Cardy–Frobenius algebra

ABSTRACT

This paper proposes an axiomatic form for cyclic foam topological field theories, that is, topological field theories corresponding to string theories where particles are arbitrary graphs. World surfaces in this case are 2-manifolds with one-dimensional singularities. I prove that cyclic foam topological field theories are in one-to-one correspondence with graph-Cardy–Frobenius algebras that are families (A, B_*, ϕ) where $A = \{A^s | s \in S\}$ are families of commutative associative Frobenius algebras, $B_* = \bigoplus_{\sigma \in \Sigma} B_\sigma$ is an associative algebra of Frobenius type graduated by graphs, and $\phi = \{\phi_\sigma^s : A^s \rightarrow \text{End}(B_\sigma) | s \in S, \sigma \in \Sigma\}$ is a family of special representations. Examples of cyclic foam topological field theories and graph-Cardy–Frobenius algebras are constructed.

1. Introduction

Two-dimensional topological field theories were introduced by Segal [1], Atiyah [2] and Witten [3]. An example of such a theory is the rough topological approach of string theory. It treats particles as one-dimensional objects. A path of a particle is represented by a world sheet, that is, a two-dimensional space. The rough topological approach assumes that the probability of a world sheet depends only on the state of the particle at the moments of creation/annihilation and on the topological type of the world surface. The standard properties of the measure on world lines extend to properties of correlators of primary fields [4].

The topological field theory is a direct axiomatization of this model. The topological field theory is also a function on the set of two-dimensional spaces endowed with marked points (points of creation/annihilation of a string) and also with vectors at the marked points (vectors, describing states of the string). The function depends on the vectors, linearly. The additive properties of strings measure can be reformulated as properties of correlators with respect to a surgery of surfaces.

The simplest model treats particles as closed contours. Thus its world sheet is a closed surface, that is, a two-dimensional topological manifold without a boundary. The corresponding topological field theory was constructed in [2,5] for orientable surfaces and in [6] for arbitrary (orientable and non-orientable) surfaces.

In this case, the values of a topological field theory on spheres with one, two and three marked points determine the values of the topological field theory on all oriented surfaces. Also, the values of a topological field theory on spheres with one, two and three marked points are structure constants for some associative, commutative Frobenius algebra A with a unit. Moreover, this construction gives a one-to-one correspondence between topological field theories on closed orientable surfaces and associative, commutative Frobenius algebras with a unit [5]. To extend a topological field theory to non-orientable surfaces one has to add new structures to A , namely, an involution of A and an element $U \in A$ which defines the value of the topological field theory on a projective sphere with a marked point [6].

If particles are closed contours and segments, then sheet surfaces are surfaces without a boundary or with a boundary consisting of closed contours. If, in addition, the surfaces are orientable, that leads to open–closed topological field

Fig. 1.

theory, which gives rise to a pair of Frobenius algebras, connected by a special homomorphism ϕ [7,8]. The first algebra A corresponds to closed surfaces. The second algebra B , which in general is non-commutative, corresponds to disks with marked points at the boundary. The one-to-one correspondence between open–closed topological field theories and the families (A, B, ϕ) was proved in [6] and later, independently, in [9,10].

The topological field theory for orientable and non-orientable surfaces with a boundary was constructed in [6]. We call it Klein topological field theory. Klein topological field theories are in one-to-one correspondence with Cardy–Frobenius algebras, which are the tuples (A, B, ϕ) with equipments [6].

In the present paper I construct cyclic foam topological field theories that correspond to particles that are arbitrary graphs (for a physical motivation see [11], and also [12] and references therein). In this case the world sheets are CW-complexes that glued from finitely many surfaces (“patches”) by segments of the boundaries. The glued boundaries of surfaces form a “seamed graph” which is the singular part of the complex. Complexes of this type are called “foam” or “seamed surfaces”. They appear also in A-models [13] and Landau–Ginzburg models [14]. Foams are used also in a description of link invariants [15–20].

In this paper I consider a special class of foams which I call cyclic foams. They satisfy the following conditions: (1) glued boundary contours of patches have compatible orientation; (2) different boundary contours of a patch are included to different connected components of the seamed graph. I assume also that any patch has a “color” from a set S and that the closures of two patches have no intersections if they have the same color.

We start with the definition of cyclic foam topological field theories on cyclic foams where all patches are disks (Section 2). In Section 3 we define “graph-Frobenius algebras” and we prove that topological field theories from Section 2 are in one-to-one correspondence with graph-Frobenius algebras. A graph-Frobenius algebra is presented as a sum of finite dimensional vector spaces $B_\star = \bigoplus_{\sigma \in \Sigma} B_\sigma$ where Σ is the set of oriented colored graphs.

In Section 4 we define topological field theories for arbitrary cyclic foams. Later (Section 5) we prove that cyclic foam topological field theories are in one-to-one correspondence with families (A, B_\star, ϕ) , where $A = \{A^s | s \in S\}$ is a family of commutative associative Frobenius algebras with units and $\phi = \{\phi_\sigma^s : A^s \rightarrow \text{End}(B_\sigma) | s \in S, \sigma \in \Sigma\}$ is a special family of representations in B_σ .

In Section 6 of the present paper we construct examples of cyclic foam topological field theories and corresponding graph-Cardy–Frobenius algebras. These examples extend to cyclic foams the Klein topological field theories for Hurwitz numbers from [21,6,22–25].

2. Film topological field theories

2.1. Film surfaces

In this paper a *graph* is a compact simplicial complex that consists of simplexes of dimension 1 (*edges*) and dimension 0 (*vertices*). An edge is either a segment or a loop depending on the topological type of its closure. A graph is said to be *regular* if all of its edges are segments.

A compact CW-complex that consists of oriented cells of dimension 2 (*disks*), cells of dimension 1 (*edges*) and cells of dimension 0 (*vertices*) is said to be *regular* if its edges form a regular graph. Thus the regular CW-complex Ω is defined by a set $(\check{\Omega}, \Delta, \varphi)$, where $\check{\Omega} = \check{\Omega}(\Omega)$ is a set of closed oriented disks, $\Delta = \Delta(\Omega)$ is a regular graph and $\varphi : \partial\check{\Omega} \rightarrow \Delta$ is a gluing map, that is, a homeomorphism on any connected component of $\partial\check{\Omega}$ and $\varphi(\partial\check{\Omega}) = \Delta$ (Fig. 1).

Recall that *cyclic order* on a set X with n elements is an arrangement of X as on a clock face, for an n -hour clock. A cyclic order on X generates the cyclic order on any subset $X' \subset X$ that we call *induced by order on X* . We say that a split of $X = X_1 \cup X_2$ is *compatible with the cyclic order on X* if there exist indexings of elements $X_1 = \{x_1, \dots, x_m\}, X_2 = \{x_{m+1}, \dots, x_n\}$ that generate the cyclic order on X .

Denote by Ω_b the set of vertices of a regular CW-complex Ω . The orientation of a disk $\omega \in \check{\Omega}(\Omega)$ generates the *standard cyclic order* on the set of vertices $\omega_b = \omega \cap \Omega_b$. We say that Ω is an *almost cyclic complex* if the vertices of any connected component of Ω are allotted in cyclic order inducing the standard cyclic order on vertices ω_b for all $\omega \in \check{\Omega}(\Omega)$.

Fig. 2.

A connected regular graph $\gamma \subset \Omega$ on a connected almost cyclic complex Ω is called a *graph-cut* if:

- the restriction of γ to any disk $\omega \in \check{\Omega}$ either is empty or forms one of the edges of γ ;
- γ divides Ω into two connected components that split the vertices of Ω into two non-empty groups, compatible with the cyclic order on Ω (Fig. 2).

