

KOSZUL ALGEBRAS ASSOCIATED TO GRAPHS

DMITRI PIONTKOVSKI

ABSTRACT. Quadratic algebras associated to graphs have been introduced by I. Gelfand, S. Gelfand, and Retakh in connection with decompositions of noncommutative polynomials. Here we show that, for each graph with rare triangular subgraphs, the corresponding quadratic algebra is a Koszul domain with global dimension equal to the number of vertices of the graph.

1. INTRODUCTION

The origin of the algebras considered here are the works of I. Gelfand, S. Gelfand, Retakh, Wilson, and others on decompositions of noncommutative polynomials and noncommutative symmetric functions, see [GGRW] and references therein. Here we sketch some their definitions and results.

Let C be a division algebra over a field k , and let $P(x) \in C[x]$ be a polynomial of degree n , where x is a central variable. An element $t \in C$ is called *pseudo-root* of the polynomial $P(x)$ if there is a decomposition

$$P(x) = L(x)(x - t)R(x),$$

where $L(x), R(x) \in C[x]$ are polynomials. For a generic monic polynomial $P(x)$, there are at least $n2^{n-1}$ different pseudo-roots, but these pseudo-roots are connected by some linear and quadratic relations. So, it is natural to consider an *universal quadratic algebra of pseudo-roots* Q_n , which is generated by these generic pseudo-roots satisfying these relations.

The algebra Q_n has been studied in several papers [GRW, GGRSW, SW, Pi1]. It is a homogeneous quadratic Koszul algebra with $2^n - 1$ generators and is very far from being commutative. These generators u_S may be naturally indexed by the nonempty subsets of the n -element set $S \subset \{1, \dots, n\}$. If we consider these subsets S as faces of the $n - 1$ -dimensional simplex Δ , it is natural to consider the ideals of I_Γ in Q_n generated by all simplicial subcomplexes Γ (that is, by the variables u_S with $S \in \Gamma$) of the simplex Δ . The quotient algebras $Q(\Gamma) = Q_n/I_\Gamma$ would lead to “noncommutative combinatorial topology” [GGRW]. We need to “glue” such algebras corresponding to different simplicial complexes in order to approximate the noncommutative structure of the algebra Q_n . To do this, we need to know, at first, the Hilbert series of the algebras $Q(\Gamma)$. Next, the algebra Q_n is Koszul and has global dimension n [SW, Pi1]. Therefore, to approximate it by some algebras $Q(\Gamma)$, it is important to answer a question stated by Vladimir Retakh: For which simplicial complexes Γ the algebra $Q(\Gamma)$ is Koszul? We hope that all such algebras are Koszul of global dimension n .

Date: February 21, 2006.

Key words and phrases. graph, Koszul algebra, noncommutative polynomial, simplicial complex.

The generators and relations of the algebras $Q(\Gamma)$ has been described in [GGR], where these algebras have been introduced. In the trivial case on 0-dimensional simplicial complex Γ (a set of n points), the algebra $Q(\Gamma)$ is an algebra of commutative polynomials in n variables. Special attention was given to the first non-trivial case of one-dimensional simplicial complex Γ (i. e., the case of a graph): correspondent algebras seems to be the "most commutative" among all algebras $Q(\Gamma)$. In particular, in the case of one-dimensional Γ a simple set of relations has been described in [GGR].

The second step has been made by Nacin [N1, N2, N3]. He proved that the algebra $Q(\Gamma)$ is Koszul for graphs of the following types: "line" (i. e., a graph with n vertices $1, \dots, n$ and the edges $(12), (23), \dots, (n-1, n)$), "star" (vertices are $(12), (13), \dots, (1n)$), "triangle" (a complete graph with vertices). It is shown that, in these 3 cases, the global dimension of the algebra $Q(\Gamma)$ is equal to the number of vertices, and Hilbert series of the algebra and its quadratic dual algebra are calculated. In particular, the following interesting fact is found in the cases of lines and stars: If $Q(\Gamma)^\dagger(z) = p_0 + p_1z + \dots + p_nz^n$ is the Hilbert series of the quadratic dual algebra $Q(\Gamma)^\dagger$ (i. e., $p_i = \dim Q(\Gamma)_i^\dagger$), then the "paliandromic" equalities $p_i = p_{n-i}$ hold for all $i \leq n$. However, in the case of triangle this paliandromic property fails.

