### ABSTRACT

In recent years, the development of novel advanced high-energy density materials has significantly shifted toward nitrogen-containing heterocyclic derivatives, which demonstrate a great potential for multipurpose application patterns. Among known heterocycles hydroxytetrazole is of special importance due to its high nitrogen-oxygen content and a possibility to serve as anion counterpart and to form a diverse array of organic and inorganic energetic salts. In this review, we summarized the main achievements on the synthesis and performance of hydroxytetrazole-based energetic materials. Potential applications of the presented high-energy compounds and their environmental compatibility are especially emphasized.

### 1. Introduction

In recent decades, the design and synthesis of novel high-energy density materials (HEDMs) became an emergent area of research.<sup>1,2</sup> HEDMs remain leading positions in a development of dual-use technologies for military and civilian purposes including space technologies, mining and explosion welding. However, advanced military, space and civilian technologies bring new increased requirements to the synthesis and performance of HEDMs.<sup>3,4</sup> Novel energetic materials should have balanced functional properties including good detonation performance, high density and high enthalpy of formation. At the same time, such materials should possess moderate sensitivity toward various mechanical stimuli to guarantee safety concerns associated with their preparation, isolation and handling. Traditional energetic materials, such as trinitrotoluene (TNT), hexogen (RDX), octogen (HMX) suffer from harsh methods for their synthesis and a lack of environmental compatibility.<sup>5,6</sup> Serious ecological issues are also connected with the wide utilization of highly toxic primary explosives lead azide and lead styphnate thus demanding their replacement for metal-free environmentally benign alternatives.<sup>7</sup> Therefore, design and synthesis of novel HEDMs with a balanced set of properties remains one of the constant multidisciplinary tasks both in fundamental and applied research areas.

A search of novel powerful HEDMs continues to evolve and nowadays it is performed among a variety of high-nitrogen and nitrogen-oxygen heterocyclic compounds.<sup>8–10</sup> A utilization of hetarene scaffolds for the construction of high-energy structures has a number of advantages compared to the cyclic and caged nitramines. Polynitrogen and nitrogen-oxygen heterocyclic derivatives have higher densities due to

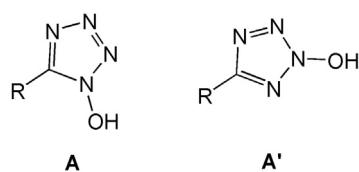

planarity and possess higher enthalpies of formation, thus providing high detonation performance of such materials.<sup>11–14</sup> In addition, due to high nitrogen-oxygen content, the amount of oxidizer in energy-rich compositions can be significantly reduced.<sup>15</sup> Therefore, the development of novel advanced HEDMs among azole and azine derivatives demonstrates a great potential for multipurpose application patterns.

In a series of nitrogen-rich heterocycles, tetrazole ring is of particular importance due to high thermal stability, good detonation performance and high level of environmental compatibility of the energy-rich tetrazole derivatives.<sup>16–19</sup> However, the tetrazole moiety has no oxygen in its structure. This disadvantage may be circumvented by an introduction of a hydroxyl motif on one of the ring nitrogen atoms to produce hydroxytetrazole scaffold (also known as tetrazole N-oxide).<sup>20</sup> As a result of regiosomerism, both 1- and 2-hydroxytetrazoles A and A' (Fig. 1) were successfully synthesized so far.

There are two main routes to an assembly of the hydroxytetrazole framework. The first one is based on a direct oxidation of the corresponding tetrazoles with oxone, which is a triple salt  $2\text{KHSO}_5\text{KH}_2\text{SO}_4$  and is widely used as a convenient, bench-stable oxidant. This approach is quite facile and tolerates well various functional groups, but has rather narrow substrate scope associated with a low oxidation ability of the tetrazole ring. The second route involves an acid-promoted cyclization of geminal azidooximes due to azide-tetrazole tautomerism. This approach enables a regiospecific construction of 1-hydroxytetrazole scaffold A for a wide range of substrates. In this review, we summarized the known approaches for the synthesis of energy-rich hydroxytetrazoles and organic/inorganic salts thereof. Main physicochemical properties of the reported HEDMs as well as their detonation

**Fig. 1.** The structures of regiosomeric hydroxytetrazoles.

performance are thoroughly discussed. In addition, potential application prospectives of the hydroxytetrazole-based HEDMs are emphasized.