An almost cyclic complex Ω is called a *cyclic complex* if for any division of vertices of Ω compatible with the cyclic order there exists a graph-cut that realizes it. A small neighborhood of a vertex q of a CW-complex is a cone over a regular *vertex graph* σ_q , with an orientation of edges generated by the orientation of the disks outside the neighborhood. It is obvious that vertex graphs of cyclic complexes are connected.

Fix a set S of colors. A graph (resp., CW-complex) is called *colored* if a color $s(l) \in S$ is assigned to each of its edges (resp., disks) l and all the colors are pairwise different for any connected component. A colored cyclic complex is called a *film surface*. The vertex graph σ_q of the vertices q of a film surface is a colored graph, where colors of edges are generated by the colors of the disks.

2.2. Topological field theory

Below we assume that all vector spaces are defined over a field $\mathbb{K} \supset \mathbb{Q}$. Let $\{X_m | m \in M\}$ be a finite set of $n = |M|$ vector spaces X_m over the field of complex numbers \mathbb{C} . The symmetric group S_n on $\{1, \dots, n\}$ induces an action on the sum of the vector spaces $(\bigoplus_{\sigma} X_{\sigma(1)} \otimes \dots \otimes X_{\sigma(n)})$ where σ runs over the bijections $\{1, \dots, n\} \rightarrow M$; an element $s \in S_n$ takes $X_{\sigma(1)} \otimes \dots \otimes X_{\sigma(n)}$ to $X_{\sigma(s(1))} \otimes \dots \otimes X_{\sigma(s(n))}$. Denote by $\bigotimes_{m \in M} X_m$ the subspace of all invariants of this action. The vector space $\bigotimes_{m \in M} X_m$ is canonically isomorphic to the tensor product of all X_m in any fixed order; the isomorphism is the projection of $\bigotimes_{m \in M} X_m$ to the summand that is equal to the tensor product of X_m in that order.

Two regular oriented colored graphs are said to be *isomorphic* if there exists a homeomorphism that maps one to the other preserving the colors and the orientations. Denote by $\Sigma = \Sigma(S)$ the set of all isomorphism classes of connected oriented colored graphs. The inversions of the orientations generate the involution $*$: $\Sigma \rightarrow \Sigma$. Denote this by $\sigma \mapsto \sigma^*$.

Consider a family of finite dimensional vector spaces $\{B_{\sigma} | \sigma \in \Sigma\}$ and a family of tensors $\{K_{\sigma}^{\otimes} \in B_{\sigma} \otimes B_{\sigma^*} | \sigma \in \Sigma\}$. Using these data, we define now a functor \mathcal{V} from the category of film surfaces to the category of vector spaces. This functor assigns the vector space $V_{\Omega} = (\bigotimes_{q \in \Omega_b} B_q)$ to any film surface Ω . Here B_q is the copy of B_{σ_q} that is a vector space with a fixed isomorphism $B_q \rightarrow B_{\sigma_q}$.

We are going to describe all morphisms of the monoidal category \mathcal{F} of film surfaces and morphisms of the category of vector spaces that correspond to it.

(1) *Isomorphism*. Let $\phi : \Omega \rightarrow \Omega'$ be a homeomorphism of film surfaces, preserving the cyclic orders, orientations of disks and colors. Define $\mathcal{V}(\phi) = \phi_* : V_{\Omega} \rightarrow V_{\Omega'}$ as the linear operator generated by the bijections $\phi|_{\Omega_b} : \Omega_b \rightarrow \Omega'_b$.

(2) *Cut*. Let Ω be a connected film surface and $\gamma \subset \Omega$ be a graph-cut. The graph γ is represented by two graphs γ_+ and γ_- on the closure $\bar{\Omega} \setminus \gamma$ of $\Omega \setminus \gamma$. Contract these graphs to points $q_+ = q_+[\gamma]$ and $q_- = q_-[\gamma]$, respectively. The contraction produces a film surface $\Omega' = \Omega[\gamma]$. Its vertices $\Omega' = \Omega[\gamma]$ are the vertices of Ω and the points q_+, q_- . The cyclic order, the orientation and the coloring of Ω induce an orientation and a coloring of Ω' . Thus we can assume that Ω' is a film surface and $V_{\Omega'} = V_{\Omega} \otimes B_{q_+} \otimes B_{q_-}$. The functor takes the morphism $\mathcal{V}(\eta)(x) = \eta_*(x) = x \otimes K_{\sigma}^{\otimes}$, where $\sigma = \sigma_{q_+} = \sigma_{q_-}^*$, to the morphism $\eta : \Omega \rightarrow \Omega'$ (Fig. 3).

(3) The tensor product in \mathcal{F} defined by the disjoint union of surfaces $\Omega' \otimes \Omega'' \rightarrow \Omega' \sqcup \Omega''$ induces the tensor product of vector spaces $\theta_* : V_{\Omega'} \otimes V_{\Omega''} \rightarrow V_{\Omega' \sqcup \Omega''}$.

The functorial properties of \mathcal{V} can be easily verified.

Fix a tuple of vector spaces and vectors $\{B_{\sigma}, K_{\sigma}^{\otimes} \in B_{\sigma} \otimes B_{\sigma^*} | \sigma \in \Sigma\}$, defining the functor \mathcal{V} . A family of linear forms $\mathcal{F} = \{\Phi_{\Omega} : V_{\Omega} \rightarrow \mathbb{K}\}$ defined for all film surfaces $\Omega \in \mathcal{F}$ is called a *film topological field theory* if it satisfies the following axioms:

Fig. 3.

1° Topological invariance.

$$\Phi_{\Omega'}(\phi_*(x)) = \Phi_{\Omega}(x)$$

for any isomorphism $\phi : \Omega \rightarrow \Omega'$ of film surfaces.

2° Non-degeneracy. Let Ω be a film surface with only two vertices q_1, q_2 . Then $\sigma_{q_2} = \sigma^*$ if $\sigma_{q_1} = \sigma$. Denote by $(\cdot, \cdot)_{\sigma}$ the bilinear form $(\cdot, \cdot)_{\sigma} : B_{\sigma} \times B_{\sigma^*} \rightarrow \mathbb{K}$, where $(x', x'')_{\sigma} = \Phi_{\Omega}(x'_{q_1} \otimes x''_{q_2})$. Axiom 2° asserts that the forms $(\cdot, \cdot)_{\sigma}$ are non-degenerate for all $\sigma \in \Sigma$.

3° Cut invariance.

$$\Phi_{\Omega'}(\eta_*(x)) = \Phi_{\Omega}(x)$$

for any cut morphism $\eta : \Omega \rightarrow \Omega'$ of film surfaces.

4° Multiplicativity.

$$\Phi_{\Omega}(\theta_*(x' \otimes x'')) = \Phi_{\Omega'}(x')\Phi_{\Omega''}(x'')$$

for $\Omega = \Omega' \amalg \Omega'', x' \in V_{\Omega'}, x'' \in V_{\Omega''}$.

Note that a topological field theory defines the tensors $\{K_{\sigma}^{\otimes} \in B_{\sigma} \otimes B_{\sigma^*} | \sigma \in \Sigma\}$, since it is not difficult to prove the following:

Lemma 2.1. Let $\{\Phi_{\Omega}\}$ be a film topological field theory. Then $(K_{\sigma}^{\otimes}, x_1 \otimes x_2)_{\sigma} = (x_1, x_2)_{\sigma}$, for all $x_1 \in B_{\sigma}, x_2 \in B_{\sigma^*}$.

