attitude on stage, such as studying and others.

As for the third type, it can be said that from this vast and diversified conceptual body of the violinist domain and property, there is a much more practical and musical literature, composed essentially of technical exercises and small musical excerpts. Most of the time, these examples and various exercises are accompanied by short technical explanations, points strictly essential to anticipate and take care of, and aim at the gradual development of a certain skill or technical difficulty.

These are the technical aspects most recurrent in the approaches of these instrumental manuals, distributed mainly, in the different tasks and competences of the left hand:

- Tuning
- Change of position
- Position and action of the fingers on the string (pressure and speed)
- Arpeggio scales
- Fingerings
- Chords
- Double stops
- Finger patterns
- Ornaments, articulation, pizzicatos
- Harmonics
- Vibrato
- Independence and finger speed

The technical evolution and awareness of the various violin methods written throughout history has been increasing exponentially. This has led to increasingly virtuous and demanding compositions and technical issues. In turn, and in order to accompany and aid this compositional evolution (that translates into more complex violin techniques), the ability to describe its operation has also increased. Also, on the detailed functioning of the left hand, there are some authors who have approached the theme of "finger patterns" such as Gerle (1983), Primrose (1960) and Bang (1919) who explain in a schematic and rational way different combinations between the interval distances between fingers which facilitates the operational mechanic of the left hand.

None of these methods deal with the prism of the biomechanical and anatomical functionality of the left upper limb, adapting it to the mechanical properties of the violin and to the different technical challenges involved.

On the other hand, and from a scientific point of view, recently a lot of research has been done on instrumental performance and in the field of biomechanics. However, the existing studies focus primarily on electromyography and on the right upper limb. Studies on the left upper limb, which in violin performance is highly demanding along the dimensions of strength, precision, and biomechanical efficiency, are rather sparse.

2.4 Anatomy and specific properties of the left upper limb

The intrinsic muscles of the hand are mostly responsible for digital adduction and abduction. With these movements, which allow individuals to tighten the fingers holding a sheet of paper between them or to separate the fingers fully, the intrinsic muscles interlock the lumbricals and the abductor muscle of the little finger.

The muscles responsible for the flexion and extension of the digital phalanges have their origin in the arm and not the hand (Magee, 2002).

One of the most relevant anatomical-functional features of the hand to be considered for this study is digital movement. The intersection point of the metacarpals and phalanges, which results from the digital rotation at the moment of the flexion of the fingers, is shown by the condyloid joints (Gardner, Gray, & Rahilly, 1978). At the moment of the flexion of the fingers these touch in the center of the palmar zone.

2.5 Entrepreneurship

Entrepreneurship and economic growth and development are related, according to the literature (Velilla et al., 2018). An additional connection may be made between entrepreneurs and being one's own boss. "As Schumpeter (1934) said, innovation signifies entrepreneurship; and Drucker (1985) defended that innovation and entrepreneurship go hand-in-hand, all successful entrepreneurs are committed to systematically practicing innovation" (Oliveira et al., 2008, p.354). Herein, we see an example of a musician innovating.

Innovation, or pioneering in some aspect relevant to society, and putting it into practice, is an essential part of entrepreneurship. Musicians are entrepreneurs who depend upon themselves and on their ability to perform

to be able to make a living. To be able to perform for as long a period as possible, without suffering injuries due to excessive practice, is an objective that this study seeks to promote.

Much as Mark Zuckerberg, the entrepreneurial co-founder of Facebook, who sought to bring a new mode of interacting and communicating to society, so do musicians also speak a global language understandable by all, whatever one's cultural background. Music speaks a universal language and needs no interpreter, as do images and videos posted on social networks such as Facebook and YouTube. Musicians attempt to give their own interpretations to often centuries-old creations, innovating once more; likewise, entrepreneurs in the technological world try to reinvent something which has been done for centuries by men and women around the world.

Musicians, though being self-employed, and thus entrepreneurial, do not pursue or otherwise receive training on how to run a business. All business activity is focused on improving the product – namely, their performance. Perhaps in the future we shall see musicians attending business and management courses, with the objective to be able to boost their careers further. Besides planning, one might foresee that such training may also involve how to choose a recording label, how to negotiate recording contracts, and how to develop relationships with music agents and other stakeholders in the music industry. Consumer segmentation and targeting may also be of use, as musicians seek out those most interested in their genre. A digital marketing competence may be deemed essential – as musicians seek to be heard by a larger audience over time and leveraging social networks in the process. To date, however, all training is, as mentioned above, mainly product-oriented, and this study follows a similar line of thought.

3. Methodology

The purpose of this research is to identify techniques that offer potential improvements in technique that may prolong careers and minimize injury. The method used was that of an experiment – and the 3D motion capture Qualysis was chosen (chosen over a number of others, a choice which took around one year), given its ability to measure in great detail the most sensitive variation of the position regarding angulation and height of the hand in relation to the scale of the violin, and to be able to analyze in a subtle form all the biomechanical functioning of the left hand. In addition, it allows to relate data and results of different parameters and in the three axes X Y Z that correspond to the three axes of the movement of the various joints that would be analyzed, as can be seen in the following image (image 1). The subject of the experiment was the lead author – due to availability and to convenience.

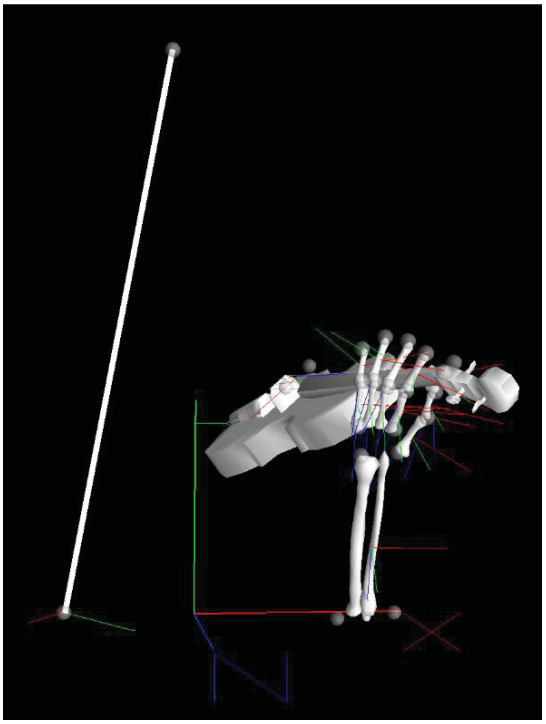

Image 1: Markers and vector system on the X, Y and Z axis (three dimensions)

A set of very practical and intuitive exercises were determined in order to eliminate the repetition variable as a way to increase the type of preparation in the execution of the exercise. The main objectives were to:

1. Analyze the mechanical behavior of the hand, with different heights, on the same string, in relation to the point of contact with the violin arm, in the same position and with the fingers on a single string.
2. Understand the behavior of the fingers, hand and the wrist, with different angulations, in the same position.
3. Analyze and compare the position of the hand in the different possible interval openings between the index and little finger, taking into account the height and the angle of the hand in relation to the violin arm. Intervals can range between perfect 4th intervals, perfect 5th intervals, 6th minor intervals.

3.1 The Types of Exercises

These were:

3.1.1 A1E and A2E exercises

Image 2: Musical exercise used for the A1E and AE2 execution

The first exercise was performed with the hand in a considerably high position, thus with a smaller distance from the metacarpophalangeal joint in relation to the violin arm, called A1E. The second exercise was performed with the same musical stretch but with the hand in a lower position, therefore with the most distal joint of the scale, called A2E.

3.1.2 A1G and A2G exercises

The two following exercises were performed on the G string since we wanted to compare a more centered / natural position and a considerably low hand position with a considerable distance from the metacarpophalangeal joint to the fingerboard edge, which would not be very feasible on the E string.

Image 3: Musical exercise used for the A1G and A2G execution

The exercise performed with the hand in a low position in relation to the violin arm was named A1G and the exercise with the hand in a slightly higher position and a more natural height for the G string was named A2G.

3.1.3 B1 and B2 exercises

These exercises were performed with longer intervals and the angulation variation in the biomechanical functioning of the hand was analyzed. Thus, the following exercise was performed with a small angulation in B1 and with a greater angulation between the metacarpophalangeal joint and the fingerboard in B2.

Image 4: Musical exercise used for the B1 and B2 execution

3.1.4 C1 and C2 exercises

The exercises were performed on the G string, but with a bigger interval, from the 6th to the lower. The first was performed with a small angle of alignment of the metacarpophalangeal articulation in relation to the fingerboard edge in C1 and with a steeper angulation at C2.

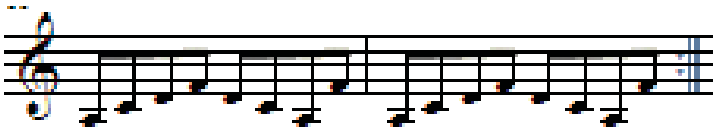

Image 5: Musical exercise used for the C1 and C2 execution

With the help from Engineer Pedro Fonseca, responsible for the development of the scientific research process in Labiomep (one of the most advanced biomechanics laboratories in the Iberian Peninsula in the analysis of movement), we consider the following procedures in the data collection process:

- Each exercise should be repeated three times to give consistency to the results.
- Each one of the exercises would be started with a metronome-controlled speed at 60 beats per minute, so in one second 4 notes would be played, and for about 5 seconds.
- Immediately in these initial 5 seconds, the same exercise was concatenated, but executed as quickly as possible, for roughly during the same time.

3.2 Execution norms

For each of the exercises, small musical excerpts, or sequences of notes, were written with the desired interval for each of the exercises. In order to analyze specific parameters in the arm and left-hand mechanism, some variables were altered in a controlled manner, but each one was repeated three times in order to obtain more credible values, creating graphs with averages drawn in a precise line, and also in order to get data such as regarding repeatability or standard deviation in a shaded area.

Within each attempt, this was divided into two different sections. The first was controlled metronomically with time at 60 beats per minute and for 5 seconds. The second part was immediately concatenated and for about the same time and was performed at the highest possible speed.

3.3 Sample

The initial sample used (made up by twelve participants) was as diverse as possible in terms of age (with participants born between 1983 and 2002), gender (with five female and seven male participants), technical training, different body compositions and different hand morphologies. However, the results were not very encouraging, since not all were able to perform the proposed exercises with the correct proposed changes of the variables, leading to a considerable standard deviation, without great consistency and regularity in the graphs. We realized that since each of the exercises had to be repeated three times, so that there could be better control of the results with the parameters we had asked to change and fix (a specific hand height or very particular angle of the metacarpophalangeal joint), at the end of the second and third attempt, these values were already different. This made it impossible to analyze the results with a broader level of participants.

Therefore, we considered that this scientific project should focus on only one individual. After a brief analysis, the individual who demonstrated more regularity in the results and greater control of the indicated variables was the lead author of this scientific project. Thus, it was decided with Professor Rui Garganta and Pedro Fonseca, that it would be best to analyze the detailed biomechanical functioning of an individual to better understand the relation of the altered variables in the left hand's biomechanical functioning and concerning performance. Thus, this experiment has shortcomings as one admits that there is much variation between individuals when playing musical instruments such as the violin. People have different physical makeups and adapt to different techniques in a unique way. Albeit, we still share the perspective that the experiment is useful in determining potential improvements in violin technique.

4. Discussion

This chapter intends to continue the discussion of the results but now on an inter-relational plane between the various exercises. It is intended to meet the initial problem and the questions elaborated at the beginning of this scientific project, pondering the results obtained from the observations.

The images (6-9) below demonstrate the strenuous positions that the left upper limb is put in in order to play at the highest level.

Image 6: Left upper limb position 1

Image 6 shows the point of contact changed, on purpose, in exercises A1 and A2 (in images 2 to 3), above, between the line of the fingerboard and the proximal phalange of the index finger. This has to be done to play a certain string and in a certain way, to the level of excellence; the distance has to be exactly right, done purposefully.

Image 7: Left upper limb position 2

Image 7 shows a different point of contact (compared to image 6), between the fingerboard and proximal phalange. As it is the biomechanically most efficient position in the E string, the metacarpophalangeal joint articulation is more distant from the line of the fingerboard than in the upper image (image 6), in G string. This position may originate awkward and wrong positions of the left hand, fingers and wrist and is not easily attainable. Albeit, the correct position is very important, and if incorrect a number of lesions may result. With the methodology followed in this study the software showed that image 7 has the correct position to avoid lesions. Image 7 is the natural correct position. Incorrect positions lead to slower, less efficient playing, more prone to error, and less regular finger articulation (as shown by the standard deviation detected and captured by the specialized software); as well as a greater tension in the hand, as detected in this study.

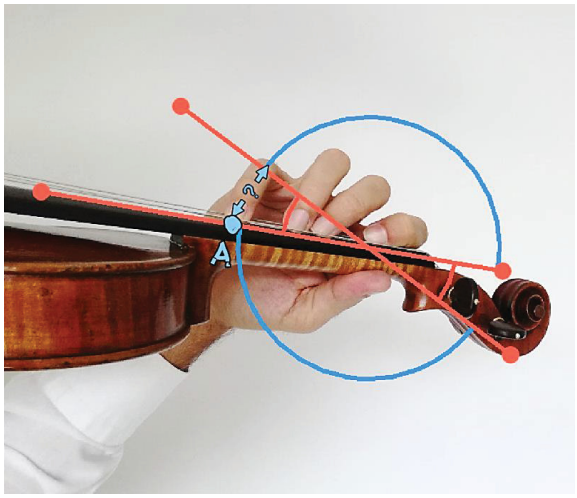

Image 8: Left upper limb position 3

Images 8 and 9 show the parameter studied in exercises B and C (images 4 and 5 above). As demonstrated, a different angulation between the metacarpophalangeal joint and the fingerboard, determines the position of the attack of the finger on the string, considering a natural and non-tense position of the hand. Of course, if one wants to attack point A (image 8) with a flat angulation of the metacarpophalangeal joint, one must tense the little finger to abduct as much as possible, to reach point A (image 9). As is shown in image 9, without finger tension and a flat angulation of the metacarpophalangeal joint and the fingerboard (the red lines, captured by the MoCap system – Qualisys AB, Sweden), the natural point of attack of the finger is point B, the wrong note, or the note not desired by the exercise.

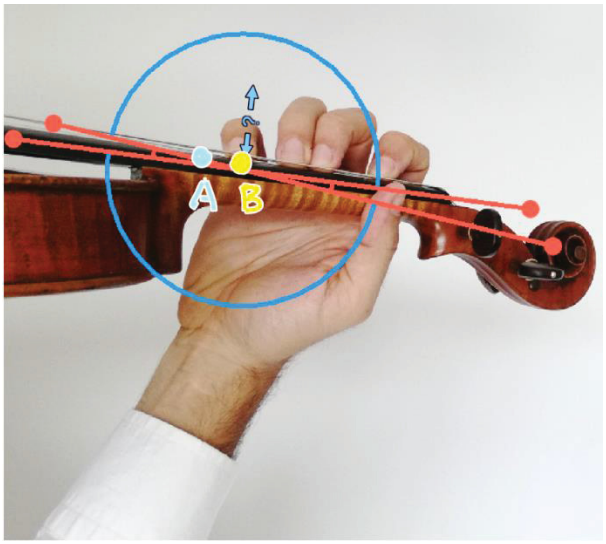

Image 9: Left upper limb position 4

5. Conclusion

Give that there are orchestras (including the famous Gulbenkian orchestra, in Portugal) with up to half of their musicians on sick leave, at any given moment in time, which represents a tremendous expense for the orchestras in question, this study could not come at a better time. In the intervals of some orchestra rehearsals (rehearsals which may go on for up to 7-8 hours at a time, for several days, before a major performance at a major venue), such as the Vienna Symphony Orchestra, there are certain group postural exercises aimed at the musicians (e.g. Pilates workouts, stretching exercises, posture exercises, and / or weight training). What our study is emphasizing is that the technique adopted – correct or incorrect – will have a very significant effect on the quality of the music produced as well as on the longevity of the musician-entrepreneur.

All violinists and violists face the difficulties of playing on a non-symmetrical instrument, which makes it quite easy to create wrong techniques. Scientific research on the left hand is very sparse. The approach described herein is unconventional and scientifically and anatomically based.

A scientific methodology was developed, composed of some simple and repeatable note patterns, and this performance was analyzed in 3D by a MoCap system (Qualisys AB, Sweden) that operates at a sampling frequency of 200 Hz, capturing the positioning of retroreflective markers on the joints of the hand, wrist, left forearm, violin and bow.

The influence of the height and angulation of the hand in relation to the violin arm at different amplitude intervals was analyzed, at both regular and fast execution speeds.

The resulting data were analyzed using Visual 3D software (C-Motion, USA) to extract relevant parameters and metrics such as flexion / extension and abduction / adduction angles on the wrist, index finger and little finger, and the relative position of the hand to the violin arm, as well as the frequency of movement during the fast execution.

The enhanced technique seems to allow the violinist to play the same score with less tension in the hand, with greater amplitude of the fingers, and a more natural position with angulations closer to the natural ones, allowing to play faster and with smaller pattern deviation, and so with more precision.

This study thus deals with the biomechanics of the left limb; 3D motion analysis; MoCap Qualisys AB; angulation and level of the metacarpophalangeal joint; an application to a virtuoso program; and an anatomical functional model.

Much as with entrepreneurs, musicians cannot interrupt their playing and practice (equivalent to interrupting the sales and source of revenue of any regular enterprise) at any point in their careers, especially not for long periods. This article and study is part of a doctoral research project and seeks to give a view on what the research project involves. The end result aims to be the longevity and general good health of musicians – in this case, violin and viola players.

6. Suggestions for future research

The lead author has had significant contact with a number of elite performers during his career. Many top athletes, in Portugal, from sports as different as the martial arts, golf and soccer (football) complain that, after many years of practice, arduous training and competition, they have acquired lesions and injuries that affect their quality of life. Some are on medication, and are postponing having operations to have artificial bones put in (knees and hips, mainly). Others have already had operations – one Portuguese martial artist expert has two "new" artificial hips. World-renowned golfers Jack Nicklaus and Tom Watson have had new hips put in. The former had both hips replaced, the latter only one. Therefore, when a former President of the Portuguese Republic, when asked about what the secret to his longevity was, answered "Sport! I never did any!" this may not be surprising. What this article has discussed is a new technique to help avoid lesions when playing the violin at an advanced level. It would be interesting to interview sportspersons and musicians to ascertain just how much they were forewarned by their teachers about such health hazards and if they would have acted differently if they had had the chance. Furthermore, what do they think of a research program to help avoid lesions for violin players? Finally, more musicians need to be involved in the experiment described herein, in order to confirm the results obtained.

Abstract: The market's evolution and ever-increasing competitiveness forces organizations to find new ways to reinvent themselves. According to the principles of the Service Dominant (SD) Logic, it is argued that Service Innovation depends on the participation of all the direct actors in any given organization, focusing on its employees as key elements for delivering the brand promise made to the consumer, regardless of any eventual direct contact between them. The success of organizations relies on their growth capability and, for this reason, the measurement of investments is fundamental to the business strategy. Thus, the tangibility of the Internal Brand Management (IBM) is essential in management decisions, only possible through the construction of Key Performance Indicators (KPI). Given the intangibility inherent to the processes of brand building, brand promise delivery and service co-creation, which are directly dependent on the definition of the business strategy, the present article proposes a method to create KPIs with the aim of understanding the alignment of employees in relation to the business strategy. Based on a literature review, which corroborates the relevance of the theme, a case study is presented on a multinational Business-to-Business (B2B) organization. Using a mixed methodology, the research is divided into two moments: 1) A qualitative analysis which a) Identifies the strategic categories of the organization being studied, b) Evaluates the focus given to those main categories through the most important internal brand dissemination documents and c) Organizes the Employee Satisfaction Questionnaire based on those same categories; 2) A quantitative analysis to evaluate the results of the alignment of the Employee Satisfaction Questionnaires' answers with those strategic categories previously referred to for the period 2011 to 2017. Therefore, it is suggested that all organizations have tangible information that allows the identification of KPIs to serve IBM. However, traditionally, there is no objective systematization of these indicators, which could lead to the measurement of the employees' alignment under this perspective.

Keywords: Service Innovation; Internal Brand Management (IBM); Key Performance Indicators (KPI)

1. Introduction

Building a business nowadays has exceeded the simple assumption of production of goods, a vision once vital in a society whose only purpose was to satisfy its basic needs. This evolution has become crucial to the growth of organizations by enforcing the adaptation of the industry's supply, from a traditional concept of production of goods to a solution of "extended product" where intangible resources, co-creation of value and relations prevail (Neely 2009; Vargo & Lusch 2004). The product is, therefore, by itself, a "service distribution vehicle" and an object to deliver "satisfaction of higher order needs" (Vargo & Lusch 2004). Vandermerwe and Rada (1988), quoted in Neely (2009), introduce the concept of «servitization» of production "in order to consolidate the paradigm shift from simple product-centric business (PCB) to "PCB's Service" («adding value and adding services») (Raddats & Easingwood 2010). Organizations have become «living beings» whose mutation is mandatory for their survival. As stated by King & Grace (2010) there *"can be no denying that in today's competitive and fragmented market, competitive advantage realized through tangible, functional benefits, is no longer sustainable."*

Organizations applying this management concept to create competitive advantage (Raddats & Easingwood 2010) aim to index their products to a set of benefits that set them apart from those of the competition. This corroborates the idea that value creation in services depends on the way the organization's resources are effectively distributed between the promotion, execution and outcome of the service process (Grönroos 1998). The creation of value and the delivery of promise by the organization thus take place transversally, involving all the actors of the organization and, as a consequence, all these points of contact influence the opinion and therefore the level of satisfaction of the consumer. To Grönroos (1989), marketing is dispersed in the organization, moving out of its borders and emerging somewhat throughout the organization, particularly in circumstances where the consumer can be influenced, both directly or indirectly.

Organizations can no longer focus exclusively on the issue of the production of goods and have evolved into more complex social structures, highly dependent both on their external environment and on internal critical mass. The organization as a whole has the responsibility to provide all the conditions needed to the production process, including development, design, manufacturing, distribution, sales and support activities (Grönroos & Ravald 2011). Given the multiplicity of nodes in the network of relationships under which business happens, it is critical for organizations to streamline their strategy so that their target audience may instantly identify everything they constitute to them, whether tangible or immaterial. "*Marketing can be viewed as the building, maintenance, and liquidation of networks and interactive relationships between the supplier and the customer, often with long-term implications*" (Gummesson 1991).

The Service is thus an experience by which the consumer is part of the production process, allowing him to withdraw the benefits sought (Vargo & Lusch 2004; Grönroos 1998). Any industry always has this line of direct contact with consumers, whether it is a B2C (Business-to-Consumer) or B2B (Business-to-Business) organisation, and its purpose is to close the sale effectively. The study of Gummesson & Mele (2010) introduces the relevance of creating a global theory about marketing in order to explain the process of co-creation of value, not only in the B2C context but also in B2B circumstances. The authors suggest that the premise of the topic should focus on the concepts of «A2A interaction» (Actor-to-Actor interaction) and on the «integration of resources». This line of contact presumes the construction of a relationship in which the empathy created between the parties assumes a role of enormous importance for the identification of the consumer with the organization. The Service, as a business logic, implies the facilitation of some interactive processes that support the creation of consumer value in their daily practices (Grönroos 1998). The role of the organization is, in turn, to create conditions so that consumers can generate the expected value (Grönroos & Ravald 2011), collaborating and learning with them and adapting to their needs (Vargo & Lusch 2004).

In any organization, the number of Part-Time Marketers (PTM's) far exceeds Full-Time Marketers (FTM's) (Gummesson & Grönroos 2012). The PTM is responsible for facilitating resources that enable the fulfilment of the promise of value creation conceived by the FTM (Grönroos 2008). Just as mentioned by Grönroos (1989), the different employees in the organization whose functions intervene in the Service orientation are considered as «internal consumers»: "*such internal customers have to be served as well as the ultimate, external customers are supposed to be*." In this sense, the aim of the present study is to evaluate the inference that Internal Brand Capital and, thus, Internal Brand Management (IBM) actions have on a group of employees and what is their involvement with the strategy, which is the point of origin of all the actions of an organization. The present research intends to promote a debate on the premise that "*all employees carry the brand promise regardless of their role and direct contact with the consumer*" (Grönroos 1989) as the fulfilment of the promises and commitments established between the parties shall be maintained if the relationship is to last over time. It is therefore intended to demonstrate the importance of the organization's investment in IBM under the assumption that its strategy and the success of its business model depends on the active participation of the employees.

2. Service Innovation and Internal Brand Management (IBM)

When thinking about Service the first reference comprises the direct interaction with the consumer and everything it constitutes, such as intangibility, heterogeneity, perishability and simultaneity. This is why we need to identify the required capabilities so that the means to implement the service will increase as firms shift their focus from PCB's to PCB's Service, as Kindström et al. (2013) refer. The authors also advocate that PCB's business model may provide opportunities, but this probability will not be enough to take the necessary advantage that service innovation has to offer. This reiterates the idea that the production of service is obtained in the co-creation process and it is made tangible by the goods associated with it.

In 2000, (Berry 2000) "*in packaged goods, the product is the primary brand. However, with services, the company is the primary brand*". This statement shows that a brand was a mere mechanism of product identification and a reference of a given producer. Nowadays, it is the vehicle for the transmission of ideas and the personification of the values of an organization as well as the tangibility of its business model strategy. Thus, the brand became the inevitable asset of the organization's sustainability, as it reflects its functional and emotional benefits (King & Grace 2010). Organizations, therefore, should focus on the brand's main lines that will allow them to achieve their organizational objectives. According to Keller & Lehmann (2003), and as already mentioned before, there are numerous contact points within the organization that affect brand equity,

and, therefore, the brand. The authors underline that every one of these individuals should be "*cognizant of relevant branding effects*", as they "*make different brand-related decisions and need different types of information*".

Consequently, the focus of organizations should rely on the importance of their brand, whereby the consumer builds relations that stimulate the sale and substantiate their repetition, thus enhancing the generation of value and the creation of financial assets for organizations. The brand could be considered as a «dead object» without conscience, and even the literature points out that it is not possible to provide it with an identity.

However, from the moment it functions as a set of values to be evoked, both internally and externally, the brand comes to life and its consciousness takes shape in its reflexive nature when considering the internal target groups of a brand, administrators and employees (Burmann et al. 2009). The literature refers to the importance of building a brand promise that allows the identification of the organization's brand positioning.

The relevance of the employees' participation in the delivery of the brand promise is vital if it is to be analysed by the consumers when delivering the organization's promise (Berry, 2000). According to the author, the employees' actions transform the concept of "*Brand Vision into Brand Reality*". To improve customer bonding, organizations should, therefore, invest in interaction capabilities as a means of increasing his/her attachment to the brand (Kindström et al. 2013).

Through the brand, organizations bring to the market not only the effective and operational business positioning, but also the meaning they intend to build in the minds of their target audience and the social ideas with which they commit. Chernatony (1999) refers to the Brand View and Culture as central elements that influence and are influenced by Positioning, Personality and Relations between stakeholders. This issue raises once again the importance of employees in the delivery of the service, because their actions will be translated into future perceptions by consumers about the brand in question. As is underlined by Piehler, Grace, & Burmann (2018), there is a paucity of scientific work within the thematic of IBM, even with the increasing interest in organizations.

The strategic choices of a business should point to some core characteristics of the organization's brand, because they will be the vehicle that allows all stakeholders, especially customers and employees, to create links of identification. Positive outcomes are more likely to emerge when employees recognize that the organization supports their work based on strong values and well-being programs (Lages & Piercy 2012).

Providing employees with a direction that influences their attitudes and behaviours ensures that tasks are performed with higher engagement with the expected performance and the organizational requirements (King & Grace 2010).

Chernatony & Cottam (2009) highlight three central departments in the construction of the brand, Marketing, Consumer Service and Human Resources, each one contributing differently to the brand's success. When we work in harmony and in synchronization with the business model it is more likely that employees are engaged with the brand and, whenever in contact with the customer, recognize the accomplishment of the promise they are looking for. Working together, the IBM programs will be more effective if they allow employees to determine how they shall construct their interpretation of the organizational brand, which will be translated into expected brand-related behaviours. Thus, IBM's goal is to influence the behaviours and attitudes of employees. As King & Grace (2010) state, "*to do this effectively, however, requires an understanding of how employees react and respond to such internal initiatives*" and "*this distinction is important because it is only through the evaluation of internal brand management outcomes i.e. employee attitudes and behaviour, that continued investment and enhanced internal brand management practices are to be realised.*"

3. Conceptual model - Internal Brand Management (IBM) Key Performance Indicators

The proximity to businesses anticipates the urgency of this issue and the relevance of the creation of effective value for organizations. Brand value measuring became paramount to the real understanding of the business model of an organization as it is, today, one of the more valuable assets despite its intangible form. "*Profitable brand management requires successfully designing and implementing a brand equity measurement system.*

Crucial to developing such a system is an understanding of how brand value gets created" (Keller & Lehmann 2003).

For this study, Piehler et al. (2018) underline the contribution of future research advocating the importance of IBM to the organization, as an intention to add value to scientific knowledge about the issue. First, aiming at validating the "*relevance of IBM for brand management and company success*", the case study intends to demonstrate that successful internal brand programs will ensure a stronger business alignment with the organization's stakeholders inside the firm and therefore a more likely increase / better financial performance. Secondly, the chosen organization is, as will be demonstrated further, an international B2B industrial manufacturing organization with a strong focus on the service area. Thirdly, it highlights that organizations build practical and pragmatic measuring instruments that allow the evaluation of the IBM investment. Finally, it is a purpose to provide a holistic view within the organization, as it is stressed that all IBM investment is part of a cycle beginning with business orientation and ending in its measurement.