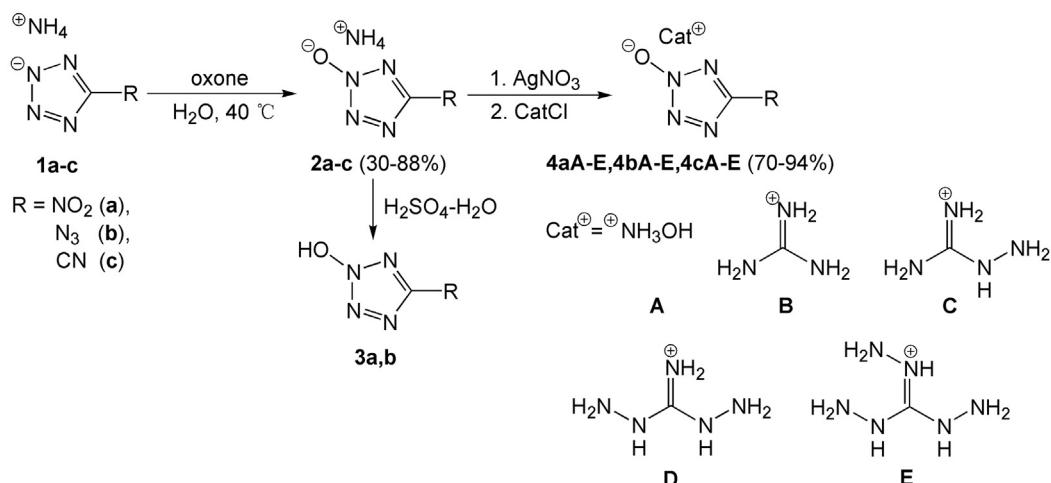

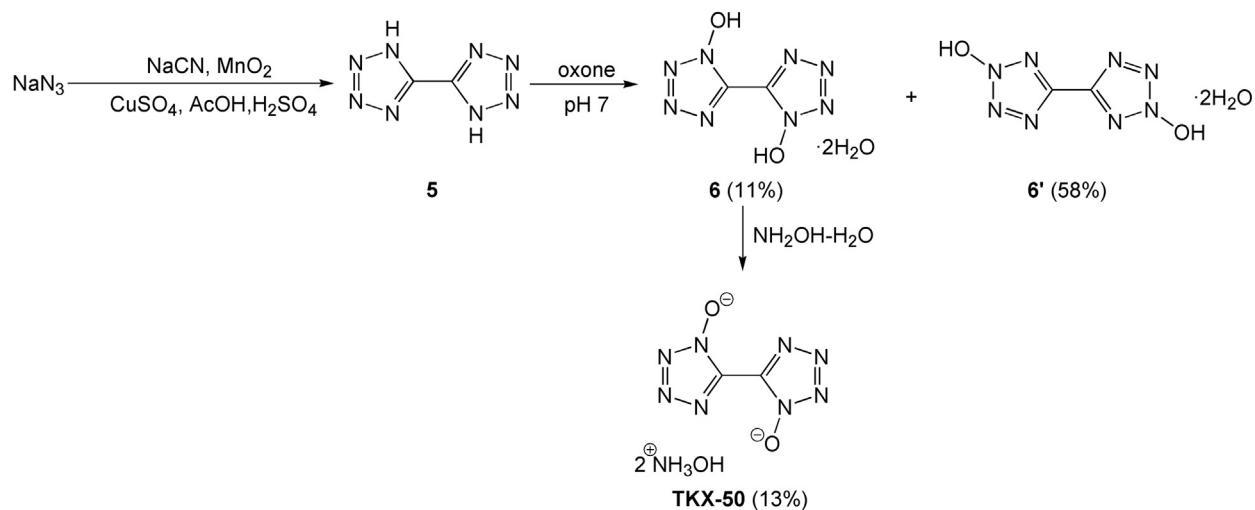

## 2. Oxidation of tetrazoles by oxone

Oxidation of tetrazolate-anions with oxone may serve as a direct approach to the assembly of hydroxytetrazole motif from available tetrazole derivatives. As a rule, this oxidation proceeds regioselectively resulting in a predominant formation of 2-hydroxytetrazole subunit. Arguably, this reactivity is attributed to the increased electron density on the N(2) atom of the tetrazole ring which is especially relevant in the case

of various energetic derivatives incorporating electron-withdrawing explosophoric moieties (e.g.  $\text{NO}_2$ ,  $\text{N}_3$ ) at the tetrazole carbon atom. For example, an oxidation of ammonium salts of 5-nitro-, 5-azido- or 5-cyano-tetrazoles **1a-c** resulted in a regioselective formation of 2*N*-oxides **2a-c**. Acidification of thus prepared salts **2a,b** afforded free 2-hydroxytetrazoles **3a,b** while double cation metathesis procedure provided a series of nitrogen-rich organic salts **4** (**Scheme 1**).<sup>21–23</sup>