In this paper, we try to make a next step in this direction. We consider a more general class of graphs, that is, the class of graphs with no overlapping triangles, i. e., our graphs do not contain subgraphs isomorphic to the "simple butterfly" $\{(12), (13), (23), (14), (15), (45)\}$ and the "square with a diagonal" $\{(12), (23), (34), (14), (13)\}$. In particular, this class includes all trees and all cyclic graphs.

Our main result is the following.

Theorem 1.1 (Theorem 4.1). *Suppose that a graph Γ with n vertices does not contain a pair of overlapping triangles. Then the algebra $Q(\Gamma)$ is a Koszul domain of global dimension n .*

Also, we give explicit formulae for Hilbert series of algebras $Q(\Gamma)$ and their dual algebras $Q(\Gamma)^\dagger$, see Corollary 4.3 and Proposition 4.4 below. In particular, we explain the phenomenon of "paliandroms" found in [N2, N3] for some graphs.

Corollary 1.2 (Corollary 4.5). *Let $p_t = \dim Q(\Gamma)_t^\dagger$ denotes the Hilbert function of the quadratic algebra $Q(\Gamma)^\dagger$ dual to $Q(\Gamma)$. If Γ does not contain two overlapping triangles, then $p_t = 0$ for $t > n$ and $p_t \geq p_{n-t}$ for all $t \leq n/2$. The equalities $p_t = p_{n-t}$ hold for all $t \leq n/2$ if and only if the graph Γ is triangle free.*

Let us say a few words about other probable properties of algebras $Q(\Gamma)$. If the graph Γ has at least one edge, then the algebra $Q(\Gamma)$ has exponential growth (since its quotient algebra Q_2 has exponential growth), hence $Q(\Gamma)$ is not Noetherian [SZ]. However, we conjecture that the algebras Q_n and $Q(\Gamma)$ are (graded) coherent, that is, the kernel of every (homogeneous) map $M \rightarrow N$ of free finitely generated $Q(\Gamma)$ -modules is finitely generated. At least, the algebra Q_2 is coherent by [Pi2]. If it is the case, the Koszul duality gives equivalences of several categories of finitely presented $Q(\Gamma)$ -modules and their derived categories with the respective categories of modules over the finitely-dimensional algebra $Q(\Gamma)^\dagger$ [BGS, MVS].

Acknowledgement. I am grateful to Vladimir Retakh for helpful discussions. I am also grateful to MPIM Bonn for their hospitality during preparation of this paper.

2. BACKGROUND

2.1. Quadratic algebras corresponding to graphs. Let $\Gamma = (W, E)$ be a graph with n vertices $1, \dots, n$, that is, 1-dimensional simplicial complex. A construction in [GGR] assigns to Γ a quadratic associative algebra $Q(\Gamma)$ with generators $\{u_i | i = 1 \dots n\} \cup \{u_{ij} | 1 \leq ji \leq n, (ij) \in E\}$ (where a sub-index “ ij ” denotes an unordered pair) and relations for all pairwise different indexes i, j, k, l

$$R(ij) := [u_i, u_j] - u_{ij}(u_i - u_j), \text{ where } i \neq j,$$

$$R(ijk) := [u_i, u_{jk}] + [u_{ik}, u_j] + [u_{ik}, u_{jk}] - u_{ij}(u_{ik} - u_{jk}),$$

$$R(ijkl) := [u_{ij}, u_{kl}]$$

(where $u_{pq} = 0$ for $(pq) \notin E$).

2.2. Koszulity. Recall that a graded connected degree-one generated algebra A over a field k (i. e. $A = k \oplus A_1 \oplus A_2 \oplus \dots$ is generated by the graded component A_1) is called *Koszul* if the trivial right A -module k_A has a linear free resolution, that is, $\text{Tor}_i^A(k, k)_j = 0$ for all i, j but $i = j$ (graded the homologies of A are concentrated in the diagonal). We will use the following criterion for Koszul algebras [PP].

Let A be a quadratic algebra. Assume that A is filtered by a \mathbb{N} -graded ordered semigroup S such that the filtration on the graded component A_n is induced by the filtration on the space of generators $V = A_1$. Then A has also an \mathbb{N} -filtration induced by the grading of S . The associated graded algebra $\mathbf{gr} A$ may in general be non-quadratic; let $R \subset A_1 \otimes A_1$ be a set of quadratic relations of the algebra $\mathbf{gr} A$ (that is, the degree two graded component of the ideal of relations) and let $B = T(A_1)/\text{id}(R)$ be its quadratic part.