4. Methodology

The main objective of the study is to provide companies with a new process of systematization and measurement of the strategic alignment of employees with the company. In this sense, a methodology is proposed for the construction of Key Performance Indicators (KIPs), aiming at allowing the measurement of the intangible component of the service from the perspective of the employees, according to the conceptual model previously exposed.

Similarly to the scientific work of the creation of constructs in the literature, the intention here was to apply the same process of model drawing to a pragmatic and real case study. Using a mixed research process, the proposed methodology was put into practice throughout the accomplishment of a case study composed of the following sequential steps (Fig. 1):

1. Qualitative research through observation and direct contact with the organization to identify the business strategy's main goals and change them into codes named, for this matter, as strategic categories (Leech & Onwuegbuzie 2007);
2. Indexation of employee satisfaction questionnaires into strategic categories, as established in the previous paragraph (King & Grace 2010);
3. Simple qualitative analysis of the most relevant documents of the organization's strategy communication to its employees, through word counting, with the purpose of quantifying the most relevant messages in the organization's discourse, without the interference of any interpretation by the research team (Leech & Onwuegbuzie 2007);
4. Descriptive quantitative analysis of the results of the employee satisfaction questionnaires, intending to measure the employees' alignment with the business strategy categories (Lages & Piercy 2012).

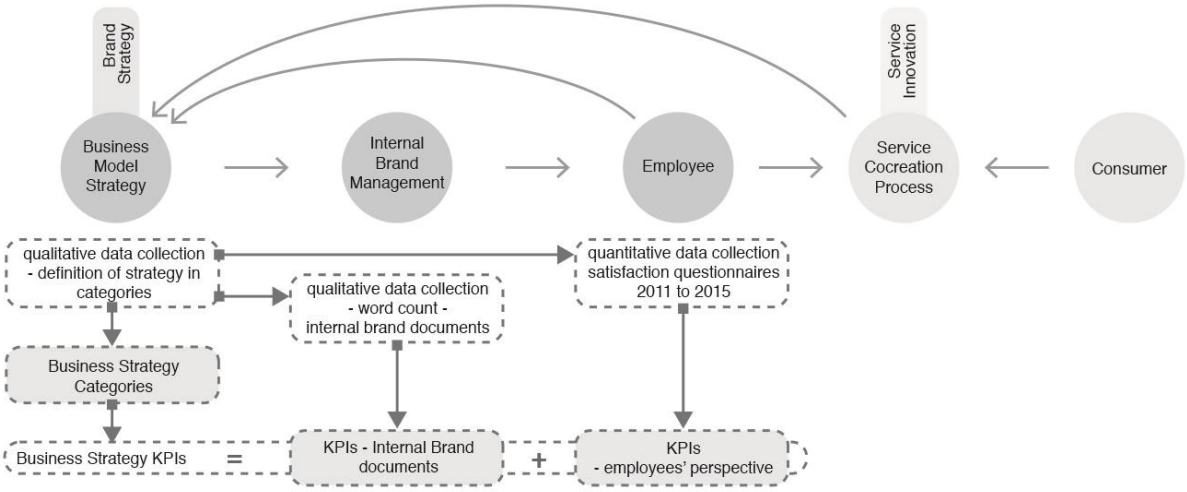

Figure 1: Purpose model

Given the claim of the present study to bring to the light of knowledge some pragmatic information, it was judged to be more realistic to approach the research using these tools rather than to construct other data collection instruments whose origin would only be supported by a bibliographic review. The ambition to contribute in a profitable and operable way to the daily life of the organization reiterates the choice for that data collection process and underlines the practicality of methodological decisions.

The organization under analysis operates in the construction sector with industrial production in the national territory since 1990. It is integrated into an international group of the same sector and positions itself as the world leader in its activity. Although being an industrial organization, it is based on the delivery of service and is focused on offering quality solutions with a close proximity to its customers as well as a close monitoring of their needs.

Consistent with the relevance of the study, it was necessary to find an organization that had a balanced investment in terms of time and operational and financial resources related to human resources programs, service customer and marketing program, which includes brand development. Therefore, we would be able to directly compare the results of each one individually and the alignment between them.

The primary reason for the choice of the organization under consideration is that it maintains this balance, but also equitably supports the strategic importance of the mentioned programs, aligns its tactical implementation on the ground with the organization's overall strategy and promotes the congruence between the actions and discourses of the mentioned programs.

4.1 Sample, Data Collection and Data analysis

The current research is based on a case study, where access to information is based on a close and long relationship between the researchers and the organization. This has enabled an extensive collection of information with the necessary reliability guarantee, obtained through the proximity with the elements that strengthen the validity of the researchers' empirical findings. The knowledge about the organization and the proximity with it made it possible to construct the strategic categories mentioned above.

On the other hand, the internal brand and strategy communication documents allowed the accomplishment of the discourse analysis through the counting of the more frequent words realized by using WebQDA software. We analysed the 500 most mentioned words with more than 3 characters. 18,02% of the words, amounting to 12.319 words out of a total of 68.374 contained in the documents, were considered relevant for the discussion. For the analysis, all words whose repetition represents 0.05% with respect to the total, which implies its use 34 times, were considered. From these, all words, such as verbs or adjectives, which would not allow a congruent interpretation given the breadth of meanings they could hold according to context, were removed. Below we can see the relevance of each strategic category in the formal discourse of the organization and thus understand which message should reveal a higher alignment by the employees.

Regarding the quantitative analysis, the sample included all employees holding a permanent contract with the organization from 2011 to 2015 (Table 1), who answered a complete questionnaire of 78 questions. The collection of data was of the responsibility of the organization and it was realised biannually in the last quarter of each year. It is important to note that the researcher did not interfere either with the questionnaire or with the data collection process. The questionnaires were organized through a Likert scale of 5 levels, as can be seen in figure 2.

Table 1: Sample Date

TABLE 1 - Sample Data	2011	2013	2015
Number of employees with contract	204	177	175
Number of responses considered valid	157	111	112
Response rate considered valid	76,96%	62,71%	64,00%

5. Findings

The result obtained is highly satisfactory from the management perspective, since the level of the employees' alignment is always positive in all categories if we consider that more than 80% of responses are positive. For this reason, the results below the typology of answers «agree» and «totally agree» are not considered for the discussion. To better understand the analysis of the results, a direct comparison is presented in Fig. 2 between the word count by category and the result of a quantitative analysis of the employee satisfaction questionnaires for the years 2011 to 2015.

The first relevant reference for the discussion concerns the investment in the brand held by the organization, given that of the total number of words considered the direct name of the organization's brand is referred to 895 times (1.31%) and the nominal associations arising directly from the brand adds another 672 references (0.98%), which makes a total weighting of 2.29% references (1,567). This leads us to the conclusion that there is a strong brand-level investment, although this cannot be corroborated by the quantitative study. In light of the experience gained, it follows that this conclusion may result in a positive response, but this can only be ascertained if research continues, as mentioned below with regard to future considerations.

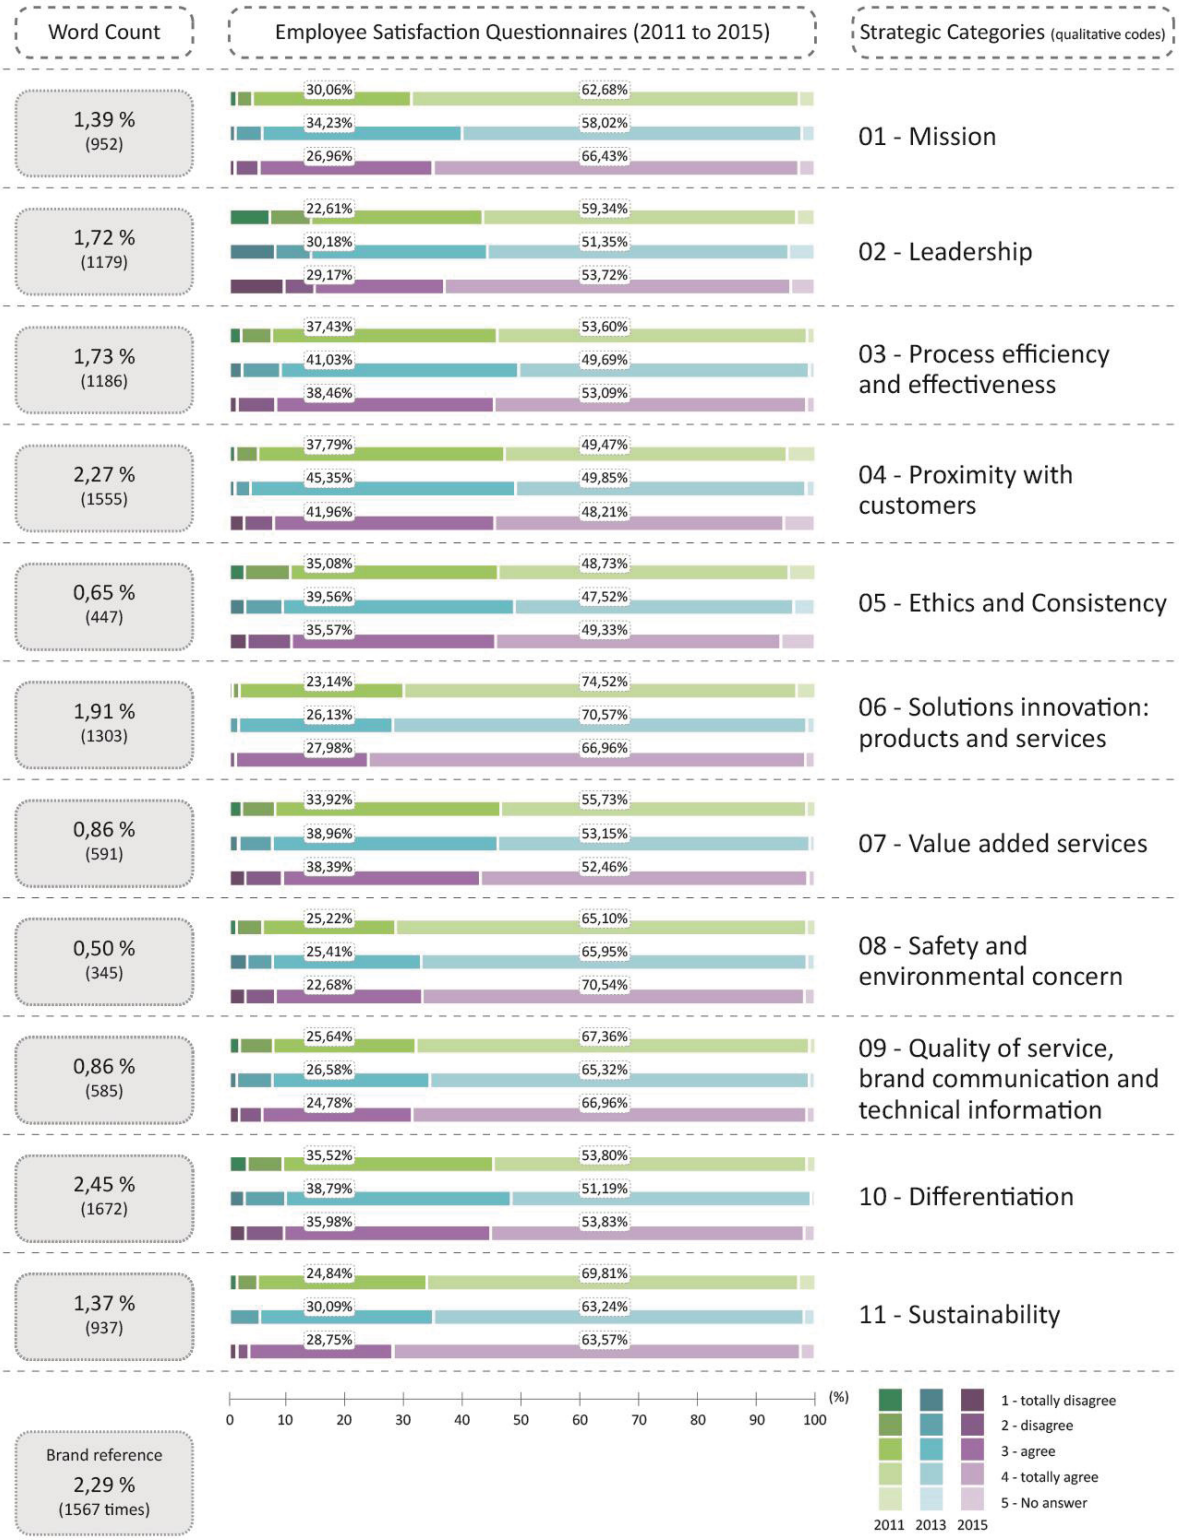

Figure 2: Findings – graphic summary

Regarding the relationship between the communication dialogue and the alignment of the employees related to the strategic categories, here are the conclusions of Figure 2:

1. There is congruence between the communication dialogue and the strategic categories «Mission», «Solutions innovation: products and services» and «Sustainability».
2. There is a discrepancy between the speech and the result in the category «Safety and environmental concern». However, this can be explained, since the internal communication documents related to this strategic category were not considered. It is known that the investment in this strategic category is high, both in time, training, communication and adaptation of industrial space. The purpose was to obtain a maximum reduction of risks and an improvement of the working conditions. The statistical analysis dates back to the year 2000, when the Frequency Index for accidents with and without casualties was higher than 50. Of the specific actions in this area, especially after 2003, a value of 0 was reached in 2016 for the same Index.
3. There is also a discrepancy in the category «Leadership», «Process efficiency and effectiveness» and «Proximity with customers» alignment and the communication dialogue. In relation to these categories, it will be interesting to probe and enquire why this happens.
4. The discrepancy between the communication dialogue and the category «Differentiation» can be explained by the fact that the documents used mostly come from the Human Resources department, since the objective is to evaluate the discourse of internal communication and the construction of categories is concretized at the level of an overall strategy. A more in-depth analysis is suggested of the documents in order to understand if this context is maintained.

Concerning the interpretation of quantitative data, it is possible to observe in all the strategic categories a decrease of «total agreement» (4) in 2011 to only «agreement» (3) in 2013 and a positive equivalent variation in 2015. This situation can be explained as was observed and accompanied by the researchers, by the strong decrease of the team size, considering the global economic crisis. During this period, particularly during 2012 and in early 2013, the organization was forced to cut its budget sharply, which has implied a contractual termination with a significant number of employees.

However, it can be observed that the category «Proximity with customers» has not changed over time, just as the «Ethics and Consistency» category has maintained a balanced result, even considering the above-mentioned economic crisis. The «Leadership» category, despite the recovery in 2015, did not keep up with the result obtained in 2011, as well as the categories «Solutions innovation: products and services» and «sustainability».

It is also possible to perceive that there is a strong orientation towards innovation, with «Solutions innovation: products and services» being the category with the superior result. The result of the «Mission» category is equally interesting, considering that it is not expected that many organizations will be able to achieve a total agreement result higher than 58%.

6. Managerial Implications and Conclusions

The article lists a wide range of literature areas whose relationships are relevant to management, particularly considering the relevance that IBM is acquiring within organizations, as well as in empirical research. The research allows us to conclude that the adopted methodology consents a monitoring of the investment made in each strategic area of the organization, which is corroborated by the overall congruence of the results exposed. Within organizations, there is a considerable amount of management-relevant data for all the different departments. Considering that IBM is merely a means of brand communication and organization strategy, we only need to find methodologies that may result in useful management data. The research presented offers managers a mechanism to understand which areas require an investment so that employees may align their behaviour with the purposes and guidelines of the organization. Thus, the present case study suggests a way of making the relationship between the business model and the employees' involvement more tangible.

7. Further research and limitations

One of the limitations of this case study involved the fact that it was not possible to influence the elaboration of the employee satisfaction questionnaire. Another limitation was the fact that the 2017 questionnaire was changed and new questions were introduced and others eliminated. Besides, it was applied with a different scale. For this reason, this survey was not included in the study. However, it would be interesting to incorporate the data in the future.

It is suggested that further research should include a comparison with the customers' satisfaction questionnaire, to understand if the employees' alignment is at the same level as the customers' comprehension of the organization. It would also be very interesting to further invest in a deeper qualitative study to understand if the concepts defined in the strategic categories are really embedded in the documents that support the internal documentation and if it is included in the direct discourse of both head and chief managers of the various departments within the organization. Such data could be compared to a direct and straightforward simple questionnaire administered to all employees about the core values of the brand, considering both tangible and intangible perspectives.

Empirical data obtained can also provide new insights if new categories are constructed in future, based on an academic point of view, by indexing the questions of the same satisfaction questionnaire to the constructs of the Employee based Brand Equity (EBBE), as recommended by King & Grace (2010): "*such a comparison may provide important insight into how internal brand management practices may, in fact, vary according to the level of employee involvement with respect to production elements that influence the brand.*"

Abstract: The retail sector, although being primarily traditional is deconstructing and modernizing itself in order to keep up with the technological and digital enhancements. The Portuguese panorama is remarkably structured upon child-oriented marketing initiatives with the involvement of technological platforms, gamification and enrolment components. The scrutiny of existing applications of innovative ICTs focused on children's marketing will serve as the basis for a new business campaign aimed at children and supported by digital marketing and innovative technological features that might trigger a future campaign's success. In addition, we conducted a small survey to parents and subsequent potential campaign customers to understand the indulgence of a children's marketing action and a triumphant social media advertisement. The in-store retail system has a huge competitor in the online configuration, in some product categories in conjunction with the privilege of buying anywhere and anytime. In what concerns child-oriented marketing, there is an understanding that actions need to focus on aspects such as interactivity, multimedia and personalized content, where the survey displayed a 99% approval in the creation and necessity of child-oriented marketing campaigns to retailers, and a 54% acclamation of a promotional social media action. This reveals that the online channel is a valid channel, and the in-store retailers, even still being preponderant, need to rethink the inclusion of an Omni-channel solution to solve the in-store versus online shopping retail system. Additionally, is recommended the creation of child-oriented actions to convert customer loyalty from a younger age and influence family consumption.

Keywords: ICT, Children Marketing, Social Media, In-store Retail, Online Retail.

1. Introduction

As individuals and organizations emerge themselves in the most recent arguments behind the Information Society buzzword, the incorporation of information and communication technologies (ICTs) in their daily lives is also becoming not a desire, but a requirement (Gonçalves, Martins, & Rocha, 2016).

As a younger public becomes more relevant, mainly due to their technology savviness, organizations are altering the way they communicate with these new prospects and how they market their products or services (Xiang, Magnini, & Fesenmaier, 2015). Confos and Davis (2016) argue that to be successful, marketing initiatives aimed at children and/or youngsters must include (innovative) technologies and platforms, such as Facebook and YouTube, gamification and enrolment components, though this is dependent on their age.

The retail sector is one of the most interested in reaching children and younger segments of prospects and, although being a typically traditional sector, the retail sector will have to modernize itself in order to keep up with the more digital requirements of its new customers (Stewart, Oliver, Cravens, & Oishi, 2017).

In what particularly concerns the retailing industry, the incorporation of ICT is changing the purchase experience process, where brick and mortar stores are progressively losing to their biggest competitor – the online stores (Galipoglu, Kotzab, Teller, Hüseyinoglu & Pöppelbuß, 2018).

The urgent transformation felt by technological growth, and its momentary status, reveals an extreme concern to pinpoint those with a longstanding stature, in serving marketing and business purposes. These ambitions are inspired through the smooth use of technological devices experienced by Generation Y and Generation Z, and with the prominence of social media platforms. Therefore, it is necessary to take into consideration customers' reactions in order to enhance customer service (Verhoef, Kannan & Inman, 2015).

Mobile technologies are empowering customers with more information about the products, providing them with the choice of finding information at their convenience and easily choosing between an online or physical store (Grewal, Motyka & Levy, 2018; Martins, Gonçalves, Branco, Barbosa, Melo & Bessa, 2017.

This paper pretends the inclusion of an extensive reference foundation as an agenda to further guide research in the retail area, with the renewal of both society and organizations, alongside a straightforward analysis of recent child-aimed campaigns made by big retail organizations, hence allowing one to acknowledge that, despite being targeted at a younger public, these dynamics are enforced and stimulated by adults, either by interacting with others to exchange campaign-related artefacts or by installing and using the campaign-related software applications. As argued by Ritch and Brownlie (2016) and Del Bucchia and Peñaloza (2016), this active parent participant is typically a consequence of social and familiar pressures that impel parents to avoid any type of negative or contrary action towards their children.

The first section includes an impact of the technological incorporation in consumer and organizational behaviour, succeeded by an understanding that retailers are a huge part of the global economy, while also trying to understand what the consequences will be concerning online implementations and the possible fusion of the offline and online in an Omni-channel future. The third section's aspiration is to study the premeditation of children and young consumers as future clients and as a marketing and communication target, prospecting new machinery tools to collapse the traditional marketing barrier built over time. Finally, spotlighting a new practice being driven by Portuguese retail giants to get customer fidelity with child-aimed campaigns – collectible campaigns – using smartphone and desktop applications and webpages in order to enact a posterior influence in family purchase decisions.

2. The incorporation of technology in consumer and organizational behaviour

According to Xiang, Magnini and Fesenmaier (2015) and Jorge, Teixeira, Correia, Gonçalves, Martins and Bessa (2018), understanding how ICTs impact consumer behaviour is crucial for organizations when developing marketing strategies. Most technologies are always in a transitory status, so there is a relevant importance in identifying those with the potential to serve long-term purposes.

In association with information technologies, a global environment has erupted in recent years, and as a matter of fact, the development of the Internet (which can be defined as a platform that facilitates technological innovations, new business practices, and a change in the competitive landscape of industry sectors) has transformed the nature of communication and marketing (Gonçalves, Martins & Rocha, 2016).

The adoption of a technological environment requires a solid perception of the long-term trends in the consumer market, rather than simply following a short-term soon-to-be obsolete technology. Capitalizing on the business environment changes is a requisite to sustained success denoting that these achievements enable opportunities for organizations to provide high-quality customer service leading to unceasing competitive advantages (Xiang, Magnini, & Fesenmaier, 2015).

As reported by Gonçalves, Martins and Rocha (2016) another concept has emerged – that of Social Networks – firmly transforming how one conducts business and affirming itself as a meaningful communication and marketing channel for goods and services, forcing institutions to seek new competitive advantages in the market.

The younger generations' involvement, triggered by the handling of information and communication devices across the Internet and by the seeking of information from multiple sources – television, video and social media – makes them an online advertising responsive target. Social media and online communications are making such an impact due to photo and video tools and also due to social networking. This meaningful tendency presents a great opportunity for marketing and management specialists to identify viable routes to

value creation over the inclusion and combination of new revenue sources into their current business models (Xiang, Magnini, & Fesenmaier, 2015).

As for organizations, there is a necessity to merge their ongoing business models with technological innovations caused by Millennial market prospects, endorsed with technological competences. Business leaders must find not only a way to provide the best customer service, but also the motivation – for employees – to achieve maximum performance while fluctuating between online and offline retailing (Stewart, Oliver, Cravens & Oishi, 2017).

To understand the proliferation and behaviour change in the use of ICTs, a research conducted by ACEPI and IDC (2017) reports that 39% of the Portuguese businesses have an online presence, where 84% have their own website and 67% own social media pages, indicating a rising necessity of being permanently connected with prospecting online customers.

The interest in ICT is motivated by the urgency in achieving better integration of new technologies with business purposes, creating a dependency due to the direct impact in compartmental behaviours. However, Martínez, Vaszquez, Estrada, Santillan and Zavala (2016) admit that business models tend to not consider the technologies in organizational requirements, making it difficult to discern how technologies are useful to their aspirations, even though productivity pressures are urging business-to-business (B2B) customers to consolidate their purchasing procedures and therefore encouraging them to entrust digital technologies, where a wide variety of tools – websites, social media, mobile applications – can assist the purchasing processes and expediting decision-making.

Thus, the peculiar development of the Internet and of e-commerce made a huge impact on the way consumers live and settle their decision making, contrasting in online and offline behaviours (Deka, 2017).

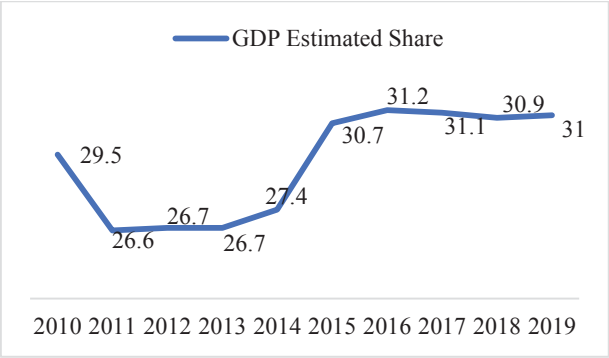
3. The modernization of the retail sector and the in-store versus online conflict

The retail industry, as exposed by von Briel (2018), is configured as one influential element of the global economy, with predictions of attaining 31% of the global domestic product by the year 2019 (figure 1) with about 28 trillion US dollars in revenues.

When analyzing the retail sales evolution between 2010 and 2019, the traditional system is shown as the prevailing one. However, when regarding online sales, we see an uninterrupted flourish representing 0.6 trillion dollars in 2010 and an expectation of 3.6 trillion dollars in 2019 (figure 2) (Falke Information, 2016).

Traditional retailers currently face a very significant upsurge of new online competitors to whom they are progressively losing customers due to the customer conversion behaviour provided by digital technologies. In effect, when customers want to search for information about a new product, they conveniently use the gadgets they have – smartphones, laptops or tablets – remaining comfortably on their sofa without having to go to a brick and mortar store in the proximity (Grewal, Motyka & Levy, 2018).

Figure 1: Gross Domestic Product Estimated Share (Source: Falke Information, 2016)

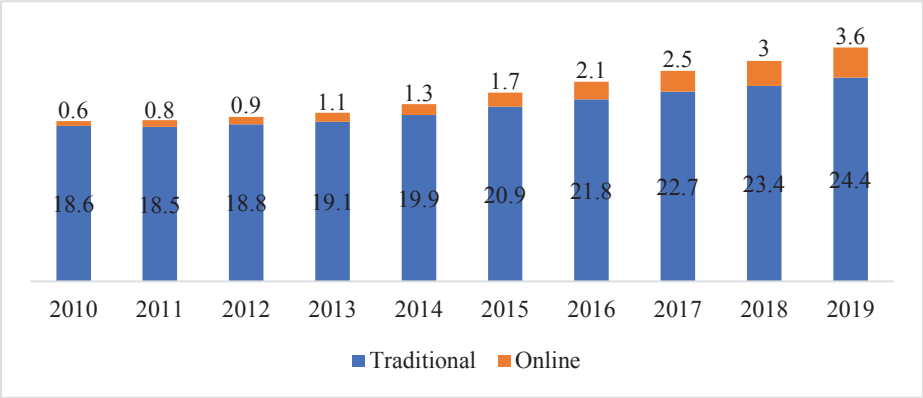


In recent years, traditional marketing channels – sponsoring, print advertising or television commercials – have been supplemented by new digital options – social media, search engines or price comparison sites – leading

to a change in the way business and marketing is done within the retail sector, while also generating new forms of competition (Grewal, Motyka & Levy, 2018).

As reported by Johansson and Kask (2016), retailers are facing a labyrinthine question of the inclusion or non-inclusion of e-commerce as a part of the retail amalgamation, in which the understanding in judging the appropriate retail configuration of whether to have a virtual or a physical store is of an extreme strategic relevance for the competitive advantage of a firm. Apart from the decision of the retail format, another vital aspect is the organization of the market standing to engage and maintain customers, either by offering lower prices than competitors or by differentiating themselves and earning a premium compensation (Hoehle, Aloysius, Chan & Venkatesh, 2017).

Figure 2: Retail Sales Evolution (US$ trillions) (Source: Falke Information, 2016)



The exponential increase of online shopping, like many other information technology activities, is bouncing in-store shopping rates and making potential niches emerge for virtual and physical shopping-related travel (Lee, Sener, Mokhtarian & Handy, 2017). Johansson and Kask (2016) argue that the implementation of an e-commerce solution is a root condition to achieve agile growth in the retail sector, and the consolidation of different communication channels – incorporating online and offline measures – may lead to sympathetic odds of triumph.

Online or in-store shopping decisions, as emphasized by Lee, Sener, Mokhtarian and Handy (2017) and later by Galipoglu, Kotzab, Teller, Hüseyinoglu and Pöppelbuß (2018) depend on different factors based, for example, on the momentum of the customer – the preference for shopping online instead of driving to get to a physical store – but also on the kind of product being purchased – the inclination to buy books online rather than food – where physical stores are still privileged crosswise multiple product categories. This authority is assumed due to the inability of inspecting online products in person, and although online shopping is on the rise, there are some identifiable disadvantages such as shipping costs and shipping wait times. Generally speaking, the periodically purchased products differ between: a) Online: purchase of non-daily products such as books, electronics or clothing; b) Offline: acquisitions of maintenance items such as gasoline or perishable goods (Statista, 2017).