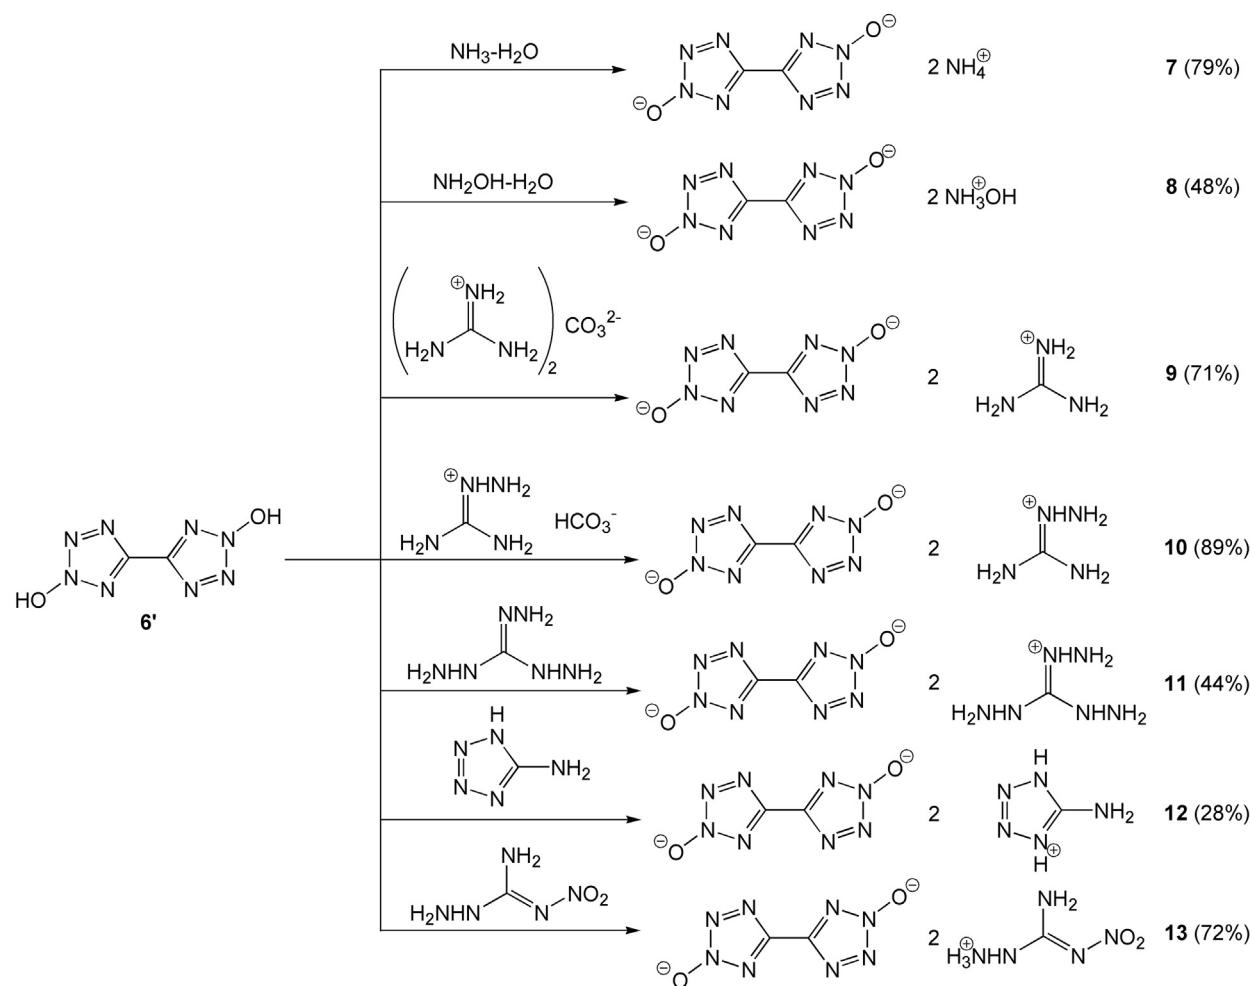

Cycloaddition of  $\text{NaN}_3$  and  $\text{NaCN}$  followed by oxidative C–C coupling of the parent tetrazole resulted in a formation of 5,5'-bitetrazole **5**. Oxidation of compound **5** with oxone afforded a mixture of 1,1'- and 2,2'-diolates **6** and **6'** with a predominance of the latter. The formed mixture can be easily separated by an addition of aqueous hydroxylamine: 1,1'-diolate **6** produced the corresponding dihydroxylammonium salt which is known as TKX-50 (**Scheme 2**).<sup>24</sup> This HEDM demonstrated excellent detonation performance and moderate mechanical sensitivity representing a potential replacement for RDX and HMX. Physicochemical properties of TKX-50 as well as of several other hydroxytetrazole salts are summarized in **Table 1**.