3. Graph-Frobenius algebras

3.1. Definitions

We say that a connected film surface Ω is a compatible surface for colored graphs $\sigma_1, \sigma_2, \dots, \sigma_n$ if these graphs are vertex graphs of Ω and the numeration the graphs σ_i generates the cyclic order of vertices of the film surface Ω . Denote by $\Omega(\sigma_1, \sigma_2, \dots, \sigma_n)$ the set of all isomorphism classes of compatible surfaces for $\sigma_1, \sigma_2, \dots, \sigma_n$. Then $\Omega(\sigma_1, \sigma_2, \dots, \sigma_n)$ is either empty or consists of a single element.

Let $\Omega(\sigma_1, \sigma_2, \sigma_3, \sigma_4) \neq \emptyset$. Then there exist unique classes of graph-cuts $\sigma_{(1,2|3,4)}, \sigma_{(4,1|2,3)} \in \Sigma$ such that $\Omega(\sigma_1, \sigma_2, \sigma_{(1,2|3,4)}) \neq \emptyset, \Omega(\sigma_{(3,4|1,2)}, \sigma_3, \sigma_4) \neq \emptyset, \Omega(\sigma_4, \sigma_1, \sigma_{(4,1|2,3)}) \neq \emptyset, \Omega(\sigma_{(4,1|2,3)}, \sigma_2, \sigma_3) \neq \emptyset$ and $\sigma_{(3,4|1,2)} = \sigma_{(1,2|3,4)}^*, \sigma_{(2,3|4,1)} = \sigma_{(4,1|2,3)}^*$.

Consider a tuple of finite dimensional vector spaces $\{B_{\sigma} | \sigma \in \Sigma\}$. Its direct sum $B_{\star} = \bigoplus_{\sigma \in \Sigma} B_{\sigma}$ is called a colored graph-graded vector space.

A colored graph-graded vector space with a bilinear form $(\cdot, \cdot) : B_{\star} \times B_{\star} \rightarrow \mathbb{K}$ and a 3-linear form $(\cdot, \cdot, \cdot) : B_{\star} \times B_{\star} \times B_{\star} \rightarrow \mathbb{K}$ is called a graph-Frobenius algebra if

- $(B_{\sigma_1}, B_{\sigma_2}) = 0$ for $\sigma_1 \neq \sigma_2^*$;
- the form (\cdot, \cdot) is non-degenerate;
- $(B_{\sigma_1}, B_{\sigma_2}, B_{\sigma_3}) = 0$ for $\Omega(\sigma_1, \sigma_2, \sigma_3) = \emptyset$;
- $\sum_{i,j} (x_1, x_2, b_i^{(1,2|3,4)}) F_{(1,2|3,4)}^{ij} (b_j^{(3,4|1,2)}, x_3, x_4) = \sum_{i,j} (x_4, x_1, b_i^{(4,1|2,3)}) F_{(4,1|2,3)}^{ij} (b_j^{(2,3|4,1)}, x_2, x_3)$.

Here $x_k \in B_{\sigma_k}, \{b_i^{(s,t|k,r)}\}$ is a basis of $B_{(s,t|k,r)}$ and $F_{(s,t|k,r)}^{ij}$ is the inverse matrix for $(b_i^{(s,t|k,r)}, b_j^{(k,r|s,t)})$.

We will consider B_{\star} as an algebra with the multiplication $(x_1 x_2, x_3) = (x_1, x_2, x_3)$, for $x_k \in B_{\sigma_k}$. The axiom $\sum_{i,j} (x_1, x_2, b_i^{(1,2|3,4)}) F_{(1,2|3,4)}^{ij} (b_j^{(3,4|1,2)}, x_3, x_4) = \sum_{i,j} (x_4, x_1, b_i^{(4,1|2,3)}) F_{(4,1|2,3)}^{ij} (b_j^{(2,3|4,1)}, x_2, x_3)$ is equivalent to associativity for the algebra B_{\star} . Moreover it is a Frobenius algebra in the sense of [26] if its dimension is finite.

3.2. One-to-one correspondence

Theorem 3.1. Let $\mathcal{F} = \{\Phi_\Omega : V_\Omega \rightarrow \mathbb{K}\}$ be a film topological field theory on a tuple of finite dimensional vector spaces $\{B_\sigma | \sigma \in \Sigma\}$. Then the multilinear forms

- $(x', x'') = \Phi_{\Omega(\sigma_1, \sigma_2)}(x'_{q_1} \otimes x''_{q_2})$, where $x' \in B_{\sigma_1}, x'' \in B_{\sigma_2}$
- $(x', x'', x''') = \Phi_{\Omega(\sigma_1, \sigma_2, \sigma_3)}(x'_{q_1} \otimes x''_{q_2} \otimes x'''_{q_3})$, where $x' \in B_{\sigma_1}, x'' \in B_{\sigma_2}, x''' \in B_{\sigma_3}$

generate a structure of graph-Frobenius algebra on $B_\star = \bigoplus_{\sigma \in \Sigma} B_\sigma$.

Proof. Only the last axiom is not obvious. Let us consider a film surface $\Omega \in \Omega(\sigma_1, \sigma_2, \sigma_3, \sigma_4)$, and a graph-cut between the pairs of vertices σ_1, σ_2 and σ_3, σ_4 . Then the cut-invariant axiom and Lemma 2.1 give $\sum_{i,j} (x_1, x_2, b_i^{(1,2|3,4)}) F_{(1,2|3,4)}^{ij} (b_j^{(3,4|1,2)}, x_3, x_4) = \Phi_\Omega(x_1, x_2, x_3, x_4)$. Similarly, $\sum_{i,j} (x_4, x_1, b_i^{(4,1|2,3)}) F_{(4,1|2,3)}^{ij} (b_j^{(2,3|4,1)}, x_2, x_3) = \Phi_\Omega(x_1, x_2, x_3, x_4)$. \square

Theorem 3.2. Let $B_\star = \bigoplus_{\sigma \in \Sigma} B_\sigma$ be a graph-Frobenius algebra with multilinear forms (\cdot, \cdot) and (\cdot, \cdot, \cdot) . Then it generates a film topological field theory on $\{B_\sigma | \sigma \in \Sigma\}$ by means of the following construction. Fix a basis $\{b_i^\sigma\}$ of any vector space $B_\sigma, \sigma \in \Sigma$. Consider the matrix F_σ^{ij} that is the inverse matrix for $F_{ij}^\sigma = (b_i^\sigma, b_j^{\sigma*})$. Define the linear functionals on connected film surfaces by

- $\Phi_{\Omega(\sigma_1, \sigma_2, \dots, \sigma_n)}(x_{q_1}^1 \otimes x_{q_2}^2 \otimes \dots \otimes x_{q_n}^n) = \sum_{s_1, s_2, \dots, s_{n-3} \in \Sigma} (x^1, x^2, b_{i_1}^{s_1}) F_{i_1 j_1}^{s_1} (b_{j_1}^{s_1*}, x_{q_3}^3, b_{i_2}^{s_2}) F_{i_2 j_2}^{s_2} (b_{j_2}^{s_2*}, x_{q_4}^4, b_{i_3}^{s_3}) \dots \dots \dots F_{i_{n-4} j_{n-4}}^{s_{n-4}} (b_{j_{n-4}}^{s_{n-4}*}, x_{q_{n-2}}^{n-2}, b_{i_{n-3}}^{s_{n-3}}) F_{i_{n-3} j_{n-3}}^{s_{n-3}} (b_{j_{n-3}}^{s_{n-3}*}, x_{q_{n-1}}^{n-1}, x_{q_n}^n)$,

where $x_{q_i}^i \in B_{\sigma_i}$.