The previously referred modernization occurs in the decision of retailers to merge themselves with technological and digital tools to meet customers' requirements. Online shopping can influence customer shopping travel through three systems: a) Substitution: the reduction of the overall travel replacing a piece of in-store by online shopping; b) Complementarity: the online shoppers stimulation to an additional shopping-related travel to a physical store in order to inspect or acquire a product; c) Modification: the manifestation that some condition in the shopping travel has changed – time of day or visited store – without affecting the decision to make the travel itself. These mechanisms do not act unilaterally, so as online shopping influences physical retailers, in-store shopping may impact virtual retailers – the customer can purchase the main item in-store and purchase the accessories online or vice versa (Lee, Sener, Mokhtarian & Handy, 2017).

Given the conjectured interdependencies between online and offline, Lee, Sener, Mokhatarian and Handy (2017) tried to understand which were the variables included in the shopping frequency decision. Customers bear dissimilar behaviours when debating about shopping decisions, since consumers with functional concerns – price, selection and convenience – tend to shop online, and although online shopping may substitute the act

of acquiring a product, it is – in the meantime – incapable to provide the social or psychological benefits that in-store shopping offers (Deka, 2017).

A broad solution is debated by Wang and Goldfarb (2016) pointing to the online channel not as an alternative or a substitute of the offline retailing, but rather as second thought complementary processes, exerting that the in-store experience must find a balance between the two channels.

Inman and Nikolova (2017) described the most disruptive retail technologies across recent decades, identifying those with the most impact in the industry (table 1).

Table 1: The most disruptive retail technologies across recent decades

Past Retail Technologies	**Present Retail Technologies**
Barcode Scanning (1974)	Mobile Apps
Videocart (1988)	Self-Checkout (1992)
Kiosks (1985)	Gravity Feed Shelving Systems (2002)
In-Store Coupon Dispensers (1992)	Smart Shelves (2003)
Walmart Smart Store (1998)	QueVision (2010)
	Personalized Promotions
	Scan and Go (2013)
	In-Store CRM (2013)

In addition, the appearance of a generation which exhaustively uses ICT contributes to the expeditious development of e-commerce (Knežević, Šipek & Jaković, 2017).

The consideration of children as a communication and marketing target is made in two different ways, equivalently with the channels used to get the adults' attention, with the modernization of the retail spectrum – in-store experience – in taking advantage of children's creativity and straightforwardly turning to technology with the implementation of character-themed tech shops and fun-featured animated candy displays; or with the use of online media tools – online experience – with the retelling of social media incorporation in marketing campaigns for children, conceiving bi-directional channels between the brand and the young consumer (Confos & Davis, 2016)

4. Children as a relevant target and child-oriented marketing techniques

Digital media is becoming an integrated part of children's lives (though we do recognize different behaviours and differentiated access to technology, according to a child's age, national culture, and social and economic status, as dictated also by their parents) and digital marketing that uses new and innovative strategies to target children – where the engaging and immersive nature of online content shapes the perfect environment within which commercial messages can be camouflaged – blurring traditional lines between content and commercial messages (Livingstone, Mascheroni & Staksrud, 2017).

Everyday social media acceptance contributed to the change of customers' buying methods, providing buyers with a great pallet of options. To store managers, it is a representation of a challenge where they need to maintain their focus. With the addition of promotions and related marketing and brand activity, the complexity is multiplied (Anderson, Steen & Stavropoulos, 2016) (Ramanathan, Subramanian & Parrott, 2017).

To speed up the online provenience options, war marketers exploit the fact that innumerable social network users post vast amounts of personal information on their profile pages – age, hobbies, brands or music – using technological tools to collect this "public" information and target them in their campaigns (Reijmersdal, Rozendaal, Smink, van Noort & Buijzen, 2017) (Livingstone, Mascheroni & Staksrud, 2017).

According to Confos and Davis (2016), children's social media usage is relevant to advertisers, taking advantage of their technology affinity to invite them, for example, to connect a specific application to their accounts or to expose them to advergames (advertising through games) – serving advertisers as another communication tool – and engaging with customers through multiple digital platforms. Advergames are exceptionally difficult for children to understand – the persuasive intention – due to the fact that the first assignment is to play the game and the second one involves the distillation of the advertising message, where the second task becomes hidden behind the first one (Vanwesenbeeck, Walrave & Ponnet, 2016). As reported

by Vandevijvere, Sagar, Kelly and Swinburn (2017), websites targeting children focus on the presence of brand logos, characters, music and sound effects and animation during the advergames.

The disjuncture between online media and traditional media is made by characteristics such as: a) ubiquitous connectivity; b) personalization; c) peer-to-peer networking; d) engagement; e) immersion; f) content creation.

These components enable new digital opportunities for those who market to young consumers, addressing aspects like interactivity, multimedia content and personalized content to this target's requirements (Confos & Davis, 2016). Websites are targeting children when they include fun, fantasy and adventure themes or games (Vandevijvere, Sagar, Kelly & Swinburn, 2017).

The younger ones created a "traditional marketing" barrier where in fact digital advertising – with the use of the above cited characteristics – proved to be strong to counter this inconstancy, impelling an immense number of organizations to use social media marketing to promote and engage Generation Z customers (Duffett, 2017).

4.1 Section IV – Social insertion in child-aimed campaigns

In 2018, the child-aimed retail campaigns are a powerful route to target not only children, but also adults. In Portugal, the retail giants are the most interested in segmenting these young consumers, working on customer loyalty since the beginning, confident of the technological incorporation with the introduction of tablet and mobile applications as well as a desktop participation to children and their parents. Some of the technological campaigns conducted in the last years are:

- "Super Animais 1", "Super Animais 2" and "Super Animais 3" by Pingo Doce: Both campaigns require the collection of cards – given after the acquisition of in-store products – where children can digitalize the cards using a mobile application, letting them play afterwards.
- "Super Gangue dos Frescos" by Lidl: Like the one above, it inspires the customer to acquire products, where in change there are eight collectible dolls and also a dedicated campaign webpage with eight interactive games allusive to these dolls.
- "Stikeez" by Lidl: Likewise, the same purchasing typology; it affiliates an android and iOS application.
- "Super Dicas" by Continente: Continente used their webpage "Kasa" tab including some DIY hints, so children may, for example, make their own personalized balloons or ice cream;
- "Turma das Sementinhas" by Jumbo: In a partnership with the Portuguese scientific toys producer Science4you, a children campaign was created, where children have access to a totally free downloadable application for iOS or android.

Another common point between these campaigns – other than the technologic embodiment – explained by Ritch and Brownlie (2016) and Del Bucchia and Peñaloza (2016) is the kid-friendly education, focusing on the fact that children need to learn something from them, either in the education or social fields, where parents are another agent particularly interested in these kinds of projects, and the ideal campaign to explain the propensity is the Super Animals from Pingo Doce.

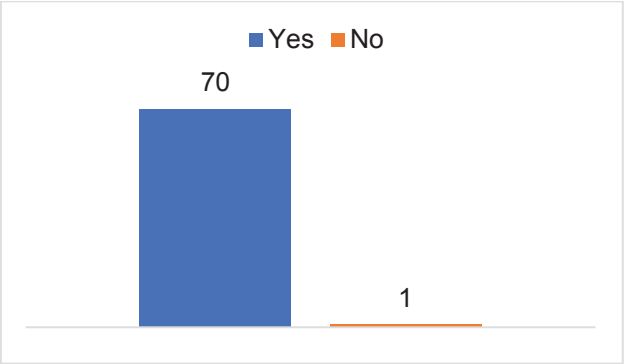
The first edition was doubtless the one that made the biggest impact on Portuguese society. With the use of social media platforms such as Facebook, people created totally dedicated groups to trading and selling the cards, while also selling advertising on pages like OLX (an online C2C/B2C e-commerce platform). The relevance of these social groups is that people looking for and selling the cards where not children at all – adults, parents or grandparents – interacting to complete the collection.

Besides these groups, thanks to this campaign the prosperity of social interactions between people with the same objective prevails. Trying to finish the collection of all the cards becomes easier and at the same time they get a feeling of satisfaction together with their children; not to mention the people trying to resell their duplicates, and thus earning some money. From a customer's point of view, this is an approbation of technological development from children, an acceptable practice in today's society.

In order to inquiry prospects of a potential child-aimed campaign, we conducted a survey (n= 71) to parents and the results, according to the above cited campaigns convinced us of the importance of these projects to prospect children and their families.

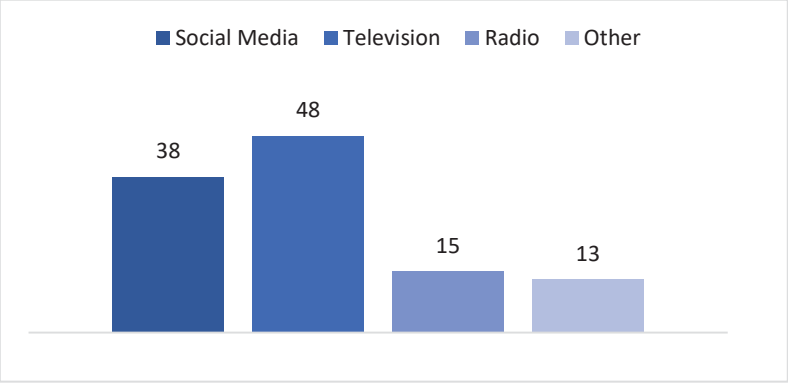
The first question highlights, as expected, the importance of these actions, where 70 people answered "yes" and only one answered "no", however pointing that that answer would easily become a "yes" depending on the construction of the campaign (figure 3).

Figure 3: Recognizing the importance of a child-aimed campaign



The second and most relevant question tried to understand the social media relevance in advertising, and in a multiple answer question we asked where in preference should the campaign promotional content be created and displayed. Even if 48 people answered "television" as a preferred way of communication, social media was chosen by 38 of them, thus calling attention to it through its overwhelming character among the rest of the choices (figure 4).

Figure 4: Advertising preference in a child-aimed campaign

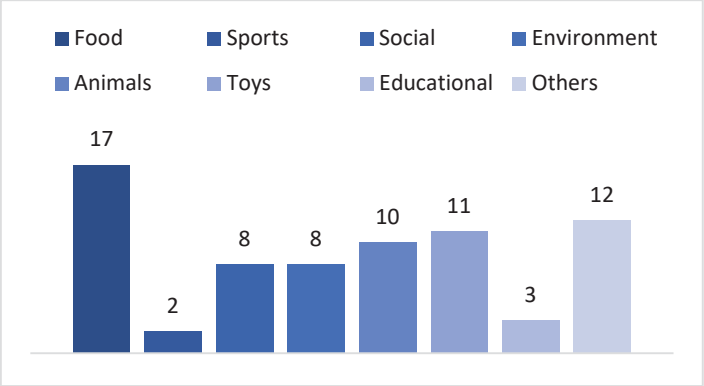


The third question intends to understand the themes that children mainly up to ten, or in some cases up to twelve years old prefer, according to their parents.

As displayed below (figure 5), food, and mainly healthy eating is an argument that parents think their children would enjoy the most in an action, followed by a physical toys campaign and an animal campaign (such as Pingo Doce, Super Animais action).

The above question is, of course, the parents' perspective of how a marketing campaign could be successful, however, this is not an exact science; in some cases, a child around the age of ten can be amazed by this kind of campaign and a twelve-year-old might prefer music-related content and social media interactions, so a target segmentation is a major question that can predict a marketing action success or failure.

Figure 5: Children preferences in child-aimed campaigns



These inquiries, although represent only three questions, show that an action oriented towards children is a valid option as social media is a communication channel praised by parents and children in advertising those contents. As argued by Ritch and Brownlie (2016), children have an influence on family consumption and this is an increasing trend, which in turn is making retailers and marketers focus on attitudinizing with these child-oriented projects, situating the child's needs on top of parental decision making.

5. Conclusions and outlook

This paper explores the question of technological incorporation in retailing, more exactly in child-oriented marketing campaigns, and reunites a contextual vision analysis of an increasing number of articles, demonstrating an outstanding interest in technological development. It also includes a generic picture of the technological sample in the retail field, mentioning some of the old technologies, which were once innovative, and some others considered innovative in some countries, but outdated in the technologically advanced countries. Humankind is caught in a dizzying, fast-paced technological growth, and long-term solutions are required to keep up this constant upgrade, not only in retailing but in all activity sectors.

Particularly in retailing, all trends work in an all-speed acquisition method, since people have less shopping availability, and online is continuing to grow; yet, a majority of people still prefer in-store shopping, so opportunities are still there for retailers to take advantage of. The best option remains the kind of business in operation and the product being sold (Galipoglu, Kotzab, Teller, Hüseyinoglu & Pöppelbuß, 2018).

Choosing between online and offline is not a simple task, although online stores grant opportunities that offline stores cannot provide to customers. An Omni-channel is probably the forthcoming tendency where customers will be able to interact with retailers across a huge diversity of platforms and devices, with the implementation of an online and offline experience at the same time (Hoehle, Aloysius, Chan & Venkatesh, 2017).

A younger public reveals as a relevant economic target to organizations due to its technological appetences, forcing organizations to change communication and marketing strategies in the implementation of campaigns and projects – particularly in the Portuguese landscape – aimed at children, and approved by parents and grandparents (Xiang, Magnini, & Fesenmaier, 2015). Such actions, as argued by Confos and Davis (2016), need to be interactive and have multimedia and personalized driven content in order to get a successful status, while also using social media platforms and innovative advertisement processes like advergames.

Finally, a child-oriented campaign action will prevail if its objective is the encouragement of social synergy, where education performs a major role in giving children access to new information – technological and non-technological – at the same time as they delight themselves with some – persuasive – retailing content.

An Innovation Support System for SMEs

João Pereira and Fernando Romero
University of Minho, Guimarães, Portugal
pg28937@alunos.uminho.pt
fromero@dps.uminho

Abstract: Although it is often viewed as a somewhat unpredictable process, the importance of defining clear strategies for innovation is recognized. For this reason, many organizations develop processes that support innovation. In Portugal, the Portuguese Standard 4457: 2007 (NP 4457), which defines the requirements for a Research, Development and Innovation Management System (RDIMS), was introduced in 2007. These requirements act as guidelines for organizations that recognize the importance of innovation. This study aims to create a set of proposals, based on the NP 4457, that support the management of innovation in a small enterprise in the food industry. A case study was carried out in a business environment with a duration of 6 months. In this case study, with an exploratory nature and a qualitative approach, data collection involved documentary analysis, participatory observation and unstructured interviews. After analysing the reality of the company, an Innovation Support System was presented, divided into three components: Strategic Definition, Innovation Process and Evaluation of the Innovation System. The Strategic Definition component has the function of defining the responsibilities and delimiting the scope of innovation for the organization. The Innovation Process includes a set of processes, all the way from the internal and external analysis of the organization, through idea management, evaluation, selection and project management to the final result of the innovation process. Finally, the Evaluation of the system has the function of analysing its performance and proposing improvements. The system proposed here is an attempt to operationalize the recommendations of the Portuguese Standard having in mind the specificities of SMEs. Although it was created for a specific firm, it is based on generic references (such as the Stage-Gate Model or the Chain-linked Interactive Model) and it does not involve specific activities or characteristics of the organization or industry for which it was intended, which makes it possible to adapt it to other SMEs that are interested in improving innovation management performance and/or in the NP 4457 implementation and certification.

Keywords: innovation projects; innovation management; R&D management; innovation management systems; certification

1. Introduction

The ability to innovate allows companies to differentiate themselves from their competitors by improving their processes or by being able to produce goods or services more valued than their competitors (Leite, Albuquerque and Leal, 2007). Innovation is often associated with technological advances, but this is a limited vision, as innovation is present in another areas than technology within organizations.

Innovation is inherently uncertain, somehow disordered, made up of some of the most complex systems and subject to change of various types. Moreover, it is also difficult to measure and requires close coordination of adequate technical knowledge and excellent market-critical ability to satisfy all constraints simultaneously (Kline and Rosenberg, 1986). Despite being popularly described as a process without rules or plans, studies have shown that successful innovators have clearly defined strategies and management processes for innovation (Schilling, 2005).

In 2007, based on the Chain-linked Interactive Model, the Portuguese Quality Institute created the Portuguese Standard 4457:2007 (NP4457). The Standard presents the necessary requirements for a Research, Development and Innovation Management System (RDIMS), and aims at the certification of organizations, ensuring the recognition of the necessary technical skills for the management of innovation.

Due to their size and their characteristics, small and medium-sized enterprises (SMEs) feel that the innovation process is often hampered. The correct application of the standard in SMEs allows a systematic planning of the innovation process, thus helping to more easily recognize the opportunities and threats to which the organization is exposed, taking more advantage of the innovation process. In addition, the standard implies a continuous evaluation of the innovation process, which may act as a reflection for the organization on its own innovation processes.

The objective of this study, which adopted a qualitative and exploratory approach, was to define procedures and practices for innovation management that are best suited for a small enterprise in the food sector, making

its innovation process more agile and that can serve as a basis for a future implementation of the NP4457. The study proposes an integrated system of innovation management, comprised of several phases, which were designed having in mind the characteristics of a resource constrained SME, and that will hopefully improve and facilitate the proper management of innovation in this category of organizations.

2. Literature Review

2.1 Innovation Definition

Innovation is nowadays a very common word in the world of organizations, but its definition remains somewhat elusive. Innovation is often associated with cutting-edge technology, but that may be a reductive view. Often, it is less a question of technology and more a way of thinking and discovering creative solutions within organizations (Amabile, 1988; Hidalgo and Albors, 2008), by adapting their knowledge and skills in their offerings or in the way their products or services are delivered (Tidd, Bessant and Pavitt, 2005). Innovation occurs in an abstract way within organizations at a technological, marketing or organizational level, generating different results from case to case, and may involve various types of innovation (product, process, marketing or organizational). In fact, the successful innovations result from a good combination of the various organizational competencies (Caraça, Ferreira and Mendonça, 2006).

Innovation can then be seen as a tool for entrepreneurs, that is, the way through which they can exploit change as an opportunity for a different business or service (Drucker, 1985). The adoption of innovation allows organizations to adapt to the environment in which they are inserted or anticipate changes in order to increase or maintain their effectiveness and competitiveness (Damanpour and Gopalakrishnan, 2001). Innovation is what agile companies do, that is, they constantly reinvent themselves in terms of their solutions to the riddle represented by the threats and opportunities in their environment. This may mean adopting new technologies, or own generation (Bessant, 2003).

This study adopts the definition given in 2005 by the Organization for Economic Co-operation and Development (OECD), which defined innovation as "the implementation of a new or significantly improved product (good or service), process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations." (OECD, 2005, p.46).

2.2 Innovation Management

Innovation can be seen as a process involving the invention of something and the exploitation of its results (Roberts, 2007). The task of managing this process is then to create specific routines for the company. Routines represent the approaches that a given organization makes to meet the challenge of innovation. Innovation routines are increasingly recognized for their contribution to competitive advantage, and can't simply be copied from one context to another, they need to be learned and practiced over a sustained period of time (Bessant, 2003).

Following are some of the areas that should be managed to facilitate innovation. It is necessary to consider that the management of these areas should be done in a joint way, creating routines, and not individually.

- Innovation strategy - managing the innovation strategy requires understanding the what, why, and when of the innovation activity. This means developing, reviewing and updating an innovation policy and strategy consistent with the organization's mission and setting innovation goals in the short and long term (Adams, Bessant and Phelps, 2006; Hamel, 2006; Cooper, 2011).
- Portfolio Management - involves the definition of a diversified portfolio that encompasses different types of innovations. Choosing the right innovation projects isn't always easy, it is necessary to recognize the lack of information that exists in the initial phases and adapt selection criteria that are more broad than the financial indicators, including criteria like business opportunity or technical feasibility according to the projects (Adams, Bessant and Phelps, 2006; Cooper, 2011, 2013; Mitchell, Phaal and Athanassopoulou, 2014).
- Project management - a project can be defined as a unique enterprise, represented by a sequence of activities, limited in time, to achieve the objectives determined within a given budget. Due to the high level of uncertainty, the application of project management methodologies allows organizations to obtain the best results during its execution (Igartua, Garrigós and Hervas-Oliver, 2010; Miguel, 2013).

- Innovation process - innovation development is managed and improved through a clear process, using a structured step-by-step logic to guide and manage innovation (Igartua, Garrigós and Hervas-Oliver, 2010; Cooper, 2011).
- Leadership and organizational culture - Organizations can provide enough freedom to allow the exploration of creative possibilities, but they also need control over the innovation process to manage it effectively and efficiently. Innovative organizations must adopt contrasting structures and attitudes as they move from initiation to the stages of implementation of innovation (Adams, Bessant and Phelps, 2006; Cooper, 2011).
- Resources – Resource management for innovation means providing adequate resources for people to explore ideas, and ensuring that people have the resources and space to develop opportunities of innovation (Igartua, Garrigós and Hervas-Oliver, 2010; Cooper, 2011).
- Human Resources - attract, recruit, motivate, reward and develop individuals are the backbone of effective resource management for innovation (COTEC, 2010).
- Knowledge management and intellectual property - knowledge management is concerned with identifying, translating, sharing and exploiting knowledge within an organization. Intellectual property is intended to protect the intangible goods created by the intellectual activity of the human being, and are owned by the companies or persons who create or own them (Teece, Pisano and Shuen, 1997; Tidd, Bessant and Pavitt, 2005).
- Technology - organizations must be aware of technological developments since they can't always create their own solutions. Clearly, technology solutions may already exist elsewhere, and an innovative organization can simply adopt or adapt them through simple modifications to a new purpose (Roberts, 2007; Teece, 2007).
- Market connection - connecting to the market can make the difference between a good idea and a successful product, since without marketing and sales, a product innovation or a new service wouldn't attract the interest of customers (Igartua, Garrigós and Hervas-Oliver, 2010).
- External networks - the creation of innovation networks allows companies to reduce the costs or risks involved in developing new technologies or entering new markets, achieving economies of scale, reducing the time to develop and sell new products and to promote the exchange of knowledge (Tidd, Bessant and Pavitt, 2005).
- Performance measurement - as with any other management aspect, innovation management requires adequate measurement systems to enable managers to calculate the impact of innovation activities on company performance (Adams, Bessant and Phelps, 2006; Saunila, 2016).

2.3 Innovation Management Standard

In Portugal, according to the Community Innovation Survey 2014, the SMEs were the companies that showed the lower rate of innovation activities and innovation results when compared with large companies and this survey also showed that they had more obstacles to innovate (DGEEC, 2016). To facilitate the innovation management process, the Portuguese Quality Institute created the Portuguese Standard 4457:2007 (NP4457) in 2007. The Standard presents the necessary requirements for a Research, Development and Innovation Management System (RDIMS). These requirements act as guidelines for organizations that recognize the importance of innovation. The standard is based on the Chain-linked Interactive Model, it is applicable to any organization, to any type of innovation and it is oriented towards continuous improvement (IPQ, 2007).

The NP4457 is divided into four sections. In the first section - Management Responsibilities, it is necessary to establish a Research, Development and Innovation (RDI) policy that guides the entire organization, and which must be aligned with organizational strategy. The RDI policy must be deployed in measurable objectives, to which are given responsibilities and methodologies for its implementation, so that later the organization's situation can be reflected and re-evaluated in the face of the results.

The RDI planning section involves planning for the detection of threats and opportunities through the interfaces, how you will capture and evaluate the ideas or opportunities arising and the management of the resulting projects.

The third section encompasses the implementation and operation of the RDIMS. At this point, RDI management activities that must be carried out by organizations, such as portfolio management and idea management, are identified by the standard. The organization shall also ensure the establishment of

appropriate external and internal communication procedures, as well as registration and control of all documentation relevant to the RDIMS.

The fourth section refers to the evaluation of results and improvement and indicates that the organization should implement procedures to evaluate the results of the innovation process. One requirement of the standard is that internal audits must be conducted, by people who aren't auditing their own work.

3. Research Methodology

This study aims to create a set of proposals that support the management of innovation in the company Gelado Colorido (which means Coloured Ice Cream), based on the NP4457 standard. This is a small company, belonging to the food industry. It was created in 2012, with the intention of offering its customers functional ice creams (an ice cream that has some health benefit). Given the high level of RDI associated with this type of products, the company intended to structure a RDIMS to facilitate the innovation process.

During the study, the perspective adopted was essentially positivist and the nature was essentially exploratory, insofar as it was based on established concepts and theories, although the approach is predominantly qualitative. In this case study, the collection of data mainly involved documentary analysis. The documentary analysis included the selection, treatment and interpretation of existing information in documents and was carried out in a systematic way and it was fundamental for the creation of the proposed system. This analysis mainly involved the NP4457, COTEC's guide to good practices for innovation management, the RDI activities manual by COTEC and the strategic analysis of the organization. Since the investigation took place in a business environment, and as a way of completing or confirming the information gathered in the documentary analysis, participatory observation and unstructured interviews were used. Participatory observation allowed to analyse the routines and procedures currently developed in the organization, while unstructured interviews allowed to understand the perception that employees had about innovation in the organization, specially the administration and the quality department.

4. The Innovation Support System

After analysing the reality of the company, an Innovation Support System was presented, divided into three components: Strategic Definition, Innovation Process and RDIMS Evaluation. This system is based on the Stage-Gate Model, on the Chain-linked Model and on selected recommendations and adjustments of the Portuguese Standard 4457:2007, which were deemed more adequate to the small firm under study. The Strategic Definition defines all the guidelines to the innovation process according to the organizational strategy. The Innovation Process includes four phases: Interface Management, Idea Management, Project Evaluation and Selection and Project Management. The phases aren't sequential, since the interfaces represent all internal and external communication of the organization's knowledge, and function as support elements to the internal process of innovation. The different phases are divided into several stages and control points/gates, which must be established during the Strategic Definition phase. The stages represent the work done, while gates represent the decision making, which ensures compliance with the requirements necessary to move to the next stage. Given the high level of uncertainty to which innovation projects are associated, these divisions can mitigate uncertainty and control costs and time during their implementation. The number of stages and gates must be adapted accordingly with the uncertainty associated with the projects. Finally, the RDIMS Evaluation aims to detect all the failures and suggesting improvements, working as an input to the Strategic Definition.

The following sections will define more clearly each phase, which were designed to address specific difficulties that a small firm faces and that can contribute to improve substantially the management of innovation in resource constrained firms.

4.1 Strategic Definition

The Strategic Definition delimits the scope of RDI activities and should have a reach not only in the short term but also in the long term. In order to make the system work, an RDI policy must be established and documented to help ensure the alignment of RDI activities with the organization's strategic objectives. In addition, the organization must define the RDI objectives. These objectives should be consistent with the RDI policy and should be SMART (SPI, 2013), specific, measurable, achievable, realistic and time-limited. The RDI policy and objectives should be regularly reviewed and updated, communicated and understood by the entire organization (COTEC, 2010).

The Strategic Definition also has the purpose of delegating the responsibilities of those involved in innovation, who need to ensure that all activities are carried out in accordance with the strategy established for the success of innovation in the organization. In addition to the person responsible for RDI, the evaluation committee should also be defined, which will be responsible for decision making during the innovation process.

The Strategic Definition should include the definition of strategic axis, so that the RDI portfolio isn't limited and can guide the employees at the time of suggesting ideas. The choice of strategic axis helps to delimit scope and can vary, for example in relation to the type of innovation, the degree of novelty or the level of risk/uncertainty. During the selection of the strategic axis, the resources must be allocated to each one of them, as well as the control points and their criteria and methods for selection should be defined. The criteria need to consider the type of projects it is evaluating, because not all projects are technology-based innovations or market related.

4.2 Innovation Process

4.2.1 Interface management

The first phase aims to manage the different interfaces presented in the Chain-linked Interactive Model, to ensure the circulation of knowledge between the organization and the environment that surrounds it. This analysis seeks to identify the agents of the external environment (macro and micro) that interact with the organization for the production of knowledge, as well as to detect the opportunities and threats that the organization faces. During this analysis it is also necessary to define which activities are crucial for the exchange of information, ensuring that these are planned, implemented, maintained and updated. Finally, it is important to establish procedures for collecting, documenting, analysing and treating, disseminating and valuing information.

The Chain-linked Interactive Model presents three distinct interfaces (technological, market, organizational) for capturing knowledge, and the organization should define the activities for each of them. The activities chosen for Interfaces Management will act as support activities for the internal process of innovation.

The Technological Interface encompasses all the activities used to guarantee Technological Surveillance, Cooperation and Forecasting. Technological Surveillance consists in the systematic observation of the surroundings with respect to the existing technology in the market and the technological advances. Technological Cooperation encompasses partnership activities with other institutions and organizations, with a view to sharing technical and scientific information and joint development of products and processes. Finally, the Technological Forecast consists of prospective activities focusing on the development of technologies of potential economic interest.

The Organizational Interface defines the activities or tools necessary to guarantee the creation or exchange of organizational knowledge, through Internal Creativity, Organizational Capacity and Knowledge Management. Internal Creativity includes the practices of harnessing and stimulating the internal creativity of the innovative company. Organizational Capacity refers to the design strategies for innovation. Knowledge management consists of the practices of generation, validation, codification and diffusion of existing knowledge in the innovative company and management of external knowledge needs.

The management of the Market Interface consists in the identification of Internal and External Analysis activities, Intellectual Property and Analysis of New Clients, to ensure the necessary knowledge about the market. The Internal and External Analysis consists of analysing the internal and external context of the innovative company and its positioning considering relative strengths and weaknesses in the environment. New Customer Analysis covers observation and analysis of potential customers and new user markets. Finally, Intellectual Property refers to the management of the possibilities offered by intellectual property regimes for the protection, exploitation and dissemination of the results obtained in the innovation process.