Isomeric 5,5'-bitetrazole-2,2'-diolate **6'** was also used as a synthetic platform for the preparation of a series of energetic salts **7–13** (**Scheme 3**). All transformations were performed by direct neutralization of the

**Scheme 4.** Plausible mechanism for the cyclization of geminal azidooximes.

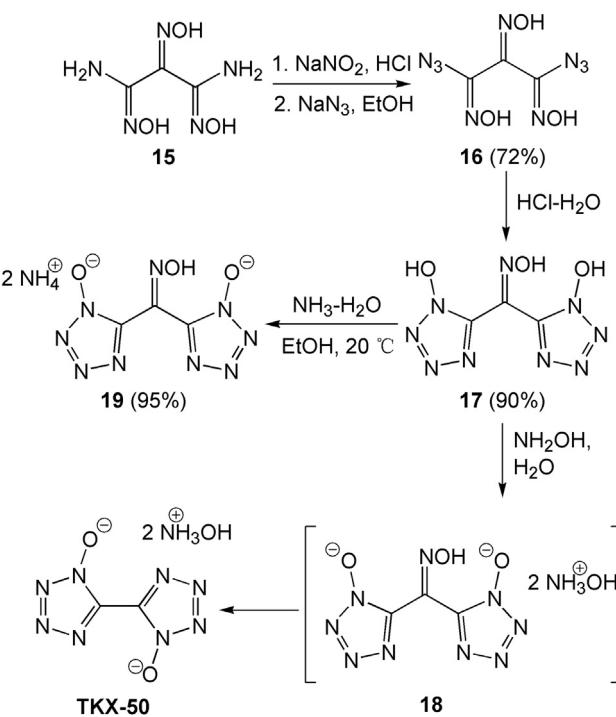

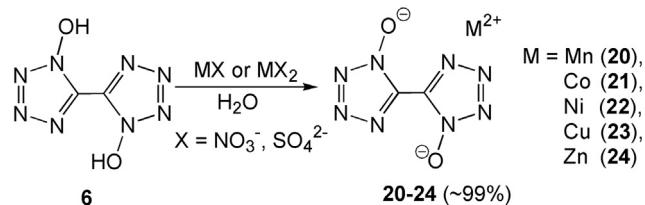

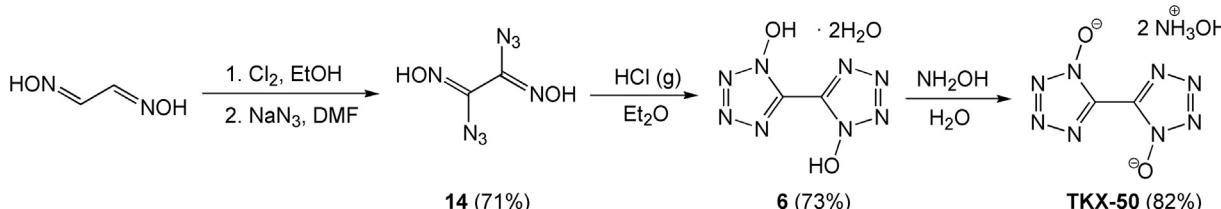

(>59%) which allows to consider these salts as environmentally benign HEDMs.

### 3. Cyclization of geminal azidooximes

A wide scope of energetic 1-hydroxytetrazoles was synthesized through a cyclization of geminal azidooxime derivatives. This approach usually provides higher yields of 1-hydroxytetrazoles comparing to the oxidation route and eliminates any regioselectivity issues. Arguably, cyclization occurs via an intramolecular nucleophilic attack of the terminal nitrogen atom of the azide moiety onto the oxime nitrogen atom followed by electronic shifts (**Scheme 4**).