Theorem 2.1 ([PP], Theorem 7.1 in Ch. 4). *Assume that, in the notation above,*

(i) *the algebra $\mathbf{gr} A$ has no nontrivial relations in degree 3*

and

(ii) *the algebra B is Koszul.*

Then $\mathbf{gr} A = B$ and A is Koszul.

The condition (i) here is equivalent to the equality $\dim A_3 = \dim B_3$, because $\dim A_3 = \dim \mathbf{gr} A_3$.

A classical particular case of this theorem is that every algebra with quadratic Groebner basis is Koszul [Pr] (since every monomial quadratic algebra B is Koszul). Another standard consequence is that every quotient of a polynomial ring or an external algebra by an ideal with quadratic Groebner basis is Koszul (because the Koszulness of a quotient of an external algebra by a set of quadratic monomials follows from the results of [F]). We will use this corollary in the case of external algebras.

For the background on Groebner basis in the free associative algebra, we refer the reader to [U].

3. ASSOCIATED QUADRATIC ALGEBRA TO $Q(\Gamma)$

Let us introduce a filtration on the algebra $A = Q(\Gamma)$ by setting new degrees of generators as $|u_i| = 1$ and $|u_{ij}| = 0$. Then the associated quadratic algebra $B = B(\Gamma)$ has the same generators as A and the relations

$$S(ij) := [u_i, u_j],$$

$$S(ijk) := [u_i, u_{jk}] + [u_{ik}, u_j],$$

$$S(ijkl) := R(ijkl) = [u_{ij}, u_{kl}]$$

(where again $u_{pq} = 0$ for $(pq) \notin E$, and the indexes i, j, k, l are pairwise different). Because these relations are linear combinations of commutators of generators, the algebra B is a universal enveloping algebra of the quadratic Lie algebra $g = g(\Gamma)$ given presented by the same generators and relations.

To use Theorem 2.1, we need

Proposition 3.1. *For every graph Γ , we have $\dim Q(\Gamma)_3 = \dim B(\Gamma)_3$.*

Proof. Let u be the minimal set of degree-one homogeneous generators of A (and B) listed above. Let $G = \{0, 1\}$ be the two-elements multiplicative semigroup. Let us introduce a G^n -grading on the free algebra $T(u)$ by assigning $\deg' u_i = \mathbf{1}_i := (0, \dots, 1, \dots, 0)$ (the unit in the i -th place) and $\deg' u_{ij} := \mathbf{1}_i + \mathbf{1}_j$. Then the relations of both algebras A and B becomes homogeneous w. r. t. this new grading, so, the new G^n -grading is correct, and the algebras become $\mathbb{Z} \times G^n$ -graded.

In order to check the equality $\dim Q(\Gamma)_3 = \dim B(\Gamma)_3$, we have to check the equalities for dimensions of graded components $\dim Q(\Gamma)_{3,g} = \dim B(\Gamma)_{3,g}$ for every $g \in G^n$. For $g = (g_1, \dots, g_n) \in G^n$, let $|g|$ denotes the number of units among g_i . Because for every generator u_* we have $|\deg' u_*| \leq 2$, hence $Q(\Gamma)_{1,g} = B(\Gamma)_{1,g} = 0$ if $|g| > 2$, therefore, $Q(\Gamma)_{3,g} = B(\Gamma)_{3,g} = 0$ for $|g| > 6$. So, it remains to check the equalities $\dim Q(\Gamma)_{3,g} = \dim B(\Gamma)_{3,g}$ for all g with $|g| \leq 6$. This means that there are some subindexes i_1, \dots, i_s , where $s \leq 6$, such that all elements in $Q(\Gamma)_{3,g}$ and $B(\Gamma)_{3,g}$ lies in the span of monomials on some generators u_* depending on these subindexes only. Hence we may ignore all the relations of algebras A and B which depend on other subindexes, that is, we work in the subgraph of Γ with vertices i_1, \dots, i_6 . This means that *it is sufficient to prove proposition 3.1 for $n \leq 6$.*