Define the linear functionals on non-connected film surfaces by the multiplicativity axiom.

Proof. The topological invariance follows from the invariance under cyclic renumbering of the vertices of Ω . The invariance under the renumbering $q_i \mapsto q_j$, where $j \equiv i+1 \pmod n$, follows from the last axiom for the 3-linear form. The cut invariance follows directly from the definition of Φ if we renumber the vertices marking the cut dividing the vertices q_1, q_2, \dots, q_k and $q_{k+1}, q_{k+2}, \dots, q_n$. \square

These two theorems determine the one-to-one correspondence between film topological field theories and isomorphic classes of graph-Frobenius algebras.

4. Cyclic foam topological field theories

4.1. Cyclic foams

Cyclic foams Ω is defined by a 4-tuple $(\check{\Omega}, \overrightarrow{\partial\check{\Omega}}, \Delta, \varphi)$, where

- $\check{\Omega} = \check{\Omega}(\Omega)$ is a compact 2-manifold with a boundary $\partial\check{\Omega}$ that consists of pairwise non-intersecting circles; moreover, some of these circles are oriented;
- $\overrightarrow{\partial\check{\Omega}} \subset \partial\check{\Omega}$ is the subset of all oriented circles; the rest of the circles are called *free circles*;
- $\Delta = \Delta(\Omega)$ is a regular graph;
- $\varphi : \overrightarrow{\partial\check{\Omega}} \rightarrow \Delta$ is a *gluing map*, that is, a homeomorphism on any circle and $\varphi(\overrightarrow{\partial\check{\Omega}}) = \Delta$.

Here:

- the cyclic foam Ω has a cyclic order; this means that the vertices of any connected component of Δ have cyclic order that agrees with the orientation of $\varphi(\overrightarrow{\partial\check{\Omega}})$;
- the cyclic foam Ω is colored; this means that a color $s(\omega) \in S$ corresponds to each connected component of $\omega \in \check{\Omega}$ and the colors $s(\omega)$ are pairwise different for any connected component of Ω ;
- for any connected component $\omega \in \check{\Omega}$ different connected components of $\partial\omega \cap \overrightarrow{\partial\check{\Omega}}$ are mapped by φ to different connected components of Δ ;
- consider a tuple of disks $\tilde{\Omega}$ with $\partial\tilde{\Omega} = \overrightarrow{\partial\check{\Omega}}$ with colors and orientation generated by the colors and orientation of $\overrightarrow{\partial\check{\Omega}}$; then the cluing map φ generates a film surface $\check{\Omega}$;
- a finite set of *marked points* is fixed on Ω :
 - (a) marked points from $\check{\Omega} \setminus \overrightarrow{\partial\check{\Omega}}$ are said to be *interior* and form a set Ω_a ; a point $a \in \Omega_a$ is equipped with a local orientation and the color $s(a) = s(\omega)$ for $a \in \omega \in \check{\Omega}$;
 - (b) the remaining marked points form a set Ω_b of *vertices* of Ω ; they are all the vertices of Δ and the marked points on the free circles; a vertex graph σ_q for the vertex $q \in \Delta$ is defined as the vertex graph for $q \in \check{\Omega}$; we assume that each free circle contains a vertex; the graph of this vertex q is a segment with an orientation (the local orientation of the marked point) and the color $s(q) = s(\omega)$ for $q \in \omega \in \check{\Omega}$.

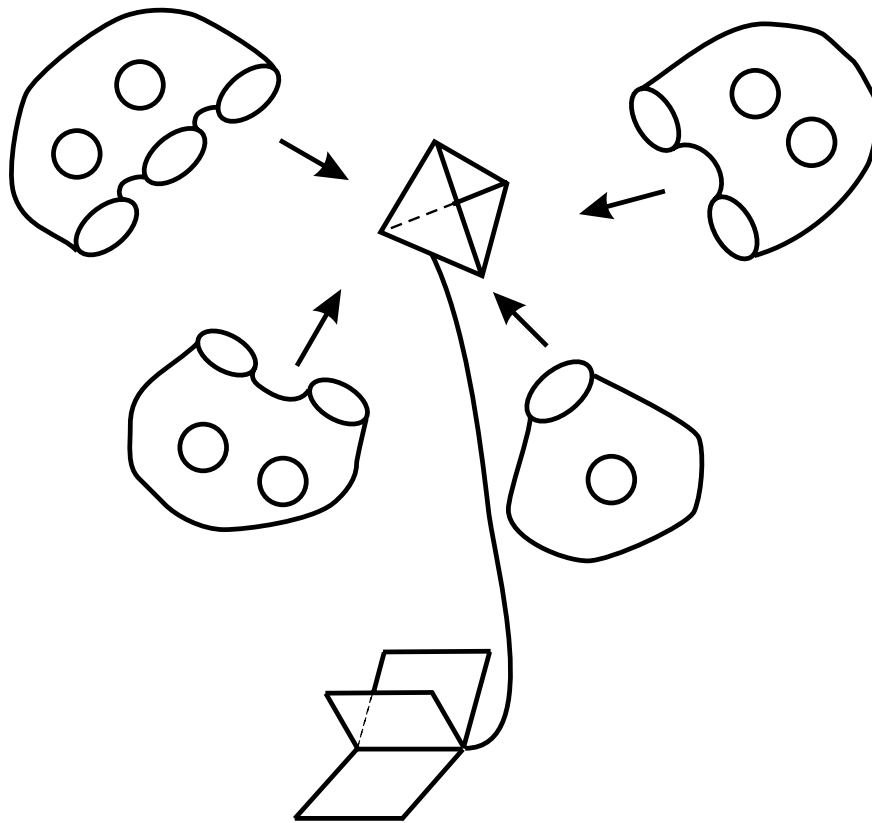

Fig. 4.

Thus the family of cyclic foams contains the family of film surfaces defined in Section 2 and the family of marked compact 2-manifolds with a boundary considered in [6] (Fig. 4).

Cuts of cyclic foam do not contain marked points. We assume three kinds of cuts:

- a contour-cut, that is a simple closed contour $\gamma \in (\check{\Omega} \setminus \partial\check{\Omega})$;
- a segment-cut, that connects without self-intersections segment $\gamma \in \check{\Omega}$ with ends on free contours, without other intersections with $\partial\check{\Omega}$;
- a regular graph $\gamma \in \Omega$, that generates a graph-cut on $\check{\Omega}$.

Denote by $I_s \in \Sigma$ the isomorphism class of oriented segments of color s . Then $I_s^* = I_s$. Consider families of finite dimensional vector spaces $\{A_s | s \in S\}$ and $\{B_\sigma | \sigma \in \Sigma\}$. Fix families of tensors $\{K_s^\otimes \in A_s \otimes A_s | s \in S\}$ and $\{K_\sigma^\otimes \in B_\sigma \otimes B_{\sigma^*} | \sigma \in \Sigma\}$. Fix families of elements $\{1_{A_s}, U_s \in A_s | s \in S\}$ and $\{1_{B_s} \in B_s | s \in S\}$. Fix families of involutions $\{*_s : A_s \rightarrow A_s | s \in S\}$ and $\{*_s : B_s \rightarrow B_s | s \in S\}$.

Define a functor \mathcal{V} from the category of cyclic foams to the category of vector spaces. This functor extends the functor on film surfaces from Section 2, and the functor on marked compact 2-manifolds with a boundary considered in [6].

The functor \mathcal{V} associates the vector space $V_\Omega = (\otimes_{p \in \Omega_a} A_{s_p}) \otimes (\otimes_{q \in \Omega_b} B_q)$ with any cyclic foam Ω . Here A_p is a copy of $A_{s(p)}$, and B_q is a copy of B_{σ_q} . We are going to describe all morphisms of a monoidal category of cyclic foams and morphisms of the category of cyclic foams that correspond to it.