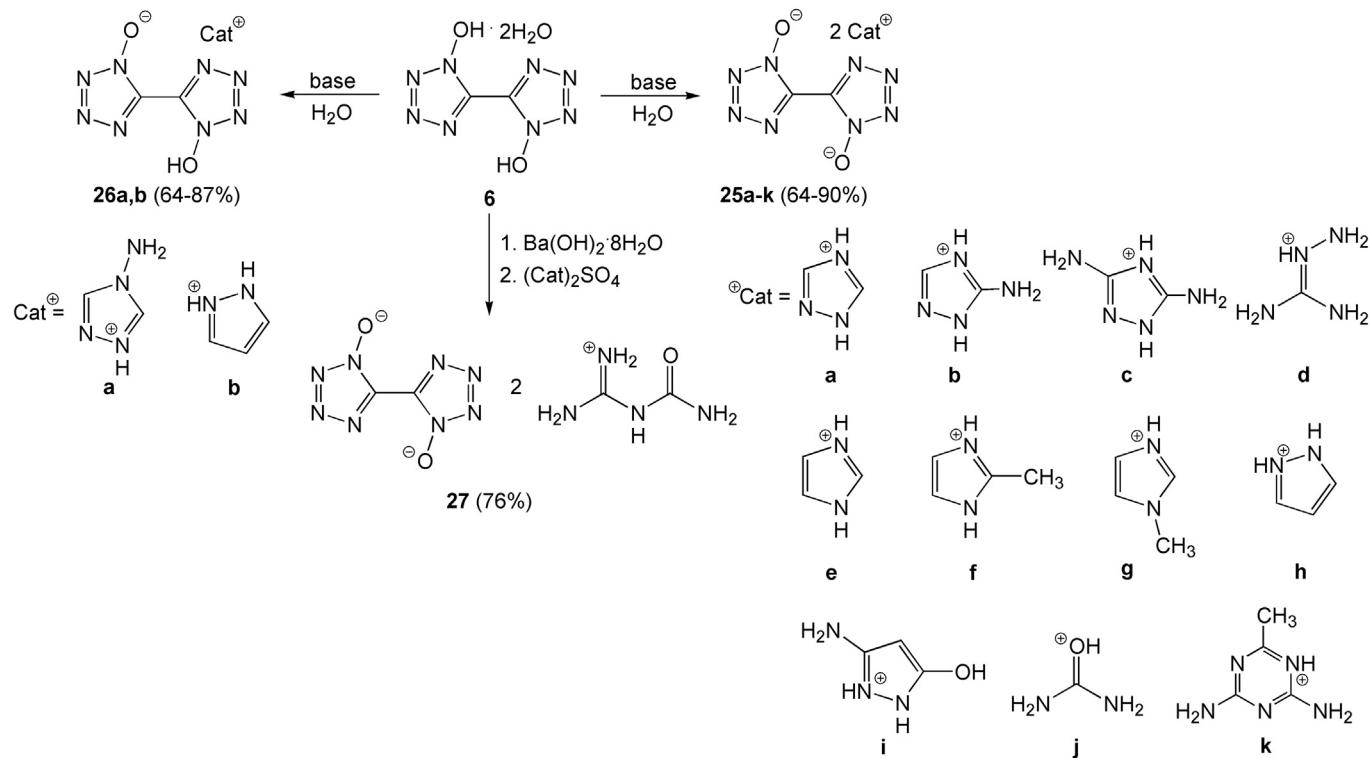

In particular, acid-promoted cyclization of diazidoglyoxime **14** afforded 5,5'-bitetrazole-1,1'-diolate **6** in a good yield. Substrate **14** was in turn prepared in two steps from unsubstituted glyoxime with an overall yield of 71% (**Scheme 5**).<sup>24</sup> This method may serve as a reliable and scalable procedure for the synthesis of TKX-50 which is prepared in a yield of 42.5% starting from commercially available glyoxime. In-depth investigation showed that the thermal stability of TKX-50 was slightly lower than that of RDX and was on the same level as that of CL-20.<sup>26</sup> Due to a favorable set of properties TKX-50 was also investigated as a co-crystallization component.<sup>27–29</sup>