4.2.2 Idea Management

The Management of Ideas comes from the Management of Interfaces, that is, many of the ideas proposed arise through threats or opportunities detected in the environment in which the company is inserted. In an

innovative company internal creativity must be encouraged, and therefore everyone must have the opportunity to give their opinion, as well as to receive feedback on ideas submitted.

Initially the employees should record all their ideas, so that in the future it is possible to evaluate the route that the idea had during its existence. The collection of ideas should allow the creation of a database or a repository which, in turn, will allow evaluation and selection based on the same criteria, and hence constituting pre-projects. The recording of ideas and the creation of the idea repository makes it easier for the organization to collect data needed for the evaluation of the RDIMS. At this stage, the criteria for the evaluation must be wide-ranging since there isn't much information about the idea. The criteria may be related to the strategic framework, the opportunity that the idea can give to the organization or the adequacy of the resources of the organization to the idea.

4.2.3 Project Evaluation and Selection

The Project Evaluation and Selection phase precedes the development of the innovation and should confirm the attractiveness of the project before there is a greater investment. This phase begins with the division of ideas into the strategic axis, so different types of projects can be separated and follow their paths according to the Strategic Definition.

During this phase business plans should be created, which must translate the customers' needs into technically and economically viable solutions, for product innovations. Innovations that aren't product related should present their advantages to the organization considering the criteria defined for their selection, focusing on technical and economic feasibility.

The selection of the projects must be made according to the strategic axis. The use of scoring models is recommended, once it allows a broader assessment, according to strategic objectives, than evaluations that are made only based on financial indicators. With the use of a scoring model, the selection criteria in the different axis can be adjusted to the characteristics of the innovations to which they refer. But pre-projects that are on the same axis should be compared according to the same criteria. The selection of the projects also depends on the resources that are available for each of the axis, as well as the number of pre-projects that are in each one. If there are no pre-projects on one axis, or the existing pre-projects don't spend the resources available, those resources can be transferred to another axis.

Pre-projects passing Project Evaluation and Selection will now be called RDI projects. At this stage it is still necessary to define the acceptance criteria for approval in the next phase/stage, as well as the role of project leader. Pre-projects that don't pass this phase are archived.

4.2.4 Project Management

Project Management involves all the activities that go from the initiation phase to the closing of the project. It is at this point that most of the project's resources are going to be spent. Each project is unique so the criteria to the gates must be adjusted to the projects. The initiation takes place during the project selection, with their approval. After initiation the project plan must be defined. According to the NP4457 each project plan must contain:

- description of the project, including identification of the problem to be solved, improvement, competitive advantage or anticipated benefits;
- identification of the team, necessary resources and estimated timeframes for the accomplishment of the project mentioned in the expected results (milestones);
- verification and validation activities, including, when appropriate, criteria for review, selection and approval of result;
- methods of controlling changes;
- identification of expected results;
- documentation of intellectual property necessities.

After planning, it comes the execution. Any kind of change that occurs in the project will require re-planning so that it is possible to analyse the impact it has on the project. Monitoring and control activities should be put in place to avoid as much as possible deviations. At the end of the project lessons learned should be presented,

which should include a project performance analysis in relation to planning, considering the objectives, time frame and budget.

The stages recommended for this phase are represented by Development, Validation and Implementation or Commercialization. The Development, as its name implies, encompasses the development of innovation and it may include updating of marketing plans and financial analysis and resolution of legal issues. The Validation tests all feasibility of the project and it opens the door to the Commercialization or Implementation of the innovation, but there is still the possibility of the project failing or returning to Development. Lastly, the Implementation or Commercialization of the innovation.

4.3 RDMIS Evaluation

The purpose of the RDIMS evaluation is to verify the benefits achieved with the implementation of the innovation system, as well as the identification of proposals for improvement in the various processes, since the system isn't static and should be adapted according to the reality of the organization.

The organization should establish procedures that allow to evaluate the innovation system, as well as the results from each RDI project. In relation to the evaluation of the innovation system, the organization should ensure that there are methodologies for regularly documenting, monitoring and evaluating RDI activities and outcomes. It is necessary to understand if the RDI policy was understood and followed, and the RDI objectives were achieved.

For the evaluation to be implemented effectively, it is advisable to evaluate the tools used, as well as to define metrics and indicators of innovation that help to perceive the state of innovation and the expected results in relation to the objectives initially proposed. When defining the metrics, it is necessary to consider the whole process.

According to NP4457, the organization should perform internal audits at planned intervals to determine if the RDIMS follows the provisions outlined and is maintained effectively. The organization should define those responsible for audits and ensure that they aren't evaluating their own work, and the selection of auditors should ensure objectivity and impartiality to the audit process.

The auditors should prepare a report that should include corrective actions for detected nonconformities and their causes, as well as the deadlines for their implementation. After the audit and according to the established deadlines, the results must be verified and reported. Audits play a key role in the analysis of RDIMS, and its results should be included in the evaluation of results. The results can be divulged to demonstrate the progress made by the organization in this area.

5. Conclusion

The innovation system created here is a starting point for the organization, and it must be adapted over time. The systematization of the innovation process can contribute to the growth of the company and its continuous improvement. Some of the advantages that stand out are: the better capture of ideas and valorisation of knowledge, the direction of innovation activities according to the established strategy and a better control over the various phases from the generation of ideas to the projects and the respective results. These are all aspects that are generally not properly managed in SMEs.

To make the most of this type of system, it is recommended to follow a set of best practices. Cooper and Edgett (2012), using studies carried out to companies in different areas on the best ways to manage the process between the generation of ideas and the launching of new products, suggest that: the process must be documented and actually used, should be made available all necessary resources to carry out the projects, compliance checks should be applied to confirm that the process is followed and the process should be adaptable. The decision makers should be defined, vary according to the risk associated with the decision and should prepare and be present at the meetings to contribute to the decision making. To improve the efficiency of the process, criteria must be defined for decision making, as well as the deliverables at each stage and the decisions taken must be supported by facts.
The system proposed here, although it was created for Gelado Colorido, is based on generic references and doesn't involve specific activities or characteristics of the organization or industry for which it is intended,

which makes it possible to adapt it to other SMEs that are interested in improving innovation management performance and/or in the NP4457 certification.

ricardo.m.afonso@outlook.com

Abstract: Innovation is increasingly more relevant to researchers. Following a literature review, which revealed that research on innovation processes in a country averse to uncertainty (e.g. Portugal), and thus inhibiting of innovation, is still lacking, a focus group was performed at a product development firm, as well as a survey of the firm's employees, with 48 valid answers. The case is of a firm which develops innovative products and services for the telecommunications and information technology market. The firm is situated in central Portugal and the focus group involved six employees – one from each operational department (pre-sales), plus two employees from sales. How innovation is managed at the firm was a main topic of discussion in the focus group. The results revealed a corporate culture focused on teamwork, where employees are free to innovate in areas not directly linked to their job description, and where innovative ideas, however disruptive, are welcomed. No formal or informal recognition is given, to more innovative employees, and there is a desire by employees to change this. At a firm where product innovation older than 24 months may no longer be seen to be innovation, numerous tools to promote innovation are used, namely: brainstorming, scrum, agile, focus groups, and design thinking. Operating in a business-to-business market, innovation is continuous and open, also involving, for example, universities. Business cases are constructed for each product, customers are surveyed for their satisfaction, all ideas are valued and none are rejected. Despite an innovation-welcoming atmosphere at the firm tact and common sense are still needed to communicate new ideas. External competition by rivals is considered at all times. Internal competition, between colleagues, however, is not seen to be healthy, and work is done towards the common good. Knowledge sharing platforms abound and include internal blogs, workshops, and the registering of projects on specific knowledge-sharing platforms. Finally, product pricing will depend on a number of factors, including the degree of innovativeness of the product in question. The main influence on pricing is, however, the market – an extreme effort must be made to make product prices fit in with what the market is prepared to pay for a technology.

Keywords: telecommunications, Portugal, pricing, innovation results, innovation process.

1. Introduction

A number of authors in the second half of the 20th century have done research about the nature of the basic problems of societies, ascertaining that culture has different dimensions (Hofstede, 2011) and is linked to development. This article is of interest as it discusses innovation processes at a successful Portuguese firm in a country not naturally receptive to new ideas, uncertainty, and innovation in general (Hofstede, 2001). The external environment in Portugal is also one where consensus and harmony are sought out, which may work against results in the innovation field (Hofstede et al., 2010).

In a list of the 50 most innovative countries, Portugal is ranked 30th (Jamrisko & Lu, 2018), which means that there is much room for improvement.

According to the Pordata database, in 2017 the Eurozone economic growth (19 countries) stood at 2.3%, while Portugal's growth stood at 2.7%. However, according Caetano (2018), despite a slight improvement, compared to 2017, Portugal remains among the worst developed countries. The "Comparative Performance: IDI (Inclusive Development Index) versus GDP (Gross Domestic Product) – Advanced Economies" is based on a scale of 1 (the worst value) to 7 (the best value). Only Greece, as stated by the World Economic Forum (Forum, 2018a) is below Portugal in the list of developed countries, with 3.7 points versus 3.97 points. Portugal is thus referred to as a "slowly retreating" country. The index is led by Norway (with 6.08 points), followed by Iceland and Luxembourg, in second and third place (both had scores of 6.07); Switzerland appears in fourth with 6.05 points; and Denmark in fifth place with 5.81 points. "Designed as an alternative to GDP, the Inclusive Development Index (IDI) reflects more closely the criteria by which people evaluate their countries' economic progress" (Forum, 2018b).

Throughout this paper, we will try to understand how a Portuguese company does or does not manage to escape the norm, whereby firms innovate slowly and ineffectively in the country. How does this company avoid the supposed unwritten rules of Portuguese national culture?

The field research involved a focus group as well as a survey – both of which with the firm's employees. Below, following the literature review, we shall discuss the methodology followed in both instances as well as the results arrived at. The firm is not named herein, for confidentiality purposes, and thus remains anonymous.

2. Literature Review

National cultures are centered on values which are acquired in the family, in the community, and at school. On the other hand, corporate cultures are differentiated by practices learned from socialization in the work environment.

Portugal is a country shaped by its traditions, its religion, and customs, and is thus a traditional country. Also, Portugal is a country where individuals prefer to act in a group and whereby individuals care about the general well-being of society, thus being a country where solidarity reigns (Hofstede, 2001; Hofstede et al., 2010).

According to Hofstede Insights (2018), Portugal stands out because it shows high power distance, which means that different incomes, for example, exist and are accepted. For example, in corporations a type of hierarchy is often seen whereby top management exercises considerable power over subordinates. Be that as it may, innovation and technology do not only come from the perhaps brilliant minds that exist in top management. The process of generating more innovative new ideas and processes comes from minds that are bright, visionary, and, above all, believe that it is possible to create something new and successful. However, there must be an opening for these to appear and be harvested, from whatever the level in the organisation.

Nowadays, many employees work in an open space to promote collaboration. In Portugal, the organizational climate may be improved by such a practice because there is a collectivist culture in Portugal (Hofstede et al., 2010) and there is relatively little competition between colleagues. One of the weaknesses of the national culture in Portugal is its aversion to risk because a negative emotional experience is created when the pre-established pattern is not followed. This may explain why Portugal is not so well ranked in the list of the most innovative countries (Jamrisko & Lu, 2018). Portugal is a country where conflict is avoided and, above all, a country that is averse to uncertainty, where consensus is promoted, thus making it much more difficult to innovate and embark on new ideas, inhibiting innovation.

Culture has been a main topic of focus for anthropologists studying different groups, cultures and societies. Only quite recently have the links between culture, organizational performance, behaviour, and the attitudes of people in companies been discovered and it is increasingly becoming a concern for leaders in power. Lou Gerstner, the former president of IBM, stated: "I came to see, in my time at IBM, that culture is not just one aspect of the game, it is the game. In the end, an organization is nothing more than the collective capacity of its people to create value" (Gerstner, 2002, as quoted by AZ Quotes). However, Gerstner also points out that even if leaders recognize the importance of culture, they are unlikely to be aware of the significant role that culture can play in the success or failure of an organization because they may not have the training, or the knowledge needed to build cultures. Hence, the sensitive and hidden line separating good from bad management (Warrick, 2017).

In current knowledge-intensive economies, companies must face strong and dynamic challenges, such as instability, uncertainty, and rapid technological change, and they need to demonstrate to their clients that they have a constant flow of innovation (Fernandes, Cesário, & Barata, 2017). It is important that companies are open to external opinions, especially from their customers, but also related to the competition (however these opinions may arrive – for example, from the *media* or from industry reports), so that they can gather all of the available information. Economic performance is also reinforced by the ability to offer solutions that meet the changing needs and infrastructures. Some companies recognize that change is not only important, but it is also obligatory since the market is constantly and rapidly changing (Fernandes, Cesário, & Barata, 2017).

According to Zhao, Teng, & Wu (2018), there are several definitions for the corporate culture concept, which involves, for example, rules and values which are widely shared, as well as strongly maintained, throughout the organization. This definition shows that culture is much more than a verbal exchange of information and involves widespread actions at the company level. Corporate culture represents a tacit code of communication, where culture is a convention that helps to coordinate people within the company (Guiso, Sapienza, & Zingales, 2015). Thus, corporate culture is the sharing of values and norms among workers of a company, guiding their professional lives and behavior within the company. Most importantly, corporate culture helps in reducing and containing the anxiety of dealing with uncertainty and unpredictability (Zhao, Teng, & Wu, 2018). Moreover, in addition to competing for resources that create value, companies must also compete for funds and resources, which are not easily imitated, negotiated, or replaced. Corporate culture may thus be a fundamental organisational variable.

Corporate culture may vary, especially if the company is public versus private. While public companies are subject to the norms and rules imposed by the government, private companies have the freedom to cultivate their own cultures, keeping in mind their ideals and objectives (Zhao, Teng, & Wu, 2018).

Corporate culture has an impact on business performance. For example, Apple's corporate culture is closely linked to technology and innovation, while at Walmart ostentation is almost a sin, which ultimately promotes a corporate culture more directed towards integrity (Gurovitz, 2011). According to Zhao, Teng, & Wu (2018), the country where the company is located can also influence corporate culture.

Corporate culture can benefit companies in three ways: better coordination and control within the company, better alignment of goals and objectives, and greater employee effort (Zhao, Teng & Wu, 2018). Without some type of control system within a company nothing would be done, so when the traditional incentive control system is not having the necessary effect, corporate culture plays a very important role (Guiso, Sapienza, & Zingales, 2015). It should also be noted that a company's corporate culture can lead to a sustained competitive advantage (Zhao, Teng, & Wu, 2018).

The pricing of innovative products was also analysed herein. Price is a marketing mix element, and relates to the monetary value customers will pay for a product or a service. In recent years, the importance of pricing decisions in companies has significantly increased (Homburg, Kuester, & Krohmer, 2013). Achieving the best price level requires an investment in time, effort, technology and in the team (van der Rest, Roper, & Wang, 2018) and only after some years do benefits start to show and accumulate.

Markets are increasingly showing signs of saturation and overcapacity, with price being used as a differentiating factor. Due to globalization, and due to the entry into international markets of a growing number of foreign companies (including from low-wage countries), the pressure on prices has intensified. It should also be noted that the products supplied by competitors are becoming more and more similar in quality, which makes price an increasingly important decision criteria for buyers.

When comparing price to other marketing mix elements, some things should be underlined: its rapid implementation; that is, decisions can be implemented and launched relatively quickly; hardly reversible, since it acts as a point of reference that customers use to evaluate subsequent price changes; its great impact on customer behavior since it can be the main reason or the main impediment of a purchase. Price is a key mechanism to generate value between the company and the client – and the internal organizational efficiency level allowing for low prices, for example, gains importance in such a scenario.

According to Töytäri, Keränen, & Rajala (2017) there are three types of prices in the literature:

- Based on cost – involving the calculation the company's own costs as a price reference and then adding a margin to arrive at the final price;
- Based on the competition – whereby the competition felt controls the prices of similar offers that exist in the market; and fixes the price by focusing on the characteristics of the offer and its competitive position in the market;
- Based on value – characterized by long-term exchanges. It requires a deep understanding of business models because it is based on what customers value.

Nowadays, we are increasingly facing a competitive scenario that includes strategic discrepancies and disequilibrium conditions. Due to new technologies with a significant impact, or the emergence of new markets, a lack of definition of industry limits, and hypercompetitive markets, an extreme emphasis on price exists, which will be linked to the continuous growth of innovation and learning, among others (Hitt, Haynes, & Serpa, 2010). It is up to managers to balance this need for stability so that planning can be conducted effectively, and decisions made with the due flexibility, so that the company can adapt to the dynamic environment and create bonds with partners to grow. The concept of globalization has become more widespread and brought about a change in companies that became increasingly multipurpose, reaching multiple markets (Hitt, Haynes, & Serpa, 2010). Competitiveness is inevitably increasing, leading companies to pay close attention to the value of the price offered to their customers.

In the 1980s, Porter introduced generic strategies for cost leadership and differentiation, arguing that companies should not implement both strategies simultaneously. The conflicting requirements that are needed to have cost leadership and to gain competitive advantage could cause companies to feel lost and ultimately fail to achieve a differentiated position in the market. The increasing trends of price, quality, and satisfaction of consumer needs – accompanied by the significant increase in competitive rivalry and new technologies – has led companies to develop an integrated system: a low-cost differentiation strategy (Hitt, Haynes, & Serpa, 2010).

All these factors make innovation increasingly important and continued technology development puts pressure on innovative companies. Companies must focus on learning, on building internal knowledge and on managing knowledge flows, as well as increasing the investment to create innovation (Hitt, Haynes, & Serpa, 2010).

3. Research questions

The research questions of this paper are the following:

1. How does an innovative firm innovate in Portugal, which is not seen to have an environment which welcomes innovation?
2. How should innovative products be priced, in the format of a formula, and in a standardized fashion ["one-size-fits-all"], if possible, and considering a cost leadership or differentiation strategic focus, or an integration of both?

4. Methodology

To answer the research questions above, a mixed methodology was followed (Bryman & Bell, 2011). This research is exploratory, having used both qualitative and quantitative research methods.

Firstly, a focus group was performed, involving eight people, six belonging to the company's different departments. The other two focus group participants were the moderators and are two co-authors of this study. The focus group was held on March 15, 2018, and had a duration of two hours. Audio recording was not allowed. Thus, hand-written notes were taken by the focus group moderators.

The main goal of this focus group was to understand how the company sees and treats innovation; and to analyse internal opinions about the generation of innovation. Problems were discussed and suggestions for improvement given. The role of customers for the company was also a topic of discussion, as was the pricing of products. How the company handles the competition and how employees see top management were also a part of the interview script questions. The focus group participants were carefully chosen in advance. Participants were given the necessary space to show their different opinions, despite the existence of an interview script.

Furthermore, an online questionnaire was administered to the whole firm. It was sent to the company's internal community and 48 valid responses were received. The survey was conducted over two weeks, from March 29, 2018, to April 16, 2018. The questions presented in the questionnaire fell into three categories: open, multiple-choice and with a Likert scale of 5 points (to measure the agreement with the statement presented) (Remenyi, 2013). The main goal of this process was to gather as many responses as possible in order to achieve a greater diversity of opinions/perspectives.

5. Presentation of the study and discussion

5.1 The focus group and the survey

This study was developed in a technological and innovative company located in a main Portuguese city, where new telecommunications technologies are the main focus of the company.

According to the focus group data, in this company collaboration and group work are preferred and competition between workers is not well received. Encouraging workers to be a part of team projects promotes cooperation. According to the focus group data, teams are coordinated amongst themselves, and individuals are motivated to try to make the most of their skills. However, those who are entrepreneurial and innovative may not feel so motivated. Although they are not excluded by the company for acting in a "different" way, one focus group participant believed that there is pressure in groups due to the different points of view. The innovative ideas that are investigated, studied and worked on are given attention, but only a few are implemented. As concerns improving the process of innovation at the firm, this is a daily concern. Continuous improvement, in an open environment, is the basis of the company. The firm's main customer is seen to be the head office (the owner of the firm), to whom they sell the new products developed. Customers are regularly surveyed for their satisfaction levels. As concerns innovation, yes Portugal is seen to be problematic. International partnerships exist for the development of certain products.

In the questionnaire (which was answered by 28 men and by 20 women, aged between 18 and 60 years of age), 58% of the respondents were of the opinion that there is a good environment for innovation in Portugal. Furthermore, 54% of the respondents are of the perspective that their firm is an innovative company. About 40% of the respondents stated that senior management accepts innovation even if it challenges the *status quo*. However, just over 21% stated that senior leadership does not accept innovation if it challenges the *status quo*. This may be worrying. Additionally, a total of 35% of the respondents think that the company is hierarchical and somewhat an authoritarian one.

In this company, cooperation between colleagues seems to work. Around 69% of the interviewees stated that the company prefers that workers work as a team rather than alone, promoted by the freedom to create teams in addition to those already created by top management. Also, encouraging dynamic alliances between workers governed by the same rules produces healthy competition. Through teamwork, workers feel more devoted to achieving mutual goals and end up being more committed to the team itself, since individual contribution turns out to be important and meaningful. Moreover, teamwork leads to better performance in activities, since each one of the employees maximizes his or her own skills in order to produce the most unique and productive work. Furthermore, 58% of the respondents agree that innovative and entrepreneurial people have different habits, stating that they like these type of people because they can create a new path for the team, motivating the team to implement new ideas.

Overly competitive workers was another important topic. Overly competitive workers create a certain environment in the company, motivating other workers to develop certain skills that may prove to be important. For the respondents, trying to work together will always be the preferred option when compared to having competition between colleagues. Around 40% of the respondents said that internal competition is important, while around 50% believe that competition is not healthy.

Finally, an association was found (chi-square test statistic at the 5% level of significance) between the age of the respondents and senior management accepting innovation, even if the innovation challenges the *status quo*. The older respondents (46-60 years of age) stated that senior leadership is receptive to innovation, whereas the younger respondents (18-30 years of age) do not have the same opinion.

5.2 The paper manager

At the end of the focus group interaction, a game was played: the paper manager. The objective was to perceive how the participants saw top management. Top management is often the main motivation and the deciding factor for workers to progress in their careers.

The "paper manager" had to be created by the focus group participants, with body parts provided beforehand, thus showing the work environment that is felt as relating to top management. Based on certain meanings, of each body element, respondents had to choose the size of the head, eyes, nose, mouth, ears, body, heart, and

legs. Of note is that only one of the six interviewees created the "paper manager" on a green work environment (a very productive work environment) (image 1), and all the other five respondents chose the white work environment (a neutral work environment when it comes to being productive).

The manager with the green environment (image 1) had a middle-sized head, meaning top management is perceived as being more or less innovative; medium-sized eyes with the gaze directed forward, meaning that top management gives some autonomy to its workers and is somewhat observant; a large-sized nose meaning that top management exercises fairly intuitive management; a small-sized mouth meaning that top management does not communicate much; medium-sized ears meaning that top management does not always listen to its colleagues; a medium-sized body meaning that the organization follows a bureaucratic line, but is also agile and entrepreneurial; a medium-sized heart meaning that some empathy is generated between colleagues and top management; and medium-sized legs meaning that top management moves, at times, through the hallways of the company.

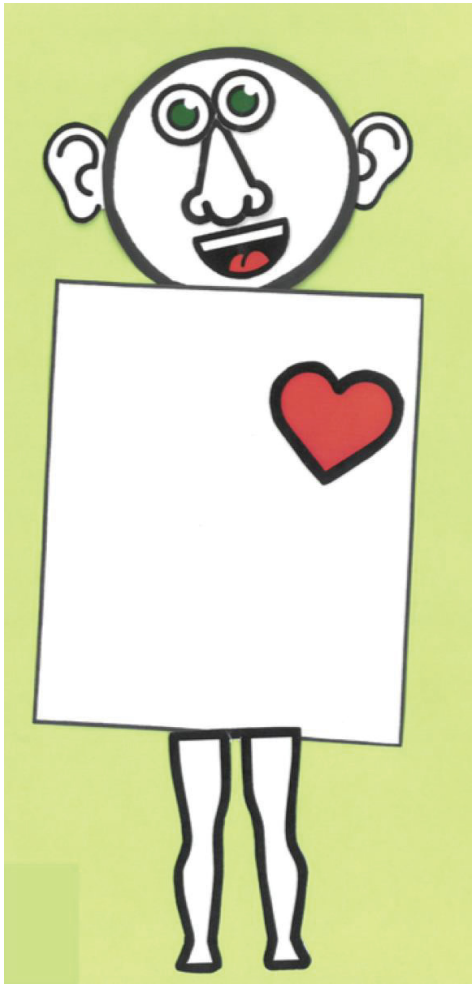

Image 1: The paper manager according to one focus group participant

For all the other "paper managers" built on a white environment, the head was average-sized (top management presents more or less innovative ideas). Regarding the size of the eyes, three respondents chose medium-sized eyes with the “paper manager” looking forward (top management gives autonomy to the workers) while one respondent chose to put the “paper manager” looking downward (management is not only observant but exerts control over workers). Their noses were medium-sized and large-sized, meaning top management follows intuition and the mouth was the bigger element, meaning top management communicates significantly. The ears were medium-sized, meaning that top management does not always listen to workers.

The body element chosen by the interviewees was the average one, which indicates that the company is bureaucratic, but also agile and entrepreneurial.

Two of the respondents (with "paper managers" built on a white environment) chose the large-sized heart, meaning empathy between workers and top management is high. Concerning the legs, one respondent chose large-sized legs, two respondents chose medium-sized legs and one respondent chose small-sized legs, meaning the opinions differ in relation to the movement of top management within the company.

5.3 Rewards

Motivation is a key aspect in the performance of both managers and subordinates. Motivation may be increased by the existence of rewards in the workplace. Through rewards, workers are encouraged to act in a certain way. In addition, rewards must also be capable of influencing workers to improve their performance and feel rewarded when completing goals (Björk & Holopainen, 2005). Mutual goals allow workers not to feel so alone even if top management rewards collaborators individually, motivating workers to develop their own skills but also to share rewards (Björk & Holopainen, 2005) while stimulating teamwork.

There are two types of rewards: formal rewards, that are real and palpable (i.e. cash, extra holidays or bonuses) and informal rewards that are more abstract and raise the workers' self-esteem (i.e. symbolic recognition, distinctions or symbolic certificates) (Björk & Holopainen, 2005). According to the questionnaire data, around 83% of the respondents stated that there is no formal reward for workers, and the remaining 17% partially agree.

The researchers also asked if workers thought they should be formally rewarded, to which 83% of respondents gave positive answers. As regards informal rewards, 77% of the workers think they should exist.

When questioned if workers would receive a recommendation after presenting something innovative to the company, 90% of the respondents gave a negative answer.

5.4 The prices of innovative products

Concerning the pricing of innovative products, this is a daunting though essential organisational task. The company follows the practice of meeting the market-established price and in so doing controlling the fixed and variable costs involved. During the focus grupo, it was mentioned that establishing the price of a product is quite complicated since there are several variables to be taken into account. Market prices need to considered and, if necessary, one may need to lower the price to be able to sell. In one of their most objective ways to formulate prices, the company takes into account the requests of customers; a certain price is established for the number of working days of a specific profile of workers; the cost of raw materials and the margin that the company establishes are also considered. Thus, a formula may be defined, as follows:

$$Price = ([\mathrm{C(rm)} + \mathrm{C(prod.)}] + [\mathrm{C(fc)} \times \mathrm{D}] + [\mathrm{C(R\&D)} \times \mathrm{K})]) \times \mathrm{M}$$

To the cost of raw materials [C (rm)], the cost of production [C (prod)] is added. The cost of fixed costs [C (fc)] is multiplied by the distribution (D) per product (varying from product to product); additionally, the cost of research and development (C(R&D)] is multiplied by the factor K (the distribution of the company's R&D costs by product, ranging from product to product). All of this will then be multiplied by the margin (M) established by each department of the company.

The company has some big competitors, some of whom are also customers, which is not an easy thing to balance. Having the customers' opinion is very important for product development. The department responsible for communicating with customers is also the first to receive their feedback and it is their responsibility to pass the feedback on to the rest of the company in order for it to be interpreted and communicated to the product managers. The different ideas coming from customers are analysed, the cost of implementation calculated, and which may later be accepted by customers. If, in the long run, the idea is not very advantageous for the company, usually it is integrated in a personalised product and sold to a particular customer. If the idea is good, the integration can be made in several products and the cost will end up being divided between all of the customers. However, in the focus group, it was mentioned that product innovation does not always reach all customers at the same time. Much of the innovation will only arrive at certain customers when there are malfunctions in a product and it has to be repaired.

6. Conclusion

A company's values influence teamwork and decision-making (Hartnell, Or, & Kinicki, 2011). Certain behaviours lead to desirable collective attitudes by workers as they create a setting for a united and responsible community.

In our study we have discussed the importance of national and corporate culture and the effects of these on innovation. In order to shed light on how the firm analysed innovates, a firm not long ago considered to be a "shining star", in the midst of other Portuguese technological enterprises, we performed a focus group and a survey.

The internal environment of the company analysed is based on collaboration, teamwork and on the exchange of ideas and opinions. Thus, internal competition, between colleagues, was considered by focus group members as being negative for the firm. Thus, the firm's workers labour towards a common shared objective and mainly working in groups (groups were actually referred to as being "the only way to work").