(1) *Isomorphism.* Let $\phi : \Omega \rightarrow \Omega'$ be a homeomorphism of cyclic foams preserving colors, orientations and other structures. Define $\mathcal{V}(\phi) = \phi_* : V_\Omega \rightarrow V_{\Omega'}$ as a linear operator generated by the bijections $\phi|_{\Omega_a} : \Omega_b \rightarrow \Omega'_a$ and $\phi|_{\Omega_b} : \Omega_b \rightarrow \Omega'_b$.

(2) *Cut.* Let Ω be a connected film surface and $\gamma \subset \Omega$ be a cut.

(a) Let $\gamma \subset \omega \in \check{\Omega}$ be a non-co-orientable contour-cut. It is represented by a simple co-orientable contour γ' on the closure $\overline{\Omega \setminus \gamma}$ of $\Omega \setminus \gamma$. Contracting γ' to a point p' with arbitrary local orientation gives the cyclic foam Ω' , where $V_{\Omega'} = V_\Omega \otimes A_{s(\omega)}$. We associate the morphism $\mathcal{V}(\eta)(x) = \eta_*(x) = x \otimes U_{s(\omega)}$ with the morphism $\eta : \Omega \rightarrow \Omega'$

(b) Let $\gamma \subset \omega \in \check{\Omega}$ be a co-orientable contour-cut. It is represented by simple contours γ_+ and γ_- on the closure $\overline{\Omega \setminus \gamma}$ of $\Omega \setminus \gamma$. Contracting γ_+ and γ_- gives points $p_+ =$ and p_- . We assume that their local orientations are not generated by an orientation of γ . Thus we have a cyclic foam Ω' and $V_{\Omega'} = V_\Omega \otimes A_{s(\omega)} \otimes A_{s(\omega)}$. We associate the morphism $\mathcal{V}(\eta)(x) = \eta_*(x) = x \otimes K_{s(\omega)}^\otimes$ with the morphism $\eta : \Omega \rightarrow \Omega'$.

(c) If $\gamma \subset \omega \in \check{\Omega}$ is a segment-cut, then we define the result of the cutting by γ and the value of the functor on it by analogy with case (b), changing K_s to K_{I_s} .

(d) If $\gamma \subset \omega \in \check{\Omega}$ is a graph-cut, then we define the result of the cutting by γ and the value of the functor on it by analogy with Section 2.

(3) *Addition of a marked point.*

(a) Let us add an unmarked point $p \in \check{\Omega} \setminus \partial\check{\Omega}$ with a local orientation to the set Ω_a . This operation generates a morphism $\xi : \Omega \rightarrow \Omega'$, where $V_{\Omega'} = V_{\Omega} \otimes A_{s(\omega)}$ and $p \in \omega \in \check{\Omega}$. Associate the morphism $\mathcal{V}(\xi)(x) = \xi_*(x) = x \otimes 1_{s(\omega)}$ with it.

(b) Similarly, let us add an unmarked point $q \in \overrightarrow{\partial\check{\Omega}} \setminus \partial\check{\Omega}$ with a local orientation to the set Ω_b . This operation generates a morphism $\xi : \Omega \rightarrow \Omega'$, where $V_{\Omega'} = V_{\Omega} \otimes B_{I_s(\omega)}$ and $p \in \omega \in \check{\Omega}$. Associate the morphism $\mathcal{V}(\xi)(x) = \xi_*(x) = x \otimes 1_{B_{I_s(\omega)}}$ with it.

(4) *Change of local orientations of marked points.*

Let $\psi : \Omega \rightarrow \Omega'$ be a morphism of the change of a local orientation of a marked point $p \in \Omega_a$ or $q \in \Omega_b$. It generates an involution $*_{s(p)} : A_p \rightarrow A_p$ or $*_{I_s(q)} : B_q \rightarrow B_q$ and thus the homomorphism $\mathcal{V}(\psi) = \psi_* : V_{\Omega} \rightarrow V_{\Omega'}$.

(5) The tensor product in \mathcal{S} defined by the disjoint union of surfaces $\Omega' \otimes \Omega'' \rightarrow \Omega' \coprod \Omega''$ induces the tensor product of vector spaces $\theta_* : V_{\Omega'} \otimes V_{\Omega''} \rightarrow V_{\Omega' \sqcup \Omega''}$.

The functorial properties of \mathcal{V} can be easily verified.

4.2. Topological field theory

Fix families of vector spaces $\{A_s | s \in S\}$ and $\{B_{\sigma} | \sigma \in \Sigma\}$ and families of tensors, elements and involutions defining the functor \mathcal{V} .

A family of linear forms $\mathcal{F} = \{\Phi_{\Omega} : V_{\Omega} \rightarrow \mathbb{K}\}$, defined for all cyclic foams $\Omega \in \mathcal{S}$, is called a *cyclic foam topological field theory* if it satisfies the following axioms:

1° *Topological invariance.*

$$\Phi_{\Omega'}(\phi_*(x)) = \Phi_{\Omega}(x)$$

for any isomorphism $\phi : \Omega \rightarrow \Omega'$ of cyclic foams.

2° *Non-degeneracy.*

Let Ω (resp., Ω^*) be a sphere with exactly two marked locally oriented points, where their orientations are induced by an orientation of the sphere (resp., there is no orientation that induces the orientations of the points). Define the bilinear forms $(\cdot, \cdot)_s, (\cdot, \cdot)_s^* : A_s \times A_s \rightarrow \mathbb{K}$ by $(x', x'')_s = \Phi_{\Omega}(x'_{p_1} \otimes x''_{p_2})$ and $(x', x'')_s^* = \Phi_{\Omega}^*(x'_{p_1} \otimes x''_{p_2})$.

Define also the bilinear forms $(\cdot, \cdot)_{I_s}, (\cdot, \cdot)_{I_s}^* : B_{I_s} \times B_{I_s} \rightarrow \mathbb{K}$. Their definitions are similar to the definitions of $(\cdot, \cdot)_s, (\cdot, \cdot)_s^*$ after a change of the sphere to a disk and the interior marked points to vertices. Axiom 2° says that the forms $(\cdot, \cdot)_s, (\cdot, \cdot)_s^*, (\cdot, \cdot)_{I_s}, (\cdot, \cdot)_{I_s}^*$ and the forms $(\cdot, \cdot)_{\sigma}$ from Section 2.2 are non-degenerate.

Let Ω be a film surface with only two vertices q_1, q_2 . Then $\sigma_{q_2} = \sigma^*$ if $\sigma_{q_1} = \sigma$. Denote by $(\cdot, \cdot)_{\sigma}$ the bilinear form $(\cdot, \cdot)_{\sigma} : B_{\sigma} \times B_{\sigma^*} \rightarrow \mathbb{K}$, where $(x', x'')_{\sigma} = \Phi_{\Omega}(x'_{q_1} \otimes x''_{q_2})$. Axiom 2° asserts that the forms $(\cdot, \cdot)_{\sigma}$ are non-degenerate for all $\sigma \in \Sigma$.

3° *Cut invariance.*

$$\Phi_{\Omega'}(\eta_*(x)) = \Phi_{\Omega}(x)$$

for any cut morphism $\eta : \Omega \rightarrow \Omega'$ of film surfaces.

4° *Invariance under addition of a marked point.*

$$\Phi_{\Omega'}(\xi_*(x)) = \Phi_{\Omega}(x)$$

for any morphism of addition of a marked point $\xi : \Omega \rightarrow \Omega'$ of the film surfaces.