An alternative synthetic route to TKX-50 was recently proposed.<sup>30</sup> This approach is based on a tandem conversion of bis-amidoxime **15** to the corresponding bis(azidooxime) **16**. Intramolecular cyclization of both azidooxime moieties in **16** afforded compound **17** incorporating two hydroxytetrazole subunits linked by an oxime moiety. Neutralization of bis(hydroxytetrazole) **17** with aqueous hydroxylamine unexpectedly resulted in a formation of TKX-50 due to a possible loss of the oxime moiety. Although detailed mechanism for this transformation has been

unknown so far, it proceeds arguably via an intermediate formation of dihydroxylammonium salt 18. Unfortunately, the authors<sup>30</sup> did not provide the yield of TKX-50 which complicates its comparison with the previously reported synthetic route. Curiously, neutralization of bis(hydroxytetrazole) 17 with aqueous ammonia afforded expected diammonium salt 19 in a quantitative yield (Scheme 6). Compound 19 has higher thermal decomposition temperature (241 °C) than TKX-50,

however it has moderate density and enthalpy of formation which resulted in lower detonation velocity (8114 m·s<sup>-1</sup>).

5,5'-Bitetrazole-1,1'-diolate 6 was thoroughly studied by a number of research groups as a valuable scaffold for the preparation of a variety of both metal and metal-free energy-rich salts. Complexation of substrate 6 with non-heavy metal salts afforded a series of energetic compounds 20–24 which represent a subclass of coordination polymers (Scheme 7).

All synthesized materials 20–24 showed good thermal stability (>270 °C), high densities and zero oxygen balance (to CO). In addition, these compounds demonstrated good detonation performance and acceptable mechanical sensitivities (Table 3).<sup>31</sup> Coordination polymers 20–22 and 24 exhibited the fast deflagration-to-detonation transition ability enabling their potential application as lead-free primary explosives. For comparison, lead complex of 5,5'-bitetrazole-1,1'-dioxide was also recently prepared.<sup>32</sup>

A wide series of nitrogen-rich organic salts incorporating mono- or bitetrazole-1,1'-dioxide was synthesized by a direct neutralization of the parent compound 6, although a cation metathesis route was also employed (Scheme 8).<sup>29,33–38</sup> All prepared compounds 25a–k, 26a,b and 27 have high nitrogen content and good detonation velocities (7.0–8.2 km·s<sup>−1</sup>). In addition, synthesized HEDMs were found to be completely insensitive to impact which enables their potential application as secondary explosives (Table 4).

An assembly of hydroxylammonium 5-aminotetrazole-1-olate **28** was accomplished through a cascade transformation of cyanogen bromide. This reaction sequence involved nucleophilic substitution of the bromide