Moreover, if $|g| = 6$, then all the monomials in the decomposition of every element $f \in Q(\Gamma)_{3,g}$ (or $f \in B(\Gamma)_{3,g}$) must have the form $\mu = u_{ij}u_{kl}u_{mn}$, where all indexes i, \dots, n are pairwise different. Let Ξ be the span of monomials of that type in the free algebra $T(A_1)$ generated by u . The intersections of Ξ with the ideal of relations of the algebras $Q(\Gamma)$ and $B(\Gamma)$ are the same as its intersection with the ideal I_Ξ generated by the relations of the type $R(ijkl)$, because $R(ijkl) \in \Xi$, while for every other relation R_* or S_* listed above, any monomial in the decomposition of this noncommutative polynomial is not a submonomial of a monomial of the form μ . Therefore, the vector spaces $Q(\Gamma)_{3,g}$ and $B(\Gamma)_{3,g}$ are isomorphic to the correspondent graded component of the algebra $T(A_1)/I_\Xi$, hence they are isomorphic to each other.

Now, it remains to consider the case $|g| \leq 5$. By the same arguments as above, it sufficient to show the following

Lemma 3.2. *If $n \leq 5$, then the statement of Proposition 3.1 is true.*

Proof of Lemma 3.2. Being a statement about dimensions of some subspaces in finite-dimensional vector spaces, this Lemma is proved by a direct computer calculation. There are 33 pairwise non-isomorphical graphs with ≤ 5 vertices. For all these cases, suitable dimensions of the third components of algebras $Q(\Gamma)$ and $B(\Gamma)$ have been calculated via computations of Hilbert series up to the 3-rd power. For this purpose, I used a software GRAAL (developed by Alexei Kondratiev). In each of these 33 cases, the calculation shows that the Hilbert series of the algebras $Q(\Gamma)$ and $B(\Gamma)$ are equal to each other at least up to $o(z^4)$; in particular, $\dim Q(\Gamma)_3 = \dim B(\Gamma)_3$. \square

So, Proposition 3.1 is proved completely. \square

In the view of Theorem 2.1, we have

Corollary 3.3. *If, for some Γ , the algebra $B(\Gamma)$ is Koszul, then the algebra $Q(\Gamma)$ is Koszul too, and both algebras are domains.*

Proof. The Koszulity is a part of Theorem 2.1. It remains to show that the algebras $Q = Q(\Gamma)$ and $B = B(\Gamma)$ have no zerodivisors. Indeed, B is an universal enveloping algebra of some graded Lie superalgebra (because the relations of the algebra B are linear combinations of commutators of some variables), hence it is a domain. By Theorem 2.1, $B = \mathbf{gr} A$, so, A is a domain too. \square

4. GRAPHS WITHOUT OVERLAPPING TRIANGLES

Theorem 4.1. *Suppose that there do not exist two triangles with common vertex in Γ . Then both algebras $A = Q(\Gamma)$ and $B = B(\Gamma)$ are Koszul domains and have global dimension n .*

Proof. The dual quadratic algebra $B^!$ is a quotient of an external algebra ΛV (where V is a span of indeterminates $\{e_i | i = 1 \dots n\} \cup \{e_{ij} | 1 \leq j < i \leq n, (ij) \in E\}$) by an ideal generated by the following relations:

$$(4.1) \quad \begin{aligned} T(ijk) &:= e_i e_{jk} + e_j e_{ki} + e_k e_{ij}, \text{ where } (ij), (jk), (ij) \in E, \\ U(ik) &:= e_i e_{ik}, \\ W(ijk) &:= e_{ik} e_{jk}. \end{aligned}$$

We claim that these relations (with $i < j$) form a Groebner basis of the ideal I in ΛV generated by them w. r. t. any degree-lexicographical order with $e_n > \dots e_1 > e_{ij}$.

We use standard Buchberger criterion.

A nontrivial s-polynomials may occur only involving some non-monomial relation $T(ijk)$, where $(jk), (ik), (ij) \in E$ with $i > j, i > k$. Its leading term is $\widetilde{T(ijk)} = e_i e_{jk}$. The following s-polynomials are obviously reduced to zero by $U(ik)$ and $W(ijk)$ (in these presentations, we omit the monomials obviously reduced to zero): $e_i T(ijk) = e_i e_j e_{ik} + e_i e_k e_{ij}$, $T(ijk) e_{jk} = e_j e_{ik} e_{jk} + e_k e_{ij} e_{jk}$, $T(ijk) e_{im} + U(im) e_{jk} = e_j e_{ik} e_{jm} + e_k e_{ij} e_{jm}$, $T(ijk) e_k + e_i U(kj) = e_{ik} e_j e_k$, and $T(ijk) e_{sk} + e_i W(sjk) = e_j e_{ik} e_{sk} + e_k e_{ij} e_{sk}$.