5° *Invariance under a change of local orientations.*

$$\Phi_{\Omega'}(\psi_*(x)) = \Phi_{\Omega}(x)$$

for any morphism of change of the local orientation of a marked point $\psi : \Omega \rightarrow \Omega'$.

6° *Multiplicativity.*

$$\Phi_{\Omega}(\theta^*(x' \otimes x'')) = \Phi_{\Omega'}(x')\Phi_{\Omega''}(x'')$$

for $\Omega = \Omega' \cup \Omega'', x' \in V_{\Omega'}, x'' \in V_{\Omega''}$ and the morphism of the tensor product $\theta : \Omega' \times \Omega'' \rightarrow \Omega$.

Note that a topological field theory defines the families of tensors, elements and involutions, defining the functor \mathcal{V} . This follows from Lemma 2.1 and [[23], Lemma 3.1].

5. Graph-Cardy–Frobenius algebras

5.1. Definitions

A 3-tuple $(D, l_D, *_D)$ is called an *equipped Frobenius algebra* (see [25]) if D is an associative Frobenius algebra with unit 1_D , $l_D : D \rightarrow \mathbb{K}$ is a linear functional such that the bilinear form $(x_1, x_2)_D = l_D(x_1 x_2)$ is non-degenerate and $*_D : D \rightarrow D$ is an involution such that $l_D(x^*) = l_D(x)$ and $(x_1 x_2)^* = x_2^* x_1^*$ (here and below $x^* = *(x)$).

Consider a basis $\{d_i | i = 1, \dots, n\} \subset D$, the matrix $F_{ij}^D = (d_i, d_j)_D$ and the matrix F_{ij}^D inverse to F_{ij}^D . The elements $K_D = F_{ij}^D d_i d_j$ and $K_D^* = F_{ij}^D d_i d_j^*$ are called the *Casimir* and the *twisted Casimir* elements, respectively. They do not depend on the choice of the basis.

We say that a pair of equipped Frobenius algebras $((A, l_A, *_A), (B, l_B, *_B))$, a homomorphism $\phi : A \rightarrow B$ and an element $U \in A$ form a *Cardy–Frobenius algebra* if

- A is commutative and the image $\phi(A)$ belongs to the center of B ;
- $\phi(x^*) = (\phi(x))^*$;
- $(\phi^*(x), \phi^*(y))_A = \text{tr } W_{x,y}$, where $x, y \in B$, $(a, \phi^*(b)) = (\phi(a), b)_B$, $W \in \text{End}(B)$ and $W(z) = xzy$;
- $U^2 = K_A^*$ and $\phi(U) = K_B$.

It is proved in [6] that Cardy–Frobenius algebras are in one-to-one correspondence with Klein topological field theories that are topological field theories on two-dimensional manifolds with a boundary. The paper [6] also contains a complete classification of semi-simple Cardy–Frobenius algebras.

Define now a *graph-Cardy–Frobenius algebra* as a family that consists of:

- a family of Cardy–Frobenius algebras $\{(A^s, l_A^s, *_A^s), (B^s, l_B^s, *_B^s), \phi^s, U^s | s \in S\}$;
- a graph-Frobenius algebra B_\star with a bilinear form $(\cdot, \cdot)_B : B_\star \times B_\star \rightarrow \mathbb{K}$, and a 3-linear form $(\cdot, \cdot, \cdot)_B : B_\star \times B_\star \times B_\star \rightarrow \mathbb{K}$;
- a family of homomorphisms $\{\phi_\sigma^s : A^s \rightarrow \text{End}(B_\sigma) | s \in S, \sigma \in \Sigma\}$, where $\phi_\sigma^s = 0$ if s is not the color of an edge of σ .

Here:

- B^s coincides with $B_{I_s} \subset B_\star$ and $\phi_{I_s}^s(a)(b) = \phi^s(a)b$ for $a \in A^s, b \in B^s$;
- $(\phi_{\sigma_1}^s(a)(x_1), x_2)_B = (x_1, \phi_{\sigma_2}^s(a)(x_2))_B$, where $a \in A^s, x_i \in B_{\sigma_i}$;
- $(\phi_{\sigma_1}^s(a)(x_1), x_2, x_3)_B = (x_1, \phi_{\sigma_2}^s(a)(x_2), x_3)_B = (x_1, x_2, \phi_{\sigma_3}^s(a)(x_3))_B$, where $a \in A^s, x_i \in B_{\sigma_i}$.

5.2. One-to-one correspondence

Let $\mathcal{F} = \{\Phi_\Omega : V_\Omega \rightarrow \mathbb{K}\}$ be a cyclic foam topological field theory. Then its restriction to two-dimensional manifolds with a boundary forms a Klein topological field theory \mathcal{F}_K and, therefore, a family of Cardy–Frobenius algebras $\{(A^s, l_A^s, *_A^s), (B^s, l_B^s, *_B^s), \phi^s, U^s | s \in S\}_{\mathcal{F}}$. The restriction to film surfaces forms the film topological field theory \mathcal{F}_N and, therefore, a graph-Frobenius algebra $(B_\star, (\cdot, \cdot)_B, (\cdot, \cdot, \cdot)_B)_{\mathcal{F}}$.

Let us define the homomorphisms $\{\phi_\sigma^s : A^s \rightarrow \text{End}(B_\sigma) | s \in S, \sigma \in \Sigma\}_{\mathcal{F}}$. Let Ω be a cyclic foam with two vertices q_1, q_2 and one interior marked point p . Put $\sigma = \sigma_{q_1}$. The functional Φ_Ω generates the homomorphism ϕ_σ^s of A^s to the space E of linear functionals on $B_\sigma \otimes B_{\sigma^*}$. The bilinear form $(\cdot, \cdot)_\sigma$ generates the isomorphism between B_{σ^*} and the space of linear functionals on B_σ . Thus we can identify E with $\text{Hom}(B_\sigma, B_\sigma)$.

Theorem 5.1. *Let $\mathcal{F} = \{\Phi_\Omega : V_\Omega \rightarrow \mathbb{K}\}$ be a cyclic foam topological field theory on families of vector spaces $\{A_s | s \in S\}$, $\{B_\sigma | \sigma \in \Sigma\}$. Then the Cardy–Frobenius algebras $\{(A^s, l_A^s, *_A^s), (B^s, l_B^s, *_B^s), \phi^s, U^s | s \in S\}_{\mathcal{F}}$, the graph-Frobenius algebra $(B_\star, (\cdot, \cdot)_B, (\cdot, \cdot, \cdot)_B)_{\mathcal{F}}$ and the homomorphisms $\{\phi_\sigma^s : A^s \rightarrow \text{End}(B_\sigma) | s \in S, \sigma \in \Sigma\}_{\mathcal{F}}$ form a graph-Cardy–Frobenius algebra.*

Proof. The properties $B^s = B_{I_s}$, and $\phi_{I_s}^s(a)(b) = \phi^s(a)b$ follow from the corresponding axiom. Let us prove that $(\phi_{\sigma_1}^s(a)(x_1), x_2)_B = (x_1, \phi_{\sigma_2}^s(a)(x_2))_B$. Consider a cyclic foam Ω that is the film surface $\Omega(\sigma_1, \sigma_2)$ with an interior marked point p of color s . Then the cut axiom gives $(\phi_{\sigma_1}^s(a)(x_1), x_2)_B = \Phi_\Omega(a \otimes x_1 \otimes x_2)$ and $(x_1, \phi_{\sigma_2}^s(a)(x_2))_B = \Phi_\Omega(a \otimes x_1 \otimes x_2)$. The proof of the identities $(\phi_{\sigma_1}^s(a)(x_1), x_2, x_3)_B = (x_1, \phi_{\sigma_2}^s(a)(x_2), x_3)_B = (x_1, x_2, \phi_{\sigma_3}^s(a)(x_3))_B$ is similar. \square