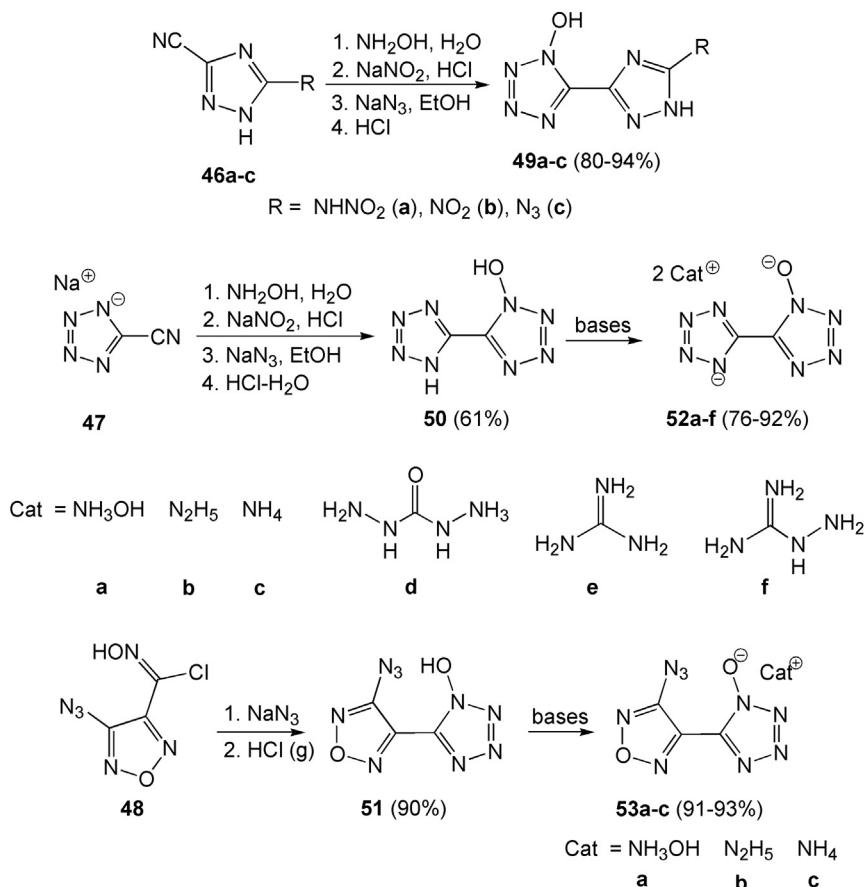

anion in BrCN with azide one generating highly toxic and explosive cyanogen azide (N<sub>3</sub>CN) which cannot be isolated. The subsequent treatment of a solution of N<sub>3</sub>CN with hydroxylamine resulted in a one-pot formation of target salt **28** through a condensation-cyclization-neutralization route. Upon acid-base treatment compound **28** can be easily converted to the corresponding ammonium salt **29**. Oxidation of amine **28** with KMnO<sub>4</sub> in basic media afforded dipotassium salt of 5,5'-azotetrazolate-1,1'-dioxide **30**.<sup>39</sup> An acid-base work-up of compound **30** afforded a series of non-heavy metal (**31a–e**)<sup>40,41</sup> and metal-free (**32a–c**)<sup>39</sup> energetic salts. In addition, azo group in azotetrazolate **30** was chemoselectively reduced to the hydrazone moiety providing 1,1'-dihydroxy-5,5'-bistetrazolylhydrazine **33** in a good yield (Scheme 9).<sup>39</sup>

Dipotassium 5,5'-azotetrazolate-1,1'-dioxide **30** showed excellent thermal stability and outstanding detonation performance (D = 9753 m·s<sup>−1</sup>; p = 41.0 GPa) far exceeding those of RDX and HMX. Furthermore, compound **30** is less sensitive to impact and completely insensitive to friction. Energetic salts **32a,b** have higher nitrogen content, but their

sensitivity is also higher.<sup>39</sup> Hydrazo derivative 33 is very sensitive both to impact and friction which restrict its potential application in practice (Table 5).

The hydroxytetrazole motif was also successfully incorporated in a number of HEDMs comprising of structurally diverse heterocyclic sub-units. 4,5-Bis(1-hydroxytetrazolyl)-2*H*-1,2,3-triazole 34 was synthesized through a standard two-step procedure from the corresponding bis(chloroxime) 35 which was in turn prepared from 4,5-dicyano-2*H*-1,2,3-triazole 36. Neutralization of compound 34 with free bases or their carbonate (bicarbonate) salts afforded a series of nitrogen-rich organic salts 37a-e (Scheme 10).<sup>42</sup> Investigation of the functional properties of the synthesized HEDMs revealed that parent heterocyclic scaffold 34 is highly sensitive to impact, while salts 37a-c are much less sensitive to impact and completely insensitive to friction. Ammonium and hydroxylammonium salts 37a,b have good thermal stability and high

detonation performance which allows to consider them as a potential replacement to RDX (Table 6).

5-(1,2,4-Oxadiazolyl)-1-hydroxytetrazole 38 was prepared by a three-step conversion of the corresponding amidoxime 39. Compound 39 was synthesized via a double condensation procedure of the commercially available unsubstituted glyoxime. Direct neutralization of the hydroxytetrazole 38 afforded a series of organic salts 40a-c bearing small nitrogen-based cations (Scheme 11).<sup>43</sup> Although salts 40a-c showed lower thermal stability than RDX and HMX, their nitrogen content is much higher which indicates their eco-friendliness. In addition, salts 40b,c have the same detonation performance and mechanical sensitivity as RDX (Table 7).