Indeed, we ascertain that the company is innovative as it works in a collective fashion as suggested in the literature (Hofstede, 2001; Hofstede et al., 2010) that Portugal favours. The firm is also somewhat autocratic, similarly in line with what the literature has to say about how Portugal functions (at the level of its national culture) (Hofstede, 2001; Hofstede et al., 2010).

Most of the respondents said that there should be formal and informal rewards (in a meritocratic environment) for those who can think differently and are able to be more innovative. However, the literature states that such practices will have a negative effect on innovation output (Poskela and Martinsuo, 2009).

We have discussed the Paper manager exercise and how different views of senior management exist.

We have also discussed how the pricing of innovative products is done at the firm, a topic which is lacking in the literature.

One is tempted to state that the firm is successful because it chooses to work intelligently, in groups and in a somewhat autocratic fashion, thus favouring the prevailing national culture, rather than going against it (Nguyen, 2016).

How Traditional Companies can Foster Innovation through Collaboration with Startups

Luise Springer, Daniel Michelis and Maximilian Senges
Anhalt University of Applied Sciences, Köthen, Germany
springer.luise@gmail.com
daniel.michelis@hs-anhalt.de
maxsenges@google.com

Abstract: Established businesses are facing enormous challenges in order to ensure their long-term growth and their overall competitiveness. The speed of innovation has increased significantly and due to digitization, they are threatened by innovative startups which arise in their initial business area. To obtain and expand their competitive advantage, they are forced to identify innovation opportunities and realize new products in a faster sequence. To do so, they often rely on startups as a source of innovation. The thesis evaluates, if the process of identification, evaluation and realization of innovation opportunities, is transferable to corporates in the case of collaboration with startups. Besides, it describes common cooperation models, identifies challenges and gives practical implications for managers. The theoretical part includes a comprehensive literature review regarding the relevant concepts whereas the empirical section contains qualitative interviews with managers of established companies and experts operating in the intersection of these two parties. The findings indicate that the process is transferable to established companies, but more likely to occur in business units that are independent from the core organization. Furthermore, the thesis reflects that the abilities to identify and evaluate innovation opportunities are particularly important for collaboration success. The presence of an overarching vision, as well as the encouragement of entrepreneurship within the company, are highly important. Both should be initiated and supported by executive-level decision makers. The research identifies organizational and cultural differences, as well as non-existent internal processes and structures, as the main challenges during collaboration. Cultural distinctions primarily occur in form of different structures, working methods and speed. The research results indicate that startup guides are a possible solution. The thesis links the concepts of open innovation and knowledge entrepreneurship and answers the question if the cooperation with startups could support traditional companies to overcome The Innovators Dilemma described by Clayton Christensen. Furthermore, it outlines challenges and influencing factors during collaboration and gives practical implications to corporates. The research is especially relevant for managers of traditional businesses who want to increase their company's level of innovation in the long term.

Keywords: knowledge entrepreneurship, entrepreneurship, open innovation, startup-corporate collaboration, organizational learning

1. Problem statement

Established companies are currently facing several challenges in order to ensure their long-term growth and their overall competitiveness. One urgent issue is linked to the growing demands associated with the digital transformation. The restructuring of the global business landscape through the rise of digital technologies, formally known as *The Big Shift*, is challenging existing organizational models (Hagel III, 2016). Another issue emerges from the radical changes in the current innovation landscape. Docherty (2015) describes the situation with the assertion “The old definition of innovation is dead” and states that growth is no longer generated by innovation in the core business, instead, it arises through the discovery of new sources and platforms (p. 7).

This transformation is being brought about by the increasing customer demand regarding the novelty and uniqueness of products as well as the speed in which they are being replaced (Docherty, 2015, p. 8). In addition, established organizations are being threatened by highly innovative startups. This has been confirmed by Hamel (1999) with the statement “Out there in some garage, an entrepreneur is forging a bullet with your company's name on it. You have only one option: you have to shoot first.”.

One explanation for the difficulties is *The Innovators Dilemma* described by Christensen (1997). Bower and Christensen (1995) describe a consistent pattern in companies: “they often fail when they stay on top of their industry and technologies or market changes” (p. 43). Another widely known concept is the idea of organizational ambidexterity. It outlines the ability of a firm to improve its core business while simultaneously searching for new business segments. O’Reilly and Tushman (2004) regard this ambition as a crucial factor for the long-term success of a firm (p. 76).

The sources of innovation are increasingly being generated through the cooperation with external partners (Chesbrough, 2003). The opening of corporate boundaries has been associated with a significant rise in innovation opportunities. Due to rapid technological change, they arise in a faster sequence (Hamel III, 2016). According to these new requirements, companies need to enable their employees to identify these opportunities, evaluate them and integrate them into their existing processes and structures (Hamel III, 2016). These skills belong to the core competencies of an entrepreneur (Hamel III, 2016; Senges, 2007, p. 299). Therefore, entrepreneurs are getting even more important in the corporate context (Hamel III, 2016).

Based on the above stated facts, the paper addresses the following research questions:

- Is knowledge entrepreneurship transferable to established companies and to what extent does it have to be adapted in order to meet the special needs associated with cooperations with startups?
- What influencing factors of knowledge entrepreneurship are most relevant when it comes to collaboration with startups?
- What challenges and further influencing factors arise within the cooperation between established companies and startups?

The thesis builds on literature analyses and an empirical section conducting interviews with experts of established companies as well as selected experts operating in the intersection of these two parties. The research aims to identify the extent of which knowledge entrepreneurship is transferable to established companies in the case of collaboration with startups. On the one hand, it takes a closer look at the components of the knowledge entrepreneurship model and which of them are more or less relevant when it comes to collaboration. On the other hand, it analyzes goals, common challenges and further influencing factors during the cooperation and provide some practical recommendations.

2. Theoretical framework

The subject of organizational learning is a crucial precondition for internal knowledge acquisition and processing and it is an opportunity for companies to remain competitive in a changing environment (Moingeon, 1996, p. 7). Nonaka and Takeuchi (1995) are regarded as some of the most influential contributors to this field of study. They differentiate between tactic and explicit knowledge (Nonaka, Takeuchi, 1995, p. 59).

Tactic knowledge is personal, context-specific and cannot be communicated or articulated (Nooteboom, 2001, p. 38; Nonaka, Takeuchi, 1995, p. 59). It is found in the culture of a company (Nooteboom, 2001, p. 38). Explicit knowledge, therefore, can be formulated, reproduced, and described by words and numbers (Nonaka, Takeuchi, 1995, p. 59). The interaction between these types continuously increases the knowledge base of a firm (Nonaka, Takeuchi, 1995, p. 70). This interaction is accompanied by a change between the four different modes of knowledge transformation.

An organization cannot produce knowledge on its own since the tactic knowledge of the individuals is required (Nonaka, Takeuchi, 1995, p. 72). For this reason, the authors understand knowledge production as a spiral, starting at the individual level and moving across divisions or business boundaries and continuously expanding the knowledge base (Nonaka, Takeuchi, 1995, p. 72).

The concept of knowledge entrepreneurship closes the gap between organizational learning and innovation (Figure 1). It describes the ability of an individual or an organization to identify opportunities and to take action with the aim to realize new products or practices (Senges, 2007, p. 5). In contrast to traditional economic entrepreneurship knowledge entrepreneurship is not driven by monetary means, but rather relies on the identification of possibilities to optimize products and to accelerate knowledge processing (Senges, 2007, p. 31).

Figure 1: Knowledge entrepreneurship as a link between organizational learning and innovation

(Source: Own representation, based on Senges, 2007, McDonald, 2002)

The capability of knowledge entrepreneurship is influenced by different factors. On the one hand the current condition of the corporation, described through its culture, leadership and ability to engage in organizational learning is classified as a crucial factor (Senges, 2007, p. 34). On the other hand, the abilities to identify, evaluate and apply innovation opportunities is described through five parameters. The factors environmental awareness and communication influence the ability to identify innovation opportunities (Senges, 2007, p. 300f.). Whereas risk tolerance and vision and strategy affect the capability to evaluate them (Senges, 2007, p. 300f.). Finally, the new project support influences the realization of these opportunities (Senges, 2007, p. 302). The interaction of the competences is described in figure 2.

The concept of innovation appropriation is used as a conceptualization and practical implementation of knowledge entrepreneurship in this research (Senges, 2007, p. 47). The approach describes the process of integrating an innovation into the organization and is based on the model of absorptive capacity by Cohen and Levinthal (Senges, 2007, p. 47; Cohen, Levinthal, 1990). Due to its non-economic orientation and dependence on the activities of individuals, the concept is classified as suitable for this study (Senges, 2007, p. 47).

3. Research Design

The research is divided into a theoretical and an empirical part. The first section includes a comprehensive literature review regarding the concepts of the learning organization, knowledge entrepreneurship and open innovation as well as the collaboration between startups and companies.

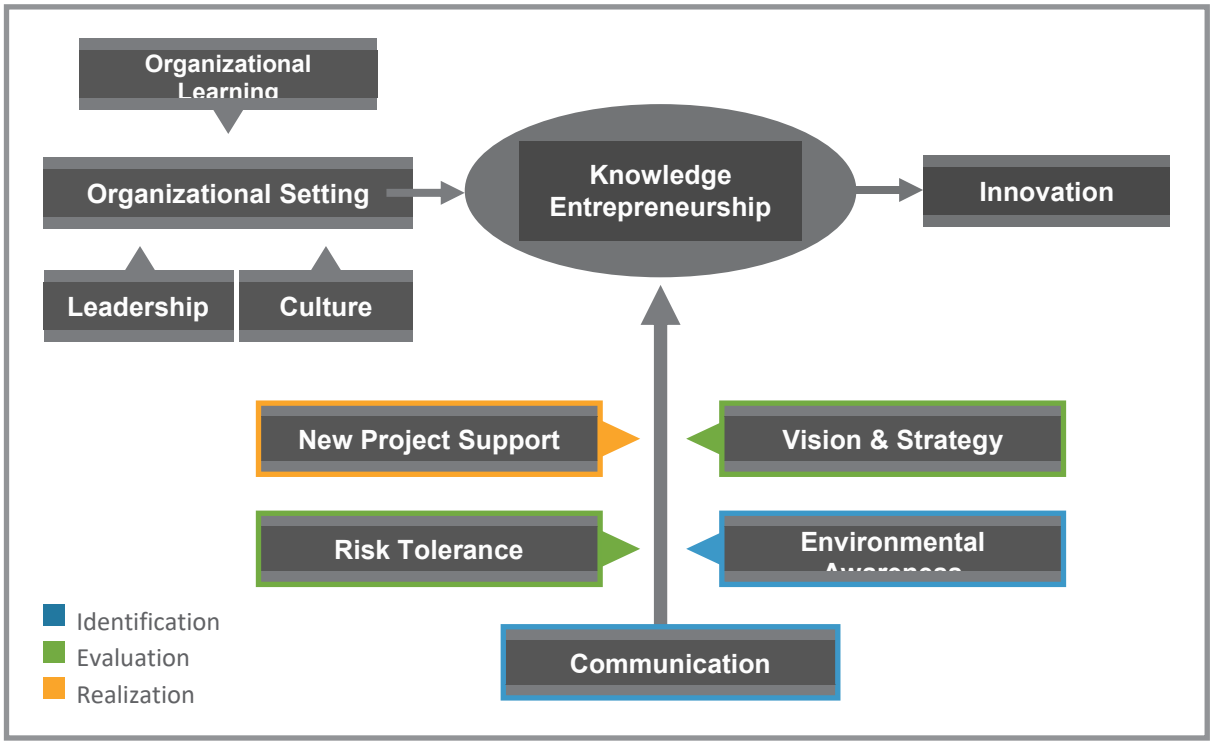

Figure 2: The knowledge entrepreneurship model

(Source: Own representation, based on Senges, 2007)

The second, empirical section, contains interviews with experts of established companies as well as interviews with selected experts operating in the intersection of these two parties. The analysis is exploratory and based on grounded theory. Therefore, no hypotheses are developed at the beginning (Glaser, Strauss, 2006, p. 2).

4. Interpretation of results and conclusion

The findings indicate that the process of identification, evaluation and realization of innovation opportunities is transferable to established companies, but more likely to occur in business units that are independent from the core organization. Furthermore, the thesis reflects that the abilities to identify and evaluate innovation opportunities are particularly important for collaboration success. The presence of an overarching vision, as

well as the encouragement of entrepreneurship within the company, are highly important. Both should be initiated and supported by executive-level decision makers. The research identifies organizational and cultural differences, as well as non-existent internal processes and structures, as the main challenges during collaboration. Cultural distinctions primarily occur in form of different structures, working methods and speed. The research results indicate that startup guides are a possible solution.

The results suggest that knowledge entrepreneurship is not explicitly supported in any of the companies investigated in this study. Instead the author found different firm structures to identify, evaluate and act on innovation opportunities.

In the following paragraph the three research questions are formally answered.

- Is knowledge entrepreneurship transferable to established companies and to what extent does it have to be adapted in order to meet the special needs associated with cooperations with startups?

The research states that knowledge entrepreneurship and the underlying influencing factors are transferable to established companies. In the case of cooperation with startups, it turns out that knowledge entrepreneurship is more likely to occur in business units that are separated from the core organization.

Through the separation of the unit, different business structures and internal processes support the development of knowledge entrepreneurship. The ability of an organization to optimize its core business while simultaneously looking for new innovations, also described as the concept of organizational ambidexterity, assumed to act as a suitable precondition for knowledge entrepreneurship to occur (O'Reilly, Tushman, 2004, p. 76). Christensen, Raynor and McDonald (2015) are also convinced that companies have to establish separate units for the development of disruptive ideas. These units should operate under the protection of the company management (Christensen, Raynor, McDonald, 2015). The study could not verify the need for the adaptation of the model with regard to cooperation with startups. Apparently knowledge entrepreneurship is suitable to increase the innovative capacity of an established organization.

- What influencing factors of knowledge entrepreneurship are most relevant when it comes to collaboration with startups?

The research found that the parameters environmental awareness as well as vision and strategy are particularly important when it comes to collaboration with startups. Given the fact that the startup environment is highly dynamic, the continuous monitoring of the direct and extended environment through events and networks is of great importance. The factor vision and strategy is another important prerequisite as it includes the presence of an overarching vision as well as the internal encouragement of entrepreneurship.

Both should be initiated and supported through the executive level. Further it was found that companies operating within an outsourced unit have a more distinctive attitude towards entrepreneurship and are more likely to defend their competitiveness by increasing their innovation opportunities. The factor risk tolerance is rather low among all investigated companies. None of the companies deliberately take risks. Potential risks are still associated with negative feelings. The communication in the investigated companies takes place very individually and usually without predetermined structures. Even the interaction with startups is highly project-dependent and includes different channels. When it comes to the initiation of long-term relationships the process is characterized by a high level of bureaucracy and low speed. None of the investigated companies has implemented specific processes to accelerate the launch of new projects or long-term relationships. The new project support parameter is consequently rather low.

- What challenges and further influencing factors arise within the cooperation between established companies and startups?

In terms of cooperation with startups, the research found that organizational and cultural differences as well as challenges regarding internal processes and structures were the main challenges. Cultural distinctions primarily occur in form of different structures, working methods and speed. These contrasts can become critical if they are accompanied by inadequate management. Startup guides are a possible solution for this challenge. These are well-chosen employees with an entrepreneurial mindset. These guides operate at the

interface between startups and companies and can minimize the impact of cultural differences by mediating challenges arising during the relationship. In addition to the guides, the organizational unit itself can act as an intermediary.

Furthermore, the research found that none of the companies had adapted their structures to the special needs of the smaller partners. When it comes to the processes of initiating of cooperations and the transition into long-term partnerships, all companies adapt the proven procedures for all types of service providers. These operations go along with reduced speed, high complexity and the involvement of various business units.

Therefore, the use of separate organizational units for identification, evaluation and integration of innovation opportunities become even more essential. These units are more likely to create structures and processes that deviate from the core business. In addition, companies have to set up separate processes for the collaboration with startups that meet their particular needs.

All in all, corporates have to speed up when it comes to collaboration with startups. A proven approach obtaining quick decisions is the integration of the top-management through a pitch or demo day. It also promotes the commitment of the management level, which has proven to be a relevant influencing factor within the cooperation.

5. Concluding remarks

Even if companies create all the structural prerequisites for successful identification, evaluation and realization of innovation opportunities, ultimately the employees themselves have to apply these processes. In order to enable this, employees need the freedom and responsibility to act independently as entrepreneurs within the company context. With regard to cooperation with startups, it is essential that the contact person has an entrepreneurial mindset and is given the competencies to act independently and responsibly. Thus, challenges relating to differences in culture, speed and organizational structures become less relevant and less critical for success.

Taking a look into the future, joint innovation programs with a range of large companies are getting more relevant. Within these so-called shared accelerators, several companies are working with startups. This promotes exchange across company boundaries since the partners often work on similar challenges that are not primarily related to an industry or market structure.

Finally, it can be said that collaboration with startups is a key innovation potential for traditional companies.

Ultimately, the organization itself always determines whether and how innovation opportunities that arise from the collaboration result in innovative products that have the potential to ensure the long-term success of the company.

What Makes my Wine E-Shop Stand Out: Evidence from the Online User Experience Research

Lucia Štefaňáková and Anida Krajina
Masaryk University, Brno, Czech Republic
stefanakova.lucia@gmail.com
anida.krajina@gmail.com

Abstract: In the digital age, people are surrounded by a vast of possibilities to buy things online. They receive hundreds of information and have many choices. Therefore, it appears more difficult for e-commerce to optimize the customer experience and encourage them to make a purchase. The main goal of this paper is to examine the behavior of wine e-shop customers and to analyze which website components influence their process of online shopping. The research deals with the importance of user´s experience and examines the question of the optimal combination of individual elements in the wine e-shop. The focus is on three areas: specific filters, graphic design and product descriptions; which are essential for purchase decision making in the process of online shopping. In order to reach the goal and examine the aforementioned areas, we looked at the following: Product impact, that includes the product information on the website; Orientation impact, including filter functions and orientation on the website and Customer service impact, that depicts the general information about the e-shop and related fees presented on the website. To achieve this, we did an A/B testing on two variants of the website, created as prototypes for this research. We combined it with „think aloud" method in order to define connections between used elements and customer behavior. Our results show the optimal combination of elements that guide purchase decision making in the case of wine e-shop, and improve the customer online shopping experience. The contribution is both academic and practical. Academia can benefit from acquiring additional knowledge regarding online customer behavior and decision making factors in online purchases. Practically, the results are useful for wine shop owners, especially those selling online, when choosing the innovative and optimal website interface to enhance customer experience and induce purchase.

Keywords: user experience, e – commerce, think aloud, online consumer behavior, online shopping

1. Introduction

The internet is growing rapidly in popularity with estimations of 3, 58 billion users worldwide (Statista, 2017). In the Czech Republic there are currently 41 047 e-shops, which expand the assortment. Compared to the number of inhabitants, Czech Republic has the highest number of e-shops within the EU (Ceska-ecomerce, 2018).

At the beginning of 2000, the researchers believed that the primary goal of e-commerce website was to facilitate economic actions, not to provide information (Brewer, 2005). However, applying internet in the commerce has grown exponentially, and it has created an efficient and effective way for retailers to maintain shopping experiences. It enables customers to make purchase decisions anywhere and at any time, thus influencing retail growth (Wei, 2016). As wine has become everyday customer good (Brewer, 2005), it is common to purchase it online nowadays. Nevertheless, the online shopping experience occurs differently than the in-store purchase, as we may talk about the online consumer response. Brewer (2005) explained that wine is an information-sensitive product and that this actually presents retailers with the opportunity to design websites that provide the right type and amount of information about their products.

This said, there is a chance that the wine consumers may have different habits and impose different behavior online. The present research is dealing with the question of how consumers behave and make decisions in wine e-shop and what do they prefer in terms of design and content.

1.1 Research aim and research question

The aim of the research is to uncover an optimal selection of individual elements in the wine e-shop that helps potential customers during their purchase and enhances user experience online. The research will explain the importance of components such as graphic design, specific filters, product descriptions and their influence on preference, user experience and purchase decision making in online shopping.

The main problem that we want to solve is how elements of the wine e-shop influence user experience and purchase decision making. Out of this statement, we have developed several research questions to answer within this research:

1. Do filters on the website enhance user experience?
   - Do filters on the website influence purchase decision making?

2. How do the product descriptions influence user website experience?
   - What are the users' preferences in terms of product descriptions?
   - Do product descriptions influence purchase decision?

3. In which way graphic design and overall orientation influence the user experience and purchase decision?

2. Theoretical background

Constantinides (2002) supposed that the traditional marketing mix paradigm is basically incompatible with e-commerce. The following marketing mix perspectives are consequently dominant in the online situation (Constantinides, 2002):

- product – the website itself is a brand image of the online shop and the prime online product
- price – the website price lists of the products work as the price of the physical product
- promotion – the website is the promotional medium and promotional content creator
- place – the website is concurrently counter, sales outlet and helpdesk where the actual transaction going on.

Since this approach, there has been a wave of studies focused on achieving a greater understanding of consumer behavior online (Merrilees & Fry, 2003). Thus, we can nowadays talk about the trends that indicate how marketers need to identify the determinants of online consumer shopping process. In this respect, theorists do recognize the rapid expansion of e-commerce, but at the same time, the limited understanding of the e-consumer (Wei, 2016). Wei (2016) concludes that the decision-making during online shopping appears to be different from that in other purchasing methods and environments. The main differences could reflect in perceived risk, brand choice, price sensitivity, delivery time, or interaction with the product (touch, smell, etc.). In addition, it is well known that online shopping is intangible, so consumers are concerned about the uncertainty including transaction, delivery and refund (Wei, 2016).

User experience in this context is perceived as effects felt by a user as an outcome of interaction with, and the application (usage) context of, system, device, or product, including the influence of usability, usefulness, and emotional impact during interaction (Hartson & Pyla, 2012). We can talk about the cognitive processes behind, as an important indicator and predictor of the interaction and behavior. For instance, the purchase decision making is influenced by decision biases- the phenomenon in which consumers show inconsistent preferences or choices when identical attribute information of products is differentially described either positively or negatively (Jin et al, 2017). Jin and colleagues (2017) describe the study from 2014 where the eye tracking method was applied to uncover the purchase intentions. The study showed that the eye movements were more active with negative frames and there and function attributed induced a greater number of those movements (Lin & Yang, 2014). Another study, therefore, explored the role of attribute framing in information processing and purchase decision making and confirmed that negative framing messages result in greater cognitive conflict and decision difficulty (Jin et al, 2017). However, to the authors' knowledge, there was no study researching the influence of positive framing and different design elements on purchase decision making and preference in wine e-shop. Previous research has suggested that insights on how exactly to attract customers to a wine retail website and retain them may be the benefit of further research in wine e-shop behavior and trends (Bruwer, 2005).

Some researchers argue that wine as a product might not be particularly suitable for online retailing (Richardson, 2002). In support of this, the characteristics of products may determine the propensity of people to shop online, meaning familiar or standardized products lead to higher customers' intention for online shopping (Wei, 2016). On the other hand, some allege that wine is an asset for internet retailing on account of

educating with tasting notes and search capabilities for special wines (Lockshin, 2000) and that it represents information-sensitive product (Brewer, 2005). Brewer (2005) further explained that visits to low-involvement product websites such as wine will have a shorter duration and generate a shorter website clickstream pattern than that of high-involvement product website. Generally speaking, elements of the consumer response process, such as perception, cognition, affection/emotional response, association, persuasion, decision-making and behaviour are important phases and points in consumer response process and can occur simultaneously.

This is especially present in the digital environment, where Hanekom et al. (2007) explain that the online consumer response levels do not necessarily follow each other in the proposed sequence, but may overlap with some even being omitted during certain response situations. In addition to this, the digital environment is an open space and it is possible for consumers to exchange and share information with all stakeholders, including the organisation and other consumers. This all affects the final attention patters, attitude formation and the decision making (Hanekom, Barker and Angelopulo, 2007).

According to Bruwer (2005) the website functionality has primary importance for the success of online wine retailers as are the security aspect of the transactions, quick fulfilment of orders and perception of online consumers that the pricing is fair. The website should provide just enough information necessary for purchase decision making. Wei (2016), argues that there are two major sources of information including the website marketing efforts and the sociocultural influences; and besides the information search, the online customers also do price comparisons and promotion evaluation much more than the customers in the stores. Online experience may play a major role in the offline consumer behavior.

3. Method

To answer the research question, a combination of two methods was applied. At first, a quantitative experimental study was implemented, through processing and comparing two similar but slightly different prototypes. The A/B test was chosen for this comparison. A significant part of measuring the possible differences was collecting data from both experimental groups. A/B testing presents each unique user with one of two versions of a design-the A version or the B-version and conversion rates for each version is compared to see which one performs best (User Testing, 2017).

Participants were given 5 tasks related to research questions. After completing the tasks, the participants were asked questions related to three areas: specific filters, graphic design and product descriptions. Think aloud method was applied while performing the tasks. Someren et al. (1994) describe thinking aloud such as a method which consists of asking people to think aloud while solving a problem. For better understanding user behaviour we recorded mouse movements and the participants' voices.

Transcript of interviews was created and further coded for obtaining results. This is explained in details in Main Findings chapter.

3.1 Sample

Ten participants (five female, five male) between 26 and 32 years living in the Czech Republic participated in the experiment. The age range was chosen based on the evaluation of the target market of the selected e-commerce wine company. Majority of their customers come from the age group 25-40 so the selected audience was from the same age group. The final selection of the sample was influenced by the contacted individuals' willingness to participate. The participants signed the consent prior to the participating. All participants were familiar with online shopping and were employed for wages. They are from the Czech Republic and Slovakia and currently live in Brno. They are also potential users of the Brno-based online shop.

Nine people claimed that they prefer the computer for shopping (over the smartphone). Five participants shop online once in two weeks, two participants shop once per week, two participants shop less than once per month and one person shop once per month.

3.2 Experiment design and flow

Before the experiment the participants filled in the demographic questionnaire. At the beginning of the meeting, moderator read basic information about the research. Participants signed the consent form and got the experiment task on the paper. At the same time, moderator read the task. The tasks were done without

moderator's help. The interview and the movements of the computer mouse were recorded. After the task was done, the moderator started with the short interview based on the task and research goals.

4. Main findings

Based on the research questions, the authors defined the themes and connected it with the descriptions obtained from the transcripts created from recordings (think aloud method). The themes that we observed were:

- Filters influence on user experience
- Filters influence on purchase decision making
- Product descriptions preferences
- Product descriptions influence on purchase decision
- Graphic design of the website
- Orientation on the website

The first research question is related to filters and their influence on the user experience and purchase decision making. Through the process of coding, we searched for definitions, both positive and negative regarding two aspects- user experience and purchase decision making. Participants did not prefer a large number of filters as they are used to see products on the top of the website and take the first on the list. For example 8 out of 10 point out to fact that they do not like a large number of filters and do not use it all.

They also preferred settings in which the filters help them reach their inner goal or intention. One of the participants had a positive response to filters, because the person uses filters in order to choose narrower and more specific product range. Others' connotations were mostly negative- the filters caused confusion.

However, for all participants the most important filter was related to the varieties of the wine. The second important filter was residual sugar of wine, while the least important was an attribute of wine. One of the website versions included special filters called *real feel of aroma, real feel of the sweetness and real feel of wine body.* These filters could be defined by values 1 to 5. As for these filters in particular, participants responded differently. For some it was something subjectively, others said it is not helpful for them and it is for the experts. Some participants indicated that the wine maker gives them the best clue about the quality of wine and they used this filter in their decision making.

The second research question focuses on product description. As with the previous question, we observed the influence of product descriptions on both user experience (what participants preferred) and purchase decision making. There was a similar number of those who like longer and who like shorter product description, 6 out of 10 points out to preference longer product description. Participants mostly read the parts related to the general impression and taste of the wine. It is important to mention that participants did not read the full descriptions, only small parts of it. For instance, respondents found useful the text about the food and wine combination. Majority of participants enhance the importance of information such as the size of the bottle and the origin of grapes (e.g. specific conditions of the land). On the other hand, they do not find the wine award crucial for their decision making.

In the third part of the research, we observed in which ways graphic design and overall orientation influences the consumer response online. In this respect, we included two random versions of the website- full text and without full text. Full text search means searching for the products by the key words. Full text search was selected in order to find out the importance of these elements for the consumers. Full text search was allowed to 5 participants. Four of them used it to find wine. Respondents who could not use full text search mentioned that they would have used it. Participants liked the graphic design of the website and consider it reliable. For example 10 out of 10 points out that nicely crafted e-shop website effects reliability. Other graphic and orientation elements that participants highlighted were shipping price, personal pick up, an assortment of goods, the reliability of the website, professionalism and the website design. 9 out of 10 point out that they take into account shipping price before purchase. The website design, according to the participants, also influence the purchase decision making because it creates the feeling of trust.

5. Discussion of the results

Considering the online consumer response, we may talk about purely psychological and individual points of view. According to the results, the large number of filters may cause the confusion and the information overload, which harms the user experience and purchase decision making. Previous research shows that the simple interface was preferred over the complex in the meaning of interface usability utility (Warden, et al, 2006). Respondents in our research explained the confusion were caused by displaying a larger number of filters, and the first products were seen after longer scrolling. As indicated in the Findings, the participants preferred filters that helped them reach the inner goal. Wei (2016) explains that as the amount of attributes on the website is narrowed down, consumers could find the 'best' option easier and more quickly.