It remains to consider the intersections between leading monomials of $T(ijk)$ and some other $T(pqr)$. If $T(pqr)$ exists, then the triangle $(pqr) = \{(pq), (qr), (pr)\}$ exists in E . If there is an overlap between the leading terms of $T(ijk)$ and $T(pqr)$, the triangles (ijk) and (pqr) must have at least one common vertex. But it is impossible, so that there is no other s-polynomials.

So, the algebra $B^!$ has quadratic Groebner basis as a quotient of ΛV . Hence it is Koszul, so that B is Koszul too. By Corollary 3.3, both algebras A and B are Koszul domains. Because $\text{gl. dim } A = \max\{d|A_d^! \neq 0\}$ and $A^!(z) = A(-z)^{-1} = B(-z)^{-1} = B^!(z)$, we have $\text{gl. dim } A = \text{gl. dim } B = \max\{d|B_d^! \neq 0\}$. To calculate this global dimension, we give a description of linear basis of the algebra $B^!$.

By the definition of the Groebner basis, there is a linear basis of $B^!$ consisting of all monomials in ΛV which are not divisible by the leading terms of the Groebner basis. These leading terms are the following:

$$(4.2) \quad \begin{aligned} & e_j e_{jk}; \\ & e_i e_{jk}, \text{ where } i > j > k \text{ and } (ij), (ik), (ij) \in E; \\ & e_{ij} e_{jk}, \text{ where } i > k. \end{aligned}$$

In particular, the only element of degree n in the basis of $B^!$ is $e_1 \dots e_n$, and there are no elements of higher degree. \square

Notice that we have obtain a linear basis of the algebra $B(\Gamma)^!$. Since the algebra $Q(\Gamma)^!$ is an associated graded algebra to a filtration on it [PP, Ch. 4, Corollary 7.3]. So, we get

Corollary 4.2. *The monomials of the form*

$$e_{i_1 i_2}, \dots, e_{i_{2p-1} i_{2p}} e_{j_1} \dots e_{j_q},$$

where where $i_1 > i_3 > \dots > i_{2p-1}$, $j_1 > \dots > j_q$, $i_1 > i_2, \dots, i_{2p-1} > i_{2p}$, all indexes $i_1, \dots, i_{2p}, j_1, \dots, j_q$ are pairwise different, and for every $s \leq p, t \leq q$ either $j_t < i_{2s-1}$ or $(j_t, i_{2s-1}) \notin E$ or $(j_t, i_{2s}) \notin E$, form a linear basis of the algebra $Q(\Gamma)^!$.

Corollary 4.3. *Suppose that there do not exist two triangles with common vertex in Γ . Then the Hilbert series of the algebra $Q(\Gamma)$ is*

$$Q(\Gamma)(z) = p_\Gamma(-z)^{-1},$$

where $p_\Gamma(z) = Q(\Gamma)^!(z) = B(\Gamma)^!(z)$ is a polynomial of degree n with positive integer coefficients.

To give an implicit formula for this polynomial $p_\Gamma(z) = p_0 + p_1 z + \dots + p_n z^n$, let us introduce some notations. Let L_p be the set of all p -elements subsets $W = \{e_{i_1 i_2}, \dots, e_{i_{2p-1} i_{2p}}\}$ (where $i_{2j-1} > i_{2j}$ for all j) such that $i_s \neq i_t$ for all $s, t = 1 \dots 2p$. Given such a subset W , let R_W denote the set of indexes $m \in [1..n]$ such that $m \neq i_s$ and for every $j = 1 \dots p$ either $m < i_{2j-1}$ or $(m, i_{2j-1}) \notin E$ or $(m, i_{2j}) \notin E$ (by the other words, we avoid all triangles $\{m, i_{2j-1}, i_{2j}\}$ with $m > i_{2j-1} > i_{2j}$). Let l_p and r_W denote the cardinalities of the sets L_p and R_W .