Interaction of dicyanofurazanyl ether 41 with hydroxylamine followed by nitrosation of formed bis(amidoxime) resulted in a formation of bis(chloroxime) 42. A treatment of compound 42 with NaN<sub>3</sub> followed by

bubbling of gaseous HCl through an ethereal solution of intermediate bis(azidooxime) afforded 4,4'-oxybis[3,3'-(1-hydroxytetrazolyl)]furazan **43** which was converted to a series of nitrogen-cation salts **44a-d** and potassium salt **44e**. Treatment of compound **43** with lead(II) nitrate resulted in a destructive cleavage of initial ether **43** to form the corresponding salt **45** (Scheme 12).<sup>44,45</sup> All synthesized HEDMs **44a-e**, **45** have high thermal stability (>200 °C) and high enthalpies of formation. Compounds **44a-c** have excellent detonation performance ( $D = 8300\text{--}8900 \text{ m}\cdot\text{s}^{-1}$ ) on the level of RDX,<sup>44</sup> while lead-based derivative **45** has even higher detonation parameters ( $D = 9210 \text{ m}\cdot\text{s}^{-1}$ ;  $p = 50.9 \text{ GPa}$ ) and surprisingly low sensitivity to impact and friction (Table 8).<sup>45</sup>

Available 3-cyano-1,2,4-triazoles **46a-c**, 5-cyanotetrazolyl sodium salt **47** and (azidofurazanyl)chloroxime **48** may also serve as suitable substrates for the construction of biheteroaryl energetic materials incorporating the 1-hydroxytetrazole subunit. 5-(1,2,4-Triazolyl)-1-

hydroxytetrazoles **49a-c** were studied as is,<sup>46</sup> while hydroxytetrazoles **50** and **51** were converted to the corresponding nitrogen-rich energetic salts **52a-f** and **53a-c**, respectively (Scheme 13).<sup>47,48</sup> A similar synthetic approach was also employed for the preparation of bis(1-hydroxytetrazolyl)-1,2,5-oxadiazoles and a series of salts thereof.<sup>49</sup> Synthesized compounds have very high nitrogen content (up to 72%) and high enthalpies of formation (470–820 kJ·mol<sup>−1</sup>). 1-Hydroxytetrazoles **49a** and **51** bearing nitramine and azidofurazanyl motifs, respectively, showed very high sensitivity to impact and friction which restrict their application potential. At the same time, HEDMs **50** and **52a** comprising of a bitetrazole core have acceptable mechanical sensitivities and very good detonation performance exceeding those of RDX, which allows to consider them as environmentally benign secondary explosives (Table 9).

(4-Aminofurazanyl)-1-hydroxytetrazole **54** was found to be a valuable scaffold for the construction of a variety of low-sensitive highly

energetic HEDMs. It was used as an anion source for the synthesis of energetic salts **55a–i** either by direct neutralization or through a double metathesis procedure.<sup>50</sup> Oxidation of the amino group in compound **54** to the azo moiety with subsequent base treatment afforded nitrogen-rich derivatives **56a,j**. Amino group was also nitrated to the corresponding nitramine which was in situ neutralized to form the dianionic salt **57a**. Subsequent double cation metathesis provided a series of dianionic salts **57b,c,f,h,j** (**Scheme 14**).<sup>51</sup> All synthesized HEDMs have very high nitrogen content (>50%) and high enthalpies of formation (>400 kJ·mol<sup>-1</sup>). Furthermore, prepared materials have excellent detonation velocities (>8500 m·s<sup>-1</sup>) and very low sensitivity toward impact and friction (**Table 10**). These advantages enable the strong potential of the presented HEDMs as a promising replacement for various secondary explosives (RDX, HMX, TATB).

#### 4. Conclusion

In conclusion, the main achievements in the design and synthesis of hydroxytetrazole-based HEDMs were summarized. Various routes to the regioselective formation of both 1- and 2-hydroxytetrazole subunits and their energetic derivatives were discussed. Hydroxytetrazole was found to be a valuable heterocyclic scaffold for the preparation of various energy-rich materials. Due to the highly acidic nature of the hydroxy moiety, hydroxytetrazoles may serve as a synthetic platform for the construction of wide arrays of structurally diverse ionic energy-rich derivatives. Variation of explosophoric motifs at the tetrazole ring as well as of cationic counterparts resulted in a formation of multipurpose energetic materials which have high potential as environmentally benign primary and secondary explosives.

Taking into account the emerging development of heterocyclic chemistry, there is no doubt that hydroxytetrazole-based HEDMs will retain their leading position in the framework of materials science. In our opinion, a search of powerful HEDMs in a hydroxytetrazole series is far from being exhausted. A combined multidisciplinary investigation will gain deep insights in structure-property relationships and will also provide new industrial applications. A high level of environmental compatibility of hydroxytetrazole-based energetic materials will guarantee the sustainability of chemical processes. Finally, the authors of this review hope that it will stimulate researchers for further work in this field.