However, some filters in our research appear to be crucial, such as the type of wine. Survey of the Wine Fund shows that 60 percent of Czech consumers prefer wine produced in their own country (Press release for Wine Fund, 2017). In addition, consumers choose the familiar wine which is produced in the Czech Republic. Consumer behavior study for wine says that regions or grape varieties with larger market shares have been more trustful (Lockshin & Corsi, 2012). Based on the 2017 survey (Wineofczechrepublic, 2017) Czechs consumers prefer the wine which they know and have already tasted. Because of that, people take into account the attribute of wine and in the most cases, the origin of wine they choose is the Czech Republic.

Many articles concerning wine choice behavior research items such as taste, alcohol content, type, age, price, brand, package and region of origin (Corduas, et al, 2012). At last, culture, lifestyle and traditions influence consumption behavior across countries and, the relevance that consumers give to the various wine characteristics (Goodman et al., 2007, 2008; Goodman, 2009).

In the case of product descriptions, the preferences between longer and shorter descriptions did not vary much in our research. The arguments for longer description were simplicity to make choice and less need for clogging. On the other hand, respondents preferred shorter descriptions. They explained that they do not read a lot of text. Easiness of navigation and choice is important for the online users in reducing their cognitive load.

In the study written by Quiroga (2004) it was concluded that the cognitive load incresed with the amount of information. Information filtering is substantial in reducing cognitive load (Quiroga, 2004). As people are used to changing their approaches to decision making due to different environment and situations, they will always try to reduce the effort related to the cognition of decision making (Wei, 2016).

As one of the important results, we highlighted the fact that participants did not read the whole descriptions. They preferred information that they considered useful, which is also related to fulfilling the goal. If we observe our sample, all of them belong to the Generation Y cohorts, which are also recognized in the literature as Millenials. In terms of content perception, some statistics show that Generation Y differs from older generations in terms of reading habits; they do read, but it is different (Millenial Marketing, 2018). In other words, they are reading for information and they are information hunters. Barber and colleagues (2006) concluded that descriptions such as ''floral'' or ''essence of peaches and dried apricots" did not add a real value for the customer who is not an expert and may be uncertain about the wine choice. Simple and basic information such as how sweet or dry is the wine, what the grape is and what foods will go well with the wine are preferred by customers (Barber et al, 2006).

The purchase decision making was influenced by engaging descriptions, which participants related to impressions, top products and similar products. Similar and related products should help people find the best option which fit their taste. Other decision elements were price and design. Some studies indicate that there is a relation between price and quality, especially in the consumers' minds. For instance, a famous study carried out by Plassman et al. in 2008 concluded that the value of a product (price of a wine bottle) had an impact on the perception regarding the quality of the product (Plassmann et al., 2008). The results of some studies confirmed that an important role in wine's promotion and presentation for consumption was overall packaging (Bloch et al. 2003; Chaney, 2000; Jennings and Wood, 1994). These studies indicate that the design can play a decisive role in consumption process.

Finally, the overall orientation on the website and the speed of the search was important for enhancing the user experience. Even those participants who did not have the access to full text search, claimed that they

would have used it. We therefore concluded that allowing the full text search is beneficial for the wine e-shop and improves the experience on the website. Some studies state that visitors are highly motivated to use site search because they exactly know what are they looking for (Moth, 2013).

One of the significant aspects of the present research is the trust that consumers need to have towards the brand, products, manufacturer and the website. Panula (2017) states the concept of trust is not so simple because it can be an individual phenomenon. The preferences based on which the trust is built can vary. There is probably no simple solution to generate customer trust in an online environment and one method is not enough. Combinations of efforts and specific steps should be beneficial (Panula, 2017). Online wine retailers should aim for a customer-oriented interface through the internet. Wine is an intensively branded, differentiated and internationally traded experience product (Brewer, 2005).

6. Conclusions and recommendations

Even our research advocates that there are inevitable motivators for consumers to shop online. According to Wei (2016), customers can shop comfortably in their familiar environment, have time to find attractive alternatives and browse. The interaction between digital environment and consumers is well explained by the online consumer response model. As the model suggests, there are different phases of this process and they may be different for different online users (Hanekom et al, 2007). Perceived exposure or the perception level in online consumer response is related to the process by which participants of the study received the information through their senses (in this case- vision) and assigned meanings to it. The information aggregation achieves further abstraction such as object recognition, semantic interpretation, and the combination of multiple objects (Barnett & Cerf, 2017). The authors explored these by thinking-outloud experiments and simultaneous questioning.

The results from the present study point out some significant elements of the wine e-shop. One of the significant elements is composition and number of filters which influences user experience. The results of the present study show that a large number of filters do not allow people to see the first products. Next important element of the website is product description which influences the purchase decision. There is no significant difference between the long and short type of descriptions. The results indicated that participants mostly read general impression and taste of the wine. They were also interested in information about the size of the bottle and the origin of grapes. The third important element of the wine e-shop is overall orientation and graphic design. The study also turned out the importance of the full text search, especially in cases when people search for a specific product. This part includes communicated information such as shipping price, personal pick up, an assortment of goods, the reliability of the website, professionalism and reliable design of the website. All these elements create the trust that consumers need to have for final purchase. The above mentioned factors influence user experience and purchase decision making.

According to the results of this study, we made several suggestions for the e-shop we did research with. We predict that the wine e-shop should adjust the website in order to enhance and affect user experience and induce purchase. Those adjustments are as follows:

- Narrow down the selection of filters to avoid confusion and information overload;
- Create compelling and informative product descriptions;
- Have simple but creative website interface;
- Present clear information about shipping price and personal pick up;
- Product descriptions should include the suggestion for wine and food combination.

6.1 Limitation of the study

The study is not without limitations. First of all, the sampling method was through personal and professional networks. The participants were from the Czech Republic and Slovakia. The sample is a representative of the target audience of the observed wine seller and e-commerce website. Another downside related to the sample was the limited number of participants. Even though, the experiment that includes qualitative data gathering does not require large samples, if the experiment included more participants, the results may have been more representative. Therefore, the future studies that may tackle the same question may think about enlarging the sample size. The experiments and interviews were done in the Czech and Slovak language, due to the easiness of communication. Therefore, the limitation of this research may be that some meanings were lost in

translation. However, we do trust that the crucial conclusions are valid in the present research. Finally, the limitation may be the experiment itself, because the participants were not in their natural environment for their online purchases. This could have caused some bias. Nevertheless, we do believe in participants' honesty in their answers and opinions.

Despite the aforementioned limitations, the results of the present research have important value for both theory and practice. From the theoretical perspective, the results may serve as a starting point to more thorough and larger research in the cases of wine e-shops and consumer preferences. On the other hand, it brings an additional understanding of online consumer response to a particular case study of an e-shop. The overall contribution of the study is principally bringing additional knowledge for e-commerce sector, especially for wine e-shops. In the practice, this research should help e-shops owners to create and modify their e-shops in order to enhance user experience and induce optimal purchase decision making and finalizing purchase. The results show significant elements which play an important role in the purchase process.

Work in Progress Papers

Identity-Transition into Entrepreneurship: A Two-Phase Theory to Explain the Propensity-Capability Paradox

Francis Dams [1] and Jesse Segers [1, 2]
[1] University of Antwerp, Belgium
[2] Sioo, the Netherlands
francis.dams@uantwerpen.be
jesse.segers@uantwerpen.be

Abstract: In view of the call by the European-Commission (2013) for more entrepreneurs and for more high-growth enterprises, this project investigates the development of entrepreneurial propensity among individuals who possess strong entrepreneurial capabilities. Scholars have modelled the development of entrepreneurial behavior by adopting the theory of planned behavior and later by applying identity transition theory (Ibarra, 2005) to entrepreneurial career transitions. More recently, Hoang and Gimeno (2010) added the construct of role-identity-complexity to the identity transition model in order to explain the likelihood of a successful transition into the entrepreneurial founder role. There is, however, a need for theory to enlighten why objective entrepreneurial capability has not shown up as a favorable explanatory variable when modelling entrepreneurial intention and career transition behavior (Bayon, Vaillant, & Lafuente, 2015). This article and this poster present a model to respond to this need and to extend the theory on developing entrepreneurial behavior by showing how objective entrepreneurial capabilities can intervene in paradoxical ways. More specifically, we broaden the identity theory for entrepreneurial career transitions by distinguishing two phases. The point where entrepreneurial intention is established separates these two phases. We argue that constructs like self-complexity, the complexity of the envisaged founder-role and objective entrepreneurial capability have opposite effects in both phases. If these factors have an inhibiting effect on generating intention and have a favorable effect on turning intention into actual behavior, then this explains why individuals who are expected to have the necessary capacities to do well in the second phase can struggle to develop entrepreneurial intention in the first place. We conclude by suggesting further quantitative and empirical research and possible practical implications.

Keywords: Entrepreneurial intention, Entrepreneurial capabilities, Identity transition, Self-complexity

1. Introduction

Policy makers envisage encouraging entrepreneurship (European-Commission, 2013) and consensus is growing that actions promoting entrepreneurship should aim beyond the mere creation of more entrepreneurs (Blanchflower, 2004; Burke, FitzRoy, & Nolan, 2000) and that these actions should focus on ambitious start-ups with high growth potential (Shane, 2009). In support of this call, scholars continue to address the following questions: firstly, what determines whether an individual decides to step into active entrepreneurship and secondly, what are the characteristics that make an individual more competent to successfully fulfil an ambitious entrepreneurial role? Dams and Segers (2018) refer to the answers to these two questions as the antecedents of entrepreneurial propensity and entrepreneurial capability. They review the most researched antecedents of these two constructs and conclude that the majority of antecedents can have opposite effects on entrepreneurial capability and propensity (Figure 1).For three of these factors: need for achievement (Begley & Boyd, 1988; Jain, 2011; David C. McClelland, 1961); innovativeness (Frese & Gielnik, 2014; Jain, 2011); and creativity (Mcmullan & Kenworthy, 2016), no references to opposite effects on entrepreneurial propensity and entrepreneurial capability were found. For the other nine most researched factors, earlier research reveals opposite effects on entrepreneurial propensity and capability. This study of the literature does not provide a quantitative proof of significantly negative correlation coefficients. However, if factors like the need for independence (Caliendo & Kritikos, 2011; Hessels, Van Gelderen, & Thurik, 2008; Mcmullan & Kenworthy, 2016; Van Gelderen & Jansen, 2006), self-efficacy (Bayon et al., 2015; Chen, Greene, & Crick, 1998), optimism (Hmieleski & Baron, 2009) overconfidence (Koellinger, Minniti, & Schade, 2007), risk propensity (Begley & Boyd, 1988; Hao, Seibert, & Lumpkin, 2009), the need for power (De Vries, 1977; David C McClelland, 1975), education (M. Van Praag, Witteloostuijn, & Van der Sluis, 2009), experience (Chandler & Jansen, 1992; Zouhar & Lukeš, 2013), teamwork (Ensley, Hmieleski, & Pearce, 2006; Fadul Ramirez, 2016), financial utility (Hartog, Van Praag, & Van Der Sluis, 2010; C. M. Van Praag & Versloot, 2007), and flexibility (Bingham, Furr, & Eisenhardt, 2014) all can have opposite influences on entrepreneurial propensity and capability, then it seems reasonable to conclude that entrepreneurial propensity and entrepreneurial capability do not go together automatically. On the contrary, the opposite is expected: individuals who engage into entrepreneurial activity might possess antecedents that work against optimal entrepreneurial capabilities,

whereas individuals who score high on the entrepreneurial capability dimension probably possess antecedents that counteract their intention to choose for active entrepreneurship. Therefore it is presumed that the passivity of the capable non-actor is not an exception, and that this passivity, which Ramoglou (2011) says should be respected, is not just a choice, it is upheld by the mechanisms that govern entrepreneurial propensity and capability

This is in line with the conclusion of Bayon et al. (2015), that objective entrepreneurial capability has not shown up as a favorable explanatory variable when modelling entrepreneurial intention and behavior.

Figure 1: Whether or not antecedents of entrepreneurial propensity and capability reveal opposite effects

If, paradoxically, objective entrepreneurial capability does not automatically lead to active entrepreneurial behavior, then this raises the question: "Why do people who are capable of founding and running a business of their own not actually turn into active entrepreneurs?" (Figure 2).

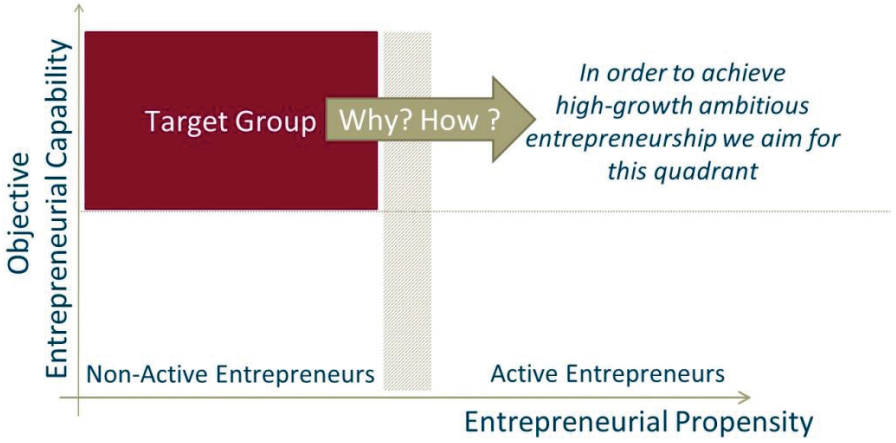

Figure 2: The research question, the target group in the entrepreneurial propensity capability plane

In this paper, we report on the search for theory that can explain why objective entrepreneurial capability does not automatically lead to active entrepreneurial behavior. First, we further analyzed the available theory on the development of entrepreneurial behavior. However, we did not find any theory to elucidate this paradoxical effect. We studied the identity-transition theory applied to the transition into entrepreneurship and we propose how the introduction of the construct of identity-complexity, can produce opposite effects. This offers a model to explain the entrepreneurial propensity-capability paradox.

2. Literature on identity transition and voluntary career change

With respect to entrepreneurial propensity, the theory of planned behavior (Ajzen, 1991) and the entrepreneurial event model (Shapero & Sokol, 1982) have been the two most extensively tested competing theories used to explain entrepreneurial intent (Schlaegel & Koenig, 2014). More recently, Ibarra (2005) has

applied the theory on possible and future selves (Markus & Nurius, 1986) and has described a process of identity transition in relation to a voluntary career change. In Figure 3 we sketch a graphical summary of the process as described by Ibarra (2005). The boxes in this sketch do not necessarily represent different variables they can also represent different states of the same variable, arrows are symbolizing transitions between these different states. The upper part shows the behavioral plane, indicating that a role change is brought into effect after deploying actual role changing behavior. This role change behavior goes together with the presence of an activated new future self in the lower part of the graph. In the lower section we represent how Ibarra (2005) expounds the underlying effects in the cognitive plane. While active in the current role an individual can develop multiple alternative selves that do not immediately culminate in a state of intention-to-change. A liminal state can emerge wherein various, divergent, possible selves co-exist. This liminal state exists until a salient future work-self prevails and becomes activated as part of the self-concept. Not the liminal state but an activated state explains proactive role transition behavior (Strauss, Griffin, & Parker, 2012) and we associate this activated state of the future work-self with the state where the intention to change is established.

In the last decade we can find research that applies identity transition theory to career transitions into entrepreneurship (Figure 4a).

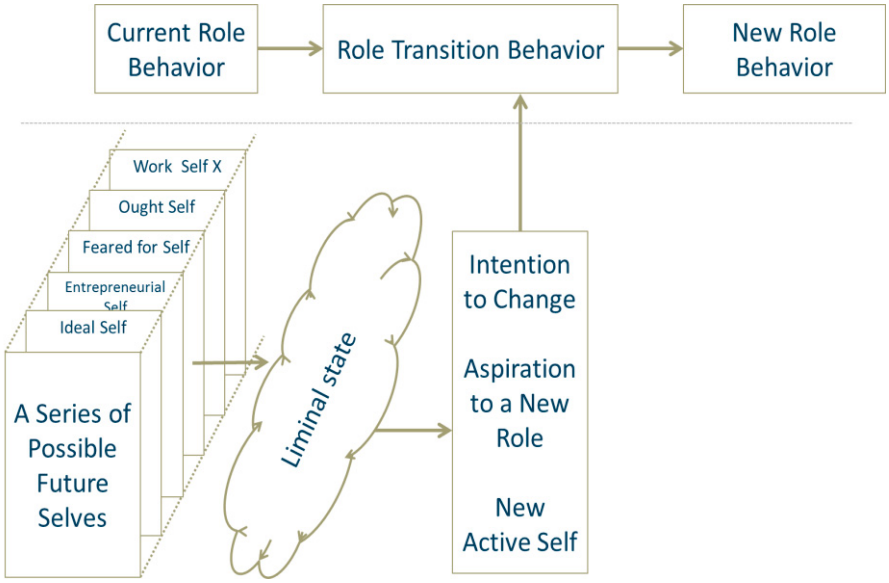

Figure 3: Graphical summary based on the description by Ibarra (2005) of the identity transition process in relation to a voluntary career change.

In view of our research question, we searched for work that applies identity transition theory to career transitions into entrepreneurship. Although a limited amount of work was found with respect to the identity transition into entrepreneurship, we found two studies that introduce constructs which contribute to explain the transitions shown in Figure 3. In Figure 4a the effect on these transitions are depicted with bold arrows [a], [b] and [c]. Farmer, Yao, and Kung-Mcintyre (2011) show empirically that congruence between the perception of the founder role and the self-perception predicts [a] the strength of the aspiration to the entrepreneurial identity. Hoang and Gimeno (2010) address the probability of whether actual role transition behavior occurs given that the identity transition into the founder role has occurred and that entrepreneurial intention is established. They put forward that founder-role-centrality [b] and founder-role-complexity [c] have a favorable effect on the likelihood of developing effective founding behavior. They define that founder-role-centrality describes the individual's strength of attachment to the founder role and that founder-role-complexity captures diversity and richness in individuals' definition of the founder role. Separate from the envisaged founder role, identity-complexity builds on self-complexity, defined as the degree in which the identity is represented by a greater number of cognitive self-aspects and the degree in which a greater distinction among self-aspects is maintained (Linville, 1987).

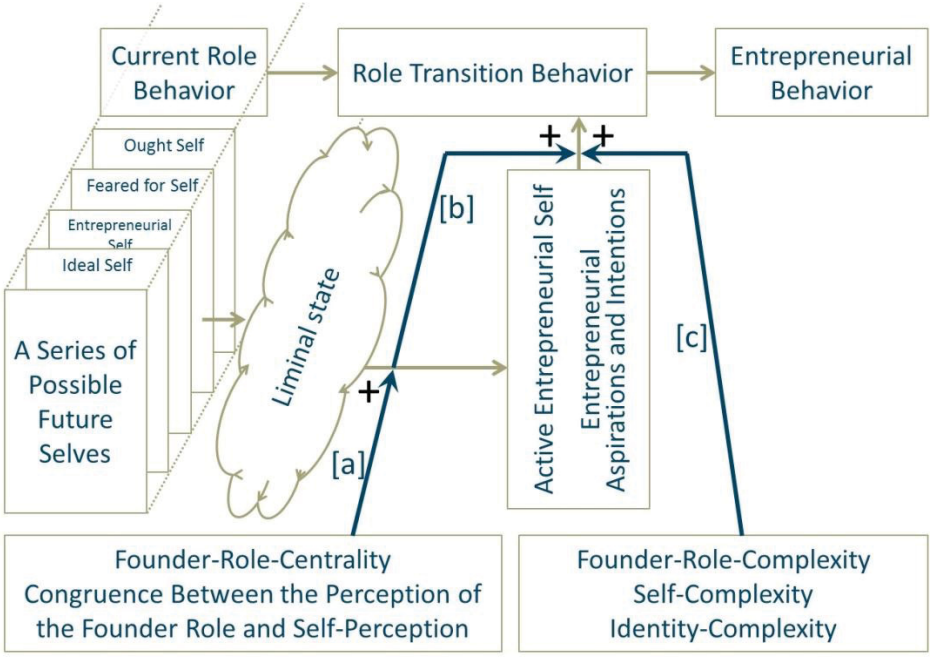

Figure 4a: Graphical representation based on the description by Hoang and Gimeno (2010) of the effect of Identity-Centrality and Identity-Complexity on identity transitions related to career transitions (Ibarra, 2005).

3. Propositions

In order to explain the paradoxical effects between entrepreneurial propensity and capability we suggest expanding the described identity transition theory on entrepreneurship (Figure 4a) using the following propositions. These propositions assign a more crucial role to identity-complexity in the identity transition process. The bold arrows in Figure 4b show how the propositions contribute to explaining opposite influences on the role and identity transitions.

3.1 Proposition 1:

Objective entrepreneurial capability correlates with high identity complexity [α].

3.2 Proposition 2:

Before and after entrepreneurial intention is established [c] and [β], Founder-role-complexity and identity-complexity generate opposite effects on the transitions and on the development of entrepreneurial role transition behavior.

Hoang and Gimeno (2010) state that these complexities of the identity and the future selves of an individual are favorable to turning intention into entrepreneurial behavior as a multifaceted identity is more robust when dealing with negative inputs and setbacks. However, we propose that, before reaching entrepreneurial intention, identity-complexity works against making a match between a complex founder role and a desired future self as: 1) more facets have to match, 2) the match is evaluated at multiple time points in the future and 3) more career alternatives are available. This proposition is supported by the empirical research of Halberstadt, Niedenthal, and Setterlund (1996) on the negative effects of identity complexity in relation to the ease of decision making.

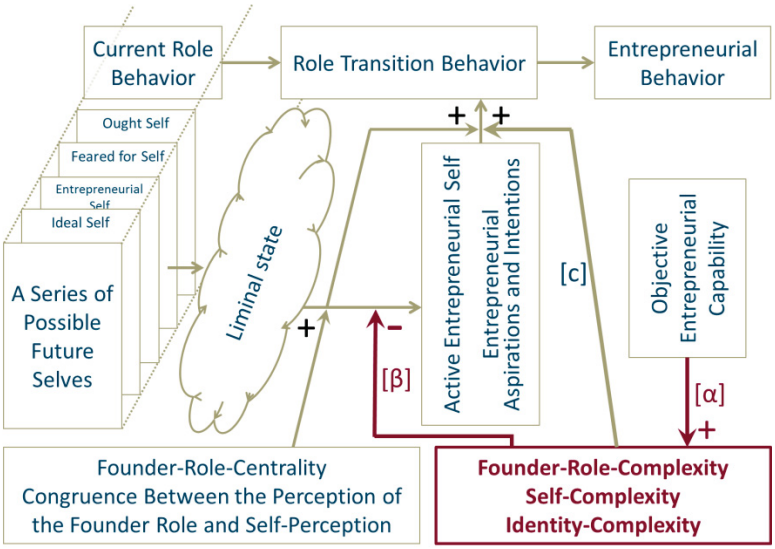

Figure 4b: Graphical representation how the proposed effects of Founder-Role-Complexity and Identity-Complexity can explain opposite influences on the role and identity transitions.

4. Conclusion

This research project proposes a model to broaden the identity theory for entrepreneurial career transitions by distinguishing two phases. The point where entrepreneurial intention is established separates these two phases. We argue that constructs like self-complexity, the complexity of the envisaged founder-role and objective entrepreneurial capability have opposite effects in both phases. If these factors have an inhibiting effect on generating intention and have a favorable effect on turning the intention into actual behavior, then this explains why individuals who are expected to have the necessary capacities to do well in the second phase can struggle to develop entrepreneurial intention in the first place.

5. Limitations, discussion and further research

We have put forward a theoretical model that can explain the paradoxical effect that seems to exist between entrepreneurial propensity and capability. Nevertheless, empirical verification is needed. Therefore, we call for empirical research to measure entrepreneurial capability, entrepreneurial propensity, founder-role-centrality, complexity of the envisaged founder role and identity-complexity in order to validate whether the proposed effects between the constructs can be established. Before setting up quantitative work, the model has to be completed with all relevant known variables that can influence the variables and relations under study. In addition, the following variables need to be operationalized: self–complexity, complexity of the founder role, objective entrepreneurial capability and how close an individual is to a possible identity transition. Self-complexity can be measured with the H statistic (Scott, 1962), however, it is to be analysed whether these propositions do not need an operationalization of self-complexity which is more directed to this specific application or whether the generic operationalization of Scott (1962) can be used. For objective entrepreneurial capability we propose to use the 'Entrespiegel 2.0' survey (Kyndt & Baert, 2015). In order to assess how close an individual is to a career transition we suggest analyzing the work on "the degree of decidedness" (Amir & Gati, 2006) and the "Career Decision-Making Difficulties Questionnaire" by Gati, Osipow, Krausz, and Saka (2000). Finally, we call to explore this empirical verification in samples that cover the entire range of the population in terms of entrepreneurial capability and entrepreneurial propensity.

Furthermore, understanding why the desired entrepreneurial capabilities do not automatically convert into actual entrepreneurial behavior can trigger the development of new strategies for policy makers who want to promote ambitious entrepreneurship among individuals who possess strong entrepreneurial capabilities. For the individual, these modified theoretical insights into paradoxical effects can generate new approaches for career development and career coaching practices.

Using Serious Games to Guide Commercial Success from the Fuzzy Front-End

Michael O'Sullivan and Con Sheahan
University of Limerick, Ireland
michael.osullivan@ul.ie
con.sheahan@ul.ie

Abstract: Despite the vast amount of research carried out on new product development (NPD) tools and techniques, studies have shown that there is a huge gap between their academic prevalence and their industry adoption. While many industrialists admit that the tools developed in academia would be beneficial to their NPD efforts, they believe that the tools are simply not worth the effort required to use them. One way to address this issue is by improving the value offered by these tools, and this research aims to achieve this by implementing the innovation game 'Buy a Feature.' Originally created for portfolio prioritization and adapted for software development projects, this 'serious game' encourages end-users to collaboratively buy and bid on potential features of a product with play money. By providing users with a total budget that is insufficient to buy all the features, it forces them to think about which features are most important to them and to discuss their reasoning behind each choice. This provides product development (PD) teams with a better idea of which features to prioritize based on how much customers are likely to spend, and at a very early stage of the process. The researcher believes that by integrating this game with the traditional NPD process, particularly the Kano Model, it can also be useful for teams developing physical products. To test this, a study was carried out with 29 teams of final year NPD students bringing a product from concept through to production specification. It is expected that teams who used the proposed methodology will have a higher confidence in their product's fit-to-market than teams who did not use it. Indeed, the study has already shown that many teams' assumptions about which features customers cared most about were incorrect. It is also evident that the game will have to be modified to include multiple 'tiers' of bidding for features categorised as 'one-dimensional' in the Kano Model, and teams should apply a 'tax' when setting prices for features to cover hidden development costs and approximate estimations made at such an early stage of the process. Overall, results thus far are very promising.

Keywords: new product development, commercial success, innovation game, serious game, buy a feature, Kano model

1. Introduction:

It is vital that companies fully understand their customers' requirements from the fuzzy front-end, as research shows that 70% of the product entire life-cycle cost are determined in the product design stage of the NPD cycle (Zhu, 2009). It is for this exact reason that academics and practitioners have spent decades researching and developing tools to help PD teams improve their probability of success. These tools range from methods of collecting and analysing the voice of the customer (VoC) to techniques like Quality Function Deployment (QFD), designed to help translate customer requirements into technical specifications.

However, research shows that they are not being adopted by industry. Thia et al. (2005) found that two of the biggest factors influencing a firm's adoption of NPD tools are usefulness and user-friendliness. While there is a general consensus among people working in product development that the tools are useful, many believe that they are not useful enough to outweigh the poor user-friendless, particularly the steep learning curves and complexity to manage them. The authors believe there are two ways to encourage a higher rate of adoption of these tools in industry; one is to increase the value of the output offered by using them, and the other is to improve the usability of them.

This research sets out to increase the value offered by using the NPD tools by making it easier for firms to predict and guide a product's success from the fuzzy front-end. It aims to achieve this by integrating the serious game 'Buy a Feature' with traditional tools in the NPD process, allowing firms to prioritize features and make decisions based on how much customers are likely to spend. The research questions of this study, thus, are: 1) Does 'Buy a Feature' add value to the traditional NPD methodology? 2) Does it integrate well with traditional NPD tools and techniques? 3) How could the new methodology be further improved?

2. Background

While techniques like demand forecasting and the Delphi Method can be used to predict market demand, and tools like the Kano Model can aid feature prioritization, they are not very well integrated with one another, i.e. feature prioritization is not based on demand prediction. While firms can prioritize features based on what

customers claim to be most important to them, it does not provide information about demand. Likewise, predicting demand for a product does not provide the PD team with much guidance on which features should be prioritized in order to achieve this demand.

Buy a Feature is a solution at the intersection of these approaches as it allows teams to prioritize features based on how much customers are likely to spend. Developed by Hohmann (2006), it is an innovation game whereby typically 5-8 potential customers/end-users are invited to purchase features of a potential product using 'play' money. The players are only provided with enough money to collectively purchase 40-50% of the features, forcing them to negotiate and pool their money together to bid on and purchase features. PD teams can then prioritize features based on which ones were bought/bid on first and why, and it is reported that the discussions between players when negotiating and justifying their spending can be even more insightful.