Theorem 5.2. *The correspondence from Theorem 5.1 generates a one-to-one correspondence between cyclic foam topological field theories and isomorphism classes of graph-Cardy–Frobenius algebras.*

Proof. Let $(\{(A^s, l_A^s, *_A^s), (B^s, l_B^s, *_B^s), \phi^s, U^s | s \in S\}, (B_\star, (\cdot, \cdot)_B, (\cdot, \cdot, \cdot)_B), \{\phi_\sigma^s : A^s \rightarrow \text{End}(B_\sigma) | s \in S, \sigma \in \Sigma\})$ be a graph-Cardy–Frobenius algebra. Let us construct a cyclic foam topological field theory $\mathcal{F} = \{\Phi_\Omega : V_\Omega \rightarrow \mathbb{K}\}$ that generates it. According to the cut axiom and the axiom $\phi_{I_s}^s(a)(b) = \phi^s(a)b$, the theory \mathcal{F} is defined by its restrictions to:

- two-dimensional manifolds with a boundary and an arbitrary number of marked points;
- film surfaces without interior marked points;
- film surfaces with two vertices and one interior marked point.

According to [6], topological field theories on two-dimensional manifolds with a boundary and an arbitrary number of marked points are in one-to-one correspondence with isomorphism classes of Cardy–Frobenius algebras $\{((A^s, I_A^s, *_{A^s}), (B^s, I_B^s, *_{B^s}), \phi^s, U^s) | s \in S\}$. According to 3.2, topological field theories on film surfaces without interior marked points are in one-to-one correspondence with isomorphism classes of graph-Frobenius algebras $(B_*, (\cdot, \cdot)_B, (\cdot, \cdot, \cdot)_B)$. Define the value of \mathcal{F} on surfaces Ω with two vertices and one interior marked point by $\Phi_\Omega(a \otimes x_1 \otimes x_2) = (\phi_\sigma^s(a)(x_1), x_2)_B$. The properties $\phi_{I^s}^s(a)(b) = \phi^s(a)b$, $(\phi_{\sigma_1}^s(x_1), x_2)_B = (x_1, \phi_{\sigma_2}^s(x_2))_B$ and $(\phi_{\sigma_1}^s(a)(x_1), x_2, x_3)_B = (x_1, \phi_{\sigma_2}^s(a)(x_2), x_3)_B = (x_1, x_2, \phi_{\sigma_3}^s(a)(x_3))_B$ guarantee that the values of \mathcal{F} satisfy the axiom of cyclic foam topological field theory. \square

Note. The category of cyclic foams contains the subcategory of *oriented foams* $\Omega = (\check{\Omega}, \overrightarrow{\partial\check{\Omega}}, \Delta, \varphi)$, where the orientation of $\overrightarrow{\partial\check{\Omega}}$ generates orientations of edges of Δ . Our constructions make it possible to define the topological field theories for oriented foams and to prove that these topological field theories are in one-to-one correspondence with the analog of graph-Cardy–Frobenius algebras where arbitrary colored graphs change to bipartite colored graphs. The category of oriented foams contains a subcategory of *strong oriented foams* that consists of oriented foams where the orientation of $\check{\Omega}$ is generated by an orientation of $\check{\Omega}$.

6. Examples of cyclic foam topological field theories

In this section we construct an example of a cyclic foam topological field theory. Its restriction to two-dimensional manifolds with a boundary is the Klein topological field theory of regular covering, constructed in [25].

For any color $s \in S$, let us consider an action of a group G_s on a set X_s . Consider the vector space A_s which is the center of the group algebra of G_s . Associate $X_{\check{S}} = \times_{s \in \check{S}} X_s$ with any finite subset $\check{S} \subset S$. The actions of G_s on X_s generate the action of $G = \bigoplus_{s \in S} G_s$ on $X_{\check{S}}$.

Let $L = L(\check{\sigma})$ be the set of edges of a colored graph $\check{\sigma}$. Let $s(l)$ be the color of $l \in L$. Denote by $\check{\sigma}^X$ the set of all maps $\psi : L \rightarrow X_{s(l)} \times X_{s(l)}$, where $\psi(l) \in X_{s(l)} \times X_{s(l)}$. Define the action of G on $\check{\sigma}^X$ by $g(\psi(l)) = g(x') \times g(x'')$ for $\psi(l) = x' \times x''$. Let $\check{\sigma}^{X_G}$ be the set of orbits of this action.

A pair $(\check{\sigma}, \psi_G)$, where $\check{\sigma}$ is a colored graph and $\psi_G \in \check{\sigma}^{X_G}$, is called an *equipped colored graph*, or a colored graph with *equipment* ψ_G . An isomorphism $\varphi : \check{\sigma}_1 \rightarrow \check{\sigma}_2$ of colored graphs is called an *isomorphism* of the equipped colored graphs $(\check{\sigma}_i, \psi_G^i)$ if it takes ψ_G^2 to ψ_G^1 . Denote by $|\text{Aut}(\check{\sigma}, \psi_G)|$ the order of the group $\{g \in G | g\psi = \psi\}$, where $\psi \in \psi_G \in \check{\sigma}^{X_G}$ and $\check{\sigma} \in \Sigma$.

Consider the set $E_{\check{\sigma}}$ of equipments of a colored graph $\check{\sigma}$. Isomorphisms of colored graphs generate the canonical bijections between the corresponding sets $E_{\check{\sigma}}$. Thus we can associate the set E_σ with any $\sigma \in \Sigma$. Let B_σ be a vector space generated by E_σ . Denote by $*$: $B_\sigma \rightarrow B_{\sigma^*}$ the involution generated by changing the orientation of σ and changing the components of $X_s \times X_s$.

Construct a cyclic foam topological field theory with families of vector spaces $\{A_s | s \in S\}$, $\{B_\sigma | \sigma \in \Sigma\}$ by its restriction to

- two-dimensional manifolds with a boundary and an arbitrary number of marked points;
- film surfaces without interior marked points;
- film surfaces with two vertices and one interior marked point.

We start with the description of \mathcal{F} on film surfaces. Consider an additional structure on film surfaces. Let $V = V(\Omega)$ be the set of edges of a film surface Ω . Denote by $S(v)$ the set of the colors of the disks that are incident to $v \in V$. Consider the set Ω^X of maps $\psi : V \rightarrow \bigcup_{v \in V} X_{S(v)}$, where $\psi(v) \in X_{S(v)}$. Denote by Ω^{X_G} the set of orbits for the action of G on Ω^X .

A pair (Ω, ψ_G) , where Ω is a colored graph and $\psi_G \in \Omega^{X_G}$, is called an *equipped film surface* or film surface with *equipment* ψ_G . An isomorphism $\varphi : \Omega_1 \rightarrow \Omega_2$ of film surfaces is called an *equivalence* of the equipment film surfaces (Ω_i, ψ_G^i) if it takes ψ_G^2 to ψ_G^1 . Denote by $|\text{Aut}(\Omega, \psi_G)|$ the order of the group $\{g \in G | g\psi = \psi\}$, where $\psi \in \psi_G \in \Omega^{X_G}$. An equipment ψ of the film surface Ω generates an equipment ψ_σ for the graph σ of any vertex of Ω . We assume that $\psi_\sigma(l) = (x_{s(l)}^1, x_{s(l)}^2)$, where $l \in L(\sigma)$ is an oriented edge from $v^1 \in V(\Omega)$ to $v^2 \in V(\Omega)$ and $\psi(v^i) = \times_{s \in S(v^i)} x_s^i$.