Proposition 4.4. *Suppose that there do not exist two triangles with common vertex in Γ . Then the Hilbert series $p(z) = Q(\Gamma)^!(z) = B(\Gamma)^!(z)$ is calculated by the formula*

$$p(z) = \sum_{p=0}^{[n/2]} z^p \sum_{W \in L_p} (1+z)^{r_W}.$$

In particular, if there is no triangle in Γ , then

$$p(z) = \sum_{p=0}^{[n/2]} l_p z^p (1+z)^{n-2p}.$$

Proof. The coefficient p_t is equal to the number of elements in the t -th graded component of the linear basis of the algebra $B^!$ described above. It follows from the description (4.2) that this graded component consists of the square free commutative monomials of the form $e_{i_1 i_2, \dots, i_{2p-1} i_{2p}} e_{j_1} \dots e_{j_{t-p}}$, where $W := \{e_{i_1 i_2, \dots, i_{2p-1} i_{2p}}\} \in L_p$ and $j_s \notin R_W$ for all $s = 1 \dots t-p$. Given such W and $t > p$, we obtain exactly $\binom{r_W}{t-p}$ monomials of this type. Now, the desired equalities immediately follow from the binomial decompositions. \square

In particular, we have

Corollary 4.5. *If Γ does not contain two overlapping triangles, we have $p_t \geq p_{n-t}$ for all $t < n/2$. The equalities $p_t = p_{n-t}$ hold for all $t < n/2$ if and only if there is no triangle in Γ .*

Proof. The first inequality holds (for every t) for the coefficients of z^t and z^{n-t} in every summand of the first sum in Proposition 4.4 (because $r_W \leq n - 2p$), hence it holds also for the whole sum. The equality means that $r_W = n - 2p$ for every $W \in L_p$, that is, there is no triangle in Γ . \square

Remark 4.6. In the view of ‘palindromic’ equalities $p_t = p_{n-t}$ for the dimensions of graded components of algebras $Q(\Gamma)^!$ and $B^!$ for triangle free graphs, one could conjecture that these algebras are Frobenius; in this case, the algebras $Q(\Gamma)$ and $B(\Gamma)$ are Gorenstein of finite global dimension, that is, generalized Artin–Shelter regular. However, for any such graph Γ with at least one edge (ij) the both these algebras are not Frobenius.

Indeed, by definition, an algebra $A = A_0 \oplus \dots \oplus A_n$ is Frobenius if $\dim A_n = \dim A_0 = 1$ and the multiplication induces a non-degenerate pairing $A_t \otimes A_{n-t} \rightarrow A_n$ for all t . However, in the algebra $B^!$ we have $B_{n-1}^! e_{ij} = \bigoplus k e_{i_1} \dots e_{i_{n-1}} e_{ij} + \bigoplus k e_{i_0 i_1} e_{i_2} \dots e_{i_{n-1}} e_{ij} = 0$, since in every summand at least one index appears twice, hence the pairing $B_{n-1}^! \otimes B_1^! \rightarrow B_n^!$ is degenerate. Moreover, all quadratic monomials on variables e_i, e_{ij} which do not appear in the relations of the algebra $Q(\Gamma)$ listed in the subsection 2.1 are monomial relations of the algebra $Q(\Gamma)^!$ (with letters ‘ u ’ replaced by ‘ e ’). In particular, we have the equalities $e_i e_{ij} = e_j e_{ij} = 0$ and $e_{ij}^2 = 0$ in the algebra $Q(\Gamma)^!$. Because $B^! = \mathbf{gr} Q(\Gamma)^!$, every monomial basis of the vector space $B_{n-1}^!$ is also a monomial basis in the vector space $Q(\Gamma)_{n-1}^!$. Therefore, given two indexes i, j , there is a basis of the vector space $Q(\Gamma)_{n-1}^!$ consisting of the monomials of the form $e_{i_1} \dots e_{i_{n-1}}, e_{i_0 i_1} e_{i_2} \dots e_{i_{n-1}}$, and $e_{i_1} \dots e_{i_{n-2}} e_{ij}$, where either $i_{n-1} = i$ or $i_{n-1} = j$. Thus, $Q(\Gamma)_{n-1}^! e_{ij} = 0$ for every edge $(ij) \in E$, so, the algebra $Q(\Gamma)^!$ is not Frobenius.