Feldmann, Adam and Bauer (2014) have proven the game's use in portfolio prioritization within companies. They found it to be an effective method for assessing ideas and reported high user engagement and enjoyment with the game – critical requirements when bringing end-users into the development process.

Ghanbari, Similä and Markkula (2015) have tested the game's use in software requirements elicitation and found it to be effective for prioritizing customers' requirements based on business value and the cost and effort needed to develop each feature.

3. Proposed new methodology

The author believes that the best way to implement the game in physical NPD is by integrating it with the traditional NPD tools in the fuzzy front-end, particularly the Kano Model and QFD. The Kano Model is a tool used to categorize customer requirements into 'must-be' (have to be included), 'one-dimensional' (the more, the better), 'attractive' (provide satisfaction if present but do not cause dissatisfaction if absent), and 'indifferent' (do not affect satisfaction and so are essentially money sinks) requirements. Meanwhile, QFD is a tool used to translate customer requirements into technical specifications that fulfil them.
The new process, thus, is as follows:

1. Collect and analyse VoC.
2. Use the Kano Model to categorize requirements.
3. Use QFD to generate technical specifications that satisfy the customer requirements.
4. Use these technical specifications to estimate development costs and prices for the various features.
5. Play Buy a Feature with potential customers, *offering only one-dimensional and attractive features*.
6. Enter product design stage with features prioritized based on how much customers are likely to pay.

The key innovation here is in step 5, where only one-dimensional and attractive features are offered as part of the game. This is essential as must-be features simply have to be included in the product regardless, and indifferent features do not add any value. Seeing which one-dimensional and attractive features players bid on (and how quick they are to do so) should help the team to prioritize the features based on maximising profits.

If players are quick to purchase a one-dimensional requirement then it likely needs to be highly implemented, but if it's slow to be bought or bid on, it is likely that the feature only needs to be implemented to a minimum level. Meanwhile, if an attractive feature is quickly bought it is likely that the value perceived by the customer outweighs the cost of implementation for that feature. If the feature is not bought or even bid on, the team should not waste resources implementing it as the Kano Model will have shown that it is not going to cause dissatisfaction if absent.

4. New methodology evaluation

To test this new methodology, a study was carried out with 29 teams of final year students from design, engineering and technology backgrounds as they completed an NPD project. These students were deemed to be suitable participants for the study as they will soon be working on product development within companies and so will be the target audience for many of the NPD tools discussed in this research. The students would normally be required to use tools like VoC, Kano and QFD with potential customers as part of the project, and this time Buy a Feature was made optional. The teams were provided with a document detailing the proposed

new methodology, the potential benefits of Buy a Feature, and instructions for an online version of the game (See Figure 1).

Figure 1: Screen capture of game being played online shows players bidding on potential features.

At the end of the project the students were asked to rate their confidence that their product design satisfied the customers' demands, and their confidence in their prioritization of features, based on their understanding of the customers' wants. It is expected that teams who used Buy a Feature will score higher in both of these areas than those who did not. The teams' reports are also being analysed to observe how they used the tool, how it influenced the direction of their product development, and any comments they had on their experience using it.

5. Results and discussion

While results are still being collected and analysed, some interesting findings have already been noted. All 19 teams that used Buy a Feature found it very useful, with many reporting that they were surprised by which features the players purchased/bid on first. Teams also stated that the discussions which took place between players provided valuable insights and these two aspects combined gave them confidence in prioritizing features based on actual data, rather than assumptions. 10 teams deemed the game unsuitable for their project. Some of the rationales include: having a concept that is too simple, developing a B2B rather than B2C product, and working with end-users who have disabilities.

Some limitations to the game are also apparent at this early stage of results analysis, though these should be seen as good opportunities to develop and adapt the game more in future research, rather than reasons to inhibit it. First, future games would likely benefit from offering 'tiers' of purchasing options for requirements that have been identified as one-dimensional by the Kano Model. Second, when estimating development costs for features and assigning corresponding prices, teams may benefit from implementing a 'tax' or 'wallflower,' as described by Weiss (2011). This is essentially a buffer that helps to cover hidden costs within that feature, as well as the fact that teams will likely under/over-estimate costs at this early stage of the product development.

Finally, it was noted that every player in the study spent all of their budget. It is not realistic that customers will spend all of their money on a product and so future research should endeavour to find a way of discouraging this. Overall, the results so far are very promising.

Application of SME Marketing Model within Higher Education Entrepreneurial Teams

Edita Petrylaite
Northumbria University, Newcastle Upon Tyne, UK
e.petrylaite@northumbria.ac.uk

Abstract: This work-in-progress paper draws upon the Contextual Marketing (CM) theory (Carson and Gilmore, 2000; Deacon and Harris, 2011) and aims to explore the entrepreneurial marketing skills of student entrepreneurs who work and study within the entrepreneurial teams at Northumbria university in the UK. Little is known about how marketing is learnt and implemented in the entrepreneurial practices by entrepreneurs studying for a business degree. This lack of knowledge is also present in the entrepreneurial team context, which despite the growing attention remains unexplored in relation to the development and application of marketing skills in business venturing by teams. In order to fill this gap, this study adopts the SME marketing model developed by Carson & Gilmore (2000) and looks into whether entrepreneurial students apply the elements of contextual SME marketing namely Standard Textbook Marketing Frameworks, Competency Marketing, Networking Marketing and Innovative Marketing when create and develop new start-ups in teams. The data gathered in the form of observed and recorded workshops reveal the tendency among the entrepreneurial student teams to network extensively in order to expand their social capital for business purposes but cautiously apply other elements of SME marketing in their practices. This suggests that entrepreneurial students could focus more on building entrepreneurial marketing competence through integration of theoretical knowledge and activities that foster innovative and creative skills needed for entrepreneurial venturing. A synthetizing approach to teaching and learning entrepreneurship can bring greater results to both parties within enterprise education with students being better prepared to compete in the job market (Brown, 2017) and enterprise education developers contributing to the economy by supporting the creation of new start-ups and student self-employment (Rae, 2017). This work-in-progress paper expands the theory of CM with the empirical findings derived from the contextual, educational and teampreneurial settings. It will shed light on whether marketing processes exercised within the entrepreneurial teams differ from the processes applied in the usual SME settings.

Keywords: contextual marketing, SME marketing model, entrepreneurship, entrepreneurial marketing, entrepreneurial teams, enterprise education

1. Introduction

Entrepreneurial research agrees that entrepreneurs so as SMEs tend to market small business ventures in less conventional ways than big organisations do (Carson and Gilmore, 2000; Martin, 2009; Miles *et al*., 2015). The entrepreneur shapes the SME's behaviour and thinking, therefore marketing by small firms tends to be more individualistic and less standardised, with limited evidence of traditional marketing being applied (Carson and Gilmore, 2000; Deacon and Harris, 2011). In addition, the context within which SMEs operate (i.e. the life stage of SMEs, the industry norms and the characteristics of SMEs or the entrepreneur), plays a crucial role in determining the marketing style of SMEs. According to Carson and Gilmore (2000), SMEs therefore adopt Contextual Marketing (CM) or SME marketing when market their firms.

CM model will be discussed in the following section of this work-in-progress paper before revealing the methodological design of this study and the application of the model and its practicality in the educational context of novice entrepreneurs who set up and run entrepreneurial firms when studying for the Entrepreneurial Business Management degree in the UK. The paper will conclude with further research plans and potential contribution to the educational, practical and theoretical fields of entrepreneurship.

2. Contextual or SME Marketing framework

CM is defined as a "situation specific" approach to marketing. It is contextualised to the needs of the firm and thus unique and complex at the same time (Deacon and Harris, 2011). "A pivotal issue is that this uniqueness is not uniqueness to the "generic" small firm but a uniqueness to the "individual" small firm..." (Deacon and Harris, 2011, p. 151). It corresponds to the thinking and doing of the entrepreneur/owner of the firm (Groves *et al*., 2008) and his/her belief and understanding of the appropriateness and suitability of the marketing approach for the firm (Carson and Gilmore, 2000; Deacon and Harris, 2011).

While most of entrepreneurial literature agrees that entrepreneurial practices are creative, opportunistic and spontaneous in comparison to large organisations (Hills and Hultman, 2013; Martin, 2009), there is an argument which suggests that successful entrepreneurs adopt a balanced approach to decision-making

(Groves *et al*., 2008). According to Groves *et al*. (2008), entrepreneurs take actions on the basis of both linear (for example, rational, logical and analytical) and non-linear (creative, intuitive, imaginative and emotion-driven) style of thinking. This suggests that marketing in the entrepreneurial context is practiced through a combination of strategic and more innovative and intuitive methods.

Carson and Gilmore (2000) explain their idea of "marketing in context" through the pragmatic model of SME Marketing (Figure 1. below). This model consists of a few components (i.e. Adapting Standard Textbook Marketing Frameworks, Competency Marketing, Network Marketing and Innovative Marketing) and offers practical solutions to the development of entrepreneurial business. It goes in line with the thinking style of the entrepreneur (Groves *et al*., 2008), who is very much concerned about how to do business, therefore the SME Marketing framework is a model of "how to-do-marketing" rather than "what-marketing-is" (Carson and Gilmore, 2000, p. 2).

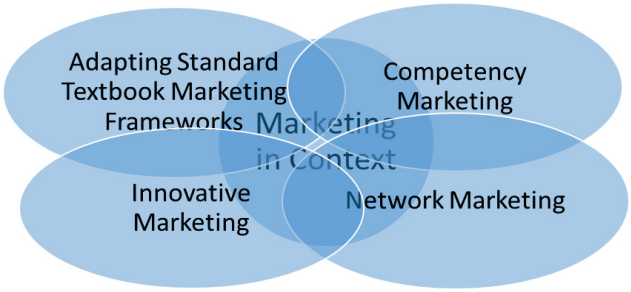

Figure 1: Carson &Gilmore's (2000) SME marketing model.

2.1.1 Adapting Standard Textbook Marketing Frameworks

According to Carson and Gilmore (2000), the implementation of theoretical knowledge of marketing in SME practices is contextual and of practical nature. Concepts are applied if they hold some relevance to the entrepreneur and the business. For example, marketing planning, which usually involves the evaluation of the external business environment, company's internal capabilities, future strategy and tactics (Blythe and Megicks, 2010), in the SME context will consider only those factors that are relevant to the small firm and suit its unique entrepreneurial capabilities (Carson and Gilmore, 2000). Thus, marketing frameworks are applied loosely and intuitively, and the planning process reflects the intrinsic characteristics of the firm or the entrepreneur (Carson and Gilmore, 2000).

2.1.2 Competency Marketing

The second component of CM is Competency Marketing. It refers to the entrepreneur's skills of "doing" marketing. "To do marketing means anything that impacts upon, or which influences marketing, as well as actually performing marketing activity" (Carson and Gilmore, 2000, p. 3). It involves both inherent and acquired skills as well as analytical and creative competency categories (Carson and Gilmore, 2000). Previous research has highlighted the importance of developing competence in marketing entrepreneurial ventures since business progress and success depends on these skills, in particular the use of personal and formal networks for business growth (Hill and McGowan, 1996).

Competency marketing is based on experiential learning. Kolb (1984) defined experiential learning as the process during which knowledge is created through experience. In the entrepreneurial marketing context, it involves experience, knowledge, communication and judgement that are all needed for running the entrepreneurial business (Carson and Gilmore, 2000). Therefore, marketing competency in SMEs can be described as "*learning acquired through experience and developed as an accumulation of knowledge and experience built upon and from communication and judgement*" (Carson and Gilmore, 2000, p. 4). Carson and Gilmore (2000) add that since marketing competency of SMEs develops together and through experiential learning, thus its effectiveness grows with the quality of experiential learning. However, it is important to mention that Kolb's (1984) theory of experiential learning constitutes not only of experience but also involves reflection, thinking and acting (Pittaway *et al*., 2015), therefore, competency in any business area, including marketing, grows if the entrepreneur engages in all fours stages of the experiential learning cycle.

2.1.3 Network Marketing

Network Marketing is defined as a natural and acquired ability of the entrepreneur (Carson and Gilmore, 2000) to build social ties for the benefit of the entrepreneurial business. Through networking, entrepreneurs not only expand their social ties but also strengthen their personal, financial and technological capabilities (Karataş-Özkan and Chell, 2010). Professional and personal networks serve as sources for knowledge and information acquisition without which the understanding of business environment and market opportunities would be limited (Hills and McGowan, 1996). Therefore, the wider the network, the more progress can be achieved and more value can be created for and with business stakeholders.

Entrepreneurial literature argues that networking process in the SME context is personal, informal, disjointed, opportunistic, spontaneous and chaotic (Carson and Gilmore, 2000; Hills and McGowan, 1996), and can be proactive and passive, overt and covert depending on the proximity of the relationship between the entrepreneur and another party involved (Carson and Gilmore, 2000). It also varies in time dimensions as it can be continuous and frequent or seldom and occasional. Given the transiency and volatility of the SME business, it is important to develop a rational approach to relationship building and make social links more diverse, planned and formal (Hills and McGowan, 1996). This helps to improve the quality of network (Hills and McGowan, 1996) and strengthen the entrepreneurial and marketing skills of the entrepreneur.

2.1.4 Innovative Marketing

Innovative Marketing is the fourth component of the CM and is inseparable from the SMEs processes. It is often assumed that innovative marketing primarily relates to product innovation since the latter is the core essence of the entrepreneurial business. Yet, innovative marketing is more versatile and goes beyond product or service marketing given that innovation in product or service is usually not much different from the competitors (Carson and Gilmore, 2000; O'Dwyer, Gilmore and Carson, 2009). Innovative marketing, as suggested by Kleindl, Mowen and Chakraborty (1996), is "doing something new with ideas, products, service, or technology and refining these ideas to a market opportunity to meet the market demand in a new way" (p. 214). It can be argued that this definition of innovative marketing widens the dimensions of marketing practices through differentiation in value creation, the delivery of the offer and the overall service that can be achieved thanks to the unique characteristics of the SME's manager, owner or the entrepreneur (Carson and Gilmore, 2000).

3. Methodology

This ongoing research through a qualitative interpretivist approach explores the marketing skills of nascent entrepreneurs who develop their enterprises whilst studying for the Entrepreneurial Business Management degree at Northumbria University in the UK. The initial thematic analysis of two out of nine observed and recorded workshops, during which entrepreneurs worked in teams, reveal a tendency among the students to network for the growth and development of entrepreneurial business. However, the application of other components, in particular theoretical frameworks, of the CM model in students' practices is rather limited.

This suggests that entrepreneurial marketing in the SME context is informal and bound to the competencies, knowledge and experiences of the SME's owner. "Formal marketing may be interesting to the entrepreneur but it is unlikely to relate closely enough to his/her situation specific requirements or solve company problems" (Carson, 1993, p. 194).

Although this research has been conducted in the educational context with the participants of the study setting up and running their businesses within the premises of the higher education institution, the preliminary results are in line with previous research and suggest that students, despite available support, develop their marketing skills and entrepreneurial practices through experience.

4. Conclusions

This paper has provided initial insight into the marketing skills of the entrepreneurs studying for the entrepreneurial degree in the UK. More analysis is required to finalise the findings of this study in order to draw comparisons with other research conducted in the SME context. It will reveal whether entrepreneurs with and without entrepreneurial education practice CM in a similar way and whether their business management methods need to change in order to diminish the gap between informal and formal marketing.

This knowledge can then be used by both practitioners and marketing and entrepreneurial educators to make entrepreneurial marketing more applicable to both small and large businesses.

Abstract: This paper explores the role of accelerator programmes for participating entrepreneurs and the internationalization of their startups. Our theoretical point of departure is effectuation theory, arguing that entrepreneurs' decisions are developed on the basis of who the entrepreneurs are, what they know, and who they know (Sarasvathy, 2001). Building on Andersson (2011), we investigate how participation in an accelerator program influence personal qualities of the entrepreneur, how and with whom they interact in idea/strategy development, and progress of the internationalization process. We apply explorative case study research to examine Norwegian startups that have participated in governmental acceleration programmes organized by Innovation Norway, a state organization that supports innovation and growth in Norwegian industries. The findings indicate that participation increases the entrepreneur's self-confidence, provides new knowledge, and increases understanding of risk/resource considerations related to international issues. Thus, participation may accelerate or slow down the internationalization process. This study contributes to the literature on accelerator programmes, as well as the entrepreneurship literature.

Keywords: INVs, internationalization process, entrepreneurial process, entrepreneur, accelerator programme

1. Introduction

Most economies depend on growth-oriented firms to prosper, and the presence of entrepreneurs and entrepreneurial activities are important in this respect (Shafritz et al. 2015). Of particular interest are startups seeking international markets right after inception, referred to as international new ventures or INVs (McDougall et al. 1994). The entrepreneur's decision to enter foreign markets from inception is a decision with high risk in an uncertain situation (Andersson, 2011). Many new ventures suffer from high failure rates given their liabilities of newness and smallness, which imply limited resources and numerous investment needs, including R&D, organization building, and market development (Battistella et al., 2017). Awareness of these liabilities has given rise to various governmental policies, including accelerator programmes (Miller and Bound, 2011, Cohen and Hochberg, 2014, Pauwels et al., 2016). Accelerator programmes are designed to increase the speed and upscaling of new ventures by providing entrepreneurs with new knowledge, tools, and training that increase the likelihood of making more well-informed decisions (Cohen and Hochberg, 2014, Stiberg-Jamt et al., 2016). Previous research on governmental policies supporting entrepreneurs with international ambitions has focused on incubators and export-promotion programmes (see Leonidou et al. (2015) for a review). As accelerator programmes are a relatively new phenomenon, there are few empirical studies on such programmes (Cohen and Hochberg, 2014, Sarmento et al., 2016).

The aim of this paper is to address this gap and shed light on the effects of participation in accelerator programmes on entrepreneurs' capabilities (who they are, what they know, and who they know) and how this influences internationalization decisions, building on effectuation theory. An advantage of effectuation theory is its explicit concern with both the individual entrepreneurs and the new ventures (Andersson, 2011). The context for this research is two Norwegian accelerator programmes intended to accelerate the growth of startups with international potential.

2. Theoretical Framework

2.1 Entrepreneurial learning and decision-making

The foundation of INVs involves consecutive decision-making as opportunities emerge (or diminish) in high-risk situations. The ability to identify and seize new opportunities, and how the entrepreneur organizes and

manages the company, depend on the entrepreneur's knowledge and skills (Politis, 2005). Entrepreneurial learning is described as a continuous process that facilitates the development of the necessary knowledge required to effectively start up and develop new companies (Politis, 2005, Wang and Chugh, 2014). This involves skills in sales and pitching of the idea, the ability to build a strong product, and ability to lead a company in development (Kuivalainen et al., 2010). The entrepreneurial learning process is a social, contextual, and an experience-based phenomenon where the entrepreneur or team of entrepreneurs learn through interaction with various stakeholders (Sarasvathy, 2001, 2008). Still, most of the research on entrepreneurs' learning and assessment of opportunities involves a static perspective, largely ignoring the possibility that the way that entrepreneurs react to opportunities changes as they achieve new knowledge (Shepherd et al., 2015).

An exception is Sarasvathy's work on effectual decision-making, suggesting that there is a mutual relationship between changes in entrepreneurs' knowledge and resources and changes in their assessment of opportunities.

According to Sarasvathy (2001, 2008), entrepreneurs start with a generalized aspiration for their firms and seek to satisfy that aspiration using the means at their immediate disposal, i.e. who they are (traits, abilities, etc.), what they know (knowledge), and who they know (networks), and this will affect their decisions (Sarasvathy et al., 2014). Andersson (2011) argued that the means will vary between decision makers, e.g. previous international experience or startup experience. Entrepreneurs following an effectuation approach are likely to adjust their goals and strategies as the situation develops based on the resources at hand, and thereby are associated with more emergent strategies (Mintzberg, 1978) and grounded in a learning-by-doing method. Effectuation implies that the entrepreneurs do not analyse all of the opportunities available for the new venture, but consider the means available and then, based on possible courses of action, decide which goals to pursue. The decisions are made in interaction with others, both inside and outside the organization (Kalinic et al., 2014). Effectuation is based on five principles of entrepreneurial action (Sarmento et al., 2016): 1) decisions based on resources that are available for the entrepreneurs and not on goals to be achieved; 2) identification and administration of an affordable level of loss; 3) partnerships for obtaining resources that are not yet available; 4) transformation of contingencies into opportunity; and 5) co-creation of future conditions through interactions with other agents instead of using techniques that attempt to predict the future. A model of effectuation is presented below in Figure 1.

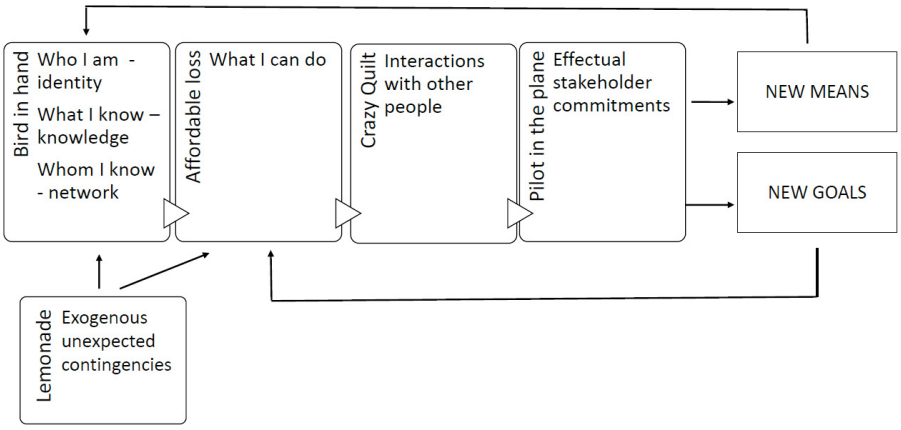

Figure 1: Dynamic model of effectuation, based in Sarasvathy (2008)

Effectuation contrasts causation (Sarasvathy, 2001), as it is assumed that entrepreneurs rule out opportunities that do not lend themselves to ex ante planning based on prediction (Harms and Schiele, 2012, Perry et al., 2012). Causation processes are considered more effective in static environments where the future is possible to predict (Sarasvathy, 2001), something that seldom characterizes the situation for a new venture seeking international opportunities.

2.2 Accelerators as sources of entrepreneurial learning and decisions

Accelerators provide examples of interventions designed to influence entrepreneurial learning and cognitive processes, and enable entrepreneurs to improve their assessment of opportunities. Accelerators are organizations that aim to accelerate venture creation by developing entrepreneurs' skills (Pauwels et al., 2016)

and assisting the entrepreneurs to develop their ideas, and to provide mentorship and access to a network of individuals in different industries, thus leading to quicker growth (Cohen and Hochberg, 2014) and reducing the high failure rates of new ventures (Cohen, 2013). By participating in accelerator programmes, entrepreneurs are exposed to new knowledge and new networks (i.e. what they know and who they know), and this may also alter traits and abilities (who they are). Hence, the accelerator may influence the means that entrepreneurs have at their disposal (Sarasvathy, 2001). Accelerators' programmes provide a time-limited and intense mentorship and educator programme where the entrepreneurs enter and exit the programme as a cohort (Cohen, 2013). The mentors are often earlier entrepreneurs who have experienced success and they are responsible for counselling and other learning activities (Radojevich-Kelley and Hoffman, 2012). The accelerators also provide workshops and seminars delivered by accelerator directors or guest speakers, and the entrepreneurs receive direct feedback that is valuable for avoiding potential pitfalls (Hallen et al., 2016).

Typically, accelerator programmes conclude with participants demonstrating their pitching ability to an audience (Cohen, 2013, Cohen and Hochberg, 2014).

The task of entrepreneurs is to develop opportunities by experimenting and changing directions as they learn and as new information and new knowledge emerge (Chandler et al., 2011). This process is similar to the case of an accelerator. Scant research has looked at the effect of startups participating in accelerator programmes. In a study of new ventures, Cohen (2013) found that participation in accelerator programmes caused accelerated learning compared with usual conditions. Levinsohn (2015) explored learning among social entrepreneurs based on a longitudinal case study involving 24 social entrepreneurs and three accelerators run by the same organization. He found that learning was more a product of co-creation than of effective programme design. Additionally, the characteristics and dynamics of the accelerator cohort had a significant impact on learning, with heterogeneity in terms of industry as a key stimulus. Battistella et al. (2017) investigated how services provided by an accelerator in the UK affected the participating startups from an open innovation perspective. The findings showed that the open innovation environment offered by the accelerator effected successful growth by being an intermediary between the new ventures and external networks of knowledge and resources that support ventures' development processes. This was especially the case for open-minded entrepreneurs. Battistella et al. (2017) argued that the intrinsic characteristics of founder teams, such as personal background and problematic relationship dynamics within the team, were unaffected by participation.

In a rare study of the role of accelerators in the internationalization of new ventures from an effectuation perspective, Sarmento et al. (2016) found that a technology-based startup participating in a Brazilian accelerator programme was able to accelerate its internationalization process by benefitting from the resources and knowledge obtained through the accelerators' network of mentors and international contacts.

This result was based on a single case study. To our knowledge, no studies have investigated how the knowledge obtained through participation in government accelerator programmes influences the entrepreneurs' decision-making processes.

2.3 Positioning of the study

Our literature review reveals that by participating in accelerator programmes, entrepreneurs may develop improved entrepreneurial skills, new knowledge, and new networks, i.e. affecting their means-at-disposal for entrepreneurial growth (Sarasvathy, 2001). According to effectuation theory, a change of means or goals is expected to affect strategic decisions, including international issues (Sarasvathy et al., 2014). Scant research has focused on how participation in accelerator programmes affects entrepreneurs' means-at-disposal and the role they play in decisions related to growth and internationalization of the ventures. The aim of this study is to contribute to an improved understanding of these issues by exploring how accelerator participation affects entrepreneurs' available means and whether (and how) this influences their decisions regarding growth and internationalization.

3. Methods

3.1 Setting

The context of the study is Norwegian entrepreneurs with different levels of experience participating in either of two governmental accelerator programmes organized by Innovation Norway (IN), The Tech Incubator in

Silicon Valley (TINC), and Entrepreneurial Marketing in New York (EM). Innovation Norway is the Norwegian authorities' most important instrument for innovation and development in firms and industries. Their accelerator programmes aim to connect high-potential startups to global networks and expertise in leading hubs around the globe.

Both programmes take place outside Norway, and are shorter and more intensive than most accelerator programmes. They are developed in collaboration with tech-startups, investors, and industry professionals. The programmes are based on the experimental Lean Start-Up methodology (Ries, 2011), described as a product development process emphasizing experimenting over planning, customer feedback over intuition, and interactive development over fixed design (Johansson, 2017, Blank, 2013). The methodology resembles the effectuation logic as described by Sarasvathy (2001) and elaborated in later studies. Figure 2 illustrates the intended participant developmental stage at time of participation.

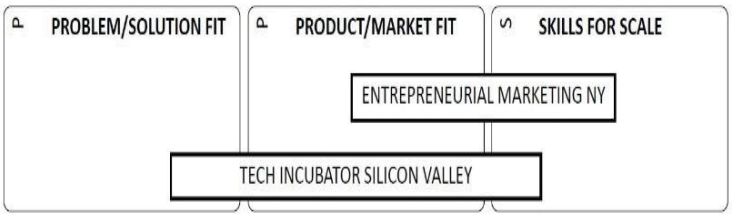

Figure 2: Intended development stage at time of participation, based on Stiberg-Jamt et al. (2016)

TINC was established in Silicon Valley in 2012. It targets Nordic technology startups with a global vision. TINC is based on on-the-job training, as the entrepreneurs work on their own problem/solution fit through several workshops and individual mentoring. Furthermore, the programme provides entrepreneurs with knowledge and simulation of real-life training activities. The programme consists of a two-day preparation at home and a four-week stay in Silicon Valley. Central to the programme is validation of technologies, evaluation of business models, and practice in pitching business ideas to peers and venture capitalists.

EM is a shorter programme in New York, introduced in 2014. The programme's main purpose is to improve the participants' skills, tools, and mindset towards branding, marketing, and selling products and services internationally. The programme is hands-on, with a mix of learning days and doing days, as well as one-on-one meetings with top executives in relevant fields, and evening networking events. The programme includes a two-day introduction in Oslo, 10 intensive learning days in NYC, and a six-month post-participation goal-oriented follow-up programme. EM targets operating companies with sufficient funding in place to access the international market.

3.2 Data collection

We chose an exploratory multiple case-study approach to gain insights that are not available from large sample sizes (Yin, 2013). The approach is well adapted for studying issues in a realistic context and combining inductive and deductive research to develop theory (Eisenhardt, 1989). We used a semi-structured interview guide to ensure consistency (Yin, 2013). The questions were created to identify how participation in the accelerator had changed the entrepreneurs' interpretations of the means and objectives of growing their firms, and were based on research on accelerators, INVs, and entrepreneurial decision-making.

The data were collected during the spring of 2017 by the last two authors (as part of their Master's theses). The informants (entrepreneurs) participated in the accelerator programme in 2015 or 2016. An advantage of recent participation is more accurate memory of the programme, while a disadvantage is that the effects of post-participation decisions may not yet be visible. Six entrepreneurs where chosen as informants, all recruited through IN. Each interview lasted 30 to 60 minutes, was recorded and subsequently transcribed to ensure reliability (Yin, 2013). The primary data were supplemented with secondary data from sources such as websites, newspaper articles, and podcasts.