We say that a connected equipped film surface (Ω, ψ_G) is a *compatible surface* for equipped colored graphs $\zeta_1, \zeta_2, \dots, \zeta_n$ if these graphs are the vertex graphs of Ω and the numeration the graphs σ_i generates the cyclic order of vertices of film surface Ω . Denote by $\Psi(\zeta_1, \zeta_2, \dots, \zeta_n)$ the set of all isomorphism classes of compatible surfaces for $\zeta_1, \zeta_2, \dots, \zeta_n$.

Define a set of linear functionals $\mathcal{F}_N = \{\Phi_\Omega : V_\Omega \rightarrow \mathbb{K}\}$ on connected equipped film surfaces by $\Phi_\Omega(\zeta_1 \otimes \zeta_2 \otimes \dots \otimes \zeta_n) = \sum_{\Psi \in \Psi(\zeta_1, \zeta_2, \dots, \zeta_n)} \frac{1}{|\text{Aut}(\Psi)|}$.

Lemma 6.1. *The set $\mathcal{F}_N = \{\Phi_\Omega : V_\Omega \rightarrow \mathbb{K}\}$ generates a film topological field theory.*

Proof. It follows from our definition that $(\zeta_1, \zeta_2^*)_\sigma = \frac{\delta_{\zeta_1, \zeta_2^*}}{|\text{Aut}(\zeta_1)|}$ for $\zeta_1, \zeta_2 \in E_\sigma$, and thus $K_\sigma = \sum_{\zeta \in E_\sigma} |\text{Aut}(\zeta)| \zeta \otimes \zeta^*$. Let us prove the cut invariance.

Consider an equipment film surface $\Psi \in \Psi(\zeta_1, \zeta_2, \dots, \zeta_n) = (\Omega(\sigma_1, \sigma_2, \dots, \sigma_n), \psi_G)$. Let η be the cut morphism produced by graph-cut $\gamma \subset \Omega(\sigma_1, \sigma_2, \dots, \sigma_n)$. It associates the pair of film surfaces $\Omega(\sigma_1, \sigma_2, \dots, \sigma_k, \sigma')$, $\Omega(\sigma'', \sigma_{k+1}, \sigma_2, \dots, \sigma_n)$ with the film surface $\Omega(\sigma_1, \sigma_2, \dots, \sigma_n)$. Any equipment of $\Omega(\sigma_1, \sigma_2, \dots, \sigma_n)$ generates equipments of $\Omega(\sigma_1, \sigma_2, \dots, \sigma_k, \sigma')$, $\Omega(\sigma'', \sigma_{k+1}, \sigma_2, \dots, \sigma_n)$. Thus we obtain equipment film surfaces Ψ' and Ψ'' and an equipment of σ' .

Fix an equipped colored graph $\zeta' = (\sigma', \psi'_G)$ and consider the set of equipped film surfaces $\Psi_{\zeta'}(\zeta_1, \zeta_2, \dots, \zeta_n) \subset \Psi(\zeta_1, \zeta_2, \dots, \zeta_n)$ that generate the equipment ψ'_G on σ' . Then $\sum_{\Psi \in \Psi_{\zeta'}(\zeta_1, \zeta_2, \dots, \zeta_n)} \frac{1}{|\text{Aut}(\Psi)|} = \frac{|\text{Aut}(\zeta')|}{|\text{Aut}(\Psi')||\text{Aut}(\Psi'')|}$. Summation over all equipments ψ'_G of σ' gives $\Phi_{\Omega}(\zeta_1 \otimes \zeta_2 \otimes \dots \otimes \zeta_n) = \sum_{\Psi \in \Psi_{\sigma'}(\zeta_1, \zeta_2, \dots, \zeta_n)} \frac{1}{|\text{Aut}(\Psi)|} = \sum_{\zeta \in E_{\sigma}} \frac{|\text{Aut}(\zeta)|}{|\text{Aut}(\Psi_+)||\text{Aut}(\Psi_-)|} = \Phi_{\Omega'} \eta_*(\zeta_1 \otimes \zeta_2 \otimes \dots \otimes \zeta_n)$. \square

It follows from the previous section that \mathcal{F}_N is generated and is defined by the graph-Frobenius algebra B_* . This algebra has the basis $E = \bigcup_{\sigma \in \Sigma} E_{\sigma}$ and is defined by multilinear forms

- $(\zeta_1, \zeta_2)_B = \sum_{\Psi \in \Psi(\zeta_1, \zeta_2)} \frac{1}{|\text{Aut}(\Psi)|} = \frac{\delta_{\zeta_1, \zeta_2}^*}{|\text{Aut}(\zeta_1)|}$ for $\zeta_1, \zeta_2 \in E$;
- $(\zeta_1, \zeta_2, \zeta_3)_B = \sum_{\Psi \in \Psi(\zeta_1, \zeta_2, \zeta_3)} \frac{1}{|\text{Aut}(\Psi)|}$ for $\zeta_1, \zeta_2, \zeta_3 \in E$.

Define now the action of the group algebra A_s on B_{σ} . It is identical if there are no edges of color s between the edges of σ . Let $s(l) = s$, $\psi \in \psi_G \in \sigma^{X_G}$, $\psi(l) = (x', x'')$ and $a = \sum_{g \in G} \lambda_g g$. Then we assume that $\phi_{\sigma}^s(a)(\psi) = (\sum_{g \in G} \lambda_g g x', x'')$ on l and $\phi_{\sigma}^s(a)(\psi) = \psi$ on the other edges of σ . The function $\phi_{\sigma}^s(a)(\psi)$ depends only on its orbit ψ_G , and thus generates the linear operator $\phi_{\sigma}^s(a) : B_{\sigma} \rightarrow B_{\sigma}$.

Define now the system of linear operators $\mathcal{F}_C = \{\Phi_{\Omega} : V_{\Omega} \rightarrow \mathbb{K}\}$ on cyclic foams with two vertices by $\Phi_{\Omega}(a^1 \otimes \dots \otimes a^r \otimes x_1 \otimes x_2) = (\phi_{\sigma}^{s(a^1)}(a^1) \dots \phi_{\sigma}^{s(a^r)}(a^r))(x_1, x_2)_B$.

Define a system of linear operators $\mathcal{F}_s = \{\Phi_{\Omega} : V_{\Omega} \rightarrow \mathbb{K}\}$ on two-dimensional manifolds with a boundary of color s . We set it to be the Klein topological field theory of the G_s -regular covering with a trivial stationary subgroup from [25].

Theorem 6.1. *There exists a unique cyclic foam topological field theory \mathcal{F} with the restrictions \mathcal{F}_N , \mathcal{F}_C and \mathcal{F}_s .*

Proof. It follows from Lemma 6.1 and [25] that the families \mathcal{F}_N and \mathcal{F}_s satisfy the axioms of cyclic foam topological field theory. By our definitions, the value of \mathcal{F}_C on Ω is equal to the product of the values \mathcal{F}_s on the disks that form Ω . Thus \mathcal{F}_C also satisfies the axioms of cyclic foam topological field theory. Moreover, the families \mathcal{F}_N , \mathcal{F}_C , and \mathcal{F}_s coincide on common areas of the definition.

To define \mathcal{F} on an arbitrary cyclic foam one can use the cut axiom and cut the surface into two-dimensional manifolds with a boundary, film surfaces without interior marked points and surfaces with two vertices. The result does not depend on the cut system because any two such systems are different only on two-dimensional manifolds with a boundary, film surfaces without interior marked points or surfaces with two vertices. \square