3.3 Data analysis

The transcripts were imported into NVivo 11 and coded following a thematic analysis (Braun and Clarke, 2006). We started by reading and re-reading the interviews and taking initial notes. First, the respondent characteristics were established. Initial coding was based on a pre-conception of the initial theoretical

framework. As the analysis and interpretation of the data emerged, we analysed patterns in the data, searching for categories and themes. The combination of deductive and inductive analyses resulted in a code tree consisting of three main groups and several subgroups (see Figure 3). The first and second authors conducted the data analysis together, which improved the validity and reliability of the analysis and reduced potential personal bias (Miles et al., 2014, Yin, 2013).

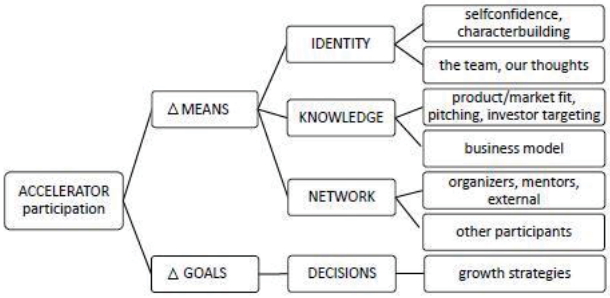

Figure 3: Code tree

4. Results and Discussion

4.1 The ventures and entrepreneurs

The ventures were established between 2012 and 2016 and the founders are still active in the firms. Students participating in entrepreneurial education programmes at a technical university founded three of the firms.

Experienced entrepreneurs with international and industry backgrounds founded two of the firms. The last firm is a spin-off from a closed business. Three of the startups are configured as value networks, two as value chains, and one as a value shop (Stabell and Fjeldstad, 1998). Three of the startups operate in B2B markets, and three in B2C.

Three firms participated at TINC, two at EM, and one at both. Four firms were invited by IN to apply to the programme, and the other two firms initiated their applications based on recommendations from earlier applicants. The startups were encouraged to send multiple delegates to these events, and all but one firm sent an entrepreneurial team. Only two participants had explicit goals for participation, while the others followed the more general approach of "learning as much as possible" in an international environment.

4.2 Benefits from participation: Identity, knowledge, and network

Most informants claimed that participation changed their perception of identity, of who they are. All six informants reported to have achieved some personal development and personal insight. They became more aware of who they are and their own skills. They said they became motivated and inspired through participation in the program and by staying in the business milieu of Silicon Valley and New York for several weeks. It was seen as a valuable experience, and they felt they got into the "American mindset" and business culture, with its focus on ambitions. "*You must dare to think big"* was stated by one informant. Other informants underlined the value of being challenged at a personal level, referring to undisguised and critical feedback on, e.g. presentations and business ideas as "character building". They argued that this would be a valuable experience for them when in contact with potential investors or other stakeholders in the future. All informants reported increased self-confidence and faith in their own capabilities after participation, something that made them believe more in their own ideas and decisions, and made the decision-making process easier.

Contrary to (Battistella et al., 2017), we found that the accelerator affected team development. The informants found this advantageous as the team could develop a more common mindset and work better as a team. This was particularly relevant for members of the founding teams who did not know each other too well beforehand. The participation made them more aware of each others' strengths and weaknesses and they agreed upon who should be responsible for what. The Alpha informant put it this way: *"I felt we managed to sort out how we function as a team and how we can make the most out of our individual skills".*

All informants reported gaining new knowledge and improving their capabilities. While the student entrepreneurs in general reported increased factual competence, the more experienced entrepreneurs became more confident in their existing knowledge and choices. Several entrepreneurs pointed to the

significance of the mentors' capacity to demonstrate the importance of focusing resources and ensuring fit to the problem/solution as well as the product/market. Most informants reported that this affected their choices post-participation. In particular, the student entrepreneurs became more aware of resource constraints and how this had to be taken into consideration for strategic decisions. The Epsilon informant said: *"Our mentor put it this way: if you focus on two products or market segments with a fixed amount of resources, both go at half speed. So we decided for focus".* Sales and pitching skills are emphasized in both programmes and all informants treasured this skill. In particular the more experienced entrepreneurs (informants Alpha and Beta) argued that on-the-spot training was highly valuable and of immediate use. The Alpha informant said it like this: *"I regard this (pitching skills, authors remark) as a direct consequence of TINC. Closing the round, raising the funds, will make us accelerate (sic)".*

Another benefit of accelerators is widening the participants' networks, emphasizing that *who you know* is important for a venture. During the programme, all participants regarded interactions with mentors, organizers, and other participants as important sources of learning and knowledge sharing. Two of the firms had contact with mentors after participation; both of these firms participated at TINC. The Alpha entrepreneurs used one mentor as an advisor on a regular basis, while Epsilon's informant reported occasional contact with two mentors. Yet, all informants believed that the networks of mentors and investors they had met could be mobilized in the future if necessary. Post-participation, four informants emphasized the cohort of other participants as their most active network. They stayed in contact through a Facebook alumni group to exchange information and experiences and to support each other. The other participants thus became a valuable informal network. Eta's informant said: "*The FB group is an arena to share experiences and ask questions*", with Alpha and Delta reporting similar views. This finding is consistent with earlier studies that find learning to be a result of co-creation (Levinsohn, 2015), and willingness to share ideas with others (Galkina and Chetty, 2015, Høvig et al., 2018). Two firms had had no contact with other participants post-participation.

4.3 Post-participation results: New goals and growth strategies

The entrepreneurs developed new skills that affected their understanding of personal and firm resources. This influenced the entrepreneurs' decisions regarding their venture's strategic orientation both during and after participation in the accelerator. The findings indicate that the speed of the internationalization process increased for some (Alpha and Delta in particular), but was reduced for others (Epsilon). Epsilon decided to focus on the Norwegian market first, based on insight and interaction with the accelerator and realized that they were not prepared to enter the American market, "*we have to do our homework first*"—they saw a need for more of a causation approach prior to entry into the American market. Epsilon believed pre-participation, that it would be quite easy to get access to retailers in the USA and Europe to sell their product, but realized that this was not the case. Therefore, they searched for retailers in Norway with international networks that may help the firm to grow internationally, i.e. following an effectual logic by seeking to obtain resources that are not yet available (Sarmento et al., 2016).

Both Eta and Gamma informants focused mainly on the Norwegian market both pre- and post-participation. The entrepreneurs seemed to have no specific international ambitions pre-participation. The Gamma informant mentioned that the American market could be interesting, but it seemed more like a "thought" than an ambition and they soon realized that the American market was not relevant. This does not necessarily imply that participation was without relevance for the firms. Increased confidence and access to new knowledge can increase the chance of survival and accelerate growth in the home market. This appeared to be the case for Gamma, which now seeks to enter the Swedish market, i.e. following an incremental international strategy (Johanson and Vahlne, 1977). Alpha and Delta achieved an accelerated internationalization process after participation, because of increased funding (maybe due to the pitching skills gained through participation), but also because of their improved ability to identify new opportunities and use their prior networks in following an effectuation approach (Sarasvathy, 2008). The major empirical findings are summarized in Table 1.

5. Conclusions

This paper contributes to an enriched and more nuanced understanding of the effects of participation in an accelerator programme, at the individual/entrepreneur and venture levels. Building on an effectuation approach, we identified potential benefits for the entrepreneurs along several dimensions: who I am, what I know, and whom I know (Sarasvathy, 2001). The study confirmed the benefits related to new knowledge reported in previous studies (e.g. Cohen, 2013, Levinsohn, 2015), but identified other advantages such as increased self-esteem, faith in one's own capabilities, and team building skills. We found mixed results on

internationalization. Some entrepreneurs decided to speed up the process, others to slow the process based on new knowledge and interaction with mentors and others taking part in the accelerator programmes. This contrasts with the findings of Sarmento et al. (2016) who examined one firm. More informed risk/resource evaluations that limit speed to market may lead to a higher survival rate for the firms. The same may be the case for higher self-esteem, which can be valuable in future unpredictable situations (Andersson, 2011). The entrepreneurs seemed to become more aware of their available means and the losses they could afford (Sarasvathy, 2001). Furthermore, they were aware of the need for more planning prior to entering some markets, i.e. a mixture of effectuation and causation processes. The results indicate that access to new networks through the accelerator did not influence international decisions, and the networks acquired pre-participation seemed more valuable in this respect.

We argue that the findings have some practical implications for policy makers and participating entrepreneurs. From the accelerator viewpoint, the findings suggest a more cautious recruitment procedure to reach entrepreneurs with international ambitions who are ready to take full advantage of the programme and actually accelerate their firm's expansion. For entrepreneurs, it may be wise to have some goals prior to their participation and be more aware of how to take advantage of the networks they are exposed to in these programmes.

The study has several limitations. First, using only six participants and two accelerators limits the potential for generalization. Second, we collected data shortly after participation and the effects may need more time to manifest. A follow-up of the same firms may give greater insight into the effects of the accelerators over a longer time period. To increase our understanding, a larger sample and different research designs should be used in future studies.

Table 1: Summary of empirical findings

	Venture	**ALPHA**	**BETA**	**GAMMA**	**DELTA**	**EPSILON**	**ETA**
	Accelerator	TINC	TINC	TINC	TINC (EM)	EM	EM
	Attended by	2	2	2	2	2	1

Abstract: A market failure exists in the collaboration process between industry and the academy. Although it is expected to bring benefits to both industry and the academy and to the national economy as a whole, such collaboration does not generally take place at an optimal level. The current study shows that the collaboration between industry and academy can be supported by the intervention of an industrial association, which can play the role of a catalyst for change where government intervention does not provide a sufficient response to the market failure. This experimental study was conducted in the state of Ceara in Brazil, in two phases. The first was the elaboration of a diagnosis based on an in-depth investigation of the prevailing constraints and strengths of the local innovation system. This was done through a field study among firms that showed both a desire and preparedness for innovation, but also a lack of practical innovation activity. This led to a second field study, among leaders in the academy, industry, and government, that revealed some of the constraints that prevent innovation. The findings led to the implementation of a methodology for the identification of the local innovation ecosystem. The second phase was the elaboration of policy measures and of the implementation of practical projects oriented towards the solution of the main obstacles identified in the ecosystem. Three groups of measures were adopted and implemented by the local association of industries. The first group includes the organization of structures that contribute to an improved level of communication between industry and academia, with the support of government. In practical terms, a council was established, representing all parties involved, with the objective of devising measures for improved collaboration and exchange of knowledge. This council acts through sub-sectorial groups. A second group of measures is focused on the joint supply of information and knowledge to industry and the academy. A third group of measures includes projects that supply direct support to innovation in individual businesses. Although it is still too soon to make final evaluations, preliminary results show positive trends of increasing innovation activity.

Keywords: innovation, ecosystem, academy, industry, collaboration, promotion, government, market failure.

1. Introduction

In the process of promoting innovation, collaboration between industry and the academy is beneficial to both (Perkmann et.al, 2013). Industry gains access to knowledge and improved professional networks, while the academy gains an opportunity for the empirical application of theories, funds for research and student training, and so on. However, there is a market failure that prevents or restricts such collaboration as a result of cultural differences, a lack of communication channels, and differences in priorities and objectives, beyond the well-known existence of externalities (Garousi, Petersen, and Ozkan, 2016; de Wit-de Vries et al., 2018); Bjursell and Engström, 2017). Consequently, the potential benefits of such collaboration are not always achieved, and innovation opportunities may be missed.

The natural response to market failure in the collaboration process between industry and the academy is external intervention, which is generally expected to come from the public regulator and encourage and enable the interaction between the university and the business sector (Martin and Scott, 2000, Cheng et al., 2018). Unfortunately, such intervention is not always effectual, or at least not sufficiently effectual. The measures taken by the government do not always respond to specific needs and local conditions. Our hypothesis is that an association of industries may be able to perform this role, at least partly, as long as it is trusted by the partners involved (the industrial firms, the universities, and the relevant governmental bodies).

To some extent, an industrial association could be considered a semi-public organization and regulator (Chappin et.al, 2008). Like the government, an industrial association can consider the global benefits of the industrial sector as a whole, even if they are not relevant to specific firms.

In practical terms, we believe that a local industrial association can play the role of a catalyst, linking the actors of the ecosystem and supporting government intervention measures (Nordqvist, Picard, and Pesämaa, 2010; Bessant et al., 2012; Maennig and Olschlager, 2011; Schwartz and Bar-El, 2015). Such an association has the advantage of physical and cultural proximity to the ecosystem actors as well as familiarity with the local economic and social environment (Molina-Morales et al., 2013).

We test this hypothesis through an exploratory experiment performed through a project of the Federation of Industries of the state of Ceara in Brazil (FIEC). This project, called UNIEMPRE, was implemented from 2013, and focuses on the solution of several main elements of the market failure of innovation.

2. Diagnosis

The state of Ceara is one of the 27 states of Brazil and has approximately nine million inhabitants. It is located in the northeastern region, and its capital is Fortaleza, the fourth largest city in Brazil, which has some three million inhabitants. Its GDP per capita is approximately US$6,000, about half the average of Brazil as a whole. The main exports are shoes, cashew nuts, and fruit.

A short survey of industrial firms in the state was conducted, including 57 firms, of which a third are small and the majority medium-sized. Most of their production is focused on the state market. Almost none is exported outside of the state or the country. R&D activity takes place in 60% of the firms, with an average cost of 3% of their expenses.

Almost all the firms implemented some kind of innovation in the last three years. Most of them did so with internal R&D, but about a third of them implemented innovation through the purchase of new technologies. Almost all the firms (95%) expressed a very high level of awareness of the need for innovation, indicating its necessity not only for high-tech firms, but for traditional ones as well.

Furthermore, the firms expressed very positive expectations from the academy as an important element in the development and improvement of products and services, the upgrading of production processes, and increases in quality, efficiency, and growth. They consider the acquisition of services and professional assistance, joint research, and the use of university laboratories to be the most important channels of collaboration with the academy.

However, despite the existence of motivation for collaboration between industry and the academy, the facts reveal the existence of a market failure. A practical evaluation of the level of integration in the local innovation ecosystem resulted in quite weak results. All firm leaders were asked to evaluate on a scale of 1 (very low) to 5 (very high) the level of involvement of various factors in the innovation process of the firm. As can be seen in Table 1, the results indicate the existence of a very weak ecosystem. The main interaction is with the internal employees of the firm (3.6 on a scale of 1 to 5), and, to a much lesser extent, with other firms. The involvement of major ecosystem actors – research institutions, financial institutions, government, public consultancy, and risk capital funds – is virtually nonexistent.

Table 1: Level of involvement of actors in the innovation process: Average level in a scale of 1 (very low) to 5 (very high)

Actors involved in innovation process	Average Level (1-5)
Employees of the firm	3.6
Other firms	2.6
Financial institutions	1.5
Research institutions	1.5
Government	1.5
Public consultancy institutions	1.4
Risk capital funds	1.2

Source: interviews with leaders of 57 industrial firms in Ceara

In order to understand the gap between the needs and motivation of industry, on one hand, and the actual situation, on the other, an additional study was performed, based on 47 leaders who represent the various elements of the innovation ecosystem: business leaders, highly ranked government officers, and leading academic researchers. All of them were asked to evaluate the extent to which given factors are considered

important obstacles to collaboration between ecosystem actors. Table 2 shows the share of respondents that classified each factor as an important or very important obstacle.

Table 2: Obstacles to collaboration between ecosystem actors: % or respondents indicating factor as Important or very important obstacles

Obstacles	%
Lack of communication between industry, academy, and government	68
Lack of information in the academy about opportunities in industry	40
Lack of information in industry about opportunities in the academy	40
Conflicts of interest	36
Cultural differences	32
Lack of clear innovation policy	30
Lack of financial resources	16
Bureaucracy	10
Lack of human resources	4

Source: survey of 47 leaders in the innovation ecosystem of Ceara

A near consensus exists among all the leaders regarding the prevalence of one of the main obstacles to collaboration – the lack of communication between industry, academy, and government (68%). This result is reinforced by a corresponding obstacle – the lack of information regarding opportunities in industry and the academy (40% each). An equally interesting finding is the low importance attributed to well-known obstacles such as lack of human resources and bureaucracy. This finding does not imply that there is an abundant supply of skilled workers or no problem with bureaucracy, but rather reflects a situation in which these obstacles are not yet fully relevant because the most pertinent obstacles mentioned above constrain the innovation process at a much earlier stage. The same applies to the obstacle of the lack of financial resources; in fact, a large proportion of the funds offered by government for innovation are not used as a result of insufficient appropriate applications. The near irrelevance of these three obstacles (lack of financial resources, bureaucracy, and lack of human resources), which represent needs mainly at the second phase of innovation, actually attests to the existence of an immature ecosystem that prevents the incubation of innovation activities.

3. Identification of the innovation ecosystem of Ceara

3.1 The innovation ecosystem actors

As a preliminary step, a listing and classification of the main actors who take part in the process of innovation was performed by a group of researchers at the Federal University of Ceara (UFC). These actors are succinctly enumerated here, divided by the three major elements of the "triple helix" (Mercier-Laurent, 2011, Etzkowitz, 2003, Etzkowitz and Leydesdorff, 2000). A detailed description of the actors can be found in Cavalcante and Bar-El (2014).

The first element includes the universities and research institutions: a federal university (UFC); a state university (UECE); a private university (UNIFOR); a technological institute (IFCE); a nucleus for technological innovation (NIT); a network of universities and research institutions for the support of biology research (RENORBIO); a private network for the support of incubators (RIC); and a civil institute for technology, information, and communication (ITIC).

The second element, the business sector, includes several associations beyond the business firms. One of the most active is the Federation of Industries of Ceara (FIEC), which acts in the field of innovation through divisions for professional training (SENAI), support of the interaction between firms and academic institutions (IEL), and coordination of industrial development programs (INDI). Other organs of the business sector are: a national association for the research and development of innovative firms (ANPEI), a social organization for the promotion of research related to industry (CGEE), and a private-public organization for the promotion of training and innovation in small enterprises (SEBRAE).

The third element, the government, includes the state government of Ceara and the federal government of Brazil. Within the federal government, the Ministry of Science, Technology, Innovation and Communications (MCTI) is active in training, providing infrastructures for scientific research and so on. A national fund for scientific and technological development (FNDCT) that is related to this ministry is involved in the promotion of academy-industry relations. A national bank related to the Ministry of Development, Industry and Foreign

Trade (BNDES) supports technological innovation in specific sectors, including micro-firms and small firms. Banco do Nordeste (BNB) is a federal bank especially focused on the development of the states of the northeastern region of Brazil, where the state of Ceara is located. A unit that supports technological innovation (FUNCAP) operates within the state government of Ceara based on funding provided by the federal government (FIT). A special division (NUTEC) of the Secretariat of Science and Technology operates in the field of certification of management and quality.

3.2 The innovation ecosystem of Ceara

An optimal elaboration of policy measures needed to promote innovation requires the understanding of the mechanism behind the functioning of the innovation process. We used the methodology applied by Frenkel and Maital (2014) in five European countries to identify the innovation ecosystem in Ceara. This methodology was based on an intensive workshop that included 70 experts and high-level leaders from the academy, the business sector, and various government entities in Ceara (see the detailed methodology and results in Frenkel, 2014). The main purpose was to identify the major "anchors" of the innovation ecosystem and the processes used on the basis of these anchors.

The major anchors of the innovation ecosystem of Ceara, which we expected to provide the elements that can nurture innovation, are the following:

- A culture of empowerment: innovation creativity, adaptation ability, and so on
- A culture of entrepreneurship: desire for university-industry cooperation, an atmosphere of innovation, significant motivation of young entrepreneurs
- Market structure: potential demand for innovative products, advantageous geographical location, availability of financial funds for small and medium-sized enterprises (SMEs), and so on
- Institutional infrastructure: organization of incubators, regional dispersion of research institutes, and so on
- Educational infrastructure: availability of public and private universities, relatively good achievements of public schools, and so on
- Technological infrastructure: broadband internet, natural resources, technological networks, and so on
- Government policy: availability of incentives, regulations, access to funds for technological innovation
- Financial institutions: financial resources provided by the BNB (development bank) and the financial agency for research, FUNCAP

The processes identified by the group of experts as defined by the actions actually taken for the advancement of innovation in the state are divided into the following six categories:

- Active collaboration between elements of the ecosystem: promotion of scientific events, elaboration of open innovation projects, and so on
- Government legal and fiscal initiatives: elaboration of rules and laws for the advancement of innovation, incentive and subsidy programs, provision of venture capital
- Joint public-private initiatives: joint seminars and workshops, support for project expansion, and so on
- Skill development: consultancy programs, centers for entrepreneurship and innovation, professional training in the periphery
- Public centers for technological research: established by the Ministry of Science for specific industrial sectors
- Entrepreneurship support: entrepreneurship and innovation courses, sectoral initiatives

The effectiveness of innovation ecosystem's operation is evaluated through the relationship between anchors and processes. Table 3, below, shows a weak relationship between the two.

Table 3: Relationships between anchors and processes

Process Anchors	Active collabora-tion between elements of the ecosystem	Govern-ment legal and fiscal initiative	Joint public-private initiatives	Skill develop-ment	Public centers for technological research	Entrepre-neurship support
A culture of empowerment	+	+	*	+	+	*
A culture of entrepreneurship	++	++	+	++	+	+
Market structure	++	++	+	++	+	+
Institutional infrastructure	+	+	+	+	+/-	+
Educational infrastructure	+	*	+	+	+	*
Technological infrastructure	+	++	+	+	+	*
Government policy	+	++	+	+	+	+
Financial institutions	+	+	+	++	+/-	+

++ strong positive relationship; + weak positive relationship; +/- mixed relationship; * no relationship

As the table shows, active collaboration between the elements of the system is only strongly supported by the anchors of an existing culture of entrepreneurship and a positive market for innovation products, and weakly supported by other anchors. We also see weak responses of most other processes to the prevailing anchors: support for entrepreneurship, public-private initiatives, and the actions of public centers for technological research.

The conclusion of this section is that despite the existence of some anchors for innovation, the actions taken by all entities (government, academy, business) are not yet sufficient and do not optimally use the existing potential. Alternatively, we can state that the prevailing anchors are not yet sufficient and their influence on active measures for innovation is not yet efficient enough.

4. Industry initiatives for the enhancement of the innovation ecosystem

As in any case of the existence of a market failure, the achievement of an optimum can be reached only through an external intervention, normally from the government. The process of identification of the prevailing innovation ecosystem with the participation of government officers, university scholars and industrial leaders has shown to all parties the importance of collaboration, beyond the measures devised by the government. Each individual firm considers its own interests, but all business leaders are conscient of the need for a group action. An industrial association can contribute to the solution of the market failure of innovation, as explained above (McPherson, Smith-Lovin, and Cook,2001; Nordqvist, Picard, and Pesämaa, 2010).

On the base of the diagnosis and of the identified components of the prevailing innovation ecosystem, a set of policy measures could be derived guided by the objective of contribution to the optimization of the ecosystem. A detailed program, called UNIEMPRE, was elaborated and fully described in a book by Bar-El, Leite, and Cavalcante (2014), and academically analyzed in an article by Schwartz and Bar-El (2015).

In broad terms, the main policy measures elaborated with the collaboration of the government and the academy were implemented by the local industrial association with a focus on three main issues identified as impediments to an efficient innovation ecosystem and an optimal advance in innovation activities. The first is the lack of sufficient interactions between the business sector and the academy, as well as the poor accessibility of the business sector to services offered by government. The second is the lack of appropriate, relevant information for all parties involved in the process of innovation. The third, at the micro-level, is the

low level of knowledge and skills that prevents advancement in innovation, mainly among small and medium-sized enterprises.

4.1 Improving interactions between ecosystem elements

In order to reach a better level of communication between all parties involved in the process of innovation, the following measures were initiated by FIEC:

A strategic council was established, with the participation of business leaders, academic researchers, and high-level government officials (Cavalcante and Bar-El, 2014). This council holds regular sessions approximately once a month and conducts deliberations on the best methods of interaction between the three sectors, with the objective of advancing innovation. The social meetings facilitate information flow and openness and foster the desire for joint success.

Sectoral working groups were established, beginning in three sectors (electro mechanics, construction, and chemicals), again with the participation of representatives of industry, the academy, and government (Bar-El, 2014). Such working groups are able to work out the details of collaboration on specific projects.

Regional innovation centers were established in three peripheral regions to reach businesses with low levels of accessibility (Bentolila, 2014). In each region, local academic institutions (mainly part of IFCE, the technological institute), local economic and public leaders, and a local representative of the association of industries participate in the council's activities.

4.2 Information and knowledge provision and sharing

The following actions taken by the industrial sector in collaboration with the academic sector and the government are intended to provide at least partial solutions to the lack of information regarding options for mutual collaboration, existing and new technological knowledge, relevant ongoing research, the needs of the economy, and so on.

An internet site was established for the exchange of information on innovation needs in industry and academic updates on relevant ongoing research. This site also provides current information on new technological developments around the world, economic data on demand trends for new products, and so on.

Annual open conferences on innovation are attended by all interested populations of ecosystem actors, offer presentations by innovation leaders from the state as well as from other states and countries, relevant case studies, and more.

Mapping and continuous updating of the innovation ecosystem takes place following the original identification of the ecosystem as presented above. It is assumed that the ecosystem is dynamic, continuously evolving as a response to exogenous and endogenous changes.

Joint industry-academy courses are developed in accordance with industrial needs. Such programs have already been developed with two universities where most of the students are industrialists. Other programs are intended for regular students, with the collaboration of professional industrial leaders.

Information is provided to firms on public support programs for innovation and firms are assisted in responding to calls for research proposals on innovation. Two hundred firms applied for subsidized governmental programs, but only a small number of firms fulfilled the requirements for financial support. Continuing efforts are being made in order to achieve better results, both in the field of proposal preparation by the firms and in the field of the adaption of public programs to the needs of industry.

4.3 Direct support to firms and startups

A third type of measure implemented by the industrial association in collaboration with the academy is focused on direct support to specific business activities using an outreach approach. The decision to adopt such measures is explained by the existence of one of the major factors that causes market failure in the innovation ecosystem: lack of accessibility and insufficient awareness of the prevailing relevant services and information.

An innovation agents' project was designed and implemented primarily in small and medium-sized businesses (SMEs). This is not a consultancy program in the sense that the agents are not expected to provide professional assistance in the process of creating innovation initiatives. Instead, they are expected to provide all types of support related to integration into the innovation ecosystem. Thus, they assist in such matters as improving access to relevant technological information in the state, the country, or overseas, linking the businesses to relevant researchers, locating appropriate government support and financial programs, finding relevant providers of business and legal services, and so on. Consequently, the innovation agents are not regular business consultants, but rather graduate students who were prepared in a special course designed jointly by local universities and the association of industries.

An open innovation (OI) program was designed and mainly oriented to medium and large businesses. The open innovation strategy is already quite well known and has been implemented in many countries around the world. However, planning and implementing an open innovation project still requires quite complex procedures in the fields of law and regulations, agreements, marketing, and more. The introduction of this strategy into businesses in the state of Ceara is expected to provide a strong basis for the promotion of innovation. The program began as a pilot project with two companies: a cosmetic products company and an electronics company. Both companies launched an innovation competition that invited academic researchers, students, entrepreneurs and regular citizens to propose their ideas, giving them an opportunity to actualize them and introduce them into the market. The competitions offered cash prizes. Both companies received more than one hundred applications, and prizes were awarded to the three best ideas.

5. Conclusion

The case of the state of Ceara in Brazil illustrates a typical example of the existence of a market failure that constraints the potential innovation development and economic growth. Industrial firms are aware of the need for innovation but have only limited access to knowledge created at the academy; the academy is not fully aware of the needs of the industry; the state government operates financial and regulatory tools that do not necessarily meet the needs for innovation and do not lead to a substantive collaboration between the academy and the industry.

The classical approach of the solution of the market failure through the intervention of the government is certainly productive, but apparently not sufficient. This article suggests three probably most important conclusions:

The first conclusion is that the external intervention of the government needed for the solution of the market failure should be complemented by the external (to the firm) intervention of the industrial sector, through its organizations (syndicates, associations). An industrial association has a global interest in innovation (beyond the interest of individual businesses) and possesses the tools for such intervention.

The second conclusion is that the policy measures devised for the advance of innovation should be elaborated jointly by the industry and the academy, in collaboration with the government. Permanent organizational structures (such as a joint innovation council, joint sectoral working groups) have made in the case of the state of Ceara a significant contribution to mutual flows of information between the industry and the academy, and to clear signalization of the needs to the government.

A third conclusion is that the adoption of a clear practical model for the elaboration of a policy for the advance of innovation is vital. The model shown in this research project includes the elaboration of a diagnosis, the identification of the prevailing innovation ecosystem, and the derivation of practical measures.

The case of the state of Ceara shows that such a strategy may actually be efficient. The local association of industries, jointly with the academy and with the government, have the ability to identify bottlenecks in the process of innovation, evaluate the functioning and malfunctioning of the local innovation ecosystem, and devise the measures that can contribute to the wellbeing of the sector as a whole.

This experiment led to a satisfactory improvement of the local innovation ecosystem, with better interaction between the industry and the academy, enabling the elaboration and implementation of appropriate measures focused on the main impediments to innovation. This led to the establishment of a structure of

collaboration between industry and academy, with the support of government, as well as the provision of information and knowledge to all parties involved and the clear identification of specific areas where direct support to specific businesses is most needed.
